$\Upsilon(1D)$

$$I^{G}(J^{PC}) = 0^{-}(2^{-})$$

First observed by BONVICINI 04 in the decay to $\gamma\gamma$ $\Upsilon(1S)$ and confirmed by DEL-AMO-SANCHEZ 10R in the decay to $\pi^+\pi^ \Upsilon(1S)$. Data consistent with $J^P=2^-$. The states with J=1 and 3 also possibly seen, but need confirmation.

$$I^G(J^{PC}) = 0^+(0^{++})$$

 J needs confirmation.

Observed in radiative decay of the $\Upsilon(3S)$, therefore C=+. Branching ratio requires E1 transition, M1 is strongly disfavored, therefore

au(4s) branching ratios

— *ВВ* DECAYS —

The ratio of branching fraction to charged and neutral B mesons is often derived assuming isospin invariance in the decays, and relies on the knowledge of the B^+/B^0 lifetime ratio. "OUR EVALUATION" is obtained based on averages of rescaled data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account the common dependence of the measurement on the value of the lifetime ratio.

 $I^G(J^P) = ?^+(1^+)$

OMITTED FROM SUMMARY TABLE

Observed by BONDAR 12 in $\Upsilon(5S)$ decays to $\Upsilon(\mathsf{nS})\pi^+\pi^-$ (n = 1, 2, 3) and $h_b(\text{mP})\pi^+\pi^-$ (m = 1, 2). $J^P=1^+$ is favored from angular analyses.

| _ | | | |

 $^{8}\,\mathrm{BRESSI}$ 11 uses the method of DYLLA 73 but finds serious errors in that experiment that greatly reduce its accuracy. The BRESSI 11 limit assumes that $n \to p \, e^- \, \nu_e$ conserves charge. Thus the limit applies equally to the charge of the neutron.

SENGUPTA 00 uses the difference between the observed rate of of rotational energy loss by the binary pulsar PSR B1913+16 and the rate predicted by general relativity to set this limit. See the paper for assumptions.

 $^{^2}$ TORII 99 uses the more-precisely-known constraint on the \overline{p} charge-to-mass ratio of GABRIELSE 95 (see below) to get this result. This is not independent of the TORII 99 value for $\left|q_{\overline{p}}\!+\!q_{\overline{\overline{p}}}\right|/e$, below.

⁽G. Gabrielse, private communication). ⁴ GABRIELSE 90 also measures $m_{\overline{p}}/m_{e^-}=1836.152660\pm0.000083$ and $m_p/m_{e^-}=1836.152680\pm0.000088$. Both are completely consistent with the 1986 CODATA (COHEN 87) value for m_p/m_{e^-} of 1836.152701 \pm 0.000037.

Baryon Particle Listings

- $^{10}\,\mathrm{DMITRIEV}$ 03 calculates this limit from the limit on the electric dipole moment of the $^{199} {
 m Hg\ atom}$
- $^{11}_{-1}$ This WILKENING 84 value includes a finite-size effect and a magnetic effect.
- $^{12}\mathrm{This}$ WILKENING 84 value is more cautious than the other and excludes the finite-size effect, which relies on uncertain nuclear integrals.

p ELECTRIC POLARIZABILITY α_p

For a very complete review of the "polarizability of the nucleon and Compton scattering," see SCHUMACHER 05. His recommended values for the proton are $\alpha_p=(12.0\pm0.6)\times10^{-4}~{\rm fm}^3$ and $\beta_p=(1.9\mp0.6)\times10^{-4}$ $\,$ fm 3 , almost exactly our averages.

| | | | | | | |

- 13 BEANE 03 uses effective field theory and low-energy $\gamma \rho$ and γd Compton-scattering data. It also gets for the isoscalar polarizabilities (see the erratum) $\alpha_{N} = (13.0 \pm 0.00)$ $1.9^{+3.9}_{-1.5})\times 10^{-4}~{\rm fm^3~and}~\beta_{\it N} = (-1.8\pm 1.9^{+2.1}_{-0.9})\times 10^{-4}~{\rm fm^3}.$
- 14 BLANPIED 01 gives $\alpha_p+\beta_p$ and $\alpha_p-\beta_p$. The separate α_p and β_p are provided to us by A. Sandorfi. The first error above is statistics plus systematics; the second is from
- 15 This OLMOSDELEON 01 result uses the TAPS data alone, and does not use the (reevaluated) sum-rule constraint that $lpha+eta=(13.8\pm0.4) imes10^{-4}~{
 m fm}^3$. See the paper for
- 16 MACGIBBON 95 combine the results of ZIEGER 92, FEDERSPIEL 91, and their own experiment to get a "global average" in which model errors and systematic errors are treated in a consistent way. See MACGIBBON 95 for a discussion.
- 17 BARANOV 01 combines the results of 10 experiments from 1958 through 1995 to get a global average that takes into account both systematic and model errors and does not use the theoretical constraint on the sum $\alpha_p+\beta_p$.
- 18 FEDERSPIEL 91 obtains for the (static) electric polarizability $\alpha_{_D}$, defined in terms of the induced electric dipole moment by ${\bf D}=4\pi\epsilon_0\alpha_p{\bf E}$, the value $(7.0\pm2.2\pm1.3)\times10^{-4}~{\rm fm^3}$.

p MAGNETIC POLARIZABILITY β_{D}

The electric and magnetic polarizabilities are subject to a dispersion sumrule constraint $\overline{\alpha}+\overline{\beta}=(14.2\pm0.5)\times10^{-4}~{\rm fm^3}.$ Errors here are anticorrelated with those on $\overline{\alpha}_p$ due to this constraint.

It also gets for the isoscalar polarizabilities (see the erratum) $\alpha_{N} = (13.0 \pm 1.9 ^{+3.9}_{-1.5}) \times 10^{-4} \; \mathrm{fm^3}$ and $\beta_{N} = (-1.8 \pm 1.9 ^{+2.1}_{-0.9}) \times 10^{-4} \; \mathrm{fm^3}.$
- 20 BLANPIED 01 gives $\alpha_p+\beta_p$ and $\alpha_p-\beta_p$. The separate α_p and β_p are provided to us by A. Sandorfi. The first error above is statistics plus systematics; the second is from
- 21 This OLMOSDELEON 01 result uses the TAPS data alone, and does not use the (reevaluated) sum-rule constraint that $\alpha+\beta=(13.8\pm0.4)\times10^{-4}~\text{fm}^3$. See the paper for
- 2a discussion.
 2b MACGIBBON 95 combine the results of ZIEGER 92, FEDERSPIEL 91, and their own experiment to get a "global average" in which model errors and systematic errors are treated in a consistent way. See MACGIBBON 95 for a discussion.
- 23 BARANOV 01 combines the results of 10 experiments from 1958 through 1995 to get a global average that takes into account both systematic and model errors and does not use the theoretical constraint on the sum $\alpha_p + \beta_p$.

p CHARGE RADIUS

This is the rms electric charge radius, $\sqrt{\langle r_E^2 \rangle}$

Most measurements of the radius of the proton involve electron-proton interactions, and most of the more recent values agree with one another. The most precise of these is $r_p = 0.879(8)$ fm (BERNAUER 10). The CODATA 10 value (MOHR 12), obtained from the electronic results, is 0.8775(51). However, a measurement using muonic hydrogen finds $r_p=0.84184(67)$ fm (POHL 10), which is eight times more precise and seven standard deviations (using the CODATA 10 error) from the electronic

Since POHL 10, there has been a lot of discussion about the disagreement, especially concerning the modeling of muonic hydrogen. Here is an incomplete list of papers: DERUJULA 10, CLOET 11, DISTLER 11, DERUJULA 11, ARRINGTON 11, BERNAUER 11, and HILL 11.

Until the difference between the $e\,p$ and μp values is understood, it does not make much sense to average all the values together. For the present, we stick with the less precise (and provisionally suspect) CODATA 2010 value (MOHR 12). It is up to workers in this field to solve this puzzle.

p MEAN LIFE

A test of baryon conservation. See the "p Partial Mean Lives" section below for limits for identified final states. The limits here are to "anything" or are for "disappearance" modes of a bound proton (ρ) or (n). See also the 3ν modes in the "Partial Mean Lives" section. Table 1 of BACK 03 is a nice summary.

| LIMI I (ye ars) | PARTICLE | CL% | DOCUMENT ID | | TECN | COMMENT |

- ²⁵ ARAKI 06 looks for signs of de-excitation of the residual nucleus after disappearance of a neutron from the $s\,{ ext{shell}}\,$ of $^{12}{ ext{C}}.$
- ²⁶AHMED 04 looks for γ rays from the de-excitation of a residual ¹⁵ O* or ¹⁵ N* following the disappearance of a neutron or proton in $^{16}\mathrm{O}.$
- 27 BACK 03 looks for decays of unstable nuclides left after N decays of parent 12 C, 13 C,
- 16O nuclei. These are "invisible channel" limits.
 28 ZDESENKO 03 gets this limit on proton disappearance in deuterium by analyzing SNO
- 29 AHMAD 02 (see its footnote 7) looks for neutrons left behind after the disappearance of the proton in deuterons.
- 30 BERNABEI 00B looks for the decay of a $^{128}_{53}$ I nucleus following the disappearance of a proton in the otherwise-stable $^{129}_{54}$ Xe nucleus.
- 31 EVANS 77 looks for the daughter nuclide 129 Xe from possible 130 Te decays in ancient Te ore samples.

| 32 This mean-life limit has been | obtained from | n a half-life limit | by dividing the | latter by In(2) |
|----------------------------------|---------------|---------------------|-----------------|-----------------|
| = 0.693. | | | | |

 $^{^{33}}$ = 0.003. TLEROV 58 looks for the spontaneous fission of a 232 Th nucleus after the disappearance of one of its nucleons.

アMEAN LIFE

Of the two astrophysical limits here, that of GEER 00D involves considerably more refinements in its modeling. The other limits come from direct observations of stored antiprotons. See also " \overline{p} Partial Mean Lives," after "p Partial Mean Lives," below, for exclusive-mode limits. The best (lifetime/branching fraction) limit there is 7×10^5 years, for $\overline{p} \rightarrow e^- \gamma$. We advance only the exclusive-mode limits to our Summary Tables.

| (years) | CL% | EVTS | DO CUMENT ID | | TECN | COMMENT |
|--------------------------------|-----------|----------|---------------------|-------------|----------|-------------------------------------|
| • • • We do no | t use the | followin | g data for averages | , fits, lii | mits, et | .c. • • • |

| $> 3.7 \times 10^{-3}$ | | | BREGMAN | 78 (| CNTR | Storage ring |

 $^{^{34}}$ GEER 00D uses agreement between a model of galactic \overline{p} production and propagation and the observed \overline{p}/p cosmic-ray spectrum to set this limit.

p DECAY MODES

See the "Note on Nucleon Decay" in our 1994 edition (Phys. Rev. **D50**, 1173) for a short review.

The "partial mean life" limits tabulated here are the limits on τ/B_j , where τ is the total mean life and B_j is the branching fraction for the mode in question. For N decays, p and n indicate proton and neutron partial lifetimes

| | Mode | Partial mean life (10 ³⁰ years) | Confidence level |
|-------------|------------------------------------------|-----------------------------------------------|------------------|

p PARTIAL MEAN LIVES

The "partial mean life" limits tabulated here are the limits on τ/B_i , where au is the total mean life for the proton and B_i is the branching fraction for the mode in question.

Decaying particle: p= proton, n= bound neutron. The same event may appear under more than one partial decay mode. Background estimates may be accurate to a factor of two.

 $^{^{39}}$ In estimating the background, this HIRATA 89c limit (as opposed to the later limits of WALL 00B and MCGREW 99) does not take into account present understanding that the flux of ν_{μ} originating in the upper atmosphere is depleted. Doing so would reduce the background and thus also would reduce the limit here. 40 We have calculated 90% CL limit from 1 confined event. 41 We have converted 2 possible events to 90% CL limit. 42 We have converted 40 No. (CL maps) life

$$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$$
 Status: ***

We have omitted some results that have been superseded by later experiments. See our earlier editions.

Anyone interested in the neutron should look at these two new review articles: D. Dubbers and M.G. Schmidt, "The neutron and its role in cosmology and particle physics," Reviews of Modern Physics 83 1111 (2011); and F.E. Wietfeldt and G.L. Greene, "The neutron lifetime," Reviews of Modern Physics 83 1173 (2011).

n MASS (atomic mass units u)

The mass is known much more precisely in u (atomic mass units) than in MeV. See the next data block.

n MASS (MeV)

The mass is known much more precisely in u (atomic mass units) than in MeV. The conversion from u to MeV, 1 u $= 931.494061(21)~{
m MeV}/c^2$ (MOHR 12, the 2010 CODATA value), involves the relatively poorly known electronic charge.

 6 The 2010 CODATA mass difference in u is $m_n-m_p=1.388\,449\,19(45)\times 10^{-3}u$.

⁷ Calculated by us from the MOHR 08 ratio $m_n/m_p = 1.00137841918(46)$. In u, $m_n = 1.00137841918(46)$. $m_D = 1.38844920(46) \times 10^{-3} \text{ u.}$

⁸ Calculated by us from the MOHR 05 ratio $m_{n}/m_{p}=1.00137841870\pm0.00000000058.$ In u, $m_n - m_p = (1.3884487 \pm 0.0000006) \times 10^{-3}$ u.

 9 Calculated by us from the MOHR 99 ratio $m_n/m_p=1.00137841887\pm0.00000000058.$ In u, $m_n-m_p=(1.3884489\pm0.0000006)\times10^{-3}$ u.

 10 Calculated by us from the COHEN 87 ratio $m_{\it n}/m_{\it p}=$ 1.001378404 \pm 0.000000009. In u, $m_n - m_p = 0.001388434 \pm 0.0000000099$ u.

n MEAN LIFE

Limits on lifetimes for bound neutrons are given in the section "p PARTIAL MEAN LIVES "

The mean life of the neutron, 878.5 \pm 0.8 s, obtained by SEREBROV 05 (for a more detailed account, see SEREBROV 08A) was so far from our average of seven other measurements, 885.7 \pm 0.8 s, that it made no sense to include it in our average. Thus our 2006, 2008, and 2010 Reviews stayed with 885.7 \pm 0.8 s; but we noted that in light of SEREBROV 05 our value should be regarded as suspect until further experiments clarified matters.

However, after our 2010 Review, PICHLMAIER 10 obtained a mean life of 880.7 ± 1.8 s, and we averaged the best seven results to get 881.5 ± 1.5 s for our 2011 off-year web update. And since then, ARZUMANOV 12, responding to comments of SEREBROV 10B, recalculated the systematic corrections to its 2000 measurement (ARZUMANOV 00) and lowered its value from 885.4 \pm 0.9 \pm 0.4 s to 881.6 \pm 0.8 \pm 1.9 s. Thus the trend is definitely toward a shorter lifetime.

There seems little better to do than to again average the best seven measurements. The result, 880.1 \pm 1.1 s (including a scale factor of 1.8), is $5.6\,s$ lower than the value we gave in 2010-a drop of 7.0 old and 5.1 new standard deviations.

For a full review of all matters concerning the neutron lifetime, see F.E. Wietfeldt and G.L. Greene, "The neutron lifetime," Reviews of Modern Physics 83 1173 (2011). In particular, there is a full discussion of the experimental methods and results; and an average lifetime is obtained making several different selections of those results. (The revised ARZU-MANOV 12 mean life was not yet available.)

¹⁶ LAMOREAUX 07 faults BAKER 06 for not including in the estimate of systematic error an effect due to the Earth's rotation. BAKER 07 replies (1) that the effect was included to the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the part of the p implicitly in the analysis and (2) that further analysis confirms that the BAKER 06 limit is correct as is. See also SILENKO 07.

This HARRIS 99 result includes the result of SMITH 90. However, the averaging of the

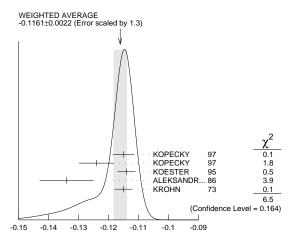

n MEAN-SQUARE CHARGE RADIUS

The mean-square charge radius of the neutron, $\langle r_n^2 \rangle$, is related to the neutron-electron scattering length $b_{n\,e}$ by $\langle r_n^2 \rangle = 3(m_e a_0/m_n) b_{n\,e}$, where m_e and m_n are the masses of the electron and neutron, and a_0 is the Bohr radius. Numerically, $\langle r_n^2 \rangle = 86.34~b_{n\,e}$, if we use a_0 for a nucleus with infinite mass with infinite mass.

LIMIT ON AT OSCILLATIONS

Mean Time for $n\overline{n}$ Transition in Vacuum

A test of $\Delta B = 2$ baryon number nonconservation. MOHAPATRA 80 and MOHAPATRA 80 discuss the theoretical motivations for looking for $n\overline{n}$ oscillations. DOVER 83 and DOVER 85 give phenomenological analyses. The best limits come from looking for the decay of neutrons bound in nuclei. However, these analyses require model-dependent corrections for nuclear effects. See KABIR 83, DOVER 89, ALBERICO 91, and GAL 00 for discussions. Direct searches for $n \rightarrow \overline{n}$ transitions using reactor neutrons are cleaner but give somewhat poorer limits. We include limits for both free and bound neutrons in the Summary Table. See MOHAPATRA 09 for a recent review.

 33 NORMAN 96 gets this limit by attributing SAGE and GALLEX counting rates to the charge-nonconserving transition $^{71}\mbox{Ga} \rightarrow ~^{71}\mbox{Ge+neutrals}$ rather than to solar-neutrino reactions.

BARYON DECAY PARAMETERS

Written 1996 by E.D. Commins (University of California, Berkeley).

$Baryon\ semileptonic\ decays$

I

The typical spin-1/2 baryon semileptonic decay is described by a matrix element, the hadronic part of which may be written

$$\overline{B}_f \left[f_1(q^2) \gamma_\lambda + i \ f_2(q^2) \sigma_{\lambda\mu} q^\mu + g_1(q^2) \gamma_\lambda \gamma_5 + g_3(q^2) \gamma_5 q_\lambda \right] B_i . \tag{1}$$

Here B_i and \overline{B}_f are spinors describing the initial and final baryons, and $q=p_i-p_f$, while the terms in f_1 , f_2 , g_1 , and g_3 account for vector, induced tensor ("weak magnetism"), axial vector, and induced pseudoscalar contributions [1]. Second-class current contributions are ignored here. In the limit of zero momentum transfer, f_1 reduces to the vector coupling constant g_V , and g_1 reduces to the axial-vector coupling constant g_A . The latter coefficients are related by Cabibbo's theory [2], generalized to six quarks (and three mixing angles) by Kobayashi and Maskawa [3]. The g_3 term is negligible for transitions in which an e^\pm is emitted, and gives a very small correction, which can be estimated by PCAC [4], for μ^\pm modes. Recoil effects include weak magnetism, and are taken into account adequately by considering terms of first order in

$$\delta = \frac{m_i - m_f}{m_i + m_f} \,, \tag{2}$$

where m_i and m_f are the masses of the initial and final baryons.

The experimental quantities of interest are the total decay rate, the lepton-neutrino angular correlation, the asymmetry coefficients in the decay of a polarized initial baryon, and the polarization of the decay baryon in its own rest frame for an unpolarized initial baryon. Formulae for these quantities are derived by standard means [5] and are analogous to formulae for nuclear beta decay [6]. We use the notation of Ref. 6 in the Listings for neutron beta decay. For comparison with experiments at higher q^2 , it is necessary to modify the form factors at $q^2 = 0$ by a "dipole" q^2 dependence, and for high-precision comparisons to apply appropriate radiative corrections [7].

The ratio q_A/q_V may be written as

$$g_A/g_V = |g_A/g_V| e^{i\phi_{AV}}. (3)$$

The presence of a "triple correlation" term in the transition probability, proportional to $\text{Im}(g_A/g_V)$ and of the form

$$\sigma_i \cdot (\mathbf{p}_\ell \times \mathbf{p}_\nu)$$
 (4)

for initial baryon polarization or

$$\sigma_f \cdot (\mathbf{p}_\ell \times \mathbf{p}_\nu)$$
 (5)

for final baryon polarization, would indicate failure of timereversal invariance. The phase angle ϕ has been measured precisely only in neutron decay (and in ¹⁹Ne nuclear beta decay), and the results are consistent with T invariance.

Hyperon nonleptonic decays

The amplitude for a spin-1/2 hyperon decaying into a spin-1/2 baryon and a spin-0 meson may be written in the form

$$M = G_F m_\pi^2 \cdot \overline{B}_f (A - B\gamma_5) B_i , \qquad (6)$$

where A and B are constants [1]. The transition rate is proportional to

$$R = 1 + \gamma \widehat{\boldsymbol{\omega}}_{f} \cdot \widehat{\boldsymbol{\omega}}_{i} + (1 - \gamma)(\widehat{\boldsymbol{\omega}}_{f} \cdot \widehat{\mathbf{n}})(\widehat{\boldsymbol{\omega}}_{i} \cdot \widehat{\mathbf{n}}) + \alpha(\widehat{\boldsymbol{\omega}}_{f} \cdot \widehat{\mathbf{n}} + \widehat{\boldsymbol{\omega}}_{i} \cdot \widehat{\mathbf{n}}) + \beta \widehat{\mathbf{n}} \cdot (\widehat{\boldsymbol{\omega}}_{f} \times \widehat{\boldsymbol{\omega}}_{i}) ,$$
 (7)

where $\hat{\mathbf{n}}$ is a unit vector in the direction of the final baryon momentum, and $\hat{\boldsymbol{\omega}}_i$ and $\hat{\boldsymbol{\omega}}_f$ are unit vectors in the directions of the initial and final baryon spins. (The sign of the last term in the above equation was incorrect in our 1988 and 1990 editions.) The parameters α , β , and γ are defined as

$$\alpha = 2 \operatorname{Re}(s^* p) / (|s|^2 + |p|^2) ,$$

$$\beta = 2 \operatorname{Im}(s^* p) / (|s|^2 + |p|^2) ,$$

$$\gamma = (|s|^2 - |p|^2) / (|s|^2 + |p|^2) ,$$
(8)

where s = A and $p = |\mathbf{p}_f| B/(E_f + m_f)$; here E_f and \mathbf{p}_f are the energy and momentum of the final baryon. The parameters α , β , and γ satisfy

$$\alpha^2 + \beta^2 + \gamma^2 = 1. \tag{9}$$

If the hyperon polarization is \mathbf{P}_Y , the polarization \mathbf{P}_B of the decay baryons is

$$\mathbf{P}_{B} = \frac{(\alpha + \mathbf{P}_{Y} \cdot \widehat{\mathbf{n}})\widehat{\mathbf{n}} + \beta(\mathbf{P}_{Y} \times \widehat{\mathbf{n}}) + \gamma\widehat{\mathbf{n}} \times (\mathbf{P}_{Y} \times \widehat{\mathbf{n}})}{1 + \alpha\mathbf{P}_{Y} \cdot \widehat{\mathbf{n}}} . \quad (10)$$

Here \mathbf{P}_B is defined in the rest system of the baryon, obtained by a Lorentz transformation along $\hat{\mathbf{n}}$ from the hyperon rest frame, in which $\hat{\mathbf{n}}$ and \mathbf{P}_Y are defined.

An additional useful parameter ϕ is defined by

$$\beta = (1 - \alpha^2)^{1/2} \sin \phi \ . \tag{11}$$

In the Listings, we compile α and ϕ for each decay, since these quantities are most closely related to experiment and are essentially uncorrelated. When necessary, we have changed the signs of reported values to agree with our sign conventions. In the Baryon Summary Table, we give α , ϕ , and Δ (defined below) with errors, and also give the value of γ without error.

Time-reversal invariance requires, in the absence of final-state interactions, that s and p be relatively real, and therefore that $\beta=0$. However, for the decays discussed here, the final-state interaction is strong. Thus

$$s = |s| e^{i\delta_s}$$
 and $p = |p| e^{i\delta_p}$, (12)

where δ_s and δ_p are the pion-baryon s- and p-wave strong interaction phase shifts. We then have

$$\beta = \frac{-2|s||p|}{|s|^2 + |p|^2} \sin(\delta_s - \delta_p) . \tag{13}$$

One also defines $\Delta = -\tan^{-1}(\beta/\alpha)$. If T invariance holds, $\Delta = \delta_s - \delta_p$. For $\Lambda \to p\pi^-$ decay, the value of Δ may be compared with the s- and p-wave phase shifts in low-energy $\pi^- p$ scattering, and the results are consistent with T invariance.

See also the note on "Radiative Hyperon Decays" in the Ξ^0 Listings in this *Review*.

e- ASYMMETRY PARAMETER A

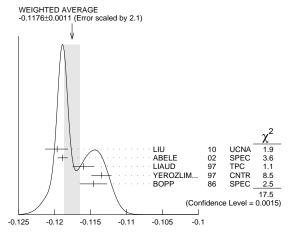

This is the neutron-spin electron-momentum correlation coefficient. Unless otherwise noted, the values are corrected for radiative effects and weak magnetism. In the Standard Model, A is related to $\lambda\equiv g_A/g_V$ by $A=-2(\lambda^2-|\lambda|)~/~(1+3\lambda^2);$ this assumes that ${\it g}_A$ and ${\it g}_V$ are real.

N's and Δ 's

N AND Δ RESONANCES

Written April 2012 by E. Klempt (University of Bonn) and R.L Workman (George Washington University).

I. Introduction

The excited states of the nucleon have been studied in a large number of formation and production experiments. The Breit-Wigner masses and widths, the pole positions, and the elasticities of the N and Δ resonances in the Baryon Summary Table come largely from partial-wave analyses of πN total, elastic, and charge-exchange scattering data. The most comprehensive analyses were carried out by the Karlsruhe-Helsinki (KH80) [1], Carnegie Mellon-Berkeley (CMB80) [2], and George Washington U (GWU) [3] groups. Partial-wave analyses have also been performed on much smaller πN reaction data sets to get $N\eta$, ΛK , and ΣK branching fractions. Other branching fractions come from analyses of $\pi N \to N\pi\pi$ data. A number of groups have undertaken multichannel analyses of these and associated photo-induced reactions (see Sec. VI).

Table 1. The status of the N resonances. Only those with an overall status of *** or **** are included in the main Baryon Summary Table.

*** Existence is certain, and properties are at least fairly well explored.

** Existence is very likely but further confirmation of quantum numbers and branching fractions is required.

- ** Evidence of existence is only fair.
- Evidence of existence is poor.

In recent years, a large amount of data on photoproduction of many final states has been accumulated, and these data are beginning to make a significant impact on the properties of baryon resonances. A survey of data on photoproduction can be found in the proceedings of recent conferences [4] and workshops [5], and in a recent review [6].

II. Naming scheme for baryon resonances

In the past, when nearly all resonance information came from elastic πN scattering, it was common to label resonances with the incoming partial wave $L_{2I,2J}$, as in $\Delta(1232)P_{33}$ and $N(1680)F_{15}$. However, most recent information has come from γN experiments. Therefore, we have replaced $L_{2I,2J}$ with the spin-parity J^P of the state, as in $\Delta(1232)$ 3/2⁺ and N(1680) 5/2⁺. This applies to all baryons, including those such as the Ξ resonances and charm baryons that are not produced in formation experiments. Names of the stable baryons $(N, \Lambda, \Sigma, \Xi, \Omega, \Lambda_c, \cdots)$ have no spin, parity, or mass attached.

Table 2. The status of the Δ resonances. Only those with an overall status of *** or **** are included in the main Baryon Summary Table.

III. Using the N and Δ listings

Tables 1 and 2 list all the N and Δ entries in the Baryon Listings and give our evaluation of the overall status, the status from $\pi N \to N\pi$ scattering data and from photoproduction experiments, and the status channel by channel. Only the established resonances (overall status 3 or 4 stars) are promoted to the Baryon Summary Table. We have omitted from the Listings information from old analyses, prior to KH80 and CMB80 which can be found in earlier editions. A rather complete survey of older results was given in our 1982 edition [7].

Baryon Particle Listings N's and Δ 's

The star rating assigned to a resonance depends on the data base and the analysis. As a rule, we award an overall status *** or **** only to those resonances which are confirmed by independent analyses and which are derived from analyses based on complete information, *i.e.*, for analyses based on three observables in πN scattering or eight properly chosen observables in photoproduction. Use of dispersion relations (as in the KH80, CMB80, and GWU analyses) may lift these requirements. Three and four-star resonances should be observed in one of their strongest decay modes. Weak signals or signals emerging in analyses with incomplete experimental information are given ** or * status. We do not consider new results without proper error evaluation.

In the Data Listings, we give first the Breit-Wigner mass and width but warn the reader that Breit-Wigner parameters depend on the formalism used, such as for angular momentum barrier factors or cut-off parameters, and the assumed or modeled background. Then we give pole-related quantities, such as the position of the pole and its elastic residue. For the first time, we give residues and phases of hadronic transition amplitudes and helicity amplitudes. Branching ratios and photoproduction amplitudes follow.

IV. Properties of resonances

Resonances are defined by poles of the scattering amplitude in the complex energy $w=\sqrt{s}$ plane [8]. In contrast to other quantities related to resonance phenomena, such as the Breit-Wigner mass or the K-matrix pole, a pole of the scattering amplitude does not depend on the chosen field parameterization, and production and decay properties factorize. It is the pole position which should be compared to eigenvalues of the Hamiltonian of full QCD.

Examining the Listings, one finds a much larger spread in Breit-Wigner parameters compared to pole parameters. In his pole-emic against Breit-Wigner parameters, Höhler [9] concluded: "In contrast to the conventional (Breit-Wigner) parameters, the pole positions and speed plots have a well-defined relation to S-matrix theory. They also give more information on the resonances and thresholds and can be used for the prediction on other reactions that couple to the excited states [italics in original]."

In scattering theory, the amplitude for the scattering process leading from the initial state a to the final state b is given by the S matrix, which can be decomposed as follows:

$$S_{ab} = I_{ab} + 2i\sqrt{\rho_a}T_{ab}\sqrt{\rho_b}.$$
 (1)

Here I_{ab} is the identity operator, and T_{ab} describes the transition from the initial state to the final state (e.g. πN to ΣK). T_{ab} contains coupling constants, the decay momenta k to the power L to yield the correct threshold behavior when angular momenta are involved, and a correction $F(L, r^2, k^2)$, e.g. in Blatt-Weisskopf form, with a range parameter r. The two-body phase-space ρ is given (see Eq. 39.17 in Sec. 39) by

$$\rho(s) = \frac{1}{16\pi} \frac{2|\vec{k}|}{\sqrt{s}} \,. \tag{2}$$

The transition amplitude T contains poles due to resonances and background terms. Above the threshold for inelastic reactions, a resonance is associated with a cluster of poles in different Riemann sheets. The pole closest to the real axis has the strongest impact on the data. It is situated on the second Riemann sheet, starting at the highest threshold below the pole position. If the threshold is close to the pole position, poles in other sheets may have an important impact as well.

Other complications may occur: Broad resonances are difficult to disentangle from background amplitudes, e.g., due to left-hand cuts originating from meson and baryon exchange forces. A two-particle subsystem generates a square-root singularity at its threshold; poles in a two-body subsystem, e.g., the ρ meson in the $\pi\pi$ system, lead to branch points in the complex energy plane. Neglecting some of these aspects leads to a model dependence of the pole position. These uncertainties increase with the particle width.

Several particle properties are related to poles. First, poles exist on multiple Riemann sheets. In the Listings, we give for each resonance the position of the most relevant pole. The poles of the scattering amplitude can be found by analytic continuation of the amplitude. The real part of the pole position in the complex energy plane defines the particle mass, the imaginary part its half width: $w_{\text{pole}} = m_{\text{pole}} - i\Gamma_{\text{pole}}/2$. Residues of transition amplitudes are the first term in a Laurent expansion and can be calculated through a contour integral of the amplitude T_{ab} around the pole position in the energy plane:

$$Res(a \to b) = \oint \frac{d\sqrt{s}}{2\pi i} \sqrt{\rho_a} T_{ab}(s) \sqrt{\rho_b}$$

$$= \frac{1}{2w_{\text{pole}}} \sqrt{\rho_a(s_{\text{pole}})} g_a g_b \sqrt{\rho_b(s_{\text{pole}})}, \qquad (4)$$

where g_a and g_b are coupling constants. In the Listings, we give normalized residues, $2 \operatorname{Res}(a \to b)/\Gamma_{\text{pole}}$. For elastic scattering, e.g., for $\pi N \to N\pi$, this gives the elastic residue:

$$Res(a \to a) = \frac{1}{2w_{\text{pole}}} \rho_a(s_{\text{pole}}) g_a^2. \tag{5}$$

Branching ratios of a pole can be defined by

$$BR_{\text{pole}}(\text{channel } b) = \frac{|Res(\pi N \to b)|^2}{|Res(\pi N \to N\pi)| \cdot (\Gamma_{\text{pole}}/2)}.$$
 (6)

This information is, however, not given in the literature.

Within models, background amplitudes can be parameterized using an effective Lagrangian approach (as in dynamical coupled-channel approaches), or by low-order polynomial functions. In the latter case, resonances are then added, sometimes in the form of Breit-Wigner amplitudes. In the Listings, particle properties related to fits to data using Breit-Wigner amplitudes are given as well. These are the Breit-Wigner mass and width, the partial decay widths, and the branching ratios. It should be noted that Breit-Wigner parameters depend on the background parameterization.

N's and Δ 's

The multichannel relativistic Breit-Wigner amplitude is given by

$$A_{ab} = \sqrt{\rho_a} T_{ab} \sqrt{\rho_b} = \frac{-g_a g_b \sqrt{\rho_a \rho_b}}{s - m_{\text{BW}}^2 + i \sum_a g_a^2 \rho_a} , \qquad (7)$$

where $m_{\rm BW}$ is called the Breit-Wigner mass. In the case of two channels, Eq. (7) is known as the Flatté formula. The inclusion of angular momenta leads to additional factors. The energy-dependent partial decay widths, defined by $\sqrt{s}\,\Gamma_a(s)=g_a^2\rho_a(s)$, can be used to bring Eq. (7) into the form of Eq. (39.57). Evaluated at the Breit-Wigner mass, it gives the partial decay width Γ_a at the resonance position

$$m_{\rm BW}\Gamma_a = g_a^2 \rho_a(m_{BW}^2). \tag{8}$$

The branching ratio for the decay of a resonance into channel a,

$$BR_a = \Gamma_a/\Gamma_{\rm BW}$$
, (9)

vanishes by definition for decay modes with thresholds above the Breit-Wigner mass. That the sum $\sum_a BR_a$ equals one follows from the definition. Unobserved decay modes lead to the inequality $\sum_a BR_a \leq 1$. In the case of broad resonances, definitions (8) and (9) may be counter-intuitive. Branching ratios can also be defined as

$$BR' = \int_{\text{threshold}}^{\infty} \frac{ds}{\pi} \frac{g_a^2 \rho(s)}{(m_{\text{BW}}^2 - s)^2 + (\sum_a g_a^2 \rho_a(s))^2}.$$
 (10)

Here $\rho(s)$ should not be continued below threshold. These branching ratios include decays of resonances into channels with thresholds above their nominal masses. The relation $\sum_a BR'_a = 1$ is needed for normalization.

V. Electromagnetic interactions

A new approach to the nucleon excitation spectrum is provided by dedicated facilities at the Universities of Bonn and Mainz, and at the national laboratories Jefferson Lab in the US and SPring-8 in Japan. High-precision cross sections and polarization observables in photoproduction of pseudoscalar mesons provide a data set that is nearly a "complete experiment," one that fully constrains the four complex amplitudes describing the spin-structure of the reaction. A large number of photoproduction reactions has been studied.

In photoproduction, the spins of the photon and nucleon can be parallel or anti-parallel, and there are spin-flip and non-flip transitions. Four independent amplitudes can be defined using the photon polarization and the hadronic current [10]. The amplitudes can be expanded in a series of electric and magnetic multipoles. In general, two amplitudes, one electric and one magnetic, contribute to one J^P combination. For a given resonance, these two amplitudes are related to the helicity amplitudes $A_{1/2}$ and $A_{3/2}$. The final state may have isospin I=1/2 or I=3/2.

If a Breit-Wigner parametrization is used, the $N\gamma$ partial width, Γ_{γ} , is given in terms of the helicity amplitudes $A_{1/2}$ and $A_{3/2}$ by

$$\Gamma_{\gamma} = \frac{k_{\text{BW}}^2}{\pi} \frac{2m_N}{(2J+1)m_{\text{BW}}} \left(|A_{1/2}|^2 + |A_{3/2}|^2 \right) . \tag{11}$$

Here m_N and $m_{\rm BW}$ are the nucleon and resonance masses, J is the resonance spin, and $k_{\rm BW}$ is the photon c.m. decay momentum. Most earlier analyses have quoted the real quantities $A_{1/2}$ and $A_{3/2}$.

Other more recent studies have quoted related complex quantities, evaluated at the T-matrix pole. The complex helicity amplitudes for photoproduction of the final state b, $\tilde{A}_{1/2}$ and $\tilde{A}_{3/2}$, are given by

$$Res\Big((\gamma N)_h \to b\Big) = \frac{\tilde{A}^h g_b}{2w_{\text{pole}}} |k_{\text{pole}}| \sqrt{\frac{2m_N}{(2J+1)\pi} \cdot \rho_b(w_{\text{pole}}^2)}.$$
(12)

 $\tilde{A}_{1/2}$ and $\tilde{A}_{3/2}$ are defined at the pole position, and are normalized to reproduce Eq. (11) when the pole position is replaced by the Breit-Wigner mass.

The amplitudes $\tilde{A}_{1/2}$ and $\tilde{A}_{3/2}$, the elastic residues, and the residues of the transition amplitudes are complex numbers. Eq. (8) defines $g_{N\pi}$ up to a sign. (Here, $g_{N\pi}$ is the $N\pi$ decay constant of a resonance, not the πN coupling constant!) Due to Eq. (12), the phase of the helicity amplitude depends on this definition. We define the phase of $g_{N\pi}$ clockwise.

The determination of eight real numbers from four complex amplitudes (with one overall phase undetermined) requires at least seven independent data points. At least one further measurement is required to resolve discrete ambiguities that result from the fact that data are proportional to squared amplitudes. Photon beams and nucleon targets can be polarized (with linear or circular polarization P_{\perp} , P_{\odot} , and \vec{T} , respectively); and the recoil polarization of the outgoing nucleon \vec{R} can be measured. Experiments can be divided into three classes: those with polarized photons and a polarized target (BT); and those measuring the baryon recoil polarization and using either a polarized photon (BR) or a polarized target (TR). Different sign conventions are used in the literature, as summarized in Ref. 12.

A large number of polarization observables has been determined that constrain energy-dependent partial-wave solutions. One of the best studied reactions is $\gamma p \to \Lambda K^+$. Published data include differential cross sections, the beam asymmetry Σ , the target asymmetry T, the recoil polarization P, and the BR double-polarization variables C_x, C_z, O_x , and O_z . For $\gamma p \to p \pi^0$, $\gamma p \to n \pi^+$, and $\gamma p \to p \eta$, differential cross sections and beam asymmetries have been published; BT data for E, F, G, and H have been presented at conferences [13].

Electroproduction of mesons provides information on the internal structure of resonances. The helicity amplitudes become functions of the momentum transfer, and a third amplitude, $S_{1/2}$, contributes to the process. Recent experimental results and their interpretation are reviewed by I.G. Aznauryan and

V.D. Burkert [14] and by L. Tiator, D. Drechsel, S.S. Kamalov, and M. Vanderhaeghen [15].

VI. Partial wave analyses

Several PWA groups are now actively involved in the analysis of the new data. Of the three "classical" analysis groups at KH, CMB, and GWU, only the GWU group is still active. This group maintains a nearly complete database, covering reactions from πN and KN elastic scattering to $\gamma N \to N\pi$, $N\eta$, and $N\eta'$. It is presently the only group determining energy-independent πN elastic amplitudes from scattering data. Given the high-precision of photoproduction data already collected and to be taken in the near future, we estimate that an improved spectrum of N and Δ resonances should become available in the forthcoming years.

Energy-dependent fits are performed by various groups with the aim to understand the reaction dynamics and to identify Nand Δ resonances. Ideally, the Bethe-Salpeter equation should be solved to describe the data. For practical reasons, approximations have to be made. We mention here: (1) The Mainz unitary isobar model [16] focusses on the correct treatment of the low-energy domain; resonances are added to the unitary amplitude as a sum of Breit-Wigner amplitudes. (2) Multichannel analyses using K-matrix parameterizations derive background terms from a chiral Lagrangian—providing a microscopical description of the background—(Giessen [17,18]), or from phenomenology (Bonn-Gatchina [19]). (3) Several groups (Argonne-Osaka [20], Bonn-Jülich [22,23], Dubna-Mainz-Taipeh [21], EBAC-Jlab [24], Valencia [25]) use dynamical reaction models, driven by chiral Lagrangians, which take dispersive parts of intermediate states into account. The Giessen group pioneered multichannel analyses of large data sets on pion- and photoinduced reactions [17,18]. The Bonn-Gatchina group included recent high-statistics data and reported systematic searches for new baryon resonances in all relevant partial waves. A summary of their results can be found in Ref. 19.

Note: Signs of couplings from $\pi\,N \to N\,\pi\,\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620)$ S_{31} coupling to $\Delta(1232)$ π .

N(1440) FOOTNOTES

- ¹ LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- ² From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix
- amplitudes.
 3 ARNDT 06 also finds a second-sheet pole with real part = 1388 MeV, $-2 \times \text{imaginary}$ part = 165 MeV, and residue with modulus 86 MeV and phase = -46 degrees.
 4 See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
 5 ARNDT 04 also finds a second-sheet pole with real part = 1385 MeV, $-2 \times \text{imaginary}$ part = 166 MeV, and residue with modulus 82 MeV and phase = -51° .
 6 ARNDT 95 also finds a second-sheet pole with real part = 1383 MeV, $-2 \times \text{imaginary}$ part = 210 MeV, and residue with modulus 92 MeV and phase = -54° .
 7 ARNDT 91 (Soln SM90) also finds a second-sheet pole with real part = 1413 MeV.

- 7 ARNDT 91 (Soln SM90) also finds a second-sheet pole with real part = 1413 MeV, $-2 \times$ imaginary part = 256 MeV, and residue = (78–153f) MeV.
- 8 LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- 9 LONGACRE 77 considers this coupling to be well determined.
- 10 WADA 84 is inconsistent with other analyses; see the Note on N and Δ Resonances.

Note: Signs of couplings from $\pi\,N \to N\,\pi\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620)\,\,S_{31}$ coupling to $\Delta(1232)\,\pi$.

N(1520) FOOTNOTES

- 1 LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi\,N\to\,M\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- $^2\,\text{From}$ method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- 3 See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- 4 LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N \pi \pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- ⁵ LONGACRE 77 considers this coupling to be well determined.
- ⁶ MUKHOPADHYAY 98 uses an effective Lagrangian approach to analyze η photoproduction data. The *ratio* of the $A_{3/2}$ and $A_{1/2}$ amplitudes is determined, with less model dependence than the amplitudes themselves, to be $A_{3/2}/A_{1/2}=-2.5\pm0.5\pm0.4$.

N(1535) DECAY MODES

The following branching fractions are our estimates, not fits or averages.

| | Mode | Fraction (Γ_i/Γ) |
|-----------------------|-----------------------------------|------------------------------|
| $\overline{\Gamma_1}$ | $N\pi$ | 35-55 % |
| Γ_2 | N η | (42 ±10)% |
| Γ_3 | $N \pi \pi$ | 1-10 % |
| Γ_4 | $\Delta\pi$ | <1 % |
| Γ_5 | Δ (1232) π , D -wave | 0-4 % |
| Γ_6 | $N \rho$ | <4 % |
| Γ_7 | $N\rho$, $S=1/2$, S -wave | (2.0 ± 1.0) % |
| Γ ₈ | $N\rho$, $S=3/2$, D -wave | (0.0 ± 1.0) % |
| Γ9 | $N(\pi\pi)_{S-\text{wave}}^{I=0}$ | (2 ± 1) % |
| Γ_{10} | $N(1440)\pi$ | (8 ± 3)% |
| Γ_{11} | $p\gamma$ | 0.15-0.30 % |
| Γ_{12} | $p\gamma$, helicity=1/2 | 0.15-0.30 % |
| Γ_{13} | n γ | 0.01-0.25 % |
| Γ_{14} | $n\gamma$, helicity=1/2 | 0.01-0.25 % |

Note: Signs of couplings from $\pi\,{\it N}\,\to\,{\it N}\,\pi\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\varDelta(1620)$ S_{31} coupling to $\varDelta(1232)\,\pi.$

N(1535) FOOTNOTES

- $^{1}\, {\sf LONGACRE}$ 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes. From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix

- amplitudes. 3 KRUSCHE 97 fits with the mass fixed at 1544 MeV. 4 See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of π N elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- 5 ARNDT 98 also lists pole residues, which display more model dependence than do the associated pole positions.
- described positions. 6 LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N \pi \pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- 7 The best value ARMSTRONG 99B obtains is \simeq 0.55; this assumes S_{11} dominance in the reaction $p(e, e'p) \eta$ at $Q^2 = 4 (GeV/c)^2$
- ⁸ This STAROSTIN 03 value is an estimate made using simplest assumptions.
- $^9\,{\sf BENMERROUCHE}$ 91 uses an effective Lagrangian approach to analyze η photoproduc-
- tion data. 10 This ANISOVICH 09A amplitude is evaluated at the pole position; the phase is $(20\pm15)^{\circ}$.
- $^{11}\,\text{This}$ A NISOVICH 09A amplitude is evaluated at the pole position; the phase is ($20\pm20)^{\circ}$.

N(1650) FOOTNOTES

- 1 ARNDT 95 finds two distinct states. 2 LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi\,N\to\,N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- ³ From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix
- Asset HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial—wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- ARNDT 98 also lists pole residues, which display more model dependence than do the associated pole positions.
- described positions. 6 LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \rightarrow N \pi \pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- 7 LONGACRE 77 considers this coupling to be well determined.
- 8 This A NISOVICH 09A amplitude is evaluated at the pole position; the phase is ($25\pm20)^\circ$.
- 9 This ANISOVICH 09A amplitude is evaluated at the pole position; the phase is ($30\pm25)^\circ$

N(1675) FOOTNOTES

- $^{
 m 1}$ LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi\,N\to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- ² From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix
- amplitudes. ³ See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- 4 LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N \pi \pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- 5 SAXON 80 finds the coupling phase is near 90°.
- ⁶LONGACRE 77 considers this coupling to be well determined.

Note: Signs of couplings from $\pi\,N\to\,N\,\pi\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620)$ S_{31} coupling to $\Delta(1232)\pi$.

N(1680) FOOTNOTES

- 1 LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- ² From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- 3 See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of π N elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- 4 LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N \pi \pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- ⁵ LONGACRE 77 considers this coupling to be well determined.

 $I(J^P) = \frac{1}{2}(??)$ Status: *

OMITTED FROM SUMMARY TABLE

There is a small literature (which we do not try to cover) on this possible narrow state. See KUZNETSOV 11A, MART 11, and the other papers for further references. This state does not gain status by being a sought-after member of a baryon anti-decuplet.

$N(1700) 3/2^{-}$

$$I(J^P) = \frac{1}{2}(\frac{3}{2}^-)$$
 Status: ***

Most of the results published before 1975 are now obsolete and have been omitted. They may be found in our 1982 edition, Physics Letters **111B** 1 (1982). Some further obsolete results published before 1984 were last included in our 2006 edition, Journal of Physics, G **33** 1 (2006).

The various partial-wave analyses do not agree very well.

The latest GWU analysis (ARNDT 06) finds no evidence for this resonance.

N(1710) 1/2

$$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$$
 Status: ***

Most of the results published before 1975 were last included in our 1982 edition, Physics Letters 111B 1 (1982). Some further obsolete results published before 1984 were last included in our 2006 edition, Journal of Physics, G 33 1 (2006).

The latest GWU analysis (ARNDT 06) finds no evidence for this resonance.

N(1710) FOOTNOTES

 1 BATINIC 10 finds evidence for a second P_{11} state with all parameters except for the phase of the pole residue very similar to the parameters we give here. 2 LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N - N\pi \pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

³From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix

4 See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of π N elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams. 5 LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first

(second) value uses, in addition to $\pi N \to N \pi \pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

Note: Signs of couplings from $\pi N \to N \pi \pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620)$ S_{31} coupling to $\Delta(1232)\pi$.

 $N(1860) 5/2^{+}$

 $I(J^P) = \frac{1}{2}(\frac{5}{2}^+)$ Status: **

OMITTED FROM SUMMARY TABLE

Before the 2012 *Review*, all the evidence for a $J^P=5/2^+$ state with a mass above 1800 MeV was filed under a two-star N(2000). There is now some evidence from ANISOVICH 12A for two $5/2^+$ states in this region, so we have split the older data (according to mass) between two two-star $5/2^+$ states, an N(1860) and an N(2000).

$N(1875) \ 3/2^-$

Ī

$$I(J^P) = \frac{1}{2}(\frac{3}{2})$$
 Status: ***

Before the 2012 *Review*, all the evidence for a $J^P=3/2^-$ state with a mass above 1800 MeV was filed under a two-star N(2080). There is now evidence from ANISOVICH 12A for two $3/2^-$ states in this region, so we have split the older data (according to mass) between a three-star N(1875) and a two-star N(2120).

The latest GWU analysis (ARNDT 06) finds no evidence for this resonance.

 Status: **

OMITTED FROM SUMMARY TABLE

Before our 2012 Review, this state appeared in our Listings as the $\mathit{N}(\text{2090}).$ Any structure in the S_{11} wave above 1800 MeV is listed here. A few early results that are now obsolete have been omitted.

The latest GWU analysis (ARNDT 06) finds no evidence for this

OMITTED FROM SUMMARY TABLE

Most of the results published before 1975 are now obsolete and have $\,$ been omitted. They may be found in our 1982 edition, Physics Letters $\mathbf{111B}\ 1\ (1982)$. Some further obsolete results published before 1984 were last included in our 2006 edition, Journal of Physics, G **33** 1 (2006).

The various analyses do not agree very well with one another.

The latest GWU analysis (ARNDT 06) finds no evidence for this resonance.

 $\Gamma(N\pi)/\Gamma_{\text{total}}$

$$I(J^P) = \frac{1}{2}(\frac{3}{2})$$
 Status: **

OMITTED FROM SUMMARY TABLE

Before the 2012 $\it Review, \ {\rm all} \ {\rm the \ evidence \ for \ a} \ \it J^P = 3/2^- \ {\rm state}$ with a mass above 1800 MeV was filed under a two-star N(2080). There is now evidence from ANISOVICH 12A for two $3/2^-$ states in this region, so we have split the older data (according to mass) between a three-star N(1875) and a two-star N(2120).

$N(\sim 3000 \text{ Region})$ Partial-Wave Analyses

OMITTED FROM SUMMARY TABLE

We list here miscellaneous high-mass candidates for isospin-1/2 resonances found in partial-wave analyses.

Our 1982 edition had an N(3245), an N(3690), and an N(3755), each a narrow peak seen in a production experiment. Since nothing has been heard from them since the 1960's, we declare them to be dead. There was also an N(3030), deduced from total cross-section and 180° elastic cross-section measurements; it is the KOCH 80 $L_{1,15}$ state below.

$\Delta(1600) \ 3/2^{+}$

$$I(J^P) = \frac{3}{2}(\frac{3}{2}^+)$$
 Status: ***

Most of the results published before 1975 are now obsolete and have been omitted. They may be found in our 1982 edition, Physics Letters $\mathbf{111B}\ 1\ (1982)$. Some further obsolete results published before 1984 were last included in our 2006 edition, Journal of Physics, G **33** 1 (2006).

The various analyses are not in good agreement.

△(1600) FOOTNOTES

- $^1\, {\rm LONGACRE}$ 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi\, N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

 2 From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.
- amplitudes. 3 See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of π N elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- 4LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N \pi \pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- 5 The range given is from the four best solutions. DEANS 75 disagrees with $\pi^{+}\,
 ho$ ightarrow
- Σ^+ K^+ data of WINNIK 77 around 1920 MeV. 6 LONGACRE 77 considers this coupling to be well determined.
- 7 WADA 84 is inconsistent with other analyses see the Note on N and Δ Resonances.

Note: Signs of couplings from $\pi\,{\it N} \to {\it N}\,\pi\,\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620)~S_{31}$ counting to A(1232) =

| $ \frac{(\Gamma_1 \Gamma_f)^{\frac{1}{2}}/\Gamma_{total} \text{ in } N\pi \to \Delta(1620) \to \Delta(1232)\pi, D\text{-wave}}{-0.36 \text{ to } -0.28 \text{ OUR ESTIMATE}} \\ -0.24 \pm 0.03 & \text{MANLEY} & 92 \text{ IPWA} & \pi N \to \pi N \& N\pi\pi \\ -0.33 \pm 0.06 & \text{BARNHAM} & 80 \text{ IPWA} & \pi N \to \pi N \& N\pi\pi \\ -0.39 & 2.6 \text{ LONGACRE} & 75 \text{ IPWA} & \pi N \to N\pi\pi \\ -0.40 & 3 \text{ LONGACRE} & 75 \text{ IPWA} & \pi N \to N\pi\pi \\ \hline (\Delta(1232)\pi, D\text{-wave})/\Gamma_{total} & \frac{\Gamma_4/\Gamma}{N^2} \\ \frac{VALUE}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} \\ \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} \\ \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} \\ \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} \\ \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} \\ \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} \\ \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} \\ \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} \\ \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} \\ \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} \\ \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} \\ \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} \\ \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} \\ \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} \\ \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} \\ \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} \\ \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} \\ \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} \\ \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} \\ \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} \\ \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} \\ \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} \\ \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} \\ \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} \\ \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}{N^2} & \frac{N}$ | coupling to $\Delta(1232) \pi$. | | | | | | | | |

△(1620) FOOTNOTES

 1 CHEW 80 reports two S_{31} resonances at somewhat higher masses than other analyses. Problems with this analysis are discussed in section 2.1.11 of HOEHLER 83.

Problems with this analysis are discussed in section 2.1.11 or HOEHLER 03. 2 LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \rightarrow N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes. 3 From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix 3 From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix

From method in General Total System ...

4 See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of π N elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

 5 LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N\pi\pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

⁶LONGACRE 77 considers this coupling to be well determined.

Note: Signs of couplings from $\pi\,N\to N\,\pi\,\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620)$ S_{31} coupling to $\Delta(1232) \pi$.

△(1700) FOOTNOTES

 1 Problems with CHEW 80 are discussed in section 2.1.11 of HOEHLER 83. 2 LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi \, N \to N \pi \pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

fits with Breit-Wigner circles to the 1-matrix amplitudes.

From method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of π N elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams of the speeds with which the amplitudes traverse the diagrams.

FLONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N \pi \pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

 $^{
m 6}$ LONGACRE 77 considers this coupling to be well determined.

△(1750) FOOTNOTES

 1 CHEW 80 reports four resonances in the P_{31} wave — see also the $\varDelta(1910).$ Problems with this analysis are discussed in section 2.1.11 of HOEHLER 83.

2 ARNDT 04 gives no corresponding Breit-Wigner parameters for this state, because the mass so obtained is about 500 MeV higher than that suggested by the position of the pole.

△(1900) FOOTNOTES

- 1 See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams. 2 LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first
- ²LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N \pi \pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.
- 3 This A NISOVICH 12A value is the complex helicity amplitude at the pole position.

△(1905) FOOTNOTES

- $1\,\text{ANISOVICH}$ 10 finds an alternate solution for this resonance. The only statistically significant differences are in the Breit-Wigner mass and γp couplings. $2\,\text{From}$ method II of LONGACRE 75: eyeball fits with Breit-Wigner circles to the T-matrix
- amplitudes. 3 See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of π N elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.
- 4 LONGACRE 78 values are from a search for poles in the unitarized T-matrix. The first (second) value uses, in addition to $\pi N \to N \pi \pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis.

△(1910) FOOTNOTES

 1 CHEW 80 reports four resonances in the P_{31} wave — see also the $\Delta(1750)$. Problems with this analysis are discussed in section 2.1.11 of HOEHLER 83. 2 LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the

²LONGACRE 77 pole positions are from a search for poles in the unitarized T-matrix; the first (second) value uses, in addition to $\pi N \to N \pi \pi$ data, elastic amplitudes from a Saclay (CERN) partial-wave analysis. The other LONGACRE 77 values are from eyeball fits with Breit-Wigner circles to the T-matrix amplitudes.

³ See HOEHLER 93 for a detailed discussion of the evidence for and the pole parameters of N and Δ resonances as determined from Argand diagrams of πN elastic partial-wave amplitudes and from plots of the speeds with which the amplitudes traverse the diagrams.

$\Delta(1920) \ 3/2^{+}$

$$I(J^P) = \frac{3}{2}(\frac{3}{2}^+)$$
 Status: ***

Most of the results published before 1975 were last included in our 1982 edition, Physics Letters $111B\ 1\ (1982)$. Some further obsolete results published before 1984 were last included in our 2006 edition, Journal of Physics, G $33\ 1\ (2006)$.

The latest GWU analysis (ARNDT 06) finds no evidence for this resonance.

Note: Signs of couplings from $\pi\,N\to N\,\pi\pi$ analyses were changed in the 1986 edition to agree with the baryon-first convention; the overall phase ambiguity is resolved by choosing a negative sign for the $\Delta(1620)\,\,S_{31}$ coupling to $\Delta(1232)\,\pi$.

$\Delta (\sim 3000 \; { m Region})$ Partial-Wave Analyses

OMITTED FROM SUMMARY TABLE

We list here miscellaneous high-mass candidates for isospin-3/2 resonances found in partial-wave analyses.

Our 1982 edition also had a $\Delta(2850)$ and a $\Delta(3230)$. The evidence for them was deduced from total cross-section and 180° elastic crosssection measurements. The $\Delta(2850)$ has been resolved into the Δ (2750) $I_{3,13}$ and Δ (2950) $K_{3,15}$. The Δ (3230) is perhaps related to the $K_{3,13}$ of HENDRY 78 and to the $L_{3,17}$ of KOCH 80.

BARYON MAGNETIC MOMENTS

Written 1994 by C.G. Wohl (LBNL).

The figure below shows the measured magnetic moments of the stable baryons. It also shows the predictions of the simplest quark model, using the measured $p,\,n,$ and Λ moments as input. In this model, the moments are [1]

$$\begin{array}{ll} \mu_p = (4\mu_u - \mu_d)/3 & \mu_n = (4\mu_d - \mu_u)/3 \\ \mu_{\Sigma^+} = (4\mu_u - \mu_s)/3 & \mu_{\Sigma^-} = (4\mu_d - \mu_s)/3 \\ \mu_{\Xi^0} = (4\mu_s - \mu_u)/3 & \mu_{\Xi^-} = (4\mu_s - \mu_d)/3 \\ \mu_{\Lambda} = \mu_s & \mu_{\Sigma^0} = (2\mu_u + 2\mu_d - \mu_s)/3 \\ \mu_{\Omega^-} = 3\mu_s \end{array}$$

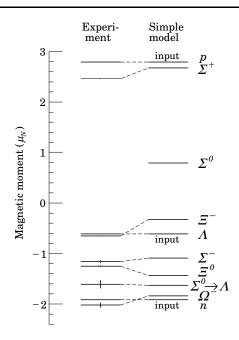

and the $\Sigma^0 \to \Lambda$ transition moment is

$$\mu_{\Sigma^0\Lambda} = (\mu_d - \mu_u)/\sqrt{3} \ .$$

The quark moments that result from this model are $\mu_u=+1.852\,\mu_N,\ \mu_d=-0.972\,\mu_N,\$ and $\mu_s=-0.613\,\mu_N.$ The corresponding effective quark masses, taking the quarks to be Dirac point particles, where $\mu=q\hbar/2m,$ are 338, 322, and 510 MeV. As the figure shows, the model gives a good first approximation to the experimental moments. For efforts to make a better model, we refer to the literature [2].

² The SCHMIDT 65 masses have been reevaluated using our April 1973 proton and K^{\pm} and π^{\pm} masses. P. Schmidt, private communication (1974).

 $^{^3}$ The mass has been raised 35 keV to take into account a 46 keV increase in the proton mass and an 11 keV decrease in the π^\pm mass (note added Reviews of Modern Physics $39\,1~(1967)).$

CONSTRAINED FIT INFORMATION

An overall fit to 5 branching ratios uses 20 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 =$ 10.5 for 16 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\left<\delta x_i\delta x_j\right>/(\delta x_i\cdot\delta x_j)$, in percent, from the fit to the branching fractions, $x_i\equiv$ $\Gamma_i/\Gamma_{
m total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

 $^{^{10}}$ CHAUVAT 85 actually gives $\alpha_+(\overline{\Lambda})/\alpha_-(\Lambda)=-1.04\pm0.29$. Assumes polarization is same in $\overline{\rho}p\to \overline{\Lambda}X$ and $pp\to \Lambda X$. Tests of this assumption, based on C-invariance and fragmentation, are satisfied by the data.

g_A / g_V FOR $\Lambda \to pe^- \overline{\nu}_e$ Measurements with fewer than 500 events have been omitted. Where necessary, signs have been changed to agree with our conventions, which are given in the "Note on Baryon Decay Parameters" in the neutron Listings. The measurements all assume that the form factor $g_2=0$. See also the footnote on DWORKIN 90.

Λ , Λ 's and Σ 's

Λ AND Σ RESONANCES

Introduction: Since our last edition, there have been a few measurements of properties of the lowest Λ and Σ resonances—mostly of masses and widths. But the field remains at a stand-still. What follows is a much abbreviated version of the note on Λ and Σ Resonances from our 1990 edition [1]. In particular, see that edition for some representative Argand plots from partial-wave analyses.

Table 1 is an attempt to evaluate the status, both overall and channel by channel, of each Λ and Σ resonance in the Particle Listings. The evaluations are of course partly subjective. A blank indicates there is no evidence at all: either the relevant couplings are small or the resonance does not really exist. The main Baryon Summary Table includes only the established resonances (overall status 3 or 4 stars). A number of the 1- and 2-star entries may eventually disappear, but there are certainly many resonances yet to be discovered underlying the established ones.

Sign conventions for resonance couplings: In terms of the isospin-0 and -1 elastic scattering amplitudes A_0 and A_1 , the amplitude for $K^-p \to \overline{K}^0n$ scattering is $\pm (A_1 - A_0)/2$, where the sign depends on conventions used in conjunction with the Clebsch-Gordan coefficients (such as, is the baryon or the meson the "first" particle). If this reaction is partial-wave analyzed and if the overall phase is chosen so that, say, the $\Sigma(1775)D_{15}$ amplitude at resonance points along the positive imaginary axis (points "up"), then any Σ at resonance will point "up" and any Λ at resonance will point "down" (along the negative imaginary axis). Thus the phase at resonance determines the isospin. The above ignores background amplitudes in the resonating partial waves.

That is the basic idea. In a similar but somewhat more complicated way, the phases of the $\overline{K}N \to \Lambda\pi$ and $\overline{K}N \to \Sigma\pi$ amplitudes for a resonating wave help determine the SU(3) multiplet to which the resonance belongs. Again, a convention has to be adopted for some overall arbitrary phases: which way is "up"? Our convention is that of Levi-Setti [2] and is shown in Fig. 1, which also compares experimental results with theoretical predictions for the signs of several resonances. In the Listings, a + or – sign in front of a measurement of an inelastic resonance coupling indicates the sign (the *absence* of a sign means that the sign is not determined, *not* that it is positive). For more details, see Appendix II of our 1982 edition [3].

Errors on masses and widths: The errors quoted on resonance parameters from partial-wave analyses are often only statistical, and the parameters can change by more than these errors when a different parametrization of the waves is used.

Furthermore, the different analyses use more or less the same data, so it is not really appropriate to treat the different determinations of the resonance parameters as independent or to average them together. In any case, the spread of the masses, widths, and branching fractions from the different analyses is certainly a better indication of the uncertainties than are the quoted errors. In the Baryon Summary Table, we usually give a range reflecting the spread of the values rather than a particular value with error.

For three states, the $\Lambda(1520)$, the $\Lambda(1820)$, and the $\Sigma(1775)$, there is enough information to make an overall fit to the various branching fractions. It is then necessary to use the quoted errors, but the errors obtained from the fit should not be taken seriously.

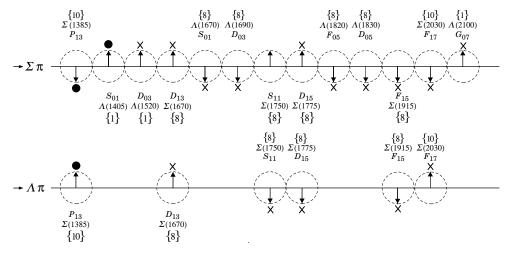

Figure 1. The signs of the imaginary parts of resonating amplitudes in the $\overline{K}N \to \Lambda\pi$ and $\Sigma\pi$ channels. The signs of the $\Sigma(1385)$ and $\Lambda(1405)$, marked with a \bullet , are set by convention, and then the others are determined relative to them. The signs required by the SU(3) assignments of the resonances are shown with an arrow, and the experimentally determined signs are shown with an \times .

Table 1. The status of the Λ and Σ resonances. Only those with an overall status of *** or **** are included in the main Baryon Summary Table.

| | | | | Status | s as seen | in — |

**** Existence is certain, and properties are at least fairly well explored.

Existence ranges from very likely to certain, but further confirmation is desirable and/or quantum numbers, branching fractions, etc. are not well determined.

Production experiments: Partial-wave analyses of course separate partial waves, whereas a peak in a cross section or an invariant mass distribution usually cannot be disentangled from background and analyzed for its quantum numbers; and more than one resonance may be contributing to the peak. Results from partial-wave analyses and from production experiments are generally kept separate in the Listings, and in the Baryon Summary Table results from production experiments are used only for the low-mass states. The $\Sigma(1385)$ and $\Lambda(1405)$ of course lie below the $\overline{K}N$ threshold and nearly everything about them is learned from production experiments; and production and formation experiments agree quite well in the case

of $\Lambda(1520)$ and results have been combined. There is some disagreement between production and formation experiments in the 1600–1700 MeV region: see the note on the $\Sigma(1670)$.

 $\Lambda(1405)~1/2^-$

$$I(J^P) = O(\frac{1}{2})$$
 Status: ***

The nature of the $\Lambda(1405)$ has been a puzzle for decades: three-quark state or hybrid; two poles or one. We cannot here survey the rather extensive literature. See, for example, CIEPLY 10, KISSLINGER 11, and SEKIHARA 11, for discussions and earlier references

It seems to be the universal opinion of the chiral-unitary community that there are two poles in the 1400-MeV region. ZYCHOR 08 presents experimental evidence against the two-pole model, but this is disputed by GENG 07A. See also REVAI 09, which finds little basis for choosing between one- and two-pole models.

A single, ordinary three-quark $\Lambda(1405)$ fits nicely into a $J^P=1/2^-$ SU(4) $\overline{4}$ multiplet, whose other members are the $\Lambda_C(2595)^+$, $\Xi_C(2790)^+$, and $\Xi_C(2790)^0$; see Fig. 1 of our note on "Charmed Baryons."

Λ(1405) FOOTNOTES

HEMINGWAY 85 HBC K^-p 4.2 GeV/c

95

<3

- 1 DALITZ 91 fits the HEMINGWAY 85 data. 2 THOMAS 73 data is fit by CHAO 73 (see next section). 3 The KIMURA $\underline{00}$ values are from fits A and B from a coupled-channel potential model using low-energy \overline{K} N and $\Sigma\pi$ data, kaonic-hydrogen x-ray measurements, and our $\Lambda(1405)$ mass and width. The results bear mainly on the *nature* of the $\Lambda(1405)$: three-quark state 4 The MARTIN 81 fit includes the $K^{\pm}p$ forward scattering amplitudes and the dispersion
- relations they must satisfy.
- ⁵ See also the accompanying paper of THOMAS 73.
- 6 Data of SAKITT 65 are used in the fit by KITTEL 66.
- $^7\,\text{An}$ asymmetric shape, with $\Gamma/2=41\,$ MeV below resonance, 14 MeV above.

 $\Lambda(1520) \ 3/2$

$$I(J^P) = O(\frac{3}{2})$$
 Status: ***

Discovered by FERRO-LUZZI 62; the elaboration in WATSON 63 is the classic paper on the Breit-Wigner analysis of a multichannel

The measurements of the mass, width, and elasticity published before 1975 are now obsolete and have been omitted. They were last listed in our 1982 edition Physics Letters 111B 1 (1982).

Production and formation experiments agree quite well, so they are $% \left(1\right) =\left(1\right) \left(1\right)$ listed together here.

CONSTRAINED FIT INFORMATION

An overall fit to 9 branching ratios uses 26 measurements and one constraint to determine 6 parameters. The overall fit has a $\chi^2=17.6$ for 21 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\left\langle \delta x_i \delta x_j \right\rangle / (\delta x_i \cdot \delta x_j),$ in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\rm total}.$ The fit constrains the x_i whose labels appear in this array to sum to one.

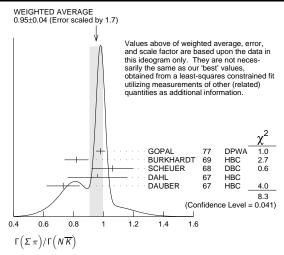

A(1520) BRANCHING RATIOS

See "Sign conventions for resonance couplings" in the Note on \varLambda and \varSigma Resonances.

Λ(1690) DECAY MODES

| | Mode | Fraction (Γ_i/Γ) | |
|-----------------------|-------------------------------|------------------------------|--|
| $\overline{\Gamma_1}$ | NK | 20-30 % | |
| Γ_2 | $\Sigma \pi$ | 20-40 % | |
| Γ_3 | $\Lambda \pi \pi$ | \sim 25 $\%$ | |
| Γ_4 | $\Sigma \pi \pi$ | \sim 20 % | |
| Γ_5 | $\Lambda\eta$ | | |
| Γ ₆ | $\Sigma(1385)\pi$, S -wave | | |

The above branching fractions are our estimates, not fits or averages.

Λ(1690) BRANCHING RATIOS

The sum of all the quoted branching ratios is more than 1.0. The two-body ratios are from partial-wave analyses, and thus probably are more reliable than the three-body ratios, which are determined from bumps in cross sections. Of the latter, the $\Sigma\pi\pi$ bump looks more significant. (The error given for the $\Lambda\pi\pi$ ratio looks unreasonably small.) Hardly any of the $\Sigma\pi\pi$ decay can be via $\Sigma(1385)$, for then seven times as much $\Lambda\pi\pi$ decay would be required. See "Sign conventions for resonance couplings" in the Note on Λ and Σ Resonances.

 $^{^1}$ The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit. Another \mathcal{D}_{03} A at 1966 MeV is also suggested by MARTIN 77, but is very uncertain.

²BARTLEY 68 uses only cross-section data. The enhancement is not seen by PRE-VOST 71.

¹ The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.

 $^{^2\,\}mathrm{The}$ published sign has been changed to be in accord with the baryon-first convention.

 $\Lambda(1810)\ 1/2^{+}$

$$I(J^P) = O(\frac{1}{2}^+)$$
 Status: ***

Almost all the recent analyses contain a P_{01} state, and sometimes two of them, but the masses, widths, and branching ratios vary greatly. See also the $\Lambda(1600)$ P_{01} .

Л(1820) 5/2⁺

$$I(J^P) = O(\frac{5}{2}^+)$$
 Status: ***

This resonance is the cornerstone for all partial-wave analyses in this region. Most of the results published before 1973 are now obsolete and have been omitted. They may be found in our 1982 edition Physics Letters **111B** 1 (1982).

Most of the quoted errors are statistical only; the systematic errors due to the particular parametrizations used in the partial-wave analyses are not included. For this reason we do not calculate weighted averages for the mass and width.

Λ(1820) FOOTNOTES

 1 The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit. 2 There is a suggestion of a bump, enough to be consistent with what is expected from $_\Sigma(1385) \to _\Sigma\pi$ decay.

The published sign has been changed to be in accord with the baryon-first convention.

 Status: *

OMITTED FROM SUMMARY TABLE

In LITCHFIELD 71, need for the state rests solely on a possibly inconsistent polarization measurement at 1.784 GeV/c. HEMINGWAY 75 does not require this state. GOPAL 77 does not need it in either $N\overline{K}$ or $\Sigma\pi$. With new K^-n angular distributions included, DECLAIS 77 sees it. However, this and other new data are included in GOPAL 80 and the state is not required. BACCARI 77 weakly supports it.

$$I(J^P) = O(\frac{7}{2})$$
 Status: ***

Discovered by COOL 66 and by WOHL 66. Most of the results published before 1973 are now obsolete and have been omitted. They may be found in our 1982 edition Physics Letters **111B** 1 (1982).

This entry only includes results from partial-wave analyses. Parameters of peaks seen in cross sections and in invariant-mass distributions around 2100 MeV used to be listed in a separate entry immediately following. It may be found in our 1986 edition Physics Letters 170B 1 (1986).

 $\Lambda(2325) 3/2$

$$I(J^P) = O(\frac{3}{2})$$
 Status: *

OMITTED FROM SUMMARY TABLE

BACCARI 77 finds this state with either $J^P=3/2^-$ or $3/2^+$ in a energy-dependent partial-wave analyses of $\mathit{K}^-\,\mathit{p}\,\rightarrow\,\mathit{\Lambda}\,\omega$ from 2070 to 2436 MeV. A subsequent semi-energy-independent analysis from threshold to 2436 MeV selects $3/2^-$. DEBELLEFON 78 (same group) also sees this state in an energy-dependent partial-wave analysis of $K^- p \rightarrow \overline{K} N$ data, and finds $J^{P} = 3/2^-$ or $3/2^+$. They again prefer $J^P=3/2^-$, but only on the basis of model-dependent considerations.

 $[\]frac{1}{2}$ Found in one of two best solutions. $\frac{2}{3}$ The published error of 0.6 was a misprint.

 $^{^4}$ The published sign has been changed to be in accord with the baryon-first convention. The CAMERON 78B upper limits on the P_3 and F_3 waves are each 0.03.

ለ(2350) 9/2⁺

$$I(J^P) = O(\frac{9}{2}^+)$$
 Status: ***

DAUM 68 favors $J^P = 7/2^- \text{ or } 9/2^+$. BRICMAN 70 favors $9/2^+$. LASINSKI 71 suggests three states in this region using a Pomeron + resonances model. There are now also three formation experiments from the College de France-Saclay group, DEBELLEFON 77, BACCARI 77, and DEBELLEFON 78, which find 9/2+ in energydependent partial-wave analyses of $\overline{K}N \to \Sigma \pi$, $\Lambda \omega$, and $N \overline{K}$.

| | | | | | |

 5 We assume $\it CPT$ invariance: this is (minus) the $\overline{\Sigma}^-$ magnetic moment as measured by MORELOS 93. See below for the moment difference testing $\it CPT$. 6 ANKENBRANDT 83 gives the value 2.38 \pm 0.02 μ_N . MORELOS 93 uses the same hyperon magnet and channel and claims to determine the field integral better, leading to the revised value given here.

$$\left(\mu_{\Sigma^+} \,+\, \mu_{\overline{\Sigma}^-}\right) \,\big/\, \mu_{\Sigma^+}$$

A test of CPT invariance

| VALUE | DO CUMENT ID | TECN | COMMENT |
|-------------|--------------|------|---------------------|
| 0.014±0.015 | 7 MORELOS 93 | SPEC | <i>p</i> Cu 800 GeV |

 $^{^7}$ This is our calculation from the MORELOS 93 measurements of the Σ^+ and $\overline{\Sigma}^-$ magnetic moments given above. The statistical error on $\mu_{\overline{\Sigma}^-}$ dominates the error here.

Σ+ DECAY MODES

CONSTRAINED FIT INFORMATION

An overall fit to 2 branching ratios uses 14 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 =$ 7.7 for 12 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv$ $\Gamma_i/\Gamma_{\mathrm{total}}$. The fit constrains the x_i whose labels appear in this array to sum to

$$\begin{array}{c|cccc} x_2 & -100 & \\ x_3 & 12 & -14 \\ \hline & x_1 & x_2 \end{array}$$

⁴ We have increased the CHANG 66 error of 0.018; see our 1970 edition, Reviews of Modern Physics 42 87 (1970).

$$I(J^P) = 1(\frac{1}{2}^+)$$
 Status: ***

COURANT 63 and ALFF 65, using $\Sigma^0
ightarrow \varLambda \, e^+ \, e^-$ decays (Dalitz decays), determined the Σ^0 parity to be positive, given that J=1/2and that certain very reasonable assumptions about form factors are true. The results of experiments involving the Primakoff effect, from which the Σ^0 mean life and $\Sigma^0 \to \Lambda$ transition magnetic moment come (see below), strongly support J=1/2.

Σ^0 MASS

The fit uses Σ^+ , Σ^0 , Σ^- , and Λ mass and mass-difference measurements.

Σ^0 MEAN LIFE

These lifetimes are deduced from measurements of the cross sections for the Primakoff process $\Lambda \to \Sigma^0$ in nuclear Coulomb fields. An alternative expression of the same information is the Σ^0 - Λ transition magnetic moment given in the following section. The relation is $(\mu_{\Sigma}_{\Lambda}/\mu_{N})^2$ $\tau=$ 1.92951×10^{-19} s (see DEVLIN 86).

CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 16 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2=8.7$ for 13 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\left\langle \delta x_i \delta x_j \right\rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one

Σ- BRANCHING RATIOS

⁷ The sign is, with our conventions, unambiguously positive. The value assumes, as usual, that $g_2=0$. If g_2 is included in the fit, than (with our sign convention) $g_2=-0.56\pm0.37$, with a corresponding reduction of g_A/g_V to $+0.20\pm0.08$.

$f_2(0)/f_1(0)$ FOR $\Sigma^- ightarrow ne^- \overline{ u}_e$

The signs have been changed to be in accord with our conventions, given in the "Note on Baryon Decay Parameters" in the neutron Listings.

$\Sigma(1385) \ 3/2^+$

$$I(J^P) = 1(\frac{3}{2}^+)$$
 Status: ***

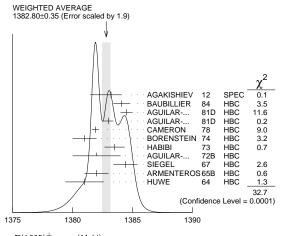

Discovered by ALSTON 60. Early measurements of the mass and width for combined charge states have been omitted. They may be found in our 1984 edition Reviews of Modern Physics **56** S1 (1984).

We average only the most significant determinations. We do not average results from inclusive experiments with large backgrounds or results which are not accompanied by some discussion of experimental resolution. Nevertheless systematic differences between experiments remain. (See the ideograms in the Listings below.) These differences could arise from interference effects that change with production mechanism and/or beam momentum. They can also be accounted for in part by differences in the parametrizations employed. (See BORENSTEIN 74 for a discussion on this point.) Thus BORENSTEIN 74 uses a Breit-Wigner with energyindependent width, since a P-wave was found to give unsatisfactory fits. CAMERON 78 uses the same form. On the other hand HOLM-GREN 77 obtains a good fit to their $\Lambda\pi$ spectrum with a P-wave Breit-Wigner, but includes the partial width for the $\Sigma\pi$ decay mode in the parametrization. AGUILAR-BENITEZ 81D gives masses and widths for five different Breit-Wigner shapes. The results vary considerably. Only the best-fit S-wave results are given here.

$\Sigma(1480)$ Bumps

 $I(J^P) = 1(??)$ Status: *

OMITTED FROM SUMMARY TABLE

These are peaks seen in $\Lambda\pi$ and $\Sigma\pi$ spectra in the reaction $\pi^+p \to$ $(Y\pi)K^+$ at 1.7 GeV/c. Also, the Y polarization oscillates in the

MILLER 70 suggests a possible alternate explanation in terms of a reflection of $N(1675) \rightarrow \Lambda K$ decay. However, such an explanation for the $(\Sigma^+ \pi^0) K^+$ channel in terms of $\Delta(1650) \rightarrow \Sigma K$ decay seems unlikely (see PAN 70). In addition such reflections would also have to account for the oscillation of the Y polarization in the 1480 MeV region.

HANSON 71, with less data than PAN 70, can neither confirm nor deny the existence of this state. MAST 75 sees no structure in this region in $K^- p \rightarrow \Lambda \pi^0$.

ENGELEN 80 performs a multichannel analysis of $K^- p \to p \overline{K}^0 \pi^$ at 4.2 ${\rm GeV}/c$. They observe a 3.5 standard-deviation signal at 1480 MeV in $\rho \, \overline{\mathcal{K}}^0$ which cannot be explained as a reflection of any competing channel.

PRAKHOV 04 sees no evidence for this or other light Σ resonances, aside from the Σ (1385), in $K^-p\to \Lambda\pi^0\pi^0$.

ZYCHOR 06 finds peaks in $pp \rightarrow pK^+(\pi^{\pm}X^{\mp})$ at $p_{\text{beam}} =$

$\Sigma(1560)$ Bumps

 $I(J^P) = 1(??)$ Status: **

OMITTED FROM SUMMARY TABLE

This entry lists peaks reported in mass spectra around 1560 MeV without implying that they are necessarily related.

DIONISI 78B observes a 6 standard-deviation enhancement at 1553 MeV in the charged $\Lambda/\Sigma\pi$ mass spectra from $K^-p\to (\Lambda/\Sigma)\pi K\overline{K}$ at 4.2 GeV/c. In a CERN ISR experiment, LOCKMAN 78 reports a narrow 6 standard-deviation enhancement at 1572 MeV in $\Lambda\pi^\pm$ from the reaction $pp\to\Lambda\pi^+\pi^-X$. These enhancements are unlikely to be associated with the $\Sigma(1580)$ (which has not been confirmed by several recent experiments – see the next entry in the Listings).

CARROLL 76 observes a bump at 1550 MeV (as well as one at 1580 MeV) in the isospin-1 $\overline{K}\,N$ total cross section, but uncertainties in cross section measurements outside the mass range of the experiment preclude estimating its significance.

See also MEADOWS 80 for a review of this state.

$\Sigma(1580) \ 3/2^{-}$

 $I(J^P) = 1(\frac{3}{2}^-)$ Status: *

OMITTED FROM SUMMARY TABLE

Seen in the isospin-1 \overline{K} N cross section at BNL (LI 73, CARROLL 76) and in a partial-wave analysis of $K^-p \to \Lambda\pi^0$ for c.m. energies 1560–1600 MeV by LITCHFIELD 74. LITCHFIELD 74 finds $J^P=3/2^-$. Not seen by ENGLER 78 or by CAMERON 78C (with larger statistics in $K^0_L p \to \Lambda\pi^+$ and $\Sigma^0\pi^+$).

Neither OLMSTED 04 (in $K^-p\to \Lambda\pi^0$) nor PRAKHOV 04 (in $K^-p\to \Lambda\pi^0\pi^0$) see any evidence for this state.

Σ (1580) FOOTNOTES

 $^{^{1}}$ CARROLL 76 sees a total-cross-section bump with (J+1/2) Γ_{el} / $\Gamma_{ ext{total}}=0.0\underline{6}.$

The main effect observed by LITCHFIELD 74 is in the $\Lambda\pi$ final state; the $\overline{K}N$ and $\Sigma\pi$ couplings are estimated from a multichannel fit including total-cross-section data of LI 73.

$\Sigma(1580)$, $\Sigma(1620)$, $\Sigma(1620)$ Production Experiments

$$I(J^P) = 1(\frac{1}{2})$$
 Status: **

OMITTED FROM SUMMARY TABLE

The S_{11} state at 1697 MeV reported by VANHORN 75 is tentatively listed under the $\Sigma(1750)$. CARROLL 76 sees two bumps in the isospin-1 total cross section near this mass.

Production experiments are listed separately in the next entry.

$\Sigma(1620)$ Production Experiments

 $I(J^P) = 1(??)$

OMITTED FROM SUMMARY TABLE

Formation experiments are listed separately in the previous entry.

The results of CRENNELL 69B at 3.9 GeV/c are not confirmed by SABRE 70 at 3.0 GeV/c. However, at 4.5 GeV/c, AMMANN 70 sees a peak at 1642 MeV which on the basis of branching ratios they do not associate with the $\Sigma(1670)$. See MILLER 70 for a review of these conflicts.

THE $\Sigma(1670)$ REGION

Production experiments: The measured $\Sigma \pi / \Sigma \pi \pi$ branching ratio for the $\Sigma(1670)$ produced in the reaction $K^-p \to \pi^-\Sigma(1670)^+$ is strongly dependent on momentum transfer. This was first discovered by EBERHARD 69, who suggested that there exist two Σ resonances with the same mass and quantum numbers: one with a large $\Sigma \pi \pi$ (mainly $\Lambda(1405)\pi$) branching fraction produced peripherally, and the other with a large $\Sigma \pi$ branching fraction produced at larger angles. The experimental results have been confirmed by AGUILAR-BENITEZ 70, ASPELL 74, ESTES 74, and TIMMERMANS 76. If, in fact, there are two resonances, the most likely quantum numbers for both the $\Sigma\pi$ and the $\Lambda(1405)\pi$ states are D_{13} . There is also possibly a third Σ in this region, the $\Sigma(1690)$ in the Listings, the main evidence for which is a large $\Lambda \pi / \Sigma \pi$ branching ratio. These topics have been reviewed by EBERHARD 73 and by MILLER 70.

Formation experiments: Two states are also observed near this mass in formation experiments. One of these, the $\Sigma(1670)D_{13}$, has the same quantum numbers as those observed in production and has a large $\Sigma\pi/\Sigma\pi\pi$ branching ratio; it may well be the $\Sigma(1670)$ produced at larger angles (see TIMMERMANS 76). The other state, the $\Sigma(1660)P_{11}$, has different quantum numbers, its $\Sigma\pi/\Sigma\pi\pi$ branching ratio is unknown, and its relation to the produced $\Sigma(1670)$ states is obscure.

 $\Sigma(1670)$

 $\Sigma(1670) \ 3/2$

 $I(J^P) = 1(\frac{3}{2})$ Status: ***

For most results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters ${\bf 111B}~1~(1982).$

Results from production experiments are listed separately in the next

Σ (1670) FOOTNOTES

- 1 The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit. 2 Results are with and without an S_{11} $\Sigma(1620)$ in the fit. 3 SIMS 68 uses only cross-section data. Result used as upper limit only. 4 Ratio only for Σ 2π system in I=1, which cannot be $\Sigma(1385)$.
- 5 Assuming the $\Lambda(1405)\,\pi$ cross-section bump is due only to $3/2^-$ resonance.
- ⁶The CAMERON 77 upper limit on *F*-wave decay is 0.03.

$\Sigma(1670)$ Bumps

 $I(J^P) = 1(??)$

OMITTED FROM SUMMARY TABLE

Formation experiments are listed separately in the preceding entry.

Probably there are two states at the same mass with the same quantum numbers, one decaying to $\Sigma\pi$ and $\Lambda\pi$, the other to $\Lambda(1405)\pi$. See the note in front of the preceding entry.

Σ (1670) FOOTNOTES

- ¹ Total cross-section bump with (J+1/2) Γ_{el} / Γ_{total} = 0.23.
- 2 Enhancements in $\Sigma\pi$ and $\Sigma\pi\pi$ cross sections. 3 Backward production in the $\Lambda\pi^ K^+$ final state.
- Depending on production angle.

 APSELL 74, ESTES 74, and TIMMERMANS 76 find strong branching ratio dependence on production angle, as in earlier production experiments.

Σ (1690) FOOTNOTES (PRODUCTIÓN EXPERIMENTS)

- ¹ From $\pi^+ p \rightarrow (\Lambda \pi^+) K^+$. J > 1/2 is not required by the data.
- $^2\,{\rm From}\,\,\pi^+\,p\,\to\,(\Lambda\,\pi^+)\,(\,K\,\pi)^+$. $J^{'}\,{>}1/2$ is indicated, but large background precludes a
- definite conclusion. 3 See the $\Sigma(1670)$ Listings. AGUILAR-BENITEZ 70B with three times the data of PRIMER 68 find no evidence for the $\Sigma(1690)$.
- 4 This analysis, which is difficult and requires several assumptions and shows no unambiguous $\Sigma(1690)$ signal, suggests $J^P=5/2^+$. Such a state would lead all previously known Y* trajectories.

$\Sigma(1750) \ 1/2$

 $I(J^P) = 1(\frac{1}{2}^-)$ Status: ***

For most results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters 111B 1 (1982).

There is evidence for this state in many partial-wave analyses, but with wide variations in the mass, width, and couplings. The latest analyses indicated significant couplings to $N\overline{K}$ and $\Lambda\pi$, as well as to $\Sigma\eta$ whose threshold is at 1746 MeV (JONES 74).

 $\Sigma(1770) \ 1/2$

 $I(J^P) = 1(\frac{1}{2}^+)$ Status: *

OMITTED FROM SUMMARY TABLE

Evidence for this state now rests solely on solution 1 of BAILLON 75, (see the footnotes) but the $\varLambda\,\pi$ partial-wave amplitudes of this solution are in disagreement with amplitudes from most other $\varLambda\,\pi$ anal-

Σ(1770) FOOTNOTES

- 1 Required to fit the isospin-1 total cross section of CARROLL 76 in the $\overline{\it K}$ N channel. The addition of new K^-p polarization and K^-n differential cross-section data in GOPAL 80 find it to be more consistent with the $\Sigma(1660)$ P_{11} .
- 2 From solution 1 of BAILLON 75; not present in solution 2.
- 3 Not required in KANE 74, which supersedes KANE 72.

$\Sigma(1775)~5/2$

$$I(J^P) = 1(\frac{5}{2})$$
 Status: ***

Discovered by GALTIERI 63, this resonance plays the same role as cornerstone for isospin-1 analyses in this region as the $\Lambda(1820)\,F_{05}$ does in the isospin-0 channel.

For most results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters 111B 1 (1982).

Σ(1775) DECAY MODES

| | Mode | Fraction (Γ_i/Γ) |
|-----------------------|---------------------------------------|------------------------------|
| $\overline{\Gamma_1}$ | NK | 37-43% |
| Γ_2 | $\Lambda\pi$ | 14-20% |
| Г3 | $\Sigma \pi$ | 2-5% |
| Γ_4 | $\Sigma(1385)\pi$ | 8-12% |
| Γ_5 | $\Sigma(1385)\pi$, $	extit{D}$ -wave | |
| Γ ₆ | $\Lambda(1520)\pi$ | 17-23% |
| Γ_7 | $\Sigma \pi \pi$ | |

The above branching fractions are our estimates, not fits or averages.

CONSTRAINED FIT INFORMATION

An overall fit to 8 branching ratios uses 16 measurements and one constraint to determine 5 parameters. The overall fit has a χ^2 = 63.9 for 12 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta x_i \delta x_j
angle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv$ $\Gamma_i/\Gamma_{
m total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

Σ(1775) BRANCHING RATIOS

See "Sign conventions for resonance couplings" in the Note on \varLambda and \varSigma Resonances. Also, the errors quoted do not include uncertainties due to the parametrization used in the partial-wave analyses and are thus too
