Σ (1775) FOOTNOTES

 $\Sigma(1385)\pi$ rate, as seen in $\Lambda\pi\pi$.

¹ The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.
2 This rate combines P-wave and F-wave decays. The CAMERON 77 results for the separate P-wave- and F-wave decays are -0.303 ± 0.010 and -0.037 ± 0.014 . The published signs have been changed here to be in accord with the baryon-first convention.
3 The CAMERON 78 upper limit on G-wave decay is 0.03.
4 For about 3/4 of this, the $\Sigma\pi$ system has I=0 and is almost entirely $\Lambda(1520)$. For the rest, the $\Sigma\pi$ has I=1, which is about what is expected from the known $\Sigma(1775) \to \Sigma(1385)$ rate as seen in $\Lambda = \pi$.

 $\Sigma(1775), \Sigma(1840), \Sigma(1880)$

Σ(1880) FOOTNOTES

- ¹ The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.
- ² From solution 1 of BAILLON 75; not present in solution 2.
- $^3\,\mbox{Only}$ unconstrained states from table 1 of LEA 73 are listed.
- ⁴ The published sign has been changed to be in accord with the baryon-first convention.

Σ (1915) FOOTNOTES

- $^{
 m 1}$ The two entries for CORDEN 77C are from two different acceptable solutions.
- 2 Preferred solution 3; see CORDEN 76 for other possibilities.
- ³ The two MARTIN 77 values are from a T-matrix pole and from a Breit-Wigner fit.
- 4 The mass and width are fixed to the GOPAL 77 values due to the low elasticity. $^{5}\,\mathrm{The}$ published sign has been changed to be in accord with the baryon-first convention.

$\Sigma(2030) 7/2^{+}$

 $I(J^P) = 1(\frac{7}{2}^+)$ Status: ***

Discovered by COOL 66 and by WOHL 66. For most results published before 1974 (they are now obsolete), see our 1982 edition Physics Letters 111B 1 (1982).

This entry only includes results from partial-wave analyses. Parameters of peaks seen in cross sections and invariant-mass distributions around 2030 MeV may be found in our 1984 edition, Reviews of Modern Physics 56 S1 (1984).

Σ (2030) FOOTNOTES

- Preferred solution 3; see CORDEN 76 for other possibilities.
- The two entries for CORDEN 77c are from two different acceptable solutions.
- ³ This coupling is extracted from unnormalized data.
- 4 The published sign has been changed to be in accord with the baryon-first convention.
- ⁵ An upper limit.
- 6 The upper limit on the G_3 wave is 0.03.

$\Sigma(2070) 5/2^{-1}$

 $I(J^P) = 1(\frac{5}{2}^+)$ Status: *

OMITTED FROM SUMMARY TABLE

This state suggested by BERTHON 70B finds support in GOPAL 80 $\,$ with new K^-p polarization and K^-n angular distributions. The very broad state seen in KANE 72 is not required in the later (KANE 74) analysis of $\overline{K}N \to \Sigma\pi$.

Σ (2250)

$$I(J^P) = 1(??)$$
 Status: ***

Results from partial-wave analyses are too weak to warrant separating them from the production and cross-section experiments. LASINSKI 71 in $\overline{K}N$ using a Pomeron + resonances model, and DEBELLEFON 76, DEBELLEFON 77, and DEBELLEFON 78 in energy-dependent partial-wave analyses of $\overline{K}N \to \Lambda\pi$, $\Sigma\pi$, and $N\overline{K}$, respectively, suggest two resonances around this mass.

$\Sigma(3170)$ Bumps

 $I(J^P) = 1(??)$ Status: *

OMITTED FROM SUMMARY TABLE

Seen by AMIRZADEH 79 as a narrow 6.5-standard-deviation enhancement in the reaction $K^-p \to Y^{*+}\pi^-$ using data from independent high statistics bubble chamber experiments at 8.25 and 6.5 GeV/c. The dominant decay modes are multibody, multistrange final states and the production is via isospin-3/2 baryon exchange. Isospin 1 is favored.

Not seen in a K^-p experiment in LASS at 11 GeV/c (ASTON 85B).

RADIATIVE HYPERON DECAYS

Revised July 2011 by J.D. Jackson (LBNL).

The weak radiative decays of spin-1/2 hyperons, $B_i \to B_f \gamma$, yield information about matrix elements (form factors) similar to that gained from weak hadronic decays. For a polarized spin-1/2 hyperon decaying radiatively via a $\Delta Q = 0$, $\Delta S = 1$ transition, the angular distribution of the direction $\hat{\mathbf{p}}$ of the final spin-1/2 baryon in the hyperon rest frame is

$$\frac{dN}{d\Omega} = \frac{N}{4\pi} \left(1 + \alpha_{\gamma} \mathbf{P}_{i} \cdot \hat{\mathbf{p}} \right) . \tag{1}$$

Here \mathbf{P}_i is the polarization of the decaying hyperon, and α_{γ} is the asymmetry parameter. In terms of the form factors $F_1(q^2)$,

 $F_2(q^2)$, and $G(q^2)$ of the effective hadronic weak electromagnetic vertex,

$$F_1(q^2)\gamma_\lambda + iF_2(q^2)\sigma_{\lambda\mu}q^\mu + G(q^2)\gamma_\lambda\gamma_5$$
,

 α_{γ} is

$$\alpha_{\gamma} = \frac{2 \operatorname{Re}[G(0) F_M^*(0)]}{|G(0)|^2 + |F_M(0)|^2} , \qquad (2)$$

where $F_M = (m_i - m_f)[F_2 - F_1/(m_i + m_f)]$. If the decaying hyperon is unpolarized, the decay baryon has a longitudinal polarization given by $P_f = -\alpha_{\gamma}$ [1].

The angular distribution for the weak hadronic decay, $B_i \to B_f \pi$, has the same form as Eq. (1), but of course with a different asymmetry parameter, α_{π} . Now, however, if the decaying hyperon is unpolarized, the decay baryon has a longitudinal polarization given by $P_f = +\alpha_{\pi}$ [2,3]. The difference of sign is because the spins of the pion and photon are different.

 $\Xi^0 \to \Lambda \gamma \ decay$ —The radiative decay $\Xi^0 \to \Lambda \gamma$ of an unpolarized Ξ^0 uses the hadronic decay $\Lambda \to p\pi^-$ as the analyzer. As noted above, the longitudinal polarization of the Λ will be $P_{\Lambda} = -\alpha_{\Xi\Lambda\gamma}$. Let α_- be the $\Lambda \to p\pi^-$ asymmetry parameter and $\theta_{\Lambda p}$ be the angle, as seen in the Λ rest frame, between the Λ line of flight and the proton momentum. Then the hadronic version of Eq. (1) applied to the $\Lambda \to p\pi^-$ decay gives

$$\frac{dN}{d\cos\theta_{\Lambda p}} = \frac{N}{2} \left(1 - \alpha_{\Xi\Lambda\gamma} \alpha_{-} \cos\theta_{\Lambda p} \right) \tag{3}$$

for the angular distribution of the proton in the Λ frame. Our current value, from the CERN NA48/1 experiment [4], is $\alpha_{\Xi\Lambda\gamma} = -0.704 \pm 0.019 \pm 0.064$.

 $\Xi^0 \to \Sigma^0 \gamma$ decay—The asymmetry parameter here, $\alpha_{\Xi\Sigma\gamma}$, is measured by following the decay chain $\Xi^0 \to \Sigma^0 \gamma$, $\Sigma^0 \to$ $\Lambda \gamma$, $\Lambda \to p\pi^-$. Again, for an unpolarized Ξ^0 , the longitudinal polarization of the Σ^0 will be $P_{\Sigma} = -\alpha_{\Xi\Sigma\gamma}$. In the $\Sigma^0 \to$ $\Lambda \gamma$ decay, a parity-conserving magnetic-dipole transition, the polarization of the Σ^0 is transferred to the Λ , as may be seen as follows. Let $\theta_{\Sigma\Lambda}$ be the angle seen in the Σ^0 rest frame between the Σ^0 line of flight and the Λ momentum. For Σ^0 helicity +1/2, the probability amplitudes for positive and negative spin states of the Σ^0 along the Λ momentum are $\cos(\theta_{\Sigma\Lambda}/2)$ and $\sin(\theta_{\Sigma\Lambda}/2)$. Then the amplitude for a negative helicity photon and a negative helicity Λ is $\cos(\theta_{\Sigma\Lambda}/2)$, while the amplitude for positive helicities for the photon and Λ is $\sin(\theta_{\Sigma\Lambda}/2)$. For Σ^0 helicity -1/2, the amplitudes are interchanged. If the Σ^0 has longitudinal polarization P_{Σ} , the probabilities for Λ helicities $\pm 1/2$ are therefore

$$p(\pm 1/2) = \frac{1}{2}(1 \mp P_{\Sigma})\cos^{2}(\theta_{\Sigma\Lambda}/2) + \frac{1}{2}(1 \pm P_{\Sigma})\sin^{2}(\theta_{\Sigma\Lambda}/2), (4)$$

and the longitudinal polarization of the Λ is

$$P_{\Lambda} = -P_{\Sigma} \cos \theta_{\Sigma \Lambda} = +\alpha_{\Xi \Sigma \gamma} \cos \theta_{\Sigma \Lambda} . \tag{5}$$

Using Eq. (1) for the $\Lambda \to p\pi^-$ decay again, we get for the joint angular distribution of the $\Sigma^0 \to \Lambda \gamma$, $\Lambda \to p\pi^-$ chain,

$$\frac{d^2N}{d\cos\theta_{\Sigma\Lambda}\,d\cos\theta_{\Lambda p}} = \frac{N}{4}\left(1 + \alpha_{\Xi\Sigma\gamma}\cos\theta_{\Sigma\Lambda}\,\alpha_{-}\cos\theta_{\Lambda p}\right)\,. \eqno(6)$$

Our current average for $\alpha_{\Xi\Sigma\gamma}$ is -0.69 ± 0.06 [4,5].

References

- 1. R.E. Behrends, Phys. Rev. 111, 1691 (1958); see Eq. (7) or
- In ancient times, the signs of the asymmetry term in the angular distributions of radiative and hadronic decays of polarized hyperons were sometimes opposite. For roughly 50 years, however, the overwhelming convention has been to make them the same. The aim, not always achieved, is to remove ambiguities.

CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 5 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2=1.0$ for 1 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\left\langle \delta x_i \delta x_j \right\rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one

 $^9\,{\rm From}$ this result and α_{Ξ} , HUANG 04 gets $\beta_{\Xi}\,=\,-\,0.037\,\pm\,0.011\,\pm\,0.010$ and $\gamma_{\Xi}\,=\,$ $0.888\pm0.0004\pm0.006$. And the strong p-s phase difference for $\Lambda\pi^-$ scattering is $(4.6\pm1.4\pm1.2)^\circ$.

 10 From this result and α_{Ξ} , CHAKRAVORTY 03 obtains $\beta_{\Xi}=-0.025\pm0.042\pm0.006$ and $\gamma_{\Xi}=0.889\pm0.001\pm0.007$. And the strong p-s phase difference for $\Lambda\pi^-$ scattering is $(3.17\pm5.28\pm0.73)^\circ$.

11 BENSINGER 85 used $\alpha_{\Lambda}=0.642\pm0.013$. 12 The errors have been multiplied by 1.2 due to approximations used for the Ξ polarization; see DAUBER 69 for a discussion.

Ξ RESONANCES

The accompanying table gives our evaluation of the present status of the Ξ resonances. Not much is known about Ξ resonances. This is because (1) they can only be produced as a part of a final state, and so the analysis is more complicated than if direct formation were possible, (2) the production cross sections are small (typically a few μ b), and (3) the final states are topologically complicated and difficult to study with electronic techniques. Thus early information about Ξ resonances came entirely from bubble chamber experiments, where the numbers of events are small, and only in the 1980's did electronic experiments make any significant contributions. However, nothing of significance on Ξ resonances has been added since our 1988

For a detailed earlier review, see Meadows [1].

Table 1. The status of the Ξ resonances. Only those with an overall status of *** or **** are included in the Baryon Summary Table.

| | | | | | Status | as seen in | _ |
|-------------|-------|-------------------|----------|-------------|------------|----------------|----------------|
| Particle | J^P | Overall status | $\Xi\pi$ | ΛK | ΣK | $\Xi(1530)\pi$ | Other channels |
| Ξ(1318) | 1/2+ | **** | | | | | Decays weakly |
| $\Xi(1530)$ | 3/2 + | **** | **** | | | | |
| $\Xi(1620)$ | | * | * | | | | |
| $\Xi(1690)$ | | *** | | *** | ** | | |
| $\Xi(1820)$ | 3/2- | *** | ** | *** | ** | ** | |
| $\Xi(1950)$ | | *** | ** | ** | | * | |
| $\Xi(2030)$ | | *** | | ** | *** | | |
| $\Xi(2120)$ | | * | | * | | | |
| $\Xi(2250)$ | | ** | | | | | 3-body decays |
| $\Xi(2370)$ | | ** | | | | | 3-body decays |
| $\Xi(2500)$ | | * | | * | * | | 3-body decays |

Existence is certain, and properties are at least fairly well explored. Existence ranges from very likely to certain, but further confirmation is desirable and/or quantum numbers, branching fractions, etc. are not well determined

- Evidence of existence is only fair.
- Evidence of existence is poor.

E(1530) 3/2⁺

$$I(J^P) = \frac{1}{2}(\frac{3}{2}^+)$$
 Status: ***

This is the only Ξ resonance whose properties are all reasonably well known. Assuming that the Λ_c^+ has $J^P=1/2^+$, AUBERT 08AK, in a study of $\Lambda_c^+ \to \Xi^- \pi^+ K^+$, finds conclusively that the spin of the $\Xi(1530)^0$ is 3/2. In conjunction with SCHLEIN 63B and BUTTON-SHAFER 66, this proves also that the parity is +.

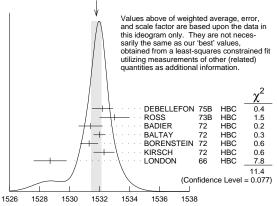

We use only those determinations of the mass and width that are accompanied by some discussion of systematics and resolution.

$\Xi(1620)$

$$I(J^P) = \frac{1}{2}(?^?)$$
 Status: *
J, P need confirmation.

OMITTED FROM SUMMARY TABLE

What little evidence there is consists of weak signals in the $\Xi\pi$ channel. A number of other experiments (e.g., BORENSTEIN 72 and HASSALL 81) have looked for but not seen any effect.

$\Xi(1690)$

$$I(J^P) = \frac{1}{2}(?^?)$$
 Status: ***

AUBERT 08AK, in a study of $\Lambda_c^+
ightarrow \, \Xi^- \pi^+ \, K^+$, finds some evidence that the $\Xi(1690)$ has $J^P = 1/2^-$.

DIONISI 78 sees a threshold enhancement in both the neutral and negatively charged $\Sigma \overline{K}$ mass spectra in $K^-p \to (\Sigma \overline{K}) K \pi$ at 4.2 GeV/c. The data from the $\Sigma \overline{K}$ channels alone cannot distinguish between a resonance and a large scattering length. Weaker evidence at the same mass is seen in the corresponding $\varLambda\,\overline{K}$ channels, and a coupled-channel analysis yields results consistent with a new \varXi .

BIAGI 81 sees an enhancement at 1700 MeV in the diffractively produced $\varLambda\, K^-$ system. A peak is also observed in the $\varLambda\, \overline{K}{}^0$ mass spectrum at 1660 MeV that is consistent with a 1720 MeV resonance decaying to $\varSigma^0\,\overline{K}^0$, with the γ from the \varSigma^0 decay not detected.

BIAGI 87 provides further confirmation of this state in diffractive dissociation of \varXi^- into $\varLambda\, K^-$. The significance claimed is 6.7 standard deviations.

ADAMOVICH 98 sees a peak of 1400 \pm 300 events in the $\Xi^-\pi^+$ spectrum produced by 345 GeV/c Σ^- -nucleus interactions.

$\Xi(1820) \ 3/2$

 $I(J^P) = \frac{1}{2}(\frac{3}{2})$ Status: ***

The clearest evidence is an 8-standard-deviation peak in $\it \Lambda \, K^-$ seen by GAY 76C. TEODORO 78 favors J=3/2, but cannot make a parity discrimination. BIAGI 87C is consistent with J=3/2 and favors negative parity for this J value.

Ξ(1820) MASS

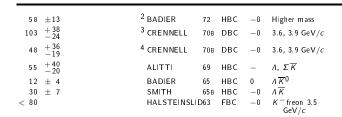

We only average the measurements that appear to us to be most significant and best determined.

Ξ(1820) FOOTNOTES

- 1 BIAGI 87 also sees weak signals in the in the $\Xi^-\pi^+\pi^-$ channel at 1782.6 \pm 1.4 MeV ($\Gamma=6.0\pm1.5$ MeV) and 1831.9 \pm 2.8 MeV ($\Gamma=9.6\pm9.9$ MeV). 2 BADIER 72 adds all channels and divides the peak into lower and higher mass regions. The data can also be fitted with a single Breit-Wigner of mass 1800 MeV and width 150 MeV. 3 From a fit to inclusive $\Xi\pi$, $\Xi\pi\pi$, and ΛK^- spectra. 4 From a fit to inclusive $\Xi\pi$ and $\Xi\pi\pi$ spectra only. 5 Including $\Xi\pi\pi$

I

- From a fit to inclusive $\equiv \pi$ and $\equiv \pi$ and $\equiv \pi$ and $\equiv \pi$. Specially, $\equiv \pi$ including $\equiv \pi\pi$. 6 DAUBER 69 uses in part the same data as SMITH 65c. 7 For the decay mode $\equiv \pi + \pi^0$ only. This limit includes $\equiv (1530)\pi$. 8 Or less. Upper limit for the 3-body decay.

 $\Xi(1950), \Xi(2030)$

$\Xi(1950)$

$$I(J^P) = \frac{1}{2}(?^?)$$
 Status: ***

We list here everything reported between 1875 and 2000 MeV. The accumulated evidence for a Ξ near 1950 MeV seems strong enough to include a Ξ (1950) in the main Baryon Table, but not much can be said about its properties. In fact, there may be more than one Ξ near this mass.

$\Xi(2030)$

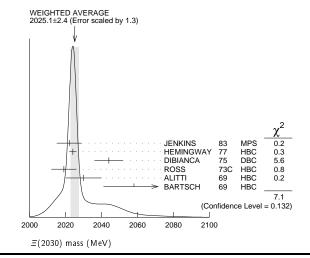

$$I(J^P) = \frac{1}{2} (\geq \frac{5}{2}?$$
\$tatus: ***

The evidence for this state has been much improved by HEMING-WAY 77, who see an eight standard deviation enhancement in $\Sigma\overline{K}$ and a weaker coupling to $\Lambda\overline{K}$. ALITTI 68 and HEMINGWAY 77 observe no signals in the $\Xi\pi\pi$ (or $\Xi(1530)\pi$) channel, in contrast to DIBIANCA 75. The decay $(\Lambda/\Sigma)\overline{K}\pi$ reported by BARTSCH 69 is also not confirmed by HEMINGWAY 77.

A moments analysis of the HEMINGWAY 77 data indicates at a level of three standard deviations that $J \geq 5/2$.

² For the decay mode $\Sigma^{\pm} K^{-} \pi^{\mp}$ only.

 $^{^1}$ CHLIAPNIKOV 79 does not uniquely identify the K^+ in the $(\overline{\Lambda}\,K^+)$ X final state. It also reports bumps with fewer events at 2240, 2540, and 2830 MeV. 2 GAY 76c sees a 4-standard deviation signal. However, HEMINGWAY 77, with more events from the same experiment points out that the signal is greatly reduced if a cut is made on the 4-momentum u. This suggests an anomalous production mechanism if the $\Xi(2120)$ is real.

 $\Xi(2250), \Xi(2370), \Xi(2500)$

(2250)

 $I(J^P) = \frac{1}{2}(?^?)$ Status: **

J, P need confirmation.

OMITTED FROM SUMMARY TABLE

The evidence for this state is mixed. BARTSCH 69 sees a bump of not much statistical significance in $\Lambda \overline{K} \pi$, $\Sigma \overline{K} \pi$, and $\Xi \pi \pi$ mass spectra. GOLDWASSER 70 sees a narrower bump in $\Xi\,\pi\,\pi$ at a higher mass. Not seen by HASSALL 81 with 45 events/ μ b at 6.5 ${\rm GeV}/c$. Seen by JENKINS 83. Perhaps seen by BIAGI 87.

Ω BARYONS (S = -3, I = 0)

$$I(J^P) = O(\frac{3}{2}^+)$$
 Status: ***

The unambiguous discovery in both production and decay was by BARNES 64. The quantum numbers follow from the assignment of the particle to the baryon decuplet. DEUTSCHMANN 78 and BAUBILLIER 78 rule out J=1/2 and find consistency with J=3/2. AUBERT,BE 06 finds from the decay angular distributions of $\Xi_c^0 \to \Omega^- K^+$ and $\Omega_c^0 \to \Omega^- K^+$ that J=3/2; this depends on the spins of the Ξ_C^0 and Ω_C^0 being J=1/2, their supposed values.

We have omitted some results that have been superseded by later experiments. See our earlier editions.

Ω^- MASS

The fit assumes the Ω^- and $\overline{\Omega}^+$ masses are the same, and averages them

 $\frac{1}{2}$ DIBIANCA 75 gives a mass for each event. We quote the average.

 2 The FRY 55 and FRY 55B events were identified as Ω^- by ALVAREZ 73. The masses assume decay to ΛK^- at rest. For FRY 55B, decay from an atomic orbit could Doppler assume use M of M and the resulting Ω^- mass by several MeV. This shift is negligible for FRY 55 because the Ω decay is approximately perpendicular to its orbital velocity, as is known because the Λ strikes the nucleus (L. Alvarez, private communication 1973). We have calculated the error assuming that the orbital N is 4 or larger. N is a summary N is a summary N is a summary N in the summary N is a summary N in the summary N is N in the summary N is N in the summary N in the summary N is N in the summary N in the summary N in the summary N is N in the summary N in the summary N in the summary N is N in the sum N in the summary N in the sum N in the sum N is N in the sum N in the sum N in the sum N is N in the sum N in the sum N in the sum N in the sum N is N in the sum N in the sum N in the sum N in the sum N is N in the sum N in the sum N in the sum N in the sum N is N in the sum N in the sum N in the sum N is N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N is sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the sum N in the

icantly from other measurements.

⁴ The EISENBERG 54 mass was calculated for decay in flight. ALVAREZ 73 has shown that the Ω interacted with an Ag nucleus to give $K = \Xi Ag$.

Ω+ MASS

The fit assumes the Ω^- and $\overline{\Omega}^+$ masses are the same, and averages them

 5 This KAMAEV 10 value uses 76 $\varOmega^-\to \Xi^-\pi^+\pi^-$ and 24 $\overline{\varOmega}^+\to \overline{\Xi}^+\pi^-\pi^+$ decays. The \varOmega^- and $\overline{\varOmega}^+$ branching fractions measurements are statistically equal. The errors given combine statistical and systematic contributions. The CP branching-fraction asymmetry, $(\Omega^- - \overline{\Omega}^+)/\text{sum}$, is $+ 0.12 \pm 0.20$.

We have omitted some papers that have been superseded by later experi-

OMITTED FROM SUMMARY TABLE A peak in the $\Omega^-\pi^+\pi^-$ mass spectrum with a signal significance claimed to be at least 5.5 standard deviations. There is no reason to seriously doubt the existence of this state, but unless the evidence $% \left(1\right) =\left(1\right) \left(1\right$ is overwhelming we usually wait for confirmation from a second experiment before elevating peaks to the Summary Table.

CHARMED BARYONS

Revised March 2012 by C.G. Wohl (LBNL).

There are 17 known charmed baryons, and four other candidates not well enough established to be promoted to the Summary Tables.* Fig. 1(a) shows the mass spectrum, and for comparison Fig. 1(b) shows the spectrum of the lightest strange baryons. The Λ_c and Σ_c spectra ought to look much like the Λ and Σ spectra, since a Λ_c or a Σ_c differs from a Λ or a Σ only by the replacement of the s quark with a c quark. However, a Ξ or an Ω has more than one s quark, only one of which is changed to a c quark to make a Ξ_c or an Ω_c . Thus the Ξ_c and Ω_c spectra ought to be richer than the Ξ and Ω spectra.**

Before discussing the observed spectra, we review the theory of SU(4) multiplets, which tells what charmed baryons to expect; this is essential, because few of the spin-parity values given in Fig. 1(a) have been measured. Rather, they have been assigned in accord with expectations of the theory. However, they are all very likely as shown (see below).

SU(4) multiplets—Baryons made from u, d, s, and c quarks belong to SU(4) multiplets. The multiplet numerology, analogous to $3\times3\times3=10+8_1+8_2+1$ for the subset of baryons made from just u, d, and s quarks, is $4\times4\times4=20+20'_1+20'_2+\bar{4}$. Figure 2(a) shows the 20-plet whose bottom level is an SU(3) decuplet, such as the decuplet that includes the $\Delta(1232)$. Figure 2(b) shows the 20'-plet whose bottom level is an SU(3) octet, such as the octet that includes the nucleon. Figure 2(c) shows the $\bar{4}$ multiplet, an inverted tetrahedron. One level up from the bottom level of each multiplet are the baryons with one c quark. All the baryons in a given multiplet have the same spin and parity. Each N or Δ or SU(3)-singlet- Λ resonance calls for another 20'- or 20- or $\bar{4}$ -plet, respectively.

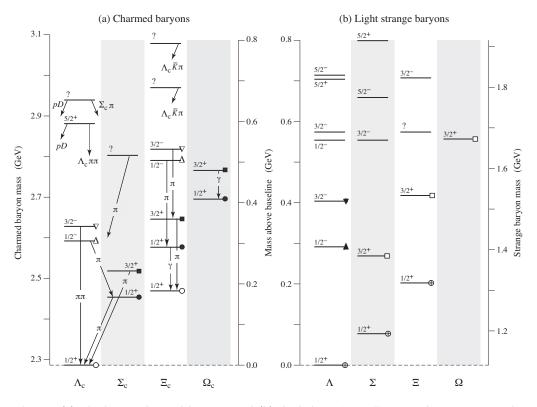

Fig. 1. (a) The known charmed baryons, and (b) the lightest "4-star" strange baryons. Note that there are two $J^P=1/2^+$ Ξ_c states, and that the lightest Ω_c does not have J=3/2. The $J^P=1/2^+$ states, all tabbed with a circle, belong to the SU(4) multiplet that includes the nucleon; states with a circle with the same fill belong to the same SU(3) multiplet within that SU(4) multiplet. Similar remarks apply to the other states: same shape of tab, same SU(4) multiplet; same fill of that shape, same SU(3) multiplet. The $J^P=1/2^-$ and $3/2^-$ states tabbed with triangles complete two SU(4) $\overline{4}$ multiplets.

Charmed Baryons

The flavor symmetries shown in Fig. 2 are of course badly broken, but the figure is the simplest way to see what charmed baryons should exist. For example, from Fig. 2(b), we expect to find, in the same $J^P=1/2^+$ 20'-plet as the nucleon, a Λ_c , a Σ_c , two Ξ_c 's, and an Ω_c . Note that this Ω_c has $J^P=1/2^+$ and is not in the same SU(4) multiplet as the famous $J^P=3/2^+$ Ω^-

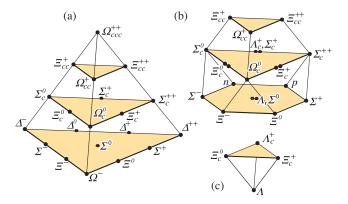

Figure 2: SU(4) multiplets of baryons made of u, d, s, and c quarks. (a) The 20-plet with an SU(3) decuplet on the lowest level. (b) The 20'-plet with an SU(3) octet on the lowest level. (c) The $\overline{4}$ -plet. Note that here and in Fig. 3, but not in Fig. 1, each charge state is shown separately.

Figure 3 shows in more detail the middle level of the 20'-plet of Fig. 2(b); it splits apart into two SU(3) multiplets, a $\bar{3}$ and a 6. The states of the $\bar{3}$ are antisymmetric under the interchange of the two light quarks (the u, d, and s quarks), whereas the states of the 6 are symmetric under this interchange. We use a prime to distinguish the Ξ_c in the 6 from the one in the $\bar{3}$.

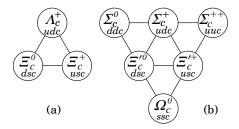

Figure 3: The SU(3) multiplets on the second level of the SU(4) multiplet of Fig. 2(b). The Λ_c and Ξ_c tabbed with open circles in Fig. 1(a) complete a $J^P = 1/2^+$ SU(3) $\overline{3}$ -plet, as in (a) here. The Σ_c , Ξ_c , and Ω_c tabbed with closed circles in Fig. 1(a) complete a $J^P = 1/2^+$ SU(3) 6-plet, as in (b) here. Together the nine particles complete the charm = +1 level of a $J^P = 1/2^+$ SU(4) 20'-plet, as in Fig. 2(b).

The observed spectra—(1) The parity of the lightest Λ_c is defined to be positive (as are the parities of the p, n, and Λ); the limited evidence about its spin is consistent with J=1/2. However, few of the J^P quantum numbers given in Fig. 1(a) have been measured. Models using spin-spin and spin-orbit interactions between the quarks, with parameters determined using a few of the masses as input, lead to the J^P assignments shown.[†] There are no surprises: the $J^P=1/2^+$ states come first, then the $J^P=3/2^+$ states . . .

- (2) There is, however, evidence that many of the J^P assignments in Fig. 1(a) must be correct. As is well known, the successive mass differences between the $J^P=3/2^+$ particles, the $\Delta(1232)^-$, $\Sigma(1385)^-$, $\Xi(1535)^-$, and Ω^- , which lie along the lower left edge of the 20-plet in Fig. 2(a), should according to SU(3) be about equal; and indeed experimentally they nearly are. In the same way, the mass differences between the $J^P=1/2^+$ $\Sigma_c(2455)^0$, Ξ_c^0 , and Ω_c^0 , the particles along the left edge of Fig. 3(b), should be about equal—assuming, of course, that they do all have the same J^P . The measured differences are 125.0 ± 2.9 MeV and 117.3 ± 3.4 MeV—not perfect, but close. Similarly, the mass differences between the presumed $J^P=3/2^+$ $\Sigma_c(2520)^0$, $\Xi_c(2645)^0$, and $\Omega_c(2770)^0$ are 127.1 ± 0.8 MeV and 120.0 ± 2.1 MeV. In Fig. 1(a), these two sets of charm particles are tabbed with solid circles and solid squares.
- (3) Other evidence comes from the decay of the $\Lambda_c(2593)$. The only allowed strong decay is $\Lambda_c(2593)^+ \to \Lambda_c^+ \pi \pi$, and this appears to be dominated by the submode $\Sigma_c(2455)\pi$, despite little available phase space for the latter (the "Q" is about 2 MeV, the c.m. decay momentum about 20 MeV/c). Thus the decay is almost certainly s-wave, which, assuming that the $\Sigma_c(2455)$ does indeed have $J^P=1/2^+$, makes $J^P=1/2^-$ for the $\Lambda_c(2593)$.

Footnotes:

- * The unpromoted states are a $\Lambda_c(2765)^+$, a $\Xi_c(2930)$, a $\Xi_c(3055)$, and a $\Xi_c(3123)$. There is also very weak evidence for a baryon with *two c* quarks, a Ξ_{cc}^+ at 3519 MeV. See the Particle Listings.
- ** For example, there are three Ω_c^0 states (properly symmetrized states of ssc, scs, and css) corresponding to each Ω^- (sss) state.
- [†] This is not the place to discuss the details of the models, nor to attempt a guide to the literature. See the discovery papers of the various charmed baryons for references to the models that lead to the quantum-number assignments.
- [‡] A reminder about the Particle Data Group naming scheme: A particle has its mass as part of its name if and only if it decays strongly. Thus $\Sigma(1385)$ and $\Sigma_c(2455)$ but Ω^- and Ξ_c' .

$$I(J^P) = O(\frac{1}{2}^+)$$
 Status: ***

The parity of the Λ_c^+ is defined to be positive (as are the parities of the proton, neutron, and Λ). The quark content is udc. Results of an analysis of $pK^-\pi^+$ decays (JEZABEK 92) are consistent with J=1/2. Nobody doubts that the spin is indeed 1/2.

The only new measurements since our 2010 Review are of limits on rare or forbidden $\Lambda_c^+ \to \rho \ell^+ \ell^-$ and $\overline{\rho} \ell^+ \ell^+$ modes.

We have omitted some results that have been superseded by later experiments. The omitted results may be found in earlier editions.

1 MASS

Our value in 2004, 2284.9 \pm 0.6 MeV, was the average of the measurements now filed below as "not used." The BABAR measurement is so much better that we use it alone. Note that it is about 2.6 (old) standard deviations above the 2004 value.

The fit also includes Σ_c – Λ_c^+ and Λ_c^{*+} – Λ_c^+ mass-difference measurements, but this doesn't affect the Λ_c^+ mass. The new (in 2006) Λ_c^+ mass simply pushes all those other masses higher.

 1 AUBERT,B 05s uses low-Q $\Lambda\,K_S^0\,K^+$ and $\Sigma^0\,K_S^0\,K^+$ decays to minimize systematic errors. The error above includes systematic as well as statistical errors. Many cross checks and adjustments to properties of the BABAR detector, as well as the large number of clean events, make this by far the best measurement of the Λ_C^+ mass.

14 MEAN LIFE

Measurements with an error $\ge 100\times 10^{-15}$ s or with fewer than 20 events have been omitted from the Listings.

1+ DECAY MODES

Nearly all branching fractions of the Λ_c^+ are measured relative to the $\rho\,K^-\pi^+$ mode, but there are no model-independent measurements of this branching fraction. We explain how we arrive at our value of $\mathrm{B}(\Lambda_c^+\to\rho\,K^-\pi^+)$ in a Note at the beginning of the branching-ratio measurements, below. When this branching fraction is eventually well determined, all the other branching fractions will slide up or down proportionally as the true value differs from the value we use here.

- [b] This branching fraction includes all the decay modes of the final-state resonance.
- [c] An ℓ indicates an e or a μ mode, not a sum over these modes.
- [d] The value is for the sum of the charge states or particle/antiparticle states indicated.

CONSTRAINED FIT INFORMATION

An overall fit to 18 branching ratios uses 33 measurements and one constraint to determine 12 parameters. The overall fit has a $\chi^2=$ 15.5 for 22 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\left\langle \delta x_i \delta x_j \right\rangle/(\delta x_i \cdot \delta x_j),$ in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}.$ The fit constrains the x_i whose labels appear in this array to sum to one.

Λ_a^+ BRANCHING FRACTIONS

Revised 2002 by P.R. Burchat (Stanford University).

Most Λ_c^+ branching fractions are measured relative to the decay mode $\Lambda_c^+ \to p K^- \pi^+$. However, there are no completely model-independent measurements of the absolute branching fraction for $\Lambda_c^+ \to p K^- \pi^+$. Here we describe the measurements that have been used to extract $\mathrm{B}(\Lambda_c^+ \to p K^- \pi^+)$, the model-dependence of the results, and the method we have used to average the results.

ARGUS (ALBRECHT 88C) and CLEO (CRAWFORD 92) measure $B(\overline{B} \to \Lambda_c^+ X) \cdot B(\Lambda_c^+ \to pK^-\pi^+)$ to be $(0.30 \pm 0.12 \pm 0.06)\%$ and $(0.273 \pm 0.051 \pm 0.039)\%$. Under the assumptions that decays of \overline{B} mesons to baryons are dominated by $\overline{B} \to \Lambda_c^+ X$ and that $\Lambda_c^+ X$ final states other than $\Lambda_c^+ \overline{N} X$ can be neglected, they also measure $B(\overline{B} \to \Lambda_c^+ X)$ to be $(6.8 \pm 0.5 \pm 0.3)\%$ (ALBRECHT 92O) and $(6.4 \pm 0.8 \pm 0.8)\%$ (CRAWFORD 92). Combining these results, we get $B(\Lambda_c^+ \to pK^-\pi^+) = (4.14 \pm 0.91)\%$. However, the assumption that \overline{B} decay modes to baryons other than $\Lambda_c^+ \overline{N} X$ are negligible is not on solid ground experimentally or theoretically [2]. Therefore, the branching fraction for $\Lambda_c^+ \to pK^-\pi^+$ given above may be low by some undetermined amount.

A second type of model-dependent determination of B($\Lambda_c^+ \to pK^-\pi^+$) is based on measurements by ARGUS (ALBRECHT 91G) and CLEO (BERGFELD 94) of $\sigma(e^+e^- \to \Lambda_c^+ {\rm X}) \cdot {\rm B}(\Lambda_c^+ \to \Lambda_c^+ \nu_\ell) = (4.15 \pm 1.03 \pm 1.18)$ pb and $(4.77 \pm 0.25 \pm 0.66)$ pb. ARGUS (ALBRECHT 96E) and CLEO (AVERY 91) have also measured $\sigma(e^+e^- \to \Lambda_c^+ {\rm X}) \cdot {\rm B}(\Lambda_c^+ \to pK^-\pi^+)$. The weighted average is (11.2 ± 1.3) pb.

From these measurements, we extract $R \equiv \mathrm{B}(\Lambda_c^+ \to p K^- \pi^+)/\mathrm{B}(\Lambda_c^+ \to \Lambda \ell^+ \nu_\ell) = 2.40 \pm 0.43$. We estimate the $\Lambda_c^+ \to p K^- \pi^+$ branching fraction from the equation

$$B(\Lambda_c^+ \to pK^-\pi^+) = R f F \frac{\Gamma(D \to X\ell^+\nu_\ell)}{1 + |V_{cd}/V_{cs}|^2} \cdot \tau(\Lambda_c^+) , \quad (1)$$

where $f = \mathrm{B}(\Lambda_c^+ \to \Lambda \ell^+ \nu_\ell)/\mathrm{B}(\Lambda_c^+ \to X_s \ell^+ \nu_\ell)$ and $F = \Gamma(\Lambda_c^+ \to X_s \ell^+ \nu_\ell)/\Gamma(D^0 \to X_s \ell^+ \nu_\ell)$. When we use $1 + |V_{cd}/V_{cs}|^2 = 1.05$ and the world averages $\Gamma(D \to \mathrm{X} \ell^+ \nu_\ell) = (0.166 \pm 0.006) \times 10^{12} \, \mathrm{s}^{-1}$ and $\tau(\Lambda_c^+) = (0.192 \pm 0.005) \times 10^{-12} \, \mathrm{s}$, we calculate $\mathrm{B}(\Lambda_c^+ \to p K^- \pi^+) = (7.3 \pm 1.4)\% \cdot f F$. Theoretical estimates for f and F are near 1.0 with significant uncertainties.

So, we have two results with significant model-dependence: $\mathrm{B}(\Lambda_c^+ \to pK^-\pi^+) = (4.14\pm0.91)\%$ from \overline{B} decays, and $\mathrm{B}(\Lambda_c^+ \to pK^-\pi^+) = (7.3\pm1.4)\% \cdot f\, F$ from semileptonic Λ_c^+ decays. If we set $f\, F = 1.0$ in the second result, and assign an uncertainty of 30% to each result to account for the unknown model-dependence, we get the consistent results $\mathrm{B}(\Lambda_c^+ \to pK^-\pi^+) = (4.14\pm0.91\pm1.24)\%$ and $\mathrm{B}(\Lambda_c^+ \to pK^-\pi^+) = (7.3\pm1.4\pm2.2)\%$. The weighted average of these two results is $\mathrm{B}(\Lambda_c^+ \to pK^-\pi^+) = (5.0\pm1.3)\%$, where the uncertainty contains both the experimental uncertainty and the 30% estimate of model dependence in each result. We assigned the value $(5.0\pm1.3)\%$ to the $\Lambda_c^+ \to pK^-\pi^+$ branching fraction in our 2000 Review [1].

A third type of measurement of $B(\Lambda_c^+ \to pK^-\pi^+)$ has been published by CLEO (JAFFE 00). Under the assumption that a \overline{D} meson and an antiproton in opposite hemispheres is evidence for a Λ_c^+ in the hemisphere of the \overline{p} , the fraction of such $\overline{D} \overline{p}$ events with a $\Lambda_c^+ \to pK^-\pi^+$ decay can be used to determine the $\Lambda_c^+ \to p K^- \pi^+$ branching fraction. CLEO measures $B(\Lambda_c^+ \to pK^-\pi^+) = (5.0 \pm 1.3)\%$, which is coincidentally exactly the same value as our PDG 00 average given above. The quoted uncertainty includes significant contributions from model-dependent effects (e.g., differences between the \overline{p} momentum spectrum in events with a Λ_c^+ and \overline{p} in the same hemisphere, and with a \overline{D} and \overline{p} in opposite hemispheres; extrapolation of the Λ_c^+ and \overline{D} momentum spectrum below the minimum value used for rejecting B decay products; and our limited understanding of backgrounds such as $D\overline{D}N\overline{p}$ events).

We have chosen to continue to assign the value $(5.0 \pm 1.3)\%$ to the $\Lambda_c^+ \to p K^- \pi^+$ branching fraction (given as PDG 02 below). As was noted earlier, most of the other Λ_c^+ decay modes are measured relative to this mode.

New methods for measuring the Λ_c^+ absolute branching fractions have been proposed [2,3].

 2 JAFFE 00 assumes that a $\overline{\it D}$ meson and an antiproton in opposite hemispheres tags for a Λ_C^+ in the hemisphere of the \overline{p} . The fraction of such $\overline{D}\,\overline{p}$ events with a $\Lambda_C^+ \to$ $\rho\,{\it K}^-\,\pi^+$ decay then gives the $\rho\,{\it K}^-\,\pi^+$ branching fraction. See the paper for assumptions, caveats, etc.

³ To extract $\Gamma(p \, K^- \, \pi^+)/\Gamma_{\text{total}}$, we use $B(\overline{B} \to \Lambda_C^+ \, X) \cdot B(\Lambda_C^+ \to p \, K^- \, \pi^+) = (0.28 \pm 0.28 \pm$ 0.06)%, which is the average of measurements from ARGUS (ALBRECHT 88c) and CLEO (CRAWFORD 92).

⁴ ALBRECHT 920 measures B($\overline{B} \rightarrow \Lambda_c^+ X$) = (6.8 ± 0.5 ± 0.3)%.

⁵ CRAWFORD 92 measures B($\overline{B} \rightarrow \Lambda_C^+ X$) = (6.4 ± 0.8 ± 0.8)%.

| -1.1 ± 0.4 | 86 | AVERY | 90B | CLEO | $e^+e^-pprox 10.6$ GeV |

 22 BISHAI 95 actually gives $\alpha{=}-0.94^{+}0.21^{+}0.12^{-}$, chopping the errors at the physical limit -1.0. However, for $\alpha{\approx}-1.0$, some experiments should get unphysical values $(\alpha<-1.0)$, and for averaging with other measurements such values (or errors that extend below -1.0) should not be chopped.

$\Lambda_c(2595)^+$

$$I(J^P) = 0(\frac{1}{2})$$
 Status: ***

The $\Lambda_c^+\pi^+\pi^-$ mode is largely, and perhaps entirely, $\Sigma_c\pi$, which is just at threshold; since the Σ_c has $J^P = 1/2^+$, the J^P here is almost certainly $1/2^-$. This result is in accord with the theoretical expectation that this is the charm counterpart of the strange $\Lambda(1405).$

$\Lambda_c(2595)^{+}$ MASS

The mass is obtained from the $\Lambda_c(2595)^+ - \Lambda_c^+$ mass-difference measure-

¹ BLECHMAN 03 finds that a more sophisticated treatment than a simple Breit-Wigner for the proximity of the threshold of the dominant decay, $\Sigma_{\mathcal{C}}(2455)\,\pi$, lowers the $\Lambda_{\it C}(25\,95)^+ - \Lambda_{\it C}^+$ mass difference by 2 or 3 MeV. The analysis of AALTONEN 11H bears this out.

 Status: *

OMITTED FROM SUMMARY TABLE

A broad, statistically significant peak (997 $^{+141}_{-129}$ events) seen in $\Lambda_c^+\pi^+\pi^-$. However, nothing at all is known about its quantum numbers, including whether it is a Λ_c^+ or a Σ_c , or whether the width might be due to overlapping states.

$\Lambda_c(2765)^{+}$ MASS

The mass is obtained from the $\Lambda_{\it C}(2765)^{+}-\Lambda_{\it C}^{+}$ mass-difference measurement below.

 $\Lambda_c(2880)^+$

$$I(J^P) = O(\frac{5}{2}^+)$$
 Status: ***

A narrow peak seen in $\Lambda_c^+\pi^+\pi^-$ and in $\rho\,D^0$. It is not seen in $\rho\,D^+$, and therefore it is probably a Λ_c^+ and not a \varSigma_c . The evidence for spin 5/2 comes from the $\varSigma_c(2455)\pi$ decay angular distribution, and the evidence for parity + comes from agreement of the $\varSigma_c(250)/\varSigma_c(2455)$ branching ratio with a prediction of heavy quark symmetry (see MIZUK 07).

 $\Sigma_c(2800), \Xi_c^+$

 $\Sigma_c(2800)$

$$I(J^P) = 1(?^?)$$
 Status: ***

Seen in the $\Lambda_c^+\pi^+$, $\Lambda_c^+\pi^0$, and $\Lambda_c^+\pi^-$ mass spectra.

$\Sigma_c(2800)$ MASSES

The charged ++ and + masses are obtained from the mass-difference measurements that follow. The neutral mass is dominated by the mass-difference measurement, but is pulled up somewhat by the less well-determined but considerably higher direct-mass measurement. It is possible, in fact, that AUBERT 08BN is seeing a different $\Sigma_{\mathcal{C}}.$

JBERT 08BN PR D78 112003 B. Aubert et al. IZUK 05 PRL 94 122002 R. Mizuk et al. (BABAR Collab.) (BELLE Collab.) Ξ_c^+

 $I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$ Status: ***

DOCUMENT ID ____ TECN COMMENT

According to the quark model, the Ξ_c^+ (quark content usc) and Ξ_c^0 form an isospin doublet, and the spin-parity ought to be $J^P=1/2^+$. None of I, J, or P has actually been measured.

Ξ_c^+ MASS

The fit uses the Ξ_c^+ and Ξ_c^0 mass and mass-difference measurements.

 $^{1}\,\mathrm{The}$ systematic error was (wrongly) given the other way round in LESIAK 05; see the erratum

erratum. Although COTEUS 87 claims to agree well with BIAGI 83 on the mass and width, there appears to be a discrepancy between the two experiments. BIAGI 83 sees a single peak (stated significance about 6 standard deviations) in the $\Lambda K^-\pi^+\pi^+$ mass spectrum. COTEUS 87 sees two peaks in the same spectrum, one at the Ξ_c^+ mass, the other 75

MeV lower. The latter is attributed to $\Xi_{+}^{+} \to \Sigma^{0} K^{-} \pi^{+} \pi^{+} \to (\Lambda \gamma) K^{-} \pi^{+} \pi^{+}$, with the γ unseen. The *combined* significance of the double peak is stated to be 5.5 standard deviations. But the absence of any trace of a lower peak in BIAGI 83 seems to us to throw into guestion the interpretation of the lower peak of COTEUS 87.

$$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$$
 Status: ***

According to the quark model, the Ξ_c^0 (quark content dsc) and Ξ_c^+ form an isospin doublet, and the spin-parity ought to be $J^P=1/2^+$. None of I,J, or P has actually been measured.

Ξ_c MASS

The fit uses the Ξ_C^0 and Ξ_C^+ mass and mass-difference measurements.

$$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$$
 Status: ***

The $\equiv_c^{\prime+}$ and $\equiv_c^{\prime0}$ presumably complete the SU(3) sextet whose other members are the Σ_c^{++} , Σ_c^+ , Σ_c^0 , and Ω_c^0 : see Fig. 3 in the Note on Charmed Baryons just before the Λ_c^+ Listings. The quantum numbers given above come from this presumption but have not been measured.

$\Xi_c^{\prime+}$ MASS

The mass is obtained from the mass-difference measurement that follows.

 Status: *

OMITTED FROM SUMMARY TABLE

This would presumably be an isospin-1/2 particle, a ccu Ξ_{cc}^{++} and a $\operatorname{\mathit{ccd}} \ \Xi_{\operatorname{\mathit{cc}}}^+.$ However, opposed to the evidence cited below, the BABAR experiment has found no evidence for a Ξ_{cc}^+ in a search in $\Lambda_c^+ K^- \pi^+$ and $\Xi_c^0 \pi^+$ modes, and no evidence of a Ξ_{cc}^{++} in $\Lambda_c^+ K^- \pi^+ \pi^+$ and $\Xi_c^0 \pi^+ \pi^+$ modes (AUBERT, B 06D). Nor has the BELLE experiment found any evidence for a Ξ_{cc}^+ in the \varLambda_c^+ $K^ \pi^+$ mode (CHISTOV 06).

1 MEAN LIFE

See b-baryon Admixture section for data on b-baryon mean life average over species of $\emph{b}\text{-}\text{baryon}$ particles.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors.

1 DECAY MODES

The branching fractions B(b-baryon $\rightarrow \Lambda \ell^- \overline{\nu}_\ell$ anything) and B($\Lambda_b^0 \rightarrow$ $\Lambda_{c}^{+}\ell^{-}\overline{
u}_{\ell}$ anything) are not pure measurements because the underlying measured products of these with B($b \rightarrow b$ -baryon) were used to determine $\mathsf{B}(b o b ext{-baryon})$, as described in the note "Production and Decay of b-Flavored Hadrons."

For inclusive branching fractions, e.g., $\Lambda_b \to \overline{\Lambda}_c$ anything, the values usually are multiplicities, not branching fractions. They can be greater

²Uses exclusively reconstructed final states containing a $J/\psi
ightarrow \mu^+\mu^-$ decays.

 $^{^3}$ ABE 97B observed 38 events with a background of 18 \pm 1.6 events in the mass range 5.60–5.65 GeV/ c^2 , a significance of > 3.4 standard deviations.

 $^{^4}$ Uses 4 fully reconstructed Λ_b events.

⁵ ABE 93B states that, based on the signal claimed by ALBAJAR 91E, CDF should have found 30 \pm 23 $\Lambda_{~b}^{~0}$ \rightarrow $~J/\psi(1S)\Lambda$ events. Instead, CDF found not more than 2 events.

 $^{^6}$ ALBAJAR 91E claims 16 \pm 5 events above a background of 9 \pm 1 events, a significance of about 5 standard deviations.

 $^{^9}$ Measured mean life using fully reconstructed $\Lambda_b^0\to J/\psi\Lambda$ decays. 10 Measured mean life using fully reconstructed $\Lambda_b^0\to\Lambda_c^+\pi^-$ decays.

 $^{^{11}}$ Measured using semileptonic decays $\Lambda^0_b \to \Lambda^+_c \mu \nu X$ and $\Lambda^+_c \to K^0_S p$.

 $^{^{12}}$ Measured using $\Lambda_{\it C}\,\ell^-$ and $\Lambda\,\ell^+\,\ell^-$

 $^{^{13}}$ Excess $\Lambda_{\it C}\ell^{-}$, decay lengths.

Baryon Particle Listings

CONSTRAINED FIT INFORMATION

An overall fit to 5 branching ratios uses 5 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2=3.9$ for 2 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\left\langle \delta x_i \delta x_j \right\rangle/(\delta x_i \cdot \delta x_j),$ in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}.$ The fit constrains the x_i whose labels appear in this array to sum to one.

$$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$$
 Status: *** I, J, P need confirmation.

In the quark model, Ξ_b^0 and Ξ_b^- are an isodoublet (*usb*, *dsb*) state; the lowest Ξ_b^0 and Ξ_b^- ought to have $J^P=1/2^+$. None of I, J, or P have actually been measured.

Ξ_b MEAN LIFE

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account correlations between the measurements and

asymmetric lifetime errors. <u>VALUE (10⁻¹² s)</u> <u>EVTS</u> DOCUMENT ID TECN COMMENT

b-baryon ADMIXTURE $(\Lambda_b, \Xi_b, \Sigma_b, \Omega_b)$

b-baryon ADMIXTURE MEAN LIFE

Each measurement of the $\emph{b}\text{-}\text{baryon}$ mean life is an average over an admixture of various b baryons which decay weakly. Different techniques emphasize different admixtures of produced particles, which could result in a different b-baryon mean life. More b-baryon flavor specific channels are not included in the measurement.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors.

b-baryon ADMIXTURE DECAY MODES $(\Lambda_b, \Xi_b, \Sigma_b, \Omega_b)$

These branching fractions are actually an average over weakly decaying b-baryons weighted by their production rates at the LHC, LEP, and Tevatron, branching ratios, and detection efficiencies. They scale with the b-baryon production fraction $\mathrm{B}(b \to b$ -baryon).

The branching fractions $\mathsf{B}(b ext{-baryon}\to \Lambda\ell^-\overline{
u}_\ell$ anything) are not pure measurements because the underlying measured products of these with $\mathsf{B}(b\to b ext{-baryon})$ were used to determine $\mathsf{B}(b\to b ext{-baryon})$, as described in the note "Production and Decay of $b ext{-Flavored Hadrons."}$ "

For inclusive branching fractions, e.g., $B\to D^\pm$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one

| | Mode | Fraction (Γ_i/Γ) |
|----------------|--------------------------------------------------|--------------------------------|
| Γ ₁ | $p\mu^-\overline{ u}$ anything | (5.3 + 2.2) % |
| Γ_2 | $ ho\ell\overline{ u}_\ell$ anything | (5.1 ± 1.2) % |
| Γ_3 | <i>p</i> a nything | (63 ±21)% |
| Γ_4 | $\Lambda \ell^- \overline{ u}_\ell$ anything | (3.4 ± 0.6) % |
| Γ_5 | $arLambda \ell^+ u_\ell$ a nything | |
| Γ_6 | Λ anything | |
| Γ_7 | $\Lambda_c^+ \ell^- \overline{ u}_\ell$ anything | |
| Γ ₈ | $\Lambda / \overline{\Lambda}$ anything | (35 ± 8)% |

MAGNETIC MONOPOLES

Updated August 2011 by D. Milstead (Stockholm Univ.) and E.J. Weinberg (Columbia Univ.).

The symmetry between electric and magnetic fields in the sourcefree Maxwell's equations naturally suggests that electric charges might have magnetic counterparts, known as magnetic monopoles. Although the greatest interest has been in the supermassive monopoles that are a firm prediction of all grand unified theories, one cannot exclude the possibility of lighter monopoles, even though there is at present no strong theoretical motivation for these.

In either case, the magnetic charge is constrained by a quantization condition first found by Dirac [1]. Consider a monopole with magnetic charge Q_M and a Coulomb magnetic field

$$\mathbf{B} = \frac{Q_M}{4\pi} \frac{\hat{\mathbf{r}}}{r^2} \,. \tag{1}$$

Any vector potential ${\bf A}$ whose curl is equal to ${\bf B}$ must be singular along some line running from the origin to spatial infinity. This Dirac string singularity could potentially be detected through the extra phase that the wavefunction of a particle with electric charge Q_E would acquire if it moved along a loop encircling the string. For the string to be unobservable, this phase must be a multiple of 2π . Requiring that this be the case for any pair of electric and magnetic charges gives the condition that all charges be integer multiples of minimum charges Q_E^{\min} and Q_M^{\min} obeying

$$Q_E^{\min} Q_M^{\min} = 2\pi. \tag{2}$$

(For monopoles which also carry an electric charge, called dyons, the quantization conditions on their electric charges can be modified. However, the constraints on magnetic charges, as well as those on all purely electric particles, will be unchanged.)

Another way to understand this result is to note that the conserved orbital angular momentum of a point electric charge moving in the field of a magnetic monopole has an additional component, with

$$\mathbf{L} = m\mathbf{r} \times \mathbf{v} - 4\pi Q_E Q_M \hat{\mathbf{r}} \tag{3}$$

Requiring the radial component of \mathbf{L} to be quantized in half-integer units yields Eq. (2).

If there are unbroken gauge symmetries in addition to the U(1) of electromagnetism, the above analysis must be modified [2,3]. For example, a monopole could have both a

U(1) magnetic charge and a color magnetic charge. The latter could combine with the color charge of a quark to give an additional contribution to the phase factor associated with a loop around the Dirac string, so that the U(1) charge could be the Dirac charge $Q_M^D \equiv 2\pi/e$, the result that would be obtained by substituting the electron charge into Eq. (2). On the other hand, for monopoles without color-magnetic charge, one would simply insert the quark electric charges into Eq. (2) and conclude that Q_M must be a multiple of $6\pi/e$.

The prediction of GUT monopoles arises from the work of 't Hooft [4] and Polyakov [5], who showed that certain spontaneously broken gauge theories have nonsingular classical solutions that lead to magnetic monopoles in the quantum theory. The simplest example occurs in a theory where the vacuum expectation value of a triplet Higgs field ϕ breaks an SU(2) gauge symmetry down to the U(1) of electromagnetism and gives a mass M_V to two of the gauge bosons. In order to have finite energy, ϕ must approach a vacuum value at infinity. However, there is a continuous family of possible vacua, since the scalar field potential determines only the magnitude v of $\langle \phi \rangle$, but not its orientation in the internal SU(2) space. In the monopole solution, the direction of ϕ in internal space is correlated with the position in physical space; i.e., $\phi^a \sim v \hat{r}^a$. The stability of the solution follows from the fact that this twisting Higgs field cannot be smoothly deformed to a spatially uniform vacuum configuration. Reducing the energetic cost of the spatial variation of ϕ requires a nonzero gauge potential, which turns out to yield the magnetic field corresponding to a charge $Q_M = 4\pi/e$. Numerical solution of the classical field equations shows that the mass of this monopole is

$$M_{\rm mon} \sim \frac{4\pi M_V}{e^2} \,. \tag{4}$$

The essential ingredient here was the fact that the Higgs fields at spatial infinity could be arranged in a topologically nontrivial configuration. A discussion of the general conditions under which this is possible is beyond the scope of this review, so we restrict ourselves to the two phenomenologically most important cases.

The first is the electroweak theory, with $SU(2) \times U(1)$ broken to U(1). There are no topologically nontrivial configurations of the Higgs field, and hence no topologically stable monopole solutions.

The second is when any simple Lie group is broken to a subgroup with a U(1) factor, a case that includes all grand unified theories. The monopole mass is determined by the mass scale of the symmetry breaking that allows nontrivial topology. For example, an SU(5) model with

$$\mathrm{SU}(5) \xrightarrow{M_X} \mathrm{SU}(3) \times \mathrm{SU}(2) \times \mathrm{U}(1) \xrightarrow{M_W} \mathrm{SU}(3) \times \mathrm{U}(1) \quad (5)$$

has a monopole [6] with $Q_M=2\pi/e$ and mass

$$M_{\rm mon} \sim \frac{4\pi M_{\rm X}}{g^2} \,, \tag{6}$$

Searches Particle Listings Magnetic Monopole Searches

where g is the SU(5) gauge coupling. For a unification scale of 10^{16} GeV, these monopoles would have a mass $M_{\rm mon} \sim 10^{17}$ – 10^{18} GeV.

In theories with several stages of symmetry breaking, monopoles of different mass scales can arise. In an SO(10) theory with

$$SO(10) \xrightarrow{M_1} SU(4) \times SU(2) \times SU(2) \xrightarrow{M_2} SU(3) \times SU(2) \times U(1)$$
(7)

there is monopole with $Q_M = 2\pi/e$ and mass $\sim 4\pi M_1/g^2$ and a much lighter monopole with $Q_M = 4\pi/e$ and mass $\sim 4\pi M_2/g^2$ [7].

The central core of a GUT monopole contains the fields of the superheavy gauge bosons that mediate baryon number violation, so one might expect that baryon number conservation could be violated in baryon–monopole scattering. The surprising feature, pointed out by Callan [8] and Rubakov [9], is that these processes are not suppressed by powers of the gauge boson mass. Instead, the cross-sections for catalysis processes such as $p + \text{monopole} \rightarrow e^+ + \pi^0 + \text{monopole}$ are essentially geometric; i.e., $\sigma_{\Delta B}\beta \sim 10^{-27} \text{ cm}^2$, where $\beta = v/c$. Note, however, that intermediate mass monopoles arising at later stages of symmetry breakings, such as the doubly charged monopoles of the SO(10) theory, do not catalyze baryon number violation.

Production and Annihilation: GUT monopoles are far too massive to be produced in any foreseeable accelerator. However, they could have been produced in the early universe as topological defects arising via the Kibble mechanism [10] in a symmetry-breaking phase transition. Estimates of the initial monopole abundance, and of the degree to which it can be reduced by monopole-antimonopole annihilation, predict a present-day monopole abundance that exceeds by many orders of magnitude the astrophysical and experimental bounds described below [11]. Cosmological inflation and other proposed solutions to this primordial monopole problem generically lead to present-day abundances exponentially smaller than could be plausibly detected, although potentially observable abundances can be obtained in scenarios with carefully tuned parameters.

If monopoles light enough to be produced at colliders exist, one would expect that these could be produced by analogs of the electromagnetic processes that produce pairs of electrically charged particles. Because of the large size of the magnetic charge, this is a strong coupling problem for which perturbation theory cannot be trusted. Indeed, the problem of obtaining reliable quantitative estimates of the production cross-sections remains an open one, on which there is no clear consensus.

Astrophysical and Cosmological Bounds: If there were no galactic magnetic field, one would expect monopoles in the galaxy to have typical velocities of the order of $10^{-3}c$, comparable to the virial velocity in the galaxy (relevant if the monopoles cluster with the galaxy) and the peculiar velocity of the galaxy with respect to the CMB rest frame (relevant if the monopoles are not bound to the galaxy). This situation is modified by the existence of a galactic magnetic field $B \sim 3\mu G$.

A monopole with the Dirac charge and mass M would be accelerated by this field to a velocity

$$v_{\text{mag}} \sim \begin{cases} c, & M \lesssim 10^{11} \text{GeV} , \\ 10^{-3} c \left(\frac{10^{17} \text{ GeV}}{M}\right)^{1/2}, & M \gtrsim 10^{11} \text{GeV} . \end{cases}$$
 (8)

Accelerating these monopoles drains energy from the magnetic field. Parker [12] obtained an upper bound on the flux of monopoles in the galaxy by requiring that the rate of this energy loss be small compared to the time scale on which the galactic field can be regenerated. With reasonable choices for the astrophysical parameters (see Ref. 13 for details), this Parker bound is

$$F < \begin{cases} 10^{-15} \,\mathrm{cm}^{-2} \,\mathrm{sr}^{-1} \,\mathrm{sec}^{-1}, & M \lesssim 10^{17} \,\mathrm{GeV}, \\ 10^{-15} \left(\frac{M}{10^{17} \,\mathrm{GeV}}\right) \,\mathrm{cm}^{-2} \,\mathrm{sr}^{-1} \,\mathrm{sec}^{-1}, & M \gtrsim 10^{17} \,\mathrm{GeV}. \end{cases}$$
(9)

Applying similar arguments to an earlier seed field that was the progenitor of the current galactic field leads to a tighter bound [14],

$$F < \left[\frac{M}{10^{17} \text{GeV}} + (3 \times 10^{-6}) \right] 10^{-16} \,\text{cm}^{-2} \text{sr}^{-1} \text{sec}^{-1}.$$
 (10)

Considering magnetic fields in galactic clusters gives a bound [15] which, although less secure, is about three orders of magnitude lower than the Parker bound.

A flux bound can also be inferred from the total mass of monopoles in the universe. If the monopole mass density is a fraction Ω_M of the critical density, and the monopoles were uniformly distributed throughout the universe, there would be a monopole flux

$$F_{\text{uniform}} = 1.3 \times 10^{-16} \Omega_M \left(\frac{10^{17} \text{ GeV}}{M} \right) \left(\frac{v}{10^{-3} c} \right) \text{cm}^{-2} \text{sr}^{-1} \text{sec}^{-1}.$$
(11)

If we assume that $\Omega_M \sim 0.1$, this gives a stronger constraint than the Parker bound for $M \sim 10^{15}$ GeV. However, monopoles with masses $\sim 10^{17}$ GeV are not ejected by the galactic field and can be gravitationally bound to the galaxy. In this case their flux within the galaxy is increased by about five orders of magnitude for a given value of Ω_M , and the mass density bound only becomes stronger than the Parker bound for $M \sim 10^{18}$ GeV.

A much more stringent flux bound applies to GUT monopoles that catalyze baryon number violation. The essential idea is that compact astrophysical objects would capture monopoles at a rate proportional to the galactic flux. These monopoles would then catalyze proton decay, with the energy released in the decay leading to an observable increase in the luminosity of the object. A variety of bounds, based on neutron stars [16–20], white dwarfs [21], and Jovian planets [22] have been obtained. These depend in the obvious manner on the catalysis cross section, but also on the details of the astrophysical scenarios; e.g., on how much the accumulated density is reduced by monopole-antimonopole annihilation, and

on whether monopoles accumulated in the progenitor star survive its collapse to a white dwarf or neutron star. The bounds obtained in this manner lie in the range

$$F\left(\frac{\sigma_{\Delta B}\beta}{10^{-27}\text{cm}^2}\right) \sim (10^{-18} - 10^{-29})\text{cm}^{-2}\text{sr}^{-1}\text{sec}^{-1}.$$
 (12)

It is important to remember that not all GUT monopoles catalyze baryon number nonconservation. In particular, the intermediate mass monopoles that arise in some GUTs at later stages of symmetry-breaking are examples of theoretically motivated monopoles that are exempt from the bound of Eq. (12).

Searches for Magnetic Monopoles: To date there have been no confirmed observations of exotic particles possessing magnetic charge. Precision measurements of the properties of known particles have led to tight limits on the values of magnetic charge they may possess. Using the induction method (see below), the electron's magnetic charge has been found to be $Q_e^m < 10^{-24} Q_M^D$ [23](where Q_M^D is the Dirac charge). Furthermore, measurements of the anomalous magnetic moment of the muon have been used to place a model dependent lower limit of 120 GeV on the monopole mass ¹ [24]. less, guided mainly by Dirac's argument and the predicted existence of monopoles from spontaneous symmetry breaking mechanisms, searches have been routinely made for monopoles produced at accelerators, in cosmic rays, and bound in mat-Although the resultant limits from such searches are usually made under the assumption of a particle possessing only magnetic charge, most of the searches are also sensitive to dyons.

Search Techniques: Search strategies are determined by the expected interactions of monopoles as they pass through matter. These would give rise to a number of striking characteristic signatures. Since a complete description of monopole search techniques falls outside of the scope of this minireview, only the most common methods are described below. More comprehensive descriptions of search techniques can be found in Refs. [26,27].

The induction method exploits the long-ranged electromagnetic interaction of the monopole with the quantum state of a superconducting ring which would lead to a monopole which passes through such a ring inducing a permanent current. The induction technique typically uses Superconducting Quantum Interference Devices (SQUID) technology for detection and is employed for searches for monopoles in cosmic rays and matter. Another approach is to exploit the electromagnetic energy loss of monopoles. Monopoles with Dirac charge would typically lose energy at a rate which is several thousand times larger than that expected from particles possessing the elementary electric charge. Consequently, scintillators, gas chambers and nuclear track detectors (NTDs) have been used in cosmic ray and collider experiments. A further approach, which has

been used at colliders, is to search for particles describing a non-helical path in a uniform magnetic field.

Searches for Monopoles Bound in Matter: Monopoles have been sought in a range of bulk materials which it is assumed would have absorbed incident cosmic ray monopoles over a long exposure time of order million years. Materials which have been studied include moon rock, meteorites, manganese modules, and sea water [28]. A stringent upper limit on the monopoles per nucleon ratio of $\sim 10^{-29}$ has been obtained [28].

Searches in Cosmic Rays: Direct searches for monopoles in cosmic rays refer to those experiments in which the passage of the monopole is measured by an active detector. Catalysis processes in which GUT monopoles could induce nucleon decay are discussed in the next section. To interpret the results of the non-catalysis searches, the cross section for the catalysis process is typically either set to zero [29] or assigned a modest value (1mb) [30]. Searches which explicitly exploit the expected catalysed decays are discussed in the next section.

Although early cosmic ray searches using the induction technique [31] and NTDs [32] observed monopole candidates, none of these apparent observations have been confirmed. Recent experiments have typically employed large scale detectors. The MACRO experiment at the Gran Sasso underground laboratory comprised three different types of detector: liquid scintillator, limited stream tubes, and NTDs, which provided a total acceptance of $\sim 10000 \mathrm{m}^2$ for an isotropic flux. As shown in Fig. 1, this experiment has so far provided the most extensive β -dependent flux limits for GUT monopoles with Dirac charge [30]. Also shown are limits from an experiment at the OHYA mine in Japan [29], which used a $2000 \mathrm{m}^2$ array of NTDs.

In Fig. 1, upper flux limits are also shown as a function of mass for monopole speed $\beta > 0.05$. In addition to MACRO and OYHA flux limits, results from the SLIM [33] high-altitude experiment are shown. The SLIM experiment provided a good sensitivity to intermediate mass monopoles $(10^5 \lesssim M \lesssim 10^{12}$ GeV). In addition to the results shown in Fig. 1, a limit of $\sim 9\times 10^{-16}~\rm cm^{-2}s^{-1}sr^{-1}$ was obtained for monopoles with $\beta=$ 0.76 by The AMANDA-II experiment [34]. This limit extends to $\sim 4 \times 10^{-17} \ \mathrm{cm^{-2} s^{-1} sr^{-1}}$ for $\beta \sim 1$. The most stringent constraints on the flux of ultra-relativistic monopoles have been obtained by the RICE [35] and ANITA-II experiments [36] at the South Pole which were sensitive to monopoles with γ values of $10^7 \lesssim \gamma \lesssim 10^{12}$ and $10^9 \lesssim \gamma \lesssim 10^{13}$, respectively, and which produced flux limits as low as 10^{-19} cm⁻²s⁻¹sr⁻¹. In addition to the aforementioned flux limits for monopoles with the Dirac charge, the OHYA experiment also presented limits for monopoles with charges up to $3Q_M^D$, as did the the SLIM experiment.

¹ Where no ambiguity is likely to arise, a reference to a monopole implies a particle possessing Dirac charge.

Searches via the Catalysis of Nucleon-Decay: Searches have also been performed for evidence of the catalysed decay of a nucleon, as predicted by the Callan-Rubakov mechanism. Searches have been made at a range of experiments which are sensitive to the induced nucleon decay of a passing monopole. For example, searches have been made with the Soudan [37] and Macro [38] experiments, using tracking detectors. Searches at Kamiokande [39], IMB [40] and the underwater Lake Baikal experiment [41] which exploit the Cerenkov effect have also been made. The resulting β -dependent flux limits from these experiments, which typically vary between $6 \times 10^{-17} - 9 \times 10^{-17}$ $10^{-14} \mathrm{cm}^{-2} \mathrm{sr}^{-1} \mathrm{s}^{-1}$ [25], are sensitive to the assumed values of the catalysis cross sections.

Searches at Colliders: Searches have been performed at hadron-hadron, electron-positron and lepton-hadron experiments. Collider searches can be broadly classed as being direct or indirect. In a direct search, evidence of the passage of a monopole through material, such as a charged particle track, is sought. In indirect searches, virtual monopole processes are assumed to influence the production rates of certain final states.

Direct Searches at Colliders: Collider experiments typically express their results in terms of upper limits on a production cross section and/or monopole mass. To calculate these limits, ansatzes are used to model the kinematics of monopoleantimonopole pair production processes since perturbative field theory cannot be used to calculate the rate and kinematic properties of produced monopoles. Limits therefore suffer from a degree of model-dependence, implying that a comparison between the results of different experiments can be problematic, in particular when this concerns excluded mass regions. A conservative approach with as little model-dependence as possible is thus to present the upper cross-section limits as a function of one half the centre-of-mass energy of the collisions, as shown in Fig. 2 for recent results from high energy colliders.

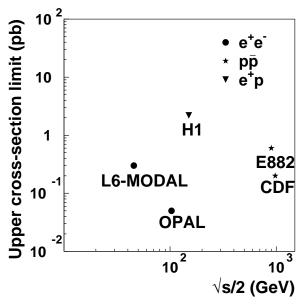

Figure 2: Upper limits on the production cross sections of monopoles from various collider-based experiments.

Searches for monopoles produced at the highest available energies in hadron-hadron collisions were made at the Tevatron by the CDF [42] and E882 [43] experiments. Complementary approaches were used; the CDF experiment used a dedicated time-of-flight system whereas the E882 experiment employed the induction technique to search for stopped monopoles in discarded detector material which had been part of the CDF and D0 detectors using periods of luminosity. Considered together, the searches provide a sensitivity to monopoles with charges between Q_M^D and $6Q_M^D$ and masses up to around 900 GeV. Earlier searches at the Tevatron, such as Ref. 44, used NTDs and were based on comparatively modest amounts of integrated luminosity. Lower energy hadron-hadron experiments have employed a variety of search techniques including plastic track detectors [45] and searches for trapped monopoles [46].

The only LEP-2 search was made by OPAL [47] which quoted cross section limits for the production of monopoles possessing masses up to around 103 GeV. At LEP-1, searches were made with NTDs deployed around an interaction region. This allowed a range of charges to be sought for masses up to ~ 45 GeV. The L6-MODAL experiment [48] gave limits for monopoles with charges in the range $0.9Q_M^D$ and $3.6Q_M^D$, whilst an earlier search by the MODAL experiment was sensitive to monopoles with charges as low as $0.1Q_M^D$ [49]. The deployment of NTDs around the beam interaction point was also used at earlier e^+e^- colliders such as KEK [50] and PETRA [51]. Searches at e^+e^- facilities have also been made for particles following non-helical trajectories [52.53].

There has so far been one search for monopole production in lepton-hadron scattering. Using the induction method,

Searches Particle Listings Magnetic Monopole Searches

monopoles were sought which could have stopped in the aluminium beampipe which had been used by the H1 experiment at HERA [54]. Cross section limits were set for monopoles with charges in the range $Q_M^D - 6Q_M^D$ for masses up to around 140 GeV.

Indirect Searches at Colliders: It has been proposed that virtual monopoles can mediate processes which give rise to multi-photon final-states [55,56]. Photon-based searches were made by the D0 [57] and L3 [58] experiments. The D0 work led to spin-dependent lower mass limits of between 610 and 1580 GeV, while L3 reported a lower mass limit of 510 GeV. However, it should be stressed that uncertainties on the theoretical calculations which were used to derive these limits are difficult to estimate.

 $^{^1}$ ABBIENDI 08 assume production of spin 1/2 monopoles with effective charge $g\beta$ (n=1), via $e^+e^- \to \gamma^* \to M\overline{M}$, so that the cross section is proportional to $(1+\cos^2\theta)$. There is no z information for such highly saturated tracks, so a parabolic track in the jet chamber is projected onto the xy plane. Charge per hit in the chamber produces a clean separation of signal and background.

vation of radio Cherenkov signals at the South Pole. Limits are speed-dependent.

² ABULENCIA 06k searches for high-ionizing signals in CDF central outer tracker and time-of-flight detector. For Drell-Yan $M\overline{M}$ production, the cross section limit implies M>360 GeV at 95% CL.

³ MY > 500 GeV at 195% CL.

3 AKTAS OSA model-dependent limits as a function of monopole mass shown for arbitrary mass of 60 GeV. Based on search for stopped monopoles in the H1 Al beam pipe.

 $^{^{4}\,\}mathrm{AKTAS}$ 05A limits with assumed elastic spin 0 monopole pair production.

⁵ AKTAS 05A limits with assumed inelastic spin 1/2 monopole pair production.

 $^{^{6}\,\}mathrm{KALBFLEISCH}$ 04 reports searches for stopped magnetic monopoles in Be, Al, and Pb samples obtained from discarded material from the upgrading of DØ and CDF. A large-aperture warm-bore cryogenic detector was used. The approach was an extension of the methods of KALBFLEISCH 00. Cross section results moderately model dependent; interpretation as a mass lower limit depends on possibly invalid perturbation expansion.

 $^{^7}$ KALBFLEISCH 00 used an induction method to search for stopped monopoles in pieces of the DØ $\,$ (FNAL) beryllium beam pipe and in extensions to the drift chamber aluminum support cylinder. Results are model dependent.

⁸ KALBFLEISCH 00 result is for aluminum. 9 KALBFLEISCH 00 result is for beryllium.

 $^{^{}m 10\,HE}$ 97 used a lead target and barium phosphate glass detectors. Cross-section limits are well below those predicted via the Drell-Yan mechanism.

¹¹ Multiphoton events.

¹² Cherenkov radiation polarization.

¹³ Re-examines CERN neutrino experiments.

pair of photons with high transverse energies. 15 ACCIARRI 95c finds a limit B($\!Z \to \gamma \gamma \gamma) < 0.8 \times 10^{-5} \!$ (which is possible via a monopole loop) at 95% CL and sets the mass limit via a cross section model.

¹⁷ ABBASI 10A was based on a Cherenkov signature in an array of optical modules which were sunk in the Antarctic ice cap. Limits are speed-dependent.

 $^{^{18}}$ BALESTRA 08 exposed of nuclear track detector modules totaling 400 m 2 for 4 years at BALESTRA to expose of induced track detector induced strains 40 kg stars in 10.4 years at the Chacaltaya Laboratory (5230 m) in search for intermediate-mass monopoles with $\beta > 0.05$. The analysis is mainly based on three CR39 modules. For $M > 5 \times 10^{13}$ GeV there can be upward-going monopoles as well, hence the flux limit is half that obtained for less massive monopoles. Previous experiments (e.g. MACRO and OHYA (ORITO 91)) had set limits only for M $> 1 \times 10^9$ GeV.

Set limits only for $M > 1 \times 10^{-5}$ GeV. 19 AMBROSIO 028 direct search final result for $m \ge 10^{17}$ GeV, based upon 4.2 to 9.5 years of running, depending upon the subsystem. Limit with CR39 track-etch detector extends the limit from $\beta = 4 \times 10^{-5}$ (3.1 $\times 10^{-16}$ cm $^{-2}$ sr $^{-1}$ s $^{-1}$) to $\beta = 1 \times 10^{-4}$ $(2.1 \times 10^{-16} \, \text{cm}^{-2} \, \text{sr}^{-1} \, \text{s}^{-1})$. Limit curve in paper is piecewise continuous due to different detection techniques for different β ranges.

- $^{\rm 20}\,\mathrm{A\,MBR\,OSIO}$ 02c limit for catalysis of nucleon decay with catalysis cross section of ≈ 1 mb. The flux limit increases by ~ 3 at the higher β limit, and increases to $1\times 10^{-14}~\rm cm^{-2}\,sr^{-1}\,s^{-1}$ if the catalysis cross section is 0.01 mb. Based upon 71193 hr of data with the streamer detector, with an acceptance of 4250 m 2 sr. 21 A MBROSIO 02D result for "more than two years of data." Ionization search using several
- 24 AMBROSIO 020 result for "more than two years of data." Ionization search using several subsystems. Limit curve as a function of β not given. Included in AMBROSIO 028. 22 AMBROSIO 97 global MACRO 90%CL is 0.78 $\times 10^{-15}$ at $\beta = 1.1 \times 10^{-4}$, goes through a minimum at 0.61×10^{-15} near $\beta = (1.1-2.7) \times 10^{-3}$, then rises to 0.84×10^{-15} at $\beta = 0.1$. The global limit in this region is below the Parker bound at 10^{-15} . Less stringent limits are established for $4 \times 10^{-5} < \beta < 1 \times 10^{-4}$. Limits set by various triggers and different subdetectors are given in the paper. All limits assume a catalysis cross section smaller than a few mb.
- triggers and different subdetectors are given in the paper. All limits assume a catalysis cross section smaller than a few mb. $^{23} \text{AHLEN 94 limit for dyons extends down to } \beta = 0.9E 4 \text{ and a limit of } 1.3E 14 \text{ extends to } \beta = 0.8E 4. \text{ Also see comment by PRICE 94 and reply of BARISH 94. One loophole in the AHLEN 94 result is that in the case of monopoles catalyzing nucleon decay, relativistic particles could veto the events. See AMBROSIO 97 for additional results.$
- 24 Catalysis of nucleon decay; sensitive to assumed catalysis cross section.
- ²⁵ ORITO 91 limits are functions of velocity. Lowest limits are given here.
- ²⁶Used DKMPR mechanism and Penning effect.
- 27 Assumes monopole attaches fermion nucleus.
- ²⁸ Limit from combining data of CAPLIN 86, BERMON 85, INCANDELA 84, and CABR-ERA 83. For a discussion of controversy about CAPLIN 86 observed event, see GUY 87. Also see SCHOUTEN 87. 29 Based on lack of high- energy solar neutrinos from catalysis in the sun. 30 Anomalous long-range α (4 He) tracks.

- $^{31}\,\text{CABRERA}$ 82 candidate event has single Dirac charge within $\pm 5\%.$
- 32 ALVAREZ 75, FLEISCHER 75, and FRIEDLANDER 75 explain as fragmenting nucleus. EBERHARD 75 and ROSS 76 discuss conflict with other experiments. HAGSTROM 77 reinterprets as antinucleus. PRICE 78 reassesses.

- ³³ Catalysis of nucleon decay.
- 34 ADAMS 93 limit based on "survival and growth of a small galactic seed field" is $10^{-16}~(m/10^{17}~{\rm GeV})~{\rm cm}^{-2}~{\rm s}^{-1}~{\rm sr}^{-1}.$ Above $10^{17}~{\rm GeV},$ limit $10^{-16}~(10^{17}~{\rm GeV}/m)$ $cm^{-2}s^{-1}sr^{-1}$ (from requirement that monopole density does not overclose the universe) is more stringent.

 35 Re-evaluates PARKER 70 limit for GUT monopoles.

Supersymmetric Particle Searches

SUPERSYMMETRY, PART I (THEORY)

Revised December 2011 by Howard E. Haber (UC Santa Cruz).

- I.1. Introduction
- I.2. Structure of the MSSM
 - I.2.1. R-parity and the lightest supersymmetric particle
 - I.2.2. The goldstino and gravitino
 - I.2.3. Hidden sectors and the structure of supersymmetrybreaking
 - I.2.4. Supersymmetry and extra dimensions
 - I.2.5. Split-supersymmetry
- I.3. Parameters of the MSSM
 - I.3.1. The supersymmetry-conserving parameters
 - I.3.2. The supersymmetry-breaking parameters
 - I.3.3. MSSM-124
- I.4. The supersymmetric-particle spectrum
 - I.4.1. The charginos and neutralinos
 - I.4.2. The squarks, sleptons and sneutrinos
- I.5. The Higgs sector of the MSSM
 - I.5.1. The tree-level MSSM Higgs sector
 - ${\rm I.5.2.}$ The radiatively-corrected MSSM Higgs sector
- I.6. Restricting the MSSM parameter freedom
 - I.6.1. Gaugino mass unification
 - I.6.2. The constrained MSSM: mSUGRA, CMSSM, ...
 - I.6.3. Gauge-mediated supersymmetry-breaking
 - I.6.4. The phenomenological MSSM
- I.7. Experimental data confronts the MSSM
 - I.7.1. Naturalness constraints and the little hierarchy
 - I.7.2. Constraints from virtual exchange of supersymmetric particles

- I.8. Massive neutrinos in low-energy supersymmetry
 - I.8.1. The supersymmetric seesaw
 - I.8.2. R-parity-violating supersymmetry
- I.9. Extensions beyond the MSSM
- I.1. Introduction: Supersymmetry (SUSY) is a generalization of the space-time symmetries of quantum field theory that transforms fermions into bosons and vice versa. The existence of such a non-trivial extension of the Poincaré symmetry of ordinary quantum field theory was initially surprising, and its form is highly constrained by theoretical principles [1]. persymmetry also provides a framework for the unification of particle physics and gravity [2-5], which is governed by the Planck energy scale, $M_P \approx 10^{19}$ GeV (where the gravitational interactions become comparable in magnitude to the gauge interactions). In particular, it is possible that supersymmetry will ultimately explain the origin of the large hierarchy of energy scales from the W and Z masses to the Planck scale [6–10]. This is the so-called *gauge hierarchy*. The stability of the gauge hierarchy in the presence of radiative quantum corrections is not possible to maintain in the Standard Model, but can be maintained in supersymmetric theories.

If supersymmetry were an exact symmetry of nature, then particles and their superpartners (which differ in spin by half a unit) would be degenerate in mass. Since superpartners have not (yet) been observed, supersymmetry must be a broken symmetry. Nevertheless, the stability of the gauge hierarchy can still be maintained if the supersymmetry breaking is soft [11,12], and the corresponding supersymmetry-breaking mass parameters are no larger than a few TeV. In particular, soft-supersymmetry-breaking terms of the Lagrangian are either linear, quadratic, or cubic in the fields, with some restrictions elucidated in Ref. 11. The impact of such terms becomes negligible at energy scales much larger than the size of the supersymmetry-breaking masses. The most interesting theories of this type are theories of "low-energy" (or "weak-scale") supersymmetry, where the effective scale of supersymmetry breaking is tied to the scale of electroweak symmetry break-The latter is characterized by the Standard Model Higgs vacuum expectation value, $v \simeq 246$ GeV.

Although there are no unambiguous experimental results (at present) that require the existence of new physics at the TeV-scale, expectations of the latter are primarily based on three theoretical arguments. First, a natural explanation (i.e., one that is stable with respect to quantum corrections) of the gauge hierarchy demands new physics at the TeV-scale [10]. Second, the unification of the three Standard Model gauge couplings at a very high energy close to the Planck scale is possible if new physics beyond the Standard Model (which modifies the running of the gauge couplings above the electroweak scale) is present. The minimal supersymmetric extension of the Standard Model, where supersymmetric masses lie below a few TeV, provides simple example of successful gauge coupling unification [13]. Third, the existence of dark matter, which

makes up approximately one quarter of the energy density of the universe, cannot be explained within the Standard Model of particle physics [14]. Remarkably, a stable weakly-interacting massive particle (WIMP) whose mass and interaction rate are governed by new physics associated with the TeV-scale can be consistent with the observed density of dark matter (this is the so-called WIMP miracle, which is reviewed in Ref. 15). The lightest supersymmetric particle is a promising (although not the unique) candidate for the dark matter [16,17]. Further aspects of dark matter can be found in Ref. 18.

I.2. Structure of the MSSM: The minimal supersymmetric extension of the Standard Model (MSSM) consists of taking the fields of the two-Higgs-doublet extension of the Standard Model and adding the corresponding supersymmetric partners [19,20]. The corresponding field content of the MSSM and their gauge quantum numbers are shown in Table 1. The electric charge $Q = T_3 + \frac{1}{2}Y$ is determined in terms of the third component of the weak isospin (T_3) and the U(1) hypercharge (Y).

Table 1: The fields of the MSSM and their $SU(3)\times SU(2)\times U(1)$ quantum numbers are listed. Only one generation of quarks and leptons is exhibited. For each lepton, quark, and Higgs super-multiplet, there is a corresponding anti-particle multiplet of charge-conjugated fermions and their associated scalar partners.

| Field Content of the MSSM | | | | | | | |
|---------------------------|----------------------------------------|---------------------------------------------|-------|-------|------|--|--|
| Super- | Boson | Fermionic | | | | | |
| Multiplets | Fields | Partners | SU(3) | SU(2) | U(1) | | |
| gluon/gluino | g | \widetilde{g} | 8 | 1 | 0 | | |
| gauge/ | W^{\pm} , W^0 | \widetilde{W}^{\pm} , \widetilde{W}^{0} | 1 | 3 | 0 | | |
| gaugino | B | \widetilde{B} | 1 | 1 | 0 | | |
| slepton/ | $(\widetilde{\nu}, \widetilde{e}^-)_L$ | $(\nu, e^-)_L$ | 1 | 2 | -1 | | |
| lepton | \tilde{e}_R^- | e_R^- | 1 | 1 | -2 | | |
| squark/ | $(\widetilde{u}_L,\widetilde{d}_L)$ | $(u,d)_L$ | 3 | 2 | 1/3 | | |
| quark | \widetilde{u}_R | u_R | 3 | 1 | 4/3 | | |
| | \widetilde{d}_R | d_R | 3 | 1 | -2/3 | | |
| Higgs/ | (H_d^0,H_d^-) | $(\widetilde{H}_d^0,\widetilde{H}_d^-)$ | 1 | 2 | -1 | | |
| higgsino | (H_u^+,H_u^0) | $(\widetilde{H}_u^+,\widetilde{H}_u^0)$ | 1 | 2 | 1 | | |

The gauge super-multiplets consist of the gluons and their gluino fermionic superpartners, and the $SU(2)\times U(1)$ gauge bosons and their gaugino fermionic superpartners. The Higgs multiplets consist of two complex doublets of Higgs fields, their higgsino fermionic superpartners, and the corresponding antiparticle fields. The matter super-multiplets consist of three generations of left-handed and right-handed quarks and lepton fields, their scalar superpartners (squark and slepton fields), and the corresponding antiparticle fields. The enlarged Higgs sector of the MSSM constitutes the minimal structure needed to guarantee the cancellation of anomalies from the introduction of the higgsino superpartners. Moreover, without a second Higgs doublet, one cannot generate mass for both "up"-type and

"down"-type quarks (and charged leptons) in a way consistent with the supersymmetry [21–23].

A general supersymmetric Lagrangian is determined by three functions of the superfields (composed of the fields of the super-multiplets): the superpotential, the Kähler potential, and the gauge kinetic-energy function [5]. malizable globally supersymmetric theories, minimal forms for the latter two functions are required in order to generate canonical kinetic energy terms for all the fields. A renormalizable superpotential, which is at most cubic in the superfields, yields supersymmetric Yukawa couplings and mass terms. A combination of gauge invariance and supersymmetry produces couplings of gaugino fields to matter (or Higgs) fields and their corresponding superpartners. The (renormalizable) MSSM Lagrangian is then constructed by including all possible supersymmetric interaction terms (of dimension four or less) that satisfy $SU(3)\times SU(2)\times U(1)$ gauge invariance and B-L conservation (where B = baryon number and L = lepton number). Finally, the most general soft-supersymmetry-breaking terms are added [11,12,24]. To generate nonzero neutrino masses, extra structure is needed as discussed in Section I.8.

I.2.1. R-parity and the lightest supersymmetric particle: As a consequence of B-L invariance, the MSSM possesses a multiplicative R-parity invariance, where $R = (-1)^{3(B-L)+2S}$ for a particle of spin S [25]. Note that this implies that all the ordinary Standard Model particles have even R parity, whereas the corresponding supersymmetric partners have odd R parity. The conservation of R parity in scattering and decay processes has a crucial impact on supersymmetric phenomenology. For example, starting from an initial state involving ordinary (Reven) particles, it follows that supersymmetric particles must be produced in pairs. In general, these particles are highly unstable and decay into lighter states. However, R-parity invariance also implies that the lightest supersymmetric particle (LSP) is absolutely stable, and must eventually be produced at the end of a decay chain initiated by the decay of a heavy unstable supersymmetric particle.

In order to be consistent with cosmological constraints, a stable LSP is almost certainly electrically and color neutral [26]. (There are some model circumstances in which a colored gluino LSP is allowed [27], but we do not consider this possibility further here.) Consequently, the LSP in an R-parity-conserving theory is weakly interacting with ordinary matter, *i.e.*, it behaves like a stable heavy neutrino and will escape collider detectors without being directly observed. Thus, the canonical signature for conventional R-parity-conserving supersymmetric theories is missing (transverse) energy, due to the escape of the LSP. Moreover, as noted at the end of Section I, the LSP is a promising candidate for dark matter [16,17].

I.2.2. The goldstino and gravitino: In the MSSM, supersymmetry breaking is accomplished by including the most general renormalizable soft-supersymmetry-breaking terms consistent with the $SU(3)\times SU(2)\times U(1)$ gauge symmetry and R-parity invariance. These terms parameterize our ignorance of

the fundamental mechanism of supersymmetry breaking. If supersymmetry breaking occurs spontaneously, then a massless Goldstone fermion called the goldstino ($\widetilde{G}_{1/2}$) must exist. The goldstino would then be the LSP, and could play an important role in supersymmetric phenomenology [28].

However, the goldstino degrees of freedom are physical only in models of spontaneously-broken global supersymmetry. If supersymmetry is a local symmetry, then the theory must incorporate gravity; the resulting theory is called supergrav-In models of spontaneously-broken supergravity, the goldstino is "absorbed" by the gravitino (G) [sometimes called $\widetilde{g}_{3/2}$ in the older literature], the spin-3/2 superpartner of the graviton [30]. By this super-Higgs mechanism, the goldstino is removed from the physical spectrum and the gravitino acquires a mass $(m_{3/2})$. In processes with center-of-mass energy $E \gg m_{3/2}$, the goldstino-gravitino equivalence theorem [31] states that the interactions of the helicity $\pm \frac{1}{2}$ gravitino (whose properties approximate those of the goldstino) dominate those of the helicity $\pm \frac{3}{2}$ gravitino. The interactions of gravitinos with with other light fields can be described by a low-energy effective Lagrangian that is determined by fundamental principles (see, e.g., Ref. 32).

I.2.3. Hidden sectors and the structure of supersymmetry breaking [24]: It is very difficult (perhaps impossible) to construct a realistic model of spontaneously-broken low-energy supersymmetry where the supersymmetry breaking arises solely as a consequence of the interactions of the particles of the MSSM. An alternative scheme posits a theory consisting of at least two distinct sectors: a hidden sector consisting of particles that are completely neutral with respect to the Standard Model gauge group, and a visible sector consisting of the particles of the MSSM. There are no renormalizable tree-level interactions between particles of the visible and hidden sectors. Supersymmetry breaking is assumed to originate in the hidden sector, and its effects are transmitted to the MSSM by some mechanism (often involving the mediation by particles that comprise an additional messenger sector). Two theoretical scenarios have been examined in detail: gravity-mediated and gauge-mediated supersymmetry breaking.

Supergravity models provide a natural mechanism for transmitting the supersymmetry breaking of the hidden sector to the particle spectrum of the MSSM. In models of gravity-mediated supersymmetry breaking, gravity is the messenger of supersymmetry breaking [33–35]. More precisely, supersymmetry breaking is mediated by effects of gravitational strength (suppressed by inverse powers of the Planck mass). In this scenario, the gravitino mass is of order the electroweak-symmetry-breaking scale, while its couplings are roughly gravitational in strength [2,36]. Such a gravitino typically plays no role in supersymmetric phenomenology at colliders (except perhaps indirectly in the case where the gravitino is the LSP [37]).

In gauge-mediated supersymmetry breaking, gauge forces transmit the supersymmetry breaking to the MSSM. A typical structure of such models involves a hidden sector where supersymmetry is broken, a messenger sector consisting of particles (messengers) with $SU(3)\times SU(2)\times U(1)$ quantum numbers, and the visible sector consisting of the fields of the MSSM [38–40]. The direct coupling of the messengers to the hidden sector generates a supersymmetry-breaking spectrum in the messenger sector. Finally, supersymmetry breaking is transmitted to the MSSM via the virtual exchange of the messengers. In models of direct gauge mediation, the supersymmetry-breaking sector includes fields that carry Standard Model quantum numbers, in which case no separate messenger sector is required [41].

The gravitino mass in models of gauge-mediated supersymmetry breaking is typically in the eV range (although in some cases it can be as large as a GeV), which implies that \widetilde{G} is the LSP. In particular, the gravitino is a potential dark matter candidate (for a recent review and guide to the literature, see Ref. 17). The couplings of the helicity $\pm \frac{1}{2}$ components of \widetilde{G} to the particles of the MSSM (which approximate those of the goldstino, cf. Section I.2.3) are significantly stronger than gravitational strength and amenable to experimental collider analyses.

The concept of a hidden sector is more general than supersymmetry. *Hidden valley* models [42] posit the existence of a hidden sector of new particles and interactions that are very weakly coupled to particles of the Standard Model. The impact of a hidden valley on supersymmetric phenomenology at colliders can be significant if the LSP lies in the valley sector [43].

I.2.4. Supersymmetry and extra dimensions:

Approaches to supersymmetry breaking have also been developed in the context of theories in which the number of space dimensions is greater than three. In particular, a number of supersymmetry-breaking mechanisms have been proposed that are inherently extra-dimensional [44]. The size of the extra dimensions can be significantly larger than $M_{\rm P}^{-1}$; in some cases on the order of (TeV)⁻¹ or even larger [45,46].

For example, in one approach, the fields of the MSSM live on some brane (a lower-dimensional manifold embedded in a higher-dimensional spacetime), while the sector of the theory that breaks supersymmetry lives on a second-separated brane. Two examples of this approach are anomaly-mediated supersymmetry breaking of Ref. 47, and gaugino-mediated supersymmetry breaking of Ref. 48; in both cases supersymmetry breaking is transmitted through fields that live in the bulk (the higher-dimensional space between the two branes). This setup has some features in common with both gravity-mediated and gauge-mediated supersymmetry breaking (e.g., a hidden and visible sector and messengers).

Alternatively, one can consider a higher-dimensional theory that is compactified to four spacetime dimensions. In this approach, supersymmetry is broken by boundary conditions on the compactified space that distinguish between fermions and bosons. This is the so-called Scherk-Schwarz mechanism [49]. The phenomenology of such models can be strikingly different

from that of the usual MSSM [50]. All these extra-dimensional ideas clearly deserve further investigation, although they will not be discussed further here.

I.2.5. Split-supersymmetry: If supersymmetry is not connected with the origin of the electroweak scale, string theory suggests that supersymmetry still plays a significant role in Planck-scale physics. However, it may still be possible that some remnant of the superparticle spectrum survives down to the TeV-scale or below. This is the idea of split-supersymmetry [51], in which supersymmetric scalar partners of the quarks and leptons are significantly heavier (perhaps by many orders of magnitude) than 1 TeV, whereas the fermionic partners of the gauge and Higgs bosons have masses on the order of 1 TeV or below (presumably protected by some chiral symmetry). With the exception of a single light neutral scalar whose properties are indistinguishable from those of the Standard Model Higgs boson, all other Higgs bosons are also taken to be very heavy.

The supersymmetry breaking required to produce such a scenario would destabilize the gauge hierarchy. In particular, split-supersymmetry cannot provide a natural explanation for the existence of the light Standard-Model-like Higgs boson, whose mass lies orders below the mass scale of the heavy scalars. Nevertheless, models of split-supersymmetry can account for the dark matter (which is assumed to be the LSP) and gauge coupling unification. Thus, there is some motivation for pursuing the phenomenology of such approaches [52]. One notable difference from the usual MSSM phenomenology is the existence of a long-lived gluino [53].

I.3. Parameters of the MSSM: The parameters of the MSSM are conveniently described by considering separately the supersymmetry-conserving sector and the supersymmetry-breaking sector. A careful discussion of the conventions used in defining the tree-level MSSM parameters can be found in Ref. 54. For simplicity, consider first the case of one generation of quarks, leptons, and their scalar superpartners.

I.3.1. The supersymmetric-conserving parameters:

The parameters of the supersymmetry-conserving sector consist of: (i) gauge couplings: g_s , g, and g', corresponding to the Standard Model gauge group $SU(3)\times SU(2)\times U(1)$ respectively; (ii) a supersymmetry-conserving higgsino mass parameter μ ; and (iii) Higgs-fermion Yukawa coupling constants: λ_u , λ_d , and λ_e (corresponding to the coupling of one generation of left-and right-handed quarks and leptons, and their superpartners to the Higgs bosons and higgsinos). Because there is no right-handed neutrino (and its superpartner) in the MSSM as defined here, one cannot introduce a Yukawa coupling λ_{ν} .

I.3.2. The supersymmetric-breaking parameters:

The supersymmetry-breaking sector contains the following set of parameters: (i) gaugino Majorana masses M_3 , M_2 , and M_1 associated with the SU(3), SU(2), and U(1) subgroups of the Standard Model; (ii) five scalar squared-mass parameters for the squarks and sleptons, $M_{\widetilde{O}}^2$, $M_{\widetilde{U}}^2$, $M_{\widetilde{D}}^2$, $M_{\widetilde{L}}^2$, and $M_{\widetilde{E}}^2$

[corresponding to the five electroweak gauge multiplets, i.e., superpartners of $(u,d)_L$, u_L^c , d_L^c , $(\nu, e^-)_L$, and e_L^c , where the superscript c indicates a charge-conjugated fermion and flavor indices are suppressed]; and (iii) Higgs-squark-squark and Higgs-slepton-slepton trilinear interaction terms, with coefficients $\lambda_u A_U$, $\lambda_d A_D$, and $\lambda_e A_E$ (which define the so-called "A-parameters"). It is traditional to factor out the Yukawa couplings in the definition of the A-parameters (originally motivated by a simple class of gravity-mediated supersymmetrybreaking models [2,4]). If the A-parameters defined in this way are parametrically of the same order (or smaller) as compared to other supersymmetry-breaking mass parameters, then only the A-parameters of the third generation will be phenomenologically relevant. Finally, we add: (iv) three scalar squared-mass parameters—two of which $(m_1^2 \text{ and } m_2^2)$ contribute to the diagonal Higgs squared-masses, given by $m_1^2 + |\mu|^2$ and $m_2^2 + |\mu|^2$, and a third which contributes to the off-diagonal Higgs squared-mass term, $m_{12}^2 \equiv B\mu$ (which defines the "B-parameter").

The breaking of the electroweak symmetry $SU(2)\times U(1)$ to $U(1)_{EM}$ is only possible after introducing the supersymmetry-breaking Higgs squared-mass parameters. Minimizing the resulting tree-level Higgs scalar potential, these three squared-mass parameters can be re-expressed in terms of the two Higgs vacuum expectation values, v_d and v_u (also called v_1 and v_2 , respectively, in the literature), and the CP-odd Higgs mass A^0 (cf. Section I.5). Here, v_d [v_u] is the vacuum expectation value of the neutral component of the Higgs field H_d [H_u] that couples exclusively to down-type (up-type) quarks and leptons. Note that $v_d^2 + v_u^2 = 4m_W^2/g^2 \simeq (246 \text{ GeV})^2$ is fixed by the W mass and the gauge coupling, whereas the ratio

$$\tan \beta = v_u/v_d \tag{1}$$

is a free parameter of the model. By convention, the phases of the Higgs field are chosen such that $0 \le \beta \le \pi/2$. Equivalently, the tree-level conditions for the scalar potential minimum relate the diagonal and off-diagonal Higgs squared-masses in terms of $m_Z^2 = \frac{1}{4}(g^2 + g'^2)(v_d^2 + v_u^2)$, the angle β and the CP-odd Higgs mass m_A :

$$\sin 2\beta = \frac{2m_{12}^2}{m_1^2 + m_2^2 + 2|\mu|^2} = \frac{2m_{12}^2}{m_A^2},\tag{2}$$

$$\frac{1}{2}m_Z^2 = -|\mu|^2 + \frac{m_1^2 - m_2^2 \tan^2 \beta}{\tan^2 \beta - 1}.$$
 (3)

Note that supersymmetry-breaking mass terms for the fermionic superpartners of scalar fields and non-holomorphic trilinear scalar interactions (*i.e.*, interactions that mix scalar fields and their complex conjugates) have not been included above in the soft-supersymmetry-breaking sector. These terms can potentially destabilize the gauge hierarchy [11] in models with a gauge-singlet superfield. The latter is not present in the MSSM; hence as noted in Ref. 12, these so-called non-standard soft-supersymmetry-breaking terms are benign. However, the coefficients of these terms (which have dimensions of mass)

are expected to be significantly suppressed compared to the TeV-scale in a fundamental theory of supersymmetry-breaking. Consequently, we follow the usual approach and omit these terms from further consideration.

I.3.3. MSSM-124: The total number of independent physical parameters that define the MSSM (in its most general form) is quite large, primarily due to the soft-supersymmetry-breaking sector. In particular, in the case of three generations of quarks, leptons, and their superpartners, $M_{\widetilde{Q}}^2$, $M_{\widetilde{U}}^2$, $M_{\widetilde{D}}^2$, $M_{\widetilde{D}}^2$, $M_{\widetilde{L}}^2$, and $M_{\widetilde{E}}^2$ are hermitian 3×3 matrices, and A_U , A_D , and A_E are complex 3×3 matrices. In addition, M_1 , M_2 , M_3 , M_4 , M_5 , and M_6 are, in general, complex. Finally, as in the Standard Model, the Higgs-fermion Yukawa couplings, λ_f (f=u, d, and e), are complex 3×3 matrices that are related to the quark and lepton mass matrices via: $M_f = \lambda_f v_f/\sqrt{2}$, where $v_e \equiv v_d$ [with v_u and v_d as defined above Eq. (1)].

However, not all these parameters are physical. Some of the MSSM parameters can be eliminated by expressing interaction eigenstates in terms of the mass eigenstates, with an appropriate redefinition of the MSSM fields to remove unphysical degrees of freedom. The analysis of Ref. 55 shows that the MSSM possesses 124 independent parameters. Of these, 18 parameters correspond to Standard Model parameters (including the QCD vacuum angle $\theta_{\rm QCD}$), one corresponds to a Higgs sector parameter (the analogue of the Standard Model Higgs mass), and 105 are genuinely new parameters of the model. The latter include: five real parameters and three CPviolating phases in the gaugino/higgsino sector, 21 squark and slepton masses, 36 real mixing angles to define the squark and slepton mass eigenstates, and 40 CP-violating phases that can appear in squark and slepton interactions. The most general R-parity-conserving minimal supersymmetric extension of the Standard Model (without additional theoretical assumptions) will be denoted henceforth as MSSM-124 [56].

I.4. The supersymmetric-particle spectrum: The supersymmetric particles (sparticles) differ in spin by half a unit from their Standard Model partners. The supersymmetric partners of the gauge and Higgs bosons are fermions, whose names are obtained by appending "ino" at the end of the corresponding Standard Model particle name. The gluino is the color-octet Majorana fermion partner of the gluon with mass $M_{\tilde{q}} = |M_3|$. The supersymmetric partners of the electroweak gauge and Higgs bosons (the gauginos and higgsinos) can mix. As a result, the physical states of definite mass are model-dependent linear combinations of the charged and neutral gauginos and higgsinos, called charginos and neutralinos, respectively. Like the gluino, the neutralinos are also Majorana fermions, which provide for some distinctive phenomenological signatures [57,58]. The supersymmetric partners of the quarks and leptons are spin-zero bosons: the squarks, charged sleptons, and sneutrinos, respectively. A complete set of Feynman rules for the sparticles of the MSSM can be found in Ref. 59. The MSSM Feynman rules also are implicitly contained in a number of Feynman diagram and amplitude generation software packages (see e.g., Refs. 60–62).

I.4.1. The charginos and neutralinos: The mixing of the charged gauginos (\widetilde{W}^{\pm}) and charged higgsinos (H_u^+) and H_d^- is described (at tree-level) by a 2×2 complex mass matrix [63–65]:

$$M_C \equiv \begin{pmatrix} M_2 & \frac{1}{\sqrt{2}}gv_u \\ \frac{1}{\sqrt{2}}gv_d & \mu \end{pmatrix} . \tag{4}$$

To determine the physical chargino states and their masses, one must perform a singular value decomposition [66,67] of the complex matrix M_C :

$$U^* M_C V^{-1} = \text{diag}(M_{\widetilde{\chi}_1^+}, M_{\widetilde{\chi}_2^+}),$$
 (5)

where U and V are unitary matrices, and the right-hand side of Eq. (5) is the diagonal matrix of (non-negative) chargino masses. The physical chargino states are denoted by $\tilde{\chi}_1^{\pm}$ and $\tilde{\chi}_2^{\pm}$. These are linear combinations of the charged gaugino and higgsino states determined by the matrix elements of U and V [63–65]. The chargino masses correspond to the singular values [66] of M_C , i.e., the positive square roots of the eigenvalues of $M_C^{\dagger}M_C$:

$$M_{\widetilde{\chi}_{1}^{+},\widetilde{\chi}_{2}^{+}}^{2} = \frac{1}{2} \left\{ |\mu|^{2} + |M_{2}|^{2} + 2m_{W}^{2} \mp \left[(|\mu|^{2} + |M_{2}|^{2} + 2m_{W}^{2})^{2} \right] \right\}$$

$$-4|\mu|^2|M_2|^2 - 4m_W^4 \sin^2 2\beta + 8m_W^2 \sin 2\beta \operatorname{Re}(\mu M_2) \bigg]^{1/2} \bigg\}, (6)$$

where the states are ordered such that $M_{\widetilde{\chi}_1^+} \leq M_{\widetilde{\chi}_2^+}$.

It is convenient to choose a convention where $\tan \beta$ and M_2 are real and positive. Note that the relative phase of M_2 and μ is meaningful. (If CP-violating effects are neglected, then μ can be chosen real but may be either positive or negative.) The sign of μ is convention-dependent; the reader is warned that both sign conventions appear in the literature. The sign convention for μ in Eq. (4) is used by the LEP collaborations [68] in their plots of exclusion contours in the M_2 vs. μ plane derived from the non-observation of $e^+e^- \to \widetilde{\chi}_1^+\widetilde{\chi}_1^-$.

The mixing of the neutral gauginos $(\widetilde{B} \text{ and } \widetilde{W}^0)$ and neutral higgsinos $(\widetilde{H}_d^0 \text{ and } \widetilde{H}_u^0)$ is described (at tree-level) by a 4×4 complex symmetric mass matrix [63,64,69,70]:

$$M_{N} \equiv \begin{pmatrix} M_{1} & 0 & -\frac{1}{2}g'v_{d} & \frac{1}{2}g'v_{u} \\ 0 & M_{2} & \frac{1}{2}gv_{d} & -\frac{1}{2}gv_{u} \\ -\frac{1}{2}g'v_{d} & \frac{1}{2}gv_{d} & 0 & -\mu \\ \frac{1}{2}g'v_{u} & -\frac{1}{2}gv_{u} & -\mu & 0 \end{pmatrix} . \quad (7)$$

To determine the physical neutralino states and their masses, one must perform a Takagi-diagonalization [66,67,71,72] of the complex symmetric matrix M_N :

$$W^T M_N W = \operatorname{diag}(M_{\widetilde{\chi}_1^0}, M_{\widetilde{\chi}_2^0}, M_{\widetilde{\chi}_3^0}, M_{\widetilde{\chi}_4^0}), \tag{8}$$

where W is a unitary matrix and the right-hand side of Eq. (8) is the diagonal matrix of (non-negative) neutralino masses. The physical neutralino states are denoted by $\tilde{\chi}_{i}^{0}$ (i = 1, ...4), where

the states are ordered such that $M_{\widetilde{\chi}_1^0} \leq M_{\widetilde{\chi}_2^0} \leq M_{\widetilde{\chi}_3^0} \leq M_{\widetilde{\chi}_4^0}$. The $\widetilde{\chi}_i^0$ are the linear combinations of the neutral gaugino and higgsino states determined by the matrix elements of W (in Ref. 63, $W=N^{-1}$). The neutralino masses correspond to the singular values of M_N (i.e., the positive square roots of the eigenvalues of $M_N^{\dagger}M_N$). Exact formulae for these masses can be found in Refs. [69] and [73]. A numerical algorithm for determining the mixing matrix W has been given by Ref. 74.

If a chargino or neutralino state approximates a particular gaugino or higgsino state, it is convenient to employ the corresponding nomenclature. Specifically, if M_1 and M_2 are small compared to m_Z and $|\mu|$, then the lightest neutralino $\tilde{\chi}_1^0$ would be nearly a pure photino, $\tilde{\gamma}$, the supersymmetric partner of the photon. If M_1 and m_Z are small compared to M_2 and $|\mu|$, then the lightest neutralino would be nearly a pure bino, \overline{B} , the supersymmetric partner of the weak hypercharge gauge boson. If M_2 and m_Z are small compared to M_1 and $|\mu|$, then the lightest chargino pair and neutralino would constitute a triplet of roughly mass-degenerate pure winos, \widetilde{W}^{\pm} , and \widetilde{W}_{3}^{0} , the supersymmetric partners of the weak SU(2) gauge bosons. Finally, if $|\mu|$ and m_Z are small compared to M_1 and M_2 , then the lightest neutralino would be nearly a pure higgsino. Each of the above cases leads to a strikingly different phenomenology. I.4.2. The squarks, sleptons and sneutrinos: For a given fermion f, there are two supersymmetric partners, f_L and f_R , which are scalar partners of the corresponding leftand right-handed fermion. (There is no $\tilde{\nu}_R$ in the MSSM.) However, in general, f_L and f_R are not mass eigenstates, since there is \widetilde{f}_L - \widetilde{f}_R mixing. For three generations of squarks, one must in general diagonalize 6×6 matrices corresponding to the basis $(\tilde{q}_{iL}, \tilde{q}_{iR})$, where i = 1, 2, 3 are the generation labels. For simplicity, only the one-generation case is illustrated in detail below. (The effects of second and third generation squark mixing can be significant and is treated in Ref. 75.)

Using the notation of the third family, the one-generation tree-level squark squared-mass matrix is given by [76]

$$M_F^2 = \begin{pmatrix} M_{\widetilde{Q}}^2 + m_q^2 + L_q & m_q X_q^* \\ m_q X_q & M_{\widetilde{R}}^2 + m_q^2 + R_q \end{pmatrix}, \qquad (9)$$

where

$$X_q \equiv A_q - \mu^*(\cot \beta)^{2T_{3q}}, \qquad (10)$$

and $T_{3q} = \frac{1}{2} [-\frac{1}{2}]$ for q = t [b]. The diagonal squared masses are governed by soft-supersymmetry-breaking squared masses $M_{\widetilde{Q}}^2$ and $M_{\widetilde{R}}^2 \equiv M_{\widetilde{U}}^2 [M_{\widetilde{D}}^2]$ for q = t [b], the corresponding quark masses m_t [m_b], and electroweak correction terms:

$$L_q \equiv (T_{3q} - e_q \sin^2 \theta_W) m_Z^2 \cos 2\beta , \quad R_q \equiv e_q \sin^2 \theta_W m_Z^2 \cos 2\beta ,$$

$$\tag{11}$$

where $e_q = \frac{2}{3}$ $[-\frac{1}{3}]$ for q = t [b]. The off-diagonal squared squark masses are proportional to the corresponding quark masses and depend on $\tan \beta$ [Eq. (1)], the soft-supersymmetry-breaking A-parameters and the higgsino mass parameter μ . The signs of the A and μ parameters are convention-dependent;

other choices appear frequently in the literature. Due to the appearance of the *quark* mass in the off-diagonal element of the squark squared-mass matrix, one expects the \tilde{q}_L – \tilde{q}_R mixing to be small, with the possible exception of the third generation, where mixing can be enhanced by factors of m_t and $m_b \tan \beta$.

In the case of third generation $\tilde{q}_L - \tilde{q}_R$ mixing, the mass eigenstates (usually denoted by \tilde{q}_1 and \tilde{q}_2 , with $m_{\tilde{q}_1} < m_{\tilde{q}_2}$) are determined by diagonalizing the 2×2 matrix M_F^2 given by Eq. (9). The corresponding squared masses and mixing angle are given by [76]:

$$\begin{split} m_{\tilde{q}_{1,2}}^2 &= \frac{1}{2} \left[\text{Tr} \, M_F^2 \mp \sqrt{(\text{Tr} M_F^2)^2 - 4 \det M_F^2} \right] \,, \\ \sin 2\theta_{\tilde{q}} &= \frac{2m_q |X_q|}{m_{\tilde{q}_2}^2 - m_{\tilde{q}_1}^2} \,. \end{split} \tag{12}$$

The one-generation results above also apply to the charged sleptons, with the obvious substitutions: $q \to \tau$ with $T_{3\tau} = -\frac{1}{2}$ and $e_{\tau} = -1$, and the replacement of the supersymmetry-breaking parameters: $M_{\widetilde{Q}}^2 \to M_{\widetilde{L}}^2$, $M_{\widetilde{D}}^2 \to M_{\widetilde{E}}^2$, and $A_q \to A_{\tau}$. For the neutral sleptons, $\widetilde{\nu}_R$ does not exist in the MSSM, so $\widetilde{\nu}_L$ is a mass eigenstate.

In the case of three generations, the supersymmetry-breaking scalar-squared masses $[M_{\widetilde{Q}}^2, M_{\widetilde{U}}^2, M_{\widetilde{D}}^2, M_{\widetilde{L}}^2]$, and $M_{\widetilde{E}}^2$ and the A-parameters that parameterize the Higgs couplings to up- and down-type squarks and charged sleptons (henceforth denoted by A_U , A_D , and A_E , respectively) are now 3×3 matrices as noted in Section I.3. The diagonalization of the 6×6 squark mass matrices yields $\tilde{f}_{iL} - \tilde{f}_{jR}$ mixing (for $i \neq j$). In practice, since the $\tilde{f}_L - \tilde{f}_R$ mixing is appreciable only for the third generation, this additional complication can often be neglected (although see Ref. 75 for examples in which the mixing between the second and third generations is relevant).

Radiative loop corrections will modify all tree-level results for masses quoted in this section. These corrections must be included in any precision study of supersymmetric phenomenol-Beyond tree level, the definition of the supersymmetric parameters becomes convention-dependent. For example, one can define physical couplings or running couplings, which differ beyond the tree level. This provides a challenge to any effort that attempts to extract supersymmetric parameters from data. The Supersymmetry Les Houches Accord (SLHA) [78] has been adopted, which establishes a set of conventions for specifying generic file structures for supersymmetric model specifications and input parameters, supersymmetric mass and coupling spectra, and decay tables. These provide a universal interface between spectrum calculation programs, decay packages, and high energy physics event generators. Ultimately, these efforts will facilitate the reconstruction of the fundamental supersymmetric theory (and its breaking mechanism) from high-precision studies of supersymmetric phenomena at future colliders.

I.5. The Higgs sector of the MSSM: Next, consider the MSSM Higgs sector [22,23,79]. Despite the large number

of potential CP-violating phases among the MSSM-124 parameters, the tree-level MSSM Higgs sector is automatically CP-conserving. That is, unphysical phases can be absorbed into the definition of the Higgs fields such that $\tan \beta$ is a real parameter (conventionally chosen to be positive). Consequently, the physical neutral Higgs scalars are CP eigenstates. The MSSM Higgs sector contains five physical spin-zero particles: a charged Higgs boson pair (H^{\pm}) , two CP-even neutral Higgs bosons (denoted by h^0 and H^0 where $m_h < m_H$), and one CP-odd neutral Higgs boson (A^0) .

I.5.1 The Tree-level MSSM Higgs sector: The properties of the Higgs sector are determined by the Higgs potential, which is made up of quadratic terms [whose squared-mass coefficients were specified above Eq. (1)] and quartic interaction terms governed by dimensionless couplings. The quartic interaction terms are manifestly supersymmetric at tree level (although these are modified by supersymmetry-breaking effects at the loop level). In general, the quartic couplings arise from two sources: (i) the supersymmetric generalization of the scalar potential (the so-called "F-terms"), and (ii) interaction terms related by supersymmetry to the coupling of the scalar fields and the gauge fields, whose coefficients are proportional to the corresponding gauge couplings (the so-called "D-terms").

In the MSSM, F-term contributions to the quartic couplings are absent (although such terms may be present in extensions of the MSSM, e.g., models with Higgs singlets). As a result, the strengths of the MSSM quartic Higgs interactions are fixed in terms of the gauge couplings. Due to the resulting constraint on the form of the two-Higgs-doublet scalar potential, all the tree-level MSSM Higgs-sector parameters depend only on two quantities: $\tan \beta$ [defined in Eq. (1)] and one Higgs mass usually taken to be m_A . From these two quantities, one can predict the values of the remaining Higgs boson masses, an angle α (which measures the component of the original $Y = \pm 1$ Higgs doublet states in the physical CP-even neutral scalars), and the Higgs boson self-couplings.

I.5.2 The radiatively-corrected MSSM Higgs sector: When radiative corrections are incorporated, additional parameters of the supersymmetric model enter via virtual loops. The impact of these corrections can be significant [80]. example, the tree-level MSSM-124 prediction for the upper bound of the lightest CP-even Higgs mass, $m_h \leq m_Z |\cos 2\beta| \leq$ m_Z [22,23], can be substantially modified when radiative corrections are included. The qualitative behavior of these radiative corrections can be most easily seen in the large topsquark mass limit, where in addition, both the splitting of the two diagonal entries and the two off-diagonal entries of the top-squark squared-mass matrix [Eq. (9)] are small in comparison to the average of the two top-squark squared masses, $M_{\rm S}^2 \equiv \frac{1}{2}(M_{\widetilde{t}_1}^2 + M_{\widetilde{t}_2}^2)$. In this case (assuming $m_A > m_Z$), the predicted upper bound for m_h (which reaches its maximum at large $\tan \beta$) is approximately given by

$$m_h^2 \lesssim m_Z^2 + \frac{3g^2 m_t^4}{8\pi^2 m_W^2} \left[\ln \left(M_{\rm S}^2/m_t^2 \right) + \frac{X_t^2}{M_{\rm S}^2} \left(1 - \frac{X_t^2}{12 M_{\rm S}^2} \right) \right], \ (13)$$

where $X_t \equiv A_t - \mu \cot \beta$ is the top-squark mixing factor [see Eq. (9)].

A more complete treatment of the radiative corrections [81] shows that Eq. (13) somewhat overestimates the true upper bound of m_h . These more refined computations, which incorporate renormalization group improvement and the leading two-loop contributions, yield $m_h \lesssim 135$ GeV (with an accuracy of a few GeV) for $m_t = 175$ GeV and $M_S \lesssim 2$ TeV [81]. This Higgs-mass upper bound can be relaxed somewhat in non-minimal extensions of the MSSM, as noted in Section I.9.

In addition, one-loop radiative corrections can introduce CP-violating effects in the Higgs sector, which depend on some of the CP-violating phases among the MSSM-124 parameters [82]. Although these effects are more model-dependent, they can have a non-trivial impact on the Higgs searches at future colliders. A summary of the current MSSM Higgs mass limits can be found in Ref. 83.

I.6. Restricting the MSSM parameter freedom: In Sections I.4 and I.5, we surveyed the parameters that comprise the MSSM-124. However, in its most general form, the MSSM-124 is not a phenomenologically-viable theory over most of its parameter space. This conclusion follows from the observation that a generic point in the MSSM-124 parameter space exhibits: (i) no conservation of the separate lepton numbers L_e , L_μ , and L_τ ; (ii) unsuppressed flavor-changing neutral currents (FCNC's); and (iii) new sources of CP violation that are inconsistent with the experimental bounds.

For example, the MSSM contains many new sources of CPIn particular, some combinations of the comviolation [84]. plex phases of the gaugino-mass parameters, the A-parameters, and μ must be less than on the order of 10^{-2} – 10^{-3} (for a supersymmetry-breaking scale of 100 GeV) to avoid generating electric dipole moments for the neutron, electron, and atoms in conflict with observed data [85–87]. The non-observation of FCNC's [88-90] places additional strong constraints on the off-diagonal matrix elements of the squark and slepton softsupersymmetry-breaking squared masses and A-parameters (see Section I.3.3). As a result of the phenomenological deficiencies listed above, almost the entire MSSM-124 parameter space is ruled out! This theory is viable only at very special "exceptional" regions of the full parameter space.

The MSSM-124 is also theoretically incomplete as it provides no explanation for the origin of the supersymmetry-breaking parameters (and in particular, why these parameters should conform to the exceptional points of the parameter space mentioned above). Moreover, there is no understanding of the choice of parameters that leads to the breaking of the electroweak symmetry. What is needed ultimately is a fundamental theory of supersymmetry breaking, which would provide a rationale for a set of soft-supersymmetry-breaking terms that is consistent with all phenomenological constraints.

The successful unification of the $SU(3)\times SU(2)\times U(1)$ gauge couplings in supersymmetric grand unified theories [8,51,91,92]

suggests the possibility that the high-energy structure of the theory may be considerable simpler than its low-energy realization. The desired phenomenological constraints of the low-energy theory can often be implemented by the dynamics which govern the more fundamental theory that resides at the high energy scale.

In this Section, we examine a number of theoretical frameworks that yield phenomenologically viable regions of the the general MSSM parameter space. The resulting supersymmetric particle spectrum is then a function of a relatively small number of input parameters. This is accomplished by imposing a simple structure on the soft-supersymmetry-breaking terms at a common high-energy scale M_X (typically chosen to be the Planck scale, $M_{\rm P}$, the grand unification scale, $M_{\rm GUT}$, or the messenger scale, $M_{\rm mess}$). Using the renormalization group equations, one can then derive the low-energy MSSM parameters relevant for collider physics. The initial conditions (at the appropriate high-energy scale) for the renormalization group equations depend on the mechanism by which supersymmetry breaking is communicated to the effective low energy theory.

Examples of this scenario are provided by models of gravity-mediated and gauge-mediated supersymmetry breaking, to be discussed in more detail below. In some of these approaches, one of the diagonal Higgs squared-mass parameters is driven negative by renormalization group evolution [93]. In such models, electroweak symmetry breaking is generated radiatively, and the resulting electroweak symmetry-breaking scale is intimately tied to the scale of low-energy supersymmetry breaking.

$I. 6.1. \ \ Gaugino\ mass\ unification:$

One prediction that arises in many grand unified supergravity models and gauge-mediated supersymmetry-breaking models is the unification of the (tree-level) gaugino mass parameters at some high-energy scale M_X :

$$M_1(M_X) = M_2(M_X) = M_3(M_X) = m_{1/2}.$$
 (14)

Consequently, the effective low-energy gaugino mass parameters (at the electroweak scale) are related:

$$M_3 = (g_s^2/g^2)M_2 \simeq 3.5M_2$$
, $M_1 = (5g'^2/3g^2)M_2 \simeq 0.5M_2$. (15)

In this case, the chargino and neutralino masses and mixing angles depend only on three unknown parameters: the gluino mass, μ , and $\tan \beta$. If in addition $|\mu| \gg M_1 \gtrsim m_Z$, then the lightest neutralino is nearly a pure bino, an assumption often made in supersymmetric particle searches at colliders.

Although Eqs. (14) and (15) are often assumed in many phenomenological studies, a truly model-independent approach would take the gaugino mass parameters, M_i , to be independent parameters to be determined by experiment. For example, although LEP data yields a lower bound of 46 GeV on the mass of the lightest neutralino [94], an exactly massless neutralino cannot be ruled out today in a model-independent analysis [95].

It is possible that the tree-level masses for the gauginos are absent. In this case, the gaugino mass parameters arise at one-loop and do not satisfy Eq. (15). In supergravity, there exists a model-independent contribution to the gaugino mass whose origin can be traced to the super-conformal (super-Weyl) anomaly, which is common to all supergravity models [47]. Eq. (15) is then replaced (in the one-loop approximation) by:

$$M_i \simeq \frac{b_i g_i^2}{16\pi^2} m_{3/2} \,,$$
 (16)

where $m_{3/2}$ is the gravitino mass (assumed to be on the order of 1 TeV), and b_i are the coefficients of the MSSM gauge beta-functions corresponding to the corresponding U(1), SU(2), and SU(3) gauge groups: $(b_1,b_2,b_3)=(\frac{33}{5},1,-3)$. Eq. (16) yields $M_1\simeq 2.8M_2$ and $M_3\simeq -8.3M_2$, which implies that the lightest chargino pair and neutralino comprise a nearly mass-degenerate triplet of winos, \widetilde{W}^\pm , \widetilde{W}^0 (c.f. Table 1), over most of the MSSM parameter space. (For example, if $|\mu|\gg m_Z$, then Eq. (16) implies that $M_{\widetilde{\chi}_1^\pm}\simeq M_{\widetilde{\chi}_1^0}\simeq M_2$ [96].)

The corresponding supersymmetric phenomenology differs significantly from the standard phenomenology based on Eq. (15), and is explored in detail in Ref. 97. Under certain theoretical assumptions on the structure of the Kähler potential (the so-called sequestered form introduced in Ref. 47), anomaly-mediated supersymmetry breaking also generates (approximate) flavor-diagonal squark and slepton mass matrices. This approach is called anomaly-mediated supersymmetry breaking (AMSB). However in its simplest formulation, AMSB yields negative squared-mass contributions for the sleptons in the MSSM. It may be possible to cure this fatal flaw in approaches beyond the minimal supersymmetric model [98]. Alternatively, one can assume that anomaly-mediation is not the sole source of supersymmetry-breaking in the slepton sector.

Finally, it should be noted that the unification of gaugino masses (and scalar masses) can be accidental. In particular, the energy scale where unification takes place may not be directly related to any physical scale. This phenomenon has been called *mirage unification* and can occur in certain theories of fundamental supersymmetry-breaking [99].

I.6.2. The constrained MSSM: mSUGRA, CMSSM, ... In the minimal supergravity (mSUGRA) framework [2–4], a form of the Kähler potential is employed that yields minimal kinetic energy terms for the MSSM fields [100]. As a result, the soft-supersymmetry-breaking parameters at the high-energy scale M_X take a particularly simple form in which the scalar squared masses and the A-parameters are flavor-diagonal and universal [34]:

$$\begin{split} M_{\widetilde{Q}}^2(M_X) &= M_{\widetilde{U}}^2(M_X) = M_{\widetilde{D}}^2(M_X) = m_0^2 \mathbf{1} \,, \\ M_{\widetilde{L}}^2(M_X) &= M_{\widetilde{E}}^2(M_X) = m_0^2 \mathbf{1} \,, \\ m_1^2(M_X) &= m_2^2(M_X) = m_0^2 \,, \\ A_U(M_X) &= A_D(M_X) = A_E(M_X) = A_0 \mathbf{1} \,, \end{split} \tag{17}$$

where $\mathbf{1}$ is a 3×3 identity matrix in generation space. As in the Standard Model, this approach exhibits minimal flavor violation, whose unique source is the nontrivial flavor structure of the Higgs-fermion Yukawa couplings. The gaugino masses are also unified according to Eq. (14).

Renormalization group evolution is then used to derive the values of the supersymmetric parameters at the low-energy (electroweak) scale. For example, to compute squark masses, one must use the low-energy values for $M_{\widetilde{Q}}^2$, $M_{\widetilde{U}}^2$, and $M_{\widetilde{D}}^2$ in Eq. (9). Through the renormalization group running with boundary conditions specified in Eqs. (15) and (17), one can show that the low-energy values of $M_{\widetilde{Q}}^2$, $M_{\widetilde{U}}^2$, and $M_{\widetilde{D}}^2$ depend primarily on m_0^2 and $m_{1/2}^2$. A number of useful approximate analytic expressions for superpartner masses in terms of the mSUGRA parameters can be found in Ref. 101.

In the mSUGRA approach, one typically finds that four flavors of squarks (with two squark eigenstates per flavor) and \widetilde{b}_R are nearly mass-degenerate. The \widetilde{b}_L mass and the diagonal \widetilde{t}_L and \widetilde{t}_R masses are reduced compared to the common squark mass of the first two generations. In addition, there are six flavors of nearly mass-degenerate sleptons (with two slepton eigenstates per flavor for the charged sleptons and one per flavor for the sneutrinos); the sleptons are expected to be somewhat lighter than the mass-degenerate squarks. Finally, third-generation squark masses and tau-slepton masses are sensitive to the strength of the respective f_L - f_R mixing, as discussed below Eq. (9). The LSP is typically the lightest neutralino, $\tilde{\chi}_1^0$, which is dominated by its bino component. In particular, mSUGRA parameter regimes in which the LSP is a chargino or the $\tilde{\tau}_1$ (the lightest scalar superpartner of the τ -lepton) are not phenomenologically viable.

One can count the number of independent parameters in the mSUGRA framework. In addition to 18 Standard Model parameters (excluding the Higgs mass), one must specify m_0 , $m_{1/2}$, A_0 , the Planck-scale values for μ and B-parameters (denoted by μ_0 and B_0), and the gravitino mass $m_{3/2}$. Without additional model assumptions, $m_{3/2}$ is independent of the parameters that govern the mass spectrum of the superpartners of the Standard Model [34]. In principle, A_0 , B_0 , μ_0 , and $m_{3/2}$ can be complex, although in the mSUGRA approach, these parameters are taken (arbitrarily) to be real.

As previously noted, renormalization group evolution is used to compute the low-energy values of the mSUGRA parameters, which then fixes all the parameters of the low-energy MSSM. In particular, the two Higgs vacuum expectation values (or equivalently, m_Z and $\tan\beta$) can be expressed as a function of the Planck-scale supergravity parameters. The simplest procedure is to remove μ_0 and B_0 in favor of m_Z and $\tan\beta$ [the sign of μ_0 , denoted $\mathrm{sgn}(\mu_0)$ below, is not fixed in this process]. In this case, the MSSM spectrum and its interaction strengths are determined by five parameters:

$$m_0$$
, A_0 , $m_{1/2}$, $\tan \beta$, and $sgn(\mu_0)$, (18)

in addition to the 18 parameters of the Standard Model and an independent gravitino mass $m_{3/2}$. This framework is conventionally called the *constrained minimal sypersymmetric extension of the Standard Model* (CMSSM).

In the early literature, additional conditions were obtained by assuming a simplifying form for the hidden sector that provides the fundamental source of supersymmetry breaking. Two additional relations emerged among the mSUGRA parameters [100]: $B_0 = A_0 - m_0$ and $m_{3/2} = m_0$. These relations characterize a theory that was called minimal supergravity when first proposed. In the more recent literature, it has been more common to omit these extra conditions in defining the mSUGRA model (in which case the mSUGRA model and the CMSSM are synonymous). The authors of Ref. 102 advocate restoring the original nomenclature in which the mSUGRA model is defined with the extra conditions as originally proposed. Additional mSUGRA variations can be considered where different relations among the CMSSM parameters are imposed.

One can also relax the universality of scalar masses by decoupling the squared-masses of the Higgs bosons and the squarks/sleptons. This leads to the non-universal Higgs mass models (NUHM), thereby adding one or two new parameters to the CMSSM depending on whether the diagonal Higgs scalar squared-mass parameters $(m_1^2 \text{ and } m_2^2)$ are set equal (NUHM1) or taken to be independent (NUHM2) at the high energy scale M_X^2 . Clearly, this modification preserves the minimal flavor violation of the mSUGRA approach. Nevertheless, the mSUGRA approach and its NUHM generalizations are probably too simplistic. Theoretical considerations suggest that the universality of Planck-scale soft-supersymmetry-breaking parameters is not generic [103]. In particular, effective operators at the Planck scale exist that do not respect flavor universality, and it is difficult to find a theoretical principle that would forbid them.

I.6.3. Gauge-mediated supersymmetry breaking: In contrast to models of gravity-mediated supersymmetry breaking, the universality of the fundamental soft-supersymmetrybreaking squark and slepton squared-mass parameters is guaranteed in gauge-mediated supersymmetry breaking because the supersymmetry breaking is communicated to the sector of MSSM fields via gauge interactions [39,40]. minimal gauge-mediated supersymmetry-breaking (GMSB) approach, there is one effective mass scale, Λ , that determines all low-energy scalar and gaugino mass parameters through loop effects (while the resulting A-parameters are suppressed). In order that the resulting superpartner masses be on the order of 1 TeV or less, one must have $\Lambda \sim 100$ TeV. The origin of the μ and B-parameters is quite model-dependent, and lies somewhat outside the ansatz of gauge-mediated supersymmetry breaking. The simplest models of this type are even more restrictive than the CMSSM, with two fewer degrees of freedom. Benchmark reference points for GMSB models have been proposed in Ref. 104 to facilitate collider studies.

The minimal GMSB is not a fully realized model. The sector of supersymmetry-breaking dynamics can be very complex,

and no complete model of gauge-mediated supersymmetry yet exists that is both simple and compelling. However, advances in the theory of dynamical supersymmetry breaking (which exploit the existence of metastable supersymmetry-breaking vacua in broad classes of models [105]) have generated new ideas and opportunities for model building. As a result, simpler models of successful gauge mediation of supersymmetry breaking have been achieved with the potential for overcoming a number of long-standing theoretical challenges [106]. In addition, model-independent techniques that encompass all known gauge mediation models have been recently formulated [107]. These methods are well-suited for a comprehensive analysis [108] of the phenomenological profile of gauge-mediated supersymmetry breaking.

It was noted in Section I.2 that the gravitino is the LSP in GMSB models. As a result, the next-to-lightest supersymmetric particle (NLSP) now plays a crucial role in the phenomenology of supersymmetric particle production and decays. Note that unlike the LSP, the NLSP can be charged. In GMSB models, the most likely candidates for the NLSP are $\widetilde{\chi}_1^0$ and $\widetilde{\tau}_R^\pm$. The NLSP will decay into its superpartner plus a gravitino (e.g., $\widetilde{\chi}_1^0 \to \gamma \widetilde{G}$, $\widetilde{\chi}_1^0 \to Z \widetilde{G}$, or $\widetilde{\tau}_R^\pm \to \tau^\pm \widetilde{G}$), with lifetimes and branching ratios that depend on the model parameters.

Different choices for the identity of the NLSP and its decay rate lead to a variety of distinctive supersymmetric phenomenologies [40,109]. For example, a long-lived $\widetilde{\chi}_1^0$ -NLSP that decays outside collider detectors leads to supersymmetric decay chains with missing energy in association with leptons and/or hadronic jets (this case is indistinguishable from the standard phenomenology of the $\widetilde{\chi}_1^0$ -LSP). On the other hand, if $\widetilde{\chi}_1^0 \to \gamma \widetilde{G}$ is the dominant decay mode, and the decay occurs inside the detector, then nearly all supersymmetric particle decay chains would contain a photon. In contrast, in the case of a $\widetilde{\tau}_R^\pm$ -NLSP, the $\widetilde{\tau}_R^\pm$ would either be long-lived or would decay inside the detector into a τ -lepton plus missing energy.

I.6.4. The phenomenological MSSM: Of course, any of the theoretical assumptions described in this Section could be wrong and must eventually be tested experimentally. To facilitate the exploration of MSSM phenomena in a more model-independent way while respecting the constraints noted at the beginning of this Section, the phenomenological MSSM (pMSSM) has been introduced [110].

The pMSSM is governed by 19 independent real parameters beyond the Standard Model, which include the three gaugino masses M_1 , M_2 and M_3 , the Higgs sector parameters m_A and $\tan \beta$, the Higgsino mass parameter μ , five squark and slepton squared-mass parameters for the degenerate first and second generations $(M_{\widetilde{Q}}^2, M_{\widetilde{U}}^2, M_{\widetilde{D}}^2, (M_{\widetilde{L}}^2 \text{ and } M_{\widetilde{L}}^2)$, the five corresponding squark and slepton squared-mass parameters for the third generation, and three third-generation A-parameters $(A_t, A_b \text{ and } A_{\tau})$. Note that the first and second generation A-parameters can be neglected as their phenomenological consequences are negligible. Search strategies at the LHC for the more general pMSSM have been examined in Ref. 111.

If supersymmetric phenomena are discovered, the measurements of (low-energy) supersymmetric parameters may eventually provide sufficient information to determine the organizing principle governing supersymmetry breaking and yield significant constraints on the values of the fundamental (high-energy) supersymmetric parameters. In particular, a number of sophisticated techniques have been recently developed for analyzing experimental data to test the viability of the particular supersymmetric framework and for measuring the fundamental model parameters and their uncertainties [112].

I.7. Experimental data confronts the MSSM:

Suppose some version of the MSSM satisfies the phenomenological constraints addressed in Section I.6. What are the expectations for the magnitude of the parameters that define such a model, and are these expectations consistent with present experimental data? For details on the constraints on supersymmetric particle masses from previous collider studies at LEP and the Tevatron and the most recent constraints from LHC data, see Ref. 94. Additional constraints arise from limits on the contributions of virtual supersymmetric particle exchange to a variety of Standard Model processes [88–90].

Recent LHC data has been especially effective in ruling out the existence of colored supersymmetric particles (primarily the gluino and the first two generations of squarks) with masses below about 1 TeV in the CMSSM [113]. However, such constraints are relaxed, in some cases by as much as a factor of two, in more generic frameworks of the MSSM [114].

I.7.1 Naturalness constraints and the little hierarchy:

In Section I, weak-scale supersymmetry was motivated as a natural solution to the hierarchy problem, which could provide an understanding of the origin of the electroweak symmetry-breaking scale without a significant fine-tuning of the fundamental MSSM parameters. In this framework, the soft-supersymmetry-breaking masses must be generally of the order of 1 TeV or below [115]. This requirement is most easily seen in the determination of m_Z by the scalar potential minimum condition. In light of Eq. (3), to avoid the fine-tuning of MSSM parameters, the soft-supersymmetry breaking squared-masses m_1^2 and m_2^2 and the higgsino squared-mass $|\mu|^2$ should all be roughly of $\mathcal{O}(m_Z^2)$. Many authors have proposed quantitative measures of fine-tuning [115,116]. One of the simplest measures is the one given by Barbieri and Giudice [115],

$$\Delta_i \equiv \left| \frac{\partial \ln m_Z^2}{\partial \ln p_i} \right|, \qquad \Delta \equiv \max \ \Delta_i,$$
(19)

where the p_i are the MSSM parameters at the high-energy scale M_X , which are set by the fundamental supersymmetry-breaking dynamics. The theory is more fine-tuned as Δ becomes larger.

One can apply the fine-tuning measure to any explicit model of supersymmetry-breaking. For example, in the approaches discussed in Section I.6, the p_i are parameters of the model at the energy scale M_X where the soft-supersymmetry breaking operators are generated by the dynamics of supersymmetry breaking. Renormalization group evolution then determines the

values of the parameters appearing in Eq. (3) at the electroweak scale. In this way, Δ is sensitive to all the supersymmetry-breaking parameters of the model (see e.g. Ref. 117).

Consequently, there is a tension between the present experimental lower limits on the masses of colored supersymmetric particles [118] and the expectation that supersymmetrybreaking is associated with the electroweak symmetry-breaking scale. Moreover, this tension is exacerbated [119,120] by the experimental lower Higgs mass bound ($m_h \gtrsim 115 \text{ GeV}$) [83], which is not far from the the MSSM upper bound $(m_h \lesssim 135 \text{ GeV})$ [the dependence of the latter on the top-squark mass and mixing was noted in Section I.5.2]. If M_{SUSY} characterizes the scale of supersymmetric particle masses, then one would expect $\Delta \sim M_{\rm SUSY}^2/m_Z^2$. For example, if $M_{\rm SUSY} \sim 1$ TeV then there must be at least a $\Delta^{-1} \sim 1\%$ fine-tuning of the MSSM parameters to achieve the observed value of the Z mass. This separation of the electroweak symmetry breaking and supersymmetry breaking scales is an example of the little hierarchy problem [119,121].

However, one must be very cautious when drawing conclusions about the viability of weak-scale supersymmetry to explain the origin of electroweak symmetry breaking. First, one must decide the largest tolerable value of Δ within the framework of weak-scale supersymmetry (should it be $\Delta \sim 10$? 100? 1000?). Second, the fine-tuning parameter Δ depends quite sensitively on the assumptions of the supersymmetry-breaking dynamics (e.g. the value of M_X and relations among supersymmetry-breaking parameters in the fundamental high energy theory).

For example, in so-called focus point supersymmetry models [122], all squark masses can be as heavy as 5 TeV without significant fine-tuning. This can be attributed to a focusing behavior of the renormalization group evolution when certain relations hold among the high-energy values of the scalar squared-mass supersymmetry-breaking parameters. In this approach, the mass of the light CP-even Higgs boson can naturally be near its maximally allowed MSSM upper bound [123]. A recent reanalysis of focus-point and related models with modest fine-tuning in the context of CMSSM can be found in Ref. 124.

Among the colored superpartners, the third generation squarks generically have the most significant impact on the naturalness constraints [125], whereas their masses are the least constrained by LHC data. Hence, in the absence of any relation between third generation squarks and those of the first two generations, the naturalness constraints due to present LHC data can be considerably weaker than those obtained in the CMSSM. Indeed, models with first and second generation squark masses in the multi-TeV range do not generically require significant fine tuning. Such models have the added benefit that undesirable FCNCs mediated by squark exchange are naturally suppressed [126]. Other MSSM mass spectra that are compatible with moderate fine tuning have been investigated in Ref. 127. Moreover, one can also consider extensions of the MSSM in which the degree of fine-tuning is relaxed [128].

Finally, experimentally reported upper limits for supersymmetric particle masses are rarely model-independent. For example, mass limits for the gluino and the first and second generation squarks obtained under the assumption of the CMSSM can often be evaded in alternative or extended MSSM models, e.g., compressed supersymmetry [129] and stealth supersymmetry [130]. Moreover, experimental limits on the masses for the third generation squarks and color-neutral supersymmetric particles are less constrained than the masses of other colored supersymmetric states. The simplified models approach [131] is sometimes advertised as being more model-independent by focusing narrowly on a specific generic production process and decay chain. However this approach also depends on assumptions of the relative masses of the produced particle and decay products and the lack of interference from competing processes.

Thus, it is certainly premature in the first few years of the LHC era to conclude that weak scale supersymmetry is on the verge of exclusion.

I.7.2 Constraints from virtual exchange of supersymmetric particles

There are a number of low-energy measurements that are sensitive to the effects of new physics through supersymmetric loop effects. For example, the virtual exchange of supersymmetric particles can contribute to the muon anomalous magnetic moment, $a_{\mu} \equiv \frac{1}{2}(g-2)_{\mu}$ [132], The Standard Model prediction for a_{μ} exhibits a 3.3 σ deviation from the experimentally observed value [133], although a very recent theoretical re-analysis claims that the deviation exceeds 4σ [134].

The rare inclusive decay $b \to s\gamma$ also provides a sensitive probe to the virtual effects of new physics beyond the Standard Model. Experimental measurements of $B \to X_s + \gamma$ by the BELLE collaboration [135] are in very good agreement with the theoretical predictions of Ref. 136. In both cases, supersymmetric corrections can contribute an observable shift from the Standard Model prediction in some regions of the MSSM parameter space [137,138].

The rare decay $B_s \to \mu^+\mu^-$ is especially sensitive to supersymmetric loop effects, with some loop contributions that scale as $\tan^6 \beta$ when $\tan \beta \gg 1$ [139]. Current experimental limits [140] are within about a factor of five of the predicted Standard Model rate. The absence of a *significant* deviation in these and other *B*-physics observables from their Standard Model predictions places interesting constraints on the low-energy supersymmetry parameters [141].

I.8. Massive neutrinos in low-energy supersymmetry: In the minimal Standard Model and its supersymmetric extension, there are no right-handed neutrinos, and Majorana mass terms for the left-handed neutrinos are absent. However, given the overwhelming evidence for neutrino masses and mixing [142,143], any viable model of fundamental particles must provide a mechanism for generating neutrino masses [144]. In extended supersymmetric models, various mechanisms exist for producing massive neutrinos [145]. Although one can devise models for generating massive Dirac neutrinos [146], the

most common approaches for incorporating neutrino masses are based on *L*-violating supersymmetric extensions of the MSSM, which generate massive Majorana neutrinos. Two classes of *L*-violating supersymmetric models will now be considered.

I.8.1. The supersymmetric seesaw: Neutrino masses can be incorporated into the Standard Model by introducing $SU(3)\times SU(2)\times U(1)$ singlet right-handed neutrinos (ν_R) and super-heavy Majorana masses (typically on the order of a grand unified mass) for the ν_R . In addition, one must also include a standard Yukawa couplings between the lepton doublets, the Higgs doublet, and the ν_R . The Higgs vacuum expectation value then induces an off-diagonal ν_L - ν_R masses on the order of the electroweak scale. Diagonalizing the neutrino mass matrix (in the three-generation model) yields three superheavy neutrino states, and three very light neutrino states that are identified as the light neutrino states observed in nature. This is the seesaw mechanism [147].

The supersymmetric generalization of the seesaw model of neutrino masses is now easily constructed [148,149]. In the seesaw-extended Standard Model, lepton number is broken due to the presence of $\Delta L=2$ terms in the Lagrangian (which include the Majorana mass terms for the light and superheavy neutrinos). Consequently, the seesaw-extended MSSM conserves R-parity. The supersymmetric analogue of the Majorana neutrino mass term in the sneutrino sector leads to sneutrino-antisneutrino mixing phenomena [149,150].

I.8.2. R-parity-violating supersymmetry: A second approach to incorporating massive neutrinos in supersymmetric models is to retain the minimal particle content of the MSSM, while removing the assumption of R-parity invariance [152]. The most general R-parity-violating (RPV) model involving the MSSM spectrum introduces many new parameters to both the supersymmetry-conserving and the supersymmetry-breaking sectors. Each new interaction term violates either B or L conservation. For example, consider new scalar-fermion Yukawa couplings derived from the following interactions:

$$(\lambda_L)_{pmn}\widehat{L}_p\widehat{L}_m\widehat{E}_n^c + (\lambda_L')_{pmn}\widehat{L}_p\widehat{Q}_m\widehat{D}_n^c + (\lambda_B)_{pmn}\widehat{U}_n^c\widehat{D}_m^c\widehat{D}_n^c, (20)$$

where $p,\ m$, and n are generation indices, and gauge group indices are suppressed. In the notation above, $\hat{Q},\ \hat{U}^c,\ \hat{D}^c,\ \hat{L}$, and \hat{E}^c respectively represent $(u,d)_L,\ u^c_L,\ d^c_L,\ (\nu,\ e^-)_L$, and e^c_L and the corresponding superpartners.

The Yukawa interactions are obtained from Eq. (20) by taking all possible combinations involving two fermions and one scalar superpartner. Note that the term in Eq. (20) proportional to λ_B violates B, while the other two terms violate L. Even if all the terms of Eq. (20) are absent, there is one more possible supersymmetric source of R-parity violation. In the notation of Eq. (20), one can add a term of the form $(\mu_L)_p \hat{H}_u \hat{L}_p$, where \hat{H}_u represents the Y=1 Higgs doublet and its higgsino superpartner. This term is the RPV generalization of the supersymmetry-conserving Higgs mass parameter μ of the MSSM, in which the Y=-1 Higgs/higgsino super-multiplet

 \widehat{H}_d is replaced by the slepton/lepton super-multiplet \widehat{L}_p . The RPV-parameters $(\mu_L)_p$ also violate L.

Phenomenological constraints derived from data on various low-energy B- and L-violating processes can be used to establish limits on each of the coefficients $(\lambda_L)_{pmn}$, $(\lambda_L')_{pmn}$, and $(\lambda_B)_{pmn}$ taken one at a time [152,153]. If more than one coefficient is simultaneously non-zero, then the limits are, in general, more complicated [154]. All possible RPV terms cannot be simultaneously present and unsuppressed; otherwise the proton decay rate would be many orders of magnitude larger than the present experimental bound. One way to avoid proton decay is to impose B or L invariance (either one alone would suffice). Otherwise, one must accept the requirement that certain RPV coefficients must be extremely suppressed.

One particularly interesting class of RPV models is one in which B is conserved, but L is violated. It is possible to enforce baryon number conservation, while allowing for lepton-number-violating interactions by imposing a discrete ${\bf Z}_3$ baryon triality symmetry on the low-energy theory [155], in place of the standard ${\bf Z}_2$ R-parity. Since the distinction between the Higgs and matter super-multiplets is lost in RPV models, R-parity violation permits the mixing of sleptons and Higgs bosons, the mixing of neutrinos and neutralinos, and the mixing of charged leptons and charginos, leading to more complicated mass matrices and mass eigenstates than in the MSSM. Recent attempts to fit neutrino masses and mixing in this framework can be found in Ref. 151.

The supersymmetric phenomenology of the RPV models exhibits features that are quite distinct from that of the MSSM [152]. The LSP is no longer stable, which implies that not all supersymmetric decay chains must yield missing-energy events at colliders. Nevertheless, the loss of the missing-energy signature is often compensated by other striking signals (which depend on which R-parity-violating parameters are dominant). For example, supersymmetric particles in RPV models can be singly produced (in contrast to R-parity-conserving models where supersymmetric particles must be produced in pairs). The phenomenology of pair-produced supersymmetric particles is also modified in RPV models due to new decay chains not present in R-parity-conserving supersymmetry [152].

In RPV models with lepton number violation (these include low-energy supersymmetry models with baryon triality mentioned above), both $\Delta L = 1$ and $\Delta L = 2$ phenomena are allowed, leading to neutrino masses and mixing [156], neutrinoless double-beta decay [157], sneutrino-antisneutrino mixing [158], s-channel resonant production of sneutrinos in e^+e^- collisions [159] and charged sleptons in $p\bar{p}$ and pp collisions [160].

I.9. Extensions beyond the MSSM: Extensions of the MSSM have been proposed to solve a variety of theoretical problems. One such problem involves the μ parameter of the MSSM. Although μ is a supersymmetric-preserving parameter, it must be of order the supersymmetry-breaking scale to yield a consistent supersymmetric phenomenology. In the MSSM, one must devise a theoretical mechanism to guarantee that the

Searches Particle Listings

Supersymmetric Particle Searches

magnitude of μ is not larger than the TeV-scale (e.g., in gravity-mediated supersymmetry, the Giudice-Masiero mechanism of Ref. 161 is the most cited explanation).

In extensions of the MSSM, new compelling solutions to the so-called μ -problem are possible. For example, one can replace μ by the vacuum expectation value of a new SU(3)×SU(2)×U(1) singlet scalar field. In such a model, the Higgs sector of the MSSM is enlarged and the corresponding fermionic higgsino superpartner is added. This is the so-called NMSSM (here, NM stands for non-minimal) [162]. There are some advantages to extending the model further by adding an additional U(1) broken gauge symmetry [163] (which yields the USSM [72]) .

Non-minimal extensions of the MSSM involving additional matter and/or Higgs super-multiplets can also yield a less restrictive bound on the mass of the lightest Higgs boson (as compared to the bound quoted in Section I.5.2). For example, MSSM-extended models consistent with gauge coupling unification can be constructed in which the upper limit on the lightest Higgs boson mass can be as high as 200—300 GeV [164] (a similar relaxation of the Higgs mass bound occurs in split supersymmetry [165] and extra-dimensional scenarios [166]).

Other MSSM extensions considered in the literature include an enlarged electroweak gauge group beyond $SU(2)\times U(1)$ [167]; and/or the addition of new, possibly exotic, matter supermultiplets (e.g., new U(1) gauge groups and a vector-like color triplet with electric charge $\frac{1}{3}e$ that appear as low-energy remnants in E₆ grand unification models [168]). A possible theoretical motivation for such new structures arises from the study of phenomenologically viable string theory ground states [169].

- II.7. Global interpretations
- II.8. Summary and Outlook

II.1. Introduction

Supersymmetry (SUSY) [1–9] is one of the most compelling possible extensions of the Standard Model of particle physics (SM), and a leading contender for a new principle about nature

that could be discovered at high-energy colliders such as the Large Hadron Collider (LHC).

On theoretical grounds SUSY is motivated as a generalization of space-time symmetries. A low-energy realization of SUSY, *i.e.*, SUSY at the TeV scale, is, however, not a necessary consequence. Instead, low-energy SUSY is motivated by the possible cancellation of quadratic divergences in radiative corrections to the Higgs boson mass [10–15]. Furthermore, it is intriguing that a weakly interacting, (meta)stable supersymmetric particle might make up some or all of the dark matter in the universe [16–18]. In addition, SUSY predicts that gauge couplings, as measured experimentally at the electroweak scale, unify at an energy scale $\mathcal{O}(10^{16}) \text{GeV}$ ("GUT scale") near the Planck scale [19–25].

In the minimal supersymmetric extension to the Standard Model, the so called MSSM [26,27,11], a supersymmetry transformation pairs bosons with fermions and therefore relates every particle in the SM to a supersymmetric partner with half a unit of spin difference, but otherwise with the same properties and quantum numbers. These are the "sfermions": squarks and sleptons, the "gauginos," and the partners of the Higgs doublets, the "higgsinos." The charged weak gauginos and higgsinos mix to "charginos," and the neutral ones mix to "neutralinos." The fact that such particles are not yet observed leads to the conclusion that, if supersymmetry is realized, it is a broken symmetry. A description of SUSY in the form of an effective Lagrangian with only "soft" SUSY-breaking terms and SUSY masses at the TeV scale maintains cancellation of quadratic divergences in particle physics models.

The phenomenology of SUSY is to a large extent determined by the SUSY-breaking mechanism and the SUSYbreaking scale. This determines the SUSY particle masses, the mass hierarchy, the field contents of physical particles, and their decay modes. In addition, phenomenology crucially depends on whether the multiplicative quantum number of R-parity [27], $R = (-1)^{3(B-L)+2S}$, where B and L are baryon and lepton numbers and S is the spin, is conserved or violated. If R-parity is conserved, SUSY particles, which have odd R-parity, are produced in pairs and the decays of each SUSY particle must involve an odd number of lighter SUSY particles. The lightest SUSY particle (LSP) is then stable and often assumed to be a weakly interacting massive particle (WIMP). If R-parity is violated, new terms λ_{ijk} , λ'_{ijk} and λ''_{ijk} appear in the superpotential, where ijk are generation indices; λ -type couplings appear between lepton superfields only, λ'' -type are between quark superfields only, and λ' -type couplings connect the two. R-parity violation implies lepton and/or baryon number violation. More details of the theoretical framework of SUSY are discussed elsewhere in this volume [28].

Today low-energy data from flavor physics experiments, high-precision electroweak observables as well as astrophysical data impose strong constraints on the allowed SUSY parameter space. Examples of such data include measurements of precision electroweak observables, of the anomalous magnetic

moment of the muon and of the cosmological dark matter relic density, as well as limits on rare B-meson and K-meson decays, on electric dipole moments, on proton decay, and on WIMP-nucleon scattering cross sections. These indirect constraints are often more sensitive to higher SUSY mass scales than experiments searching for direct SUSY particle (sparticle) production at colliders, but the interpretation of these results are often strongly model dependent. In contrast, direct searches for sparticle production at collider experiments are much less subject to interpretation ambiguities and therefore they play a crucial role in the discovery strategy for SUSY.

In the rest of this review we limit ourselves to direct searches, covering data analyses at LEP, HERA, the Tevatron and the LHC. With the advent of the LHC, the experimental situation is changing rapidly. Compared to earlier PDG reviews, more emphasis is given to LHC results; for more details on LEP and Tevatron constraints, see earlier PDG reviews [29]. The SUSY Higgs sector is covered elsewhere in this volume [30].

II.2. Experimental search program

The electron-positron collider LEP was operational at CERN between 1989 and 2000. In the initial phase, center-of-mass energies around the Z-peak were probed, but after 1995 the LEP experiments collected a significant amount of luminosity at higher center-of-mass energies, some 235 pb⁻¹ per experiment at $\sqrt{s} \ge 204$ GeV, with a maximum \sqrt{s} of 209 GeV.

Searches for new physics at e^+e^- colliders benefit from the clean experimental environment and the fact that momentum balance can be measured not only in the plane transverse to the beam, but also in the direction along the beam (up to the beam pipe holes), the longitudinal direction. Searches at LEP are dominated by the data samples taken at the highest center-of-mass energies. The LEP limits for electroweak gauginos and sleptons are still competitive.

Significant constraints on SUSY have been set by the CDF and D0 experiments at the Tevatron, a proton-antiproton collider at a center-of-mass energy of up to 1.96 TeV. CDF and D0 have collected integrated luminosities between 10 and 11 ${\rm fb}^{-1}$ each up to the end of collider operations in 2011.

The electron-proton collider HERA provided collisions to the H1 and ZEUS experiments between 1992 and 2007, at a center-of-mass energy up to 318 GeV. A total integrated luminosity of approximately $0.5~{\rm fb^{-1}}$ has been collected by each experiment. Since in ep collisions no annihilation process takes place, SUSY searches at HERA typically look for R-parity violating production of single SUSY particles.

The landscape of SUSY searches, however, has significantly changed since the Large Hadron Collider (LHC) at CERN has started proton-proton operation at a center-of-mass energy of 7 TeV in 2010. By the end of 2011 the experiments CMS and ATLAS had collected about 5 fb⁻¹ of integrated luminosity each, and the LHCb experiment had collected approximately 1 fb⁻¹.

Proton-(anti)proton colliders produce interactions at higher center-of-mass energies than those available at LEP, and cross sections of QCD-mediated processes are larger, which is reflected in the higher sensitivity for SUSY particles carrying color charge: squarks and gluinos. Large backgrounds, however, pose challenges to trigger and analysis. Such backgrounds are dominated by multijet production processes, including, particularly at the LHC, those of top quark production, as well as jet production in association with vector bosons. The proton momentum is shared between its parton constituents, and in each collision only a fraction of the total center-of-mass energy is available in the hard parton-parton scattering. Since the parton momenta in the longitudinal direction are not known on an event-by-event basis, momentum conservation is restricted to the transverse plane, leading to the use in the experimental analyses of transverse variables, such as the missing transverse momentum, and the transverse mass. Proton-proton collisions at the LHC differ from proton-antiproton collisions at the Tevatron in the sense that there are no valence anti-quarks in the proton, and that gluon-initiated processes play a more dominant role. The increased center-of-mass energy of the LHC compared to the Tevatron significantly extends the kinematic reach for SUSY searches. This is reflected foremost in the sensitivity for squarks and gluinos, but also for other SUSY particles.

The main production mechanisms of massive colored sparticles at hadron colliders are squark-squark, squark-gluino and gluino-gluino production; when "squark" is used "antisquark" is also implied. The typical SUSY search signature at hadron colliders contains high- $p_{\rm T}$ jets, which are produced in the decay chains of heavy squarks and gluinos, and significant missing momentum originating from the two lightest supersymmetric particles (LSP) produced at the end of the decay chain. Assuming R-parity conservation, the LSPs are neutral and weakly interacting massive particles which escape detection. Backgrounds to such searches arise from multijet events with real missing momentum, dominated by heavy flavor decays, but also from instrumental effects in multijet events such as nonuniform calorimeter response or jet mismeasurement. Selection variables designed to separate the SUSY signal from the backgrounds include $H_{\rm T},~E_{\rm T}^{\rm miss}$ and $m_{\rm eff}.$ The quantities $H_{\rm T}$ and $E_{\rm T}^{\rm miss}$ refer to the measured energy and missing transverse momentum in the event, respectively. They are usually defined as the scalar $(H_{\rm T})$ and negative vector sum $E_{\rm T}^{\rm miss}$ of the transverse jet energies or transverse calorimeter clusters energies measured in the event. The quantity m_{eff} is referred to as the effective mass of the event and is defined as $m_{\text{eff}} = H_{\text{T}} + |E_{\text{T}}^{\text{miss}}|$. The peak of the $m_{\rm eff}$ distribution for SUSY signal events correlates with the SUSY mass scale [31]. Additional reduction of multijet backgrounds can be achieved by demanding isolated leptons, multileptons or photons in the final states.

In the past few years alternative approaches have been developed to increase the sensitivity to pair production of heavy sparticles with masses around 1 TeV focusing on the kinematics of their decays, and to further suppress the background from multijet production. Prominent examples of these

new approaches are searches using the $\alpha_{\rm T}$ [32–34], razor [35], stransverse mass $(m_{\rm T2})$ [36], and contransverse mass $(m_{\rm CT})$ [37] variables.

II.3. Interpretation of results

Since the mechanism by which SUSY is broken is unknown, a general approach to SUSY via the most general soft SUSY breaking Lagrangian adds a significant number of new free parameters. For the minimal supersymmetric standard model, MSSM, *i.e.*, the model with the minimal particle content, these comprise 105 new parameters. A phenomenological analysis of SUSY searches leaving all these parameters free is not feasible. For the practical interpretation of SUSY searches at colliders several approaches are taken to reduce the number of free parameters.

One approach is to assume a SUSY breaking mechanism and lower the number of free parameters through the assumption of additional constraints. In particular, interpretations of experimental results are often done in constrained models of gravity mediated [38,39], gauge mediated [40,41], and anomaly mediated [42,43] SUSY breaking. The most popular model for interpretation of collider based SUSY searches is the constrained MSSM (CMSSM) [38,44,45], which in the literature is also referred to as minimal supergravity, or MSUGRA. The CMSSM is described by five parameters: the common sfermion mass m_0 , the common gaugino mass $m_{1/2}$, and the common trilinear coupling parameter A_0 , all expressed at the GUT scale, the ratio of the vacuum expectation values of the Higgs fields for up-type and down-type fermions $\tan \beta$, and the sign of the Higgsino mass parameter μ . In gauge mediation models, the paradigm of general gauge mediation (GGM) [46] is slowly replacing minimal gauge mediation, denoted traditionally as GMSB (gauge mediated SUSY breaking)

These constrained SUSY models are theoretically well motivated and provide a rich spectrum of experimental signatures. Therefore, they represent a useful framework to benchmark performance, compare limits or reaches and assess the expected sensitivity of different search strategies. However, with universality relations imposed on the soft SUSY-breaking parameters, they do not cover all possible kinematic signatures and mass relations of SUSY. For this reason, an effort has been made in the past years to complement the traditional constrained models with more flexible interpretation approaches.

One answer to study a broader and more comprehensive subset of the MSSM is via the phenomenological-MSSM, or pMSSM [47–49]. It is derived from the MSSM, using experimental data to eliminate parameters that are free in principle but have already been highly constrained by measurements of e.g., flavor mixing and CP-violation. This effective approach reduces the number of free parameters in the MSSM to 19, making it a practical compromise between the full MSSM and highly constrained universality models such as the CMSSM.

Even less dependent on fundamental assumptions are interpretations in terms of so-called simplified models [50–53]. Such models assume a limited set of SUSY particle production and decay modes and leave open the possibility to vary masses and other parameters freely. Therefore, simplified models enable comprehensive studies of individual SUSY topologies without limitations on fundamental kinematic properties such as masses, production cross sections, and decay modes.

The landscape of SUSY searches and corresponding interpretations continues to change rapidly and this review covers results up to March 2012. Since none of the searches performed so far have shown significant excess above the SM background prediction, the interpretation of the presented results are exclusion limits on SUSY parameter space. This review will mainly focus on limits expressed in the context of CMSSM, gauge mediation, pMSSM and various simplified models.

II.4. Exclusion limits on gluino and squark masses

Gluinos and squarks are the SUSY partners of gluons and quarks, and thus carry color charge. Although limits on squark masses of the order 100 GeV have been set by the LEP experiments, hadron collider experiments are able to set much higher mass limits. The results of the LHC experiments now dominate the search for direct squark and gluino production. Pair production of these massive colored sparticles at hadron colliders generally involve both s-channel and t-channel parton-parton interactions. Since there is a negligible amount of bottom and top quark content in the proton, top- and bottom squark production proceeds through s-channel diagrams only with small cross sections. Experimental analyses of squark and/or gluino production typically assume the first and second generation squarks to be approximately degenerate in mass.

Assuming R-parity conservation, squarks will predominantly decay to a quark and a neutralino or chargino, if kinematically allowed. Other decay modes depend on the masses of the weak gauginos and may involve heavier neutralinos or charginos. For first and second generation squarks, the simplest decay modes involve two jets and missing momentum, with potential extra jets stemming from initial state radiation (ISR) or from decay modes with longer cascades. Similarly, gluino pair production leads to four jets and missing momentum, and possibly additional jets from ISR or cascades. Associated production of a gluino and a (anti)squark is also possible, in particular if squarks and gluinos have similar masses, typically leading to three or more jets in the final state. In cascades, isolated photons or leptons may appear from the decays of sparticles such as neutralinos or charginos. Final states are thus characterized by significant missing transverse momentum, and at least two, and possibly many more high $p_{\rm T}$ jets, which can be accompanied by one or more isolated objects like photons or leptons, including τ leptons, in the final state. Table 1 shows a schematic overview of characteristic final state signatures of gluino and squark production for different mass hierarchy assumptions.

Table 1: Typical search signatures at hadron colliders for direct gluino and first- and second-generation squark production assuming different mass hierarchies.

| Mass | Main | Dominant | Typical | |
|---------------------------------------|-----------------------------------------|--------------------------------------------|--------------------------------------------------------|--|
| Hierarchy | Production | Decay | Signature | |
| $m_{\tilde{q}} << m_{\tilde{g}}$ | $	ilde{q}	ilde{q},	ilde{q}ar{	ilde{q}}$ | $\tilde{q} \to q \tilde{\chi}_1^0$ | $\geq 2 \text{ jets} + E_{\text{T}}^{\text{miss}} + X$ | |
| $m_{\tilde{q}} \approx m_{\tilde{g}}$ | $	ilde{q}	ilde{g},ar{	ilde{q}}	ilde{g}$ | $\tilde{q} \to q \tilde{\chi}_1^0$ | $\geq 3 \text{ jets} + E_{\text{T}}^{\text{miss}} + X$ | |
| | | $\tilde{g} \to q \bar{q} \tilde{\chi}_1^0$ | | |
| $m_{\tilde{q}} >> m_{\tilde{g}}$ | $	ilde{g}	ilde{g}$ | $\tilde{g} \to q\bar{q}\tilde{\chi}_1^0$ | $\geq 4 \text{ jets} + E_{\text{T}}^{\text{miss}} + X$ | |

II.4.1 Exclusion limits on the gluino mass

Limits set by the Tevatron experiments on the gluino mass assume the framework of the CMSSM, with $\tan \beta = 5$ (CDF) or $\tan \beta = 3$ (D0), $A_0 = 0$ and $\mu < 0$, and amount to lower limits of about 310 GeV for all squark masses, or 390 GeV for the case $m_{\tilde{q}} = m_{\tilde{q}}$ [54,55].

At the LHC, limits on the gluino mass have been set using up to approximately 5 fb⁻¹ of data. As shown in Fig. 1, in the framework of the CMSSM, gluino masses below 800 GeV are excluded by the ATLAS collaboration for all squark masses. For equal squark and gluino masses, the limit is about 1400 GeV [56]. Similar results are reported by the CMS collaboration [57]. These limits are dominated by hadronic searches, which veto any contribution from isolated leptons and, for CMS, isolated photons. Although these results are derived for $\tan \beta = 10$, $A_0 = 0$, and $\mu > 0$, they are only mildly dependent on the choice of these CMSSM parameters.

In a simplified model, assuming only gluino pair production and a single decay chain of $\tilde{g} \to q\bar{q} \tilde{\chi}^0_1,$ upper limits on gluino pair production are derived as a function of the gluino and neutralino (LSP) mass. As shown in Fig. 2, using the next to leading order cross section for gluino pair production as reference, the CMS collaboration excludes in this simplified model gluino masses below 900 GeV, for a massless neutralino. In scenarios where neutralinos are not very light, the efficiency of analyses is reduced by the fact that jets are less energetic, and there is less missing transverse momentum in the event. Therefore, limits on gluino masses are strongly affected by the assumption of the neutralino mass. For example, for a gluino mass of around 1 TeV the upper limit on the gluino pair production cross section in this simplified model ranges from a few 10^{-2} pb for a massless neutralino to about 1 pb for a neutralino of ≈ 800 GeV. Furthermore, for neutralino masses above 300 - 400 GeV no general limit on the gluino mass can be set. Similar results have been obtained by ATLAS [60].

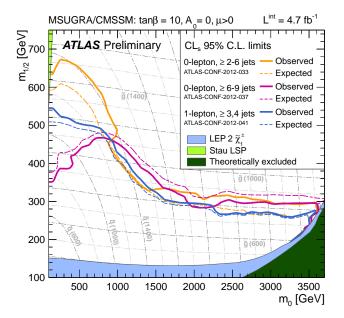

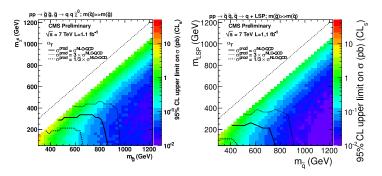

Figure 1: Limits, at 95% C.L., on the CMSSM parameters m_0 and $m_{1/2}$ derived from multi-jet analysis [56,58] and an analysis of jets and one isolated lepton [59] by the ATLAS experiment, for tan $\beta = 10$, $A_0 = 0$ and $\mu > 0$.

Upper limits, at 95% C.L., on the Figure 2: cross section of gluino pair production (left) or first- or second generation squark pair production (right) set by the CMS collaboration defined in the framework of simplified models assuming a single decay chain of $\tilde{g} \to q\bar{q}\tilde{\chi}_1^0$ (left) or $\tilde{q} \to q \tilde{\chi}_1^0$ (right). The contours illustrate where the reference cross section, calculated at next to leading order, and the upper limit on the cross section intersect. The reference cross section is scaled by a factor 3 or 1/3 to illustrate the effect of cross section or branching ratio variations. The diagonal part of $m_{\tilde{q}/\tilde{q}} - m_{\tilde{\chi}^0_1} < 200 \text{ GeV}$ is not kinematically accessible for the analysis and therefore no limit is provided.

If the gluino decay is suppressed, for example if squark masses are high, gluinos may live longer than typical hadronization times. It is expected that such gluinos will hadronize to semi-stable strongly interacting particles known as R-hadrons. Searches for R-hadrons exploit the typical signature of stable charged massive particles in the detector. As shown in Fig. 3, the CMS experiment excludes semi-stable gluino R-hadrons with masses below approximately 1 TeV [61]. The limits depend on the probability for gluinos to form bound states known as gluinoballs, as these are neutral and not observed in the tracking detectors. Similar limits are obtained by the ATLAS experiment [62].

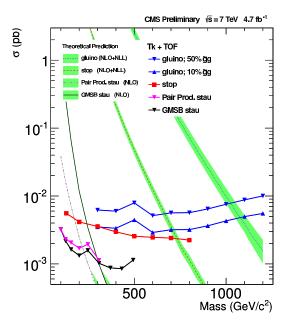

Figure 3: Observed 95% C.L. upper limits on the cross section for different combinations of models and scenarios considered: pair production of semi-stable tau sleptons, top squarks or gluinos. For gluinos, different fractions of gluinoball states produced after hadronization scenarios are indicated. The observed limits are compared with the predicted theoretical cross sections where the bands represent the theoretical uncertainties on the cross section values.

Alternatively, since such R-hadrons are strongly interacting, they may be stopped in the calorimeter or in other material, and decay later into energetic jets. These decays are searched for by identifying the jets outside the time window associated with bunch-bunch collisions [63–65]. The CMS analysis sets limits at 95% C.L. on gluino production over 13 orders of magnitude of gluino lifetime. For a mass difference $m_{\tilde{g}} - m_{\tilde{\chi}_1^0} > 100$ GeV, assuming a 100% branching fraction for gluino decay to gluon + neutralino, gluinos with lifetimes from 10 μ s to 1000 s and $m_{\tilde{g}} < 600$ GeV are excluded.

II.4.2. Exclusion limits on first and second generation squark masses

Limits on first and second generation squark masses set by the Tevatron experiments assume the CMSSM model, and amount to lower limits of about 380 GeV for all gluino masses, or 390 GeV for the case $m_{\tilde{q}} = m_{\tilde{q}}$ [54,55].

At the LHC, limits on squark masses have been set using up to approximately 5 fb⁻¹ of data. As for limits on the gluino mass, the highest sensitivity on squark production is obtained from fully-hadronic searches. As shown in Fig. 1, the ATLAS collaboration [56] excludes in the framework of the CMSSM squark masses below 1300 GeV for all gluino masses; for equal squark and gluino masses, the limit is about 1400 GeV. The limits obtained by CMS [57] are again very similar.

An interpretation of the CMS analysis using a simplified model characterizing squark pair production with only one decay chain of $\tilde{q} \to q \tilde{\chi}^0_1$ yields an exclusion of squark masses below 750 GeV for a massless neutralino (see Fig. 2). The effects of heavy neutralinos on squark limits are similar to those discussed in the gluino case (see section "Exclusion limits on the gluino mass") and only for neutralino masses below 200-300 GeV squark masses can be excluded.

The ATLAS analysis [56] is also interpreted in the framework of a simplified model with only squark and gluino production, for a massless neutralino, and assuming that all other sparticles are very massive. Results are shown in Fig. 4. In this interpretation, squark masses below 1500 GeV are excluded for $m_{\tilde{g}} \approx m_{\tilde{q}}$, while for large gluino masses the limit is reduced to about 1400 GeV in squark mass. Increasing the neutralino mass to values above ~ 200 GeV again leads to a degradation of these limits.

An overview of exclusion limits on first and second generation squark and gluino masses from CMS for different simplified models [66] is shown in Fig. 5. Like for the other simplified model limits, the reference cross sections for the different processes are calculated at next to leading order precision. To illustrate the impact of the neutralino mass on the limits, two mass scenarios for $m_{\tilde{\chi}_1^0} = 0$ GeV (dark blue) and $m_{\text{mother}} - m_{\tilde{\chi}_1^0}$ = 200 GeV (light blue) are presented. As expected, the simplified model exclusion limits vary strongly with the assumption on the mass splitting $(m_{\text{mother}} - m_{\tilde{\chi}_{1}^{0}})$ between the mother sparticle and LSP. The exclusion limits are strongest for maximal mass splitting and significantly weaken for more compressed spectra. Depending on the simplified model, the least stringent limits for compressed spectra are in the range of 400 GeV to 550 GeV, while the most stringent ones for maximal splitting are in the range of 650 GeV to 900 GeV. The corresponding results of ATLAS are very similar [67].

A summary of the most important first generation squark and gluino mass limits for different interpretations assuming R-parity conservation is shown in Table 2.

Supersymmetric Particle Searches

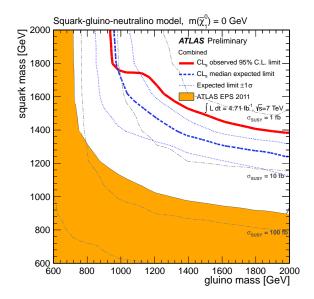

Figure 4: Limits on the masses of gluinos and first and second generation squarks, at 95% C.L., derived by ATLAS using simplified models with a massless neutralino, and assuming that the masses of all other SUSY particles are very large.

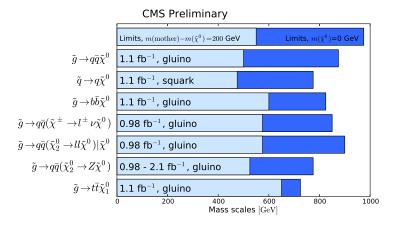

Figure 5: Exclusion limits, at 95% C.L., on first- or second generation squark and gluino masses from CMS for different simplified models. The reference cross sections for gluino and squark pair production are calculated at next to leading order precision and the branching fraction of their decays to daughter particles is assumed to be 100%. To show the impact of the neutralino mass on the limits, two mass scenarios are displayed: $m_{\tilde{\chi}_1^0} = 0$ GeV (dark blue) and $m_{\rm mother} - m_{\tilde{\chi}_1^0} = 200$ GeV (light blue).

R-parity violating production of single squarks via a λ' -type coupling has been studied at HERA. In such models, a lower limit on the squark mass of the order of 275 GeV has been set for electromagnetic-strength-like couplings $\lambda' = 0.3$ [68].

Table 2: Summary of first- or second generation squark mass and gluino mass limits using different interpretation approaches assuming R-parity conservation. Masses in this table are provided in GeV.

| Model | Assumption | $m_{	ilde{q}}$ | $m_{	ilde{g}}$ |
|-----------------------------------------|-----------------------------------------------------------------|----------------|----------------|
| | $m_{\tilde{q}} \approx m_{\tilde{g}}$ | 1400 | 1400 |
| CMSSM | all $m_{\tilde{q}}$ | - | 800 |
| | all $m_{\tilde{g}}$ | 1300 | - |
| Simplified model $\tilde{g}\tilde{g}$ | $m_{\tilde{\chi}_{1}^{0}} = 0$ | - | 900 |
| | $m_{\tilde{\chi}_1^0} > 300$ | - | no limit |
| Simplified model $\tilde{q}\tilde{q}$ | $m_{\tilde{\chi}_{1}^{0}} = 0$ | 750 | - |
| | $m_{\tilde{\chi}_1^0} > 250$ | no limit | - |
| Simplified model | $m_{\tilde{\chi}_1^0} = 0, m_{\tilde{q}} \approx m_{\tilde{g}}$ | 1500 | 1500 |
| $	ilde{g}	ilde{q},	ilde{g}ar{	ilde{q}}$ | $m_{\tilde{\chi}_1^0} = 0$, all $m_{\tilde{g}}$ | 1400 | - |
| | $m_{\tilde{\chi}_1^0} = 0$, all $m_{\tilde{q}}$ | - | 900 |

II.4.3. Exclusion limits on third generation squark masses

TeV-scale SUSY is often motivated by naturalness arguments, most notably as a solution to stabilize quadratic divergences in radiative corrections to the Higgs boson mass. In this context, the most relevant terms for SUSY phenomenology arise from the interplay between the masses of the third generation squarks and the (large) Yukawa coupling of the top quark to the Higgs boson. This motivates a potential constraint on the masses of the top squarks and the left-handed bottom squark. Due to the large top quark mass, significant mixing between $\tilde{t}_{\rm L}$ and $\tilde{t}_{\rm R}$ is expected, leading to a lighter mass state $\tilde{t}_{\rm 1}$ and a heavier mass state $\tilde{t}_{\rm 2}$. In much of MSSM parameter space, the lightest top squark ($\tilde{t}_{\rm 1}$) is also the lightest squark. Top squark masses below the top quark mass are not excluded.

In the absence of a SUSY discovery so far, searches for third generation squark production have become a major focus. Direct- and gluino mediated top and/or bottom squark production processes, leading to experimental signatures that are rich in jets originating from bottom quarks (b-jets), are either subject of re-interpretation of inclusive analyses or targets for dedicated third generation squark searches. This review contains results up to March 2012, but more results from the LHC experiments on the 2011 data sample are expected.

The top squark decay modes depend on the SUSY mass spectrum. If kinematically allowed, $\tilde{t} \to t \tilde{\chi}^0$ and $\tilde{t} \to b \tilde{\chi}^\pm$ are expected to dominate. If not, $\tilde{t} \to b f \bar{f}' \tilde{\chi}^0$ (where f and \bar{f}' denote a fermion-antifermion pair with appropriate quantum numbers) or the two-body decay $\tilde{t} \to c \tilde{\chi}^0$ is open. For light sneutrinos, $\tilde{t} \to b \ell \tilde{\nu}$ needs to be taken into account.

Limits from LEP on the \tilde{t}_1 mass are > 96 GeV in the charm plus neutralino final state, and > 93 GeV in the lepton, b-quark and sneutrino final state [69].

Direct production of top squark pairs at hadron colliders is suppressed with respect to first generation squarks, due to the absence of t-quarks in the proton. At the LHC, for example, this suppression is typically a factor 100 at $m_{\tilde{t}}=600$ GeV. Moreover, at the LHC, there is a very large background of top quark pair production, making experimental analysis of top squark pair production a challenge.

The Tevatron experiments have performed a number of searches for top squarks, often assuming direct pair production. In the $b\ell\tilde{\nu}$ decay channel, and assuming a 100% branching fraction, limits are set as $m_{\tilde{t}} > 210 \text{ GeV}$ for $m_{\tilde{\nu}} < 110 \text{ GeV}$ and $m_{\tilde{t}} - m_{\tilde{\nu}} > 30 \text{ GeV}, \text{ or } m_{\tilde{t}} > 235 \text{ GeV for } m_{\tilde{\nu}} < 50 \text{ GeV } [70,71].$ In the $\tilde{t} \to c\tilde{\chi}^0$ decay mode, a top squark with a mass below 180 GeV is excluded for a neutralino lighter than 95 GeV [72,73]. In both analyses, no limits on the top squark can be set for heavy sneutrinos or neutralinos. In the $\tilde{t} \to b\tilde{\chi}_1^{\pm}$ decay channel, searches for a relatively light top squark have been performed in the dilepton final state [74,75]. CDF sets limits in the $\tilde{t} - \tilde{\chi}_1^0$ mass plane for various branching fractions of the chargino decay to leptons and for two values of $m_{\tilde{\chi}_1^{\pm}}$. For $m_{\tilde{\chi}_1^{\pm}} = 105.8 \text{ GeV}$ and $m_{\tilde{\chi}^0_+} = 47.6$ GeV, top squarks between 128 and 135 GeV are excluded for W-like leptonic branching fractions of the chargino.

Top squarks may also be the product of gluino decays, if kinematically allowed: $\tilde{g} \to \tilde{t}t$. This leads to the characteristic "four tops" final state $tttt\tilde{\chi}_1^0\tilde{\chi}_1^0$, *i.e.*, a signature with as many as four isolated leptons, four b-jets, several light quark jets, and significant missing momentum from the neutrinos in the W decay and the two neutralinos. At the LHC, such final states are searched for in analyses demanding b-tagged jets and a lepton, or two leptons of the same charge (same-sign leptons), or many jets plus large missing momentum [76–78].

The interpretation of the results is performed in simplified models assuming specific decay modes, and MSSM production cross sections. Assuming the top squark is light enough, a simplified model with the decay chain $\tilde{g} \to \tilde{t}t$ and $\tilde{t} \to t\tilde{\chi}_1^0$ is used to characterize the reach of the searches, with gluino mass, stop mass and neutralino mass as free parameters. As shown in Fig. 6, a CMS search for same-sign lepton production accompanied with b-jets excludes gluino masses below some 850 GeV for top squark masses up to 650 GeV [78].

Taking into account top squark decay via $\tilde{t} \to t \tilde{\chi}_1^0$, and thus assuming $\tilde{g} \to t \bar{t} \tilde{\chi}_1^0$, as shown in Fig. 7, an ATLAS analysis searching for multijet plus $E_{\rm T}^{\rm miss}$ final states excludes gluino masses below 880(830) GeV for $m_{\tilde{\chi}_1^0} < 100(200)$ GeV [58]. For neutralino masses above 250 GeV, no limit can be placed on the top squark mass for this scenario.

R-parity violating production of single top squarks has been searched for at HERA [79]. Top squarks are assumed to be produced via a λ' coupling and decay either to $b\tilde{\chi}_1^{\pm}$ or R-parity-violating to a lepton and a jet. Limits are set on λ'_{131} as a function of the top squark mass in an MSSM framework with gaugino mass unification at the GUT scale. Within a variant of the CMSSM with R-parity violation, and assuming $\tan \beta = 6$, $A_0 = 0$, $\mu < 0$, a top squark with mass below 260 GeV is excluded for $\lambda' = 0.3$.

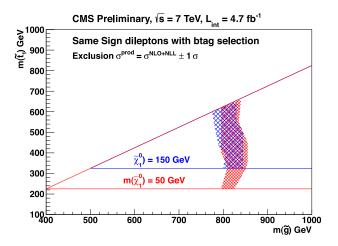

Figure 6: 95% C.L. exclusion in the stop-gluino mass plane for different choices of the neutralino mass. The used simplified model assumes the decay chain $\tilde{g} \to \tilde{t}t$, $\tilde{t} \to t\tilde{\chi}^0_1$. The bands represent the theoretical uncertainty on the gluino pair production cross-section.

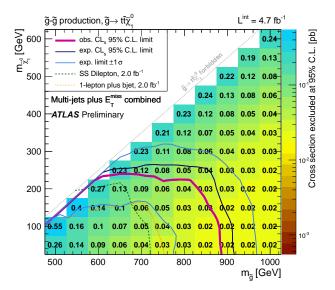

Figure 7: 95% C.L. upper limits on the cross section for gluino pair production as a function of gluino and neutralino mass. The used simplified model assumes the decay $\tilde{g} \to t\bar{t}\tilde{\chi}_1^0$. The contours illustrate where the reference cross section and the upper limit on the cross section intersect. Apart from the limit of the multijet analysis, also limits arising from a same-sign dilepton analysis, and a lepton plus b-jet analysis are shown.

Top squarks can also be long-lived and hadronize to a R-hadron, for example in the scenario where the top squark is the next-to-lightest SUSY particle (NLSP), with a small mass difference to the LSP. Searches for massive stable charged particles are sensitive to such top squarks. As shown in Fig. 3

Supersymmetric Particle Searches

for the CMS analysis [61], the LHC experiments have set limits $m_{\tilde{t}} > 720$ GeV in such scenarios, surpassing the earlier Tevatron limits of about 300 GeV [80,81].

Bottom squarks are expected to decay predominantly to $b\tilde{\chi}^0$. Direct production of bottom squark pairs has been studied at the Tevatron and at the LHC. Limits from the Tevatron are $m_{\tilde{b}} > 247$ GeV for a massless neutralino [82,83]. The LHC experiments now surpass these limits; as shown in Fig. 8, ATLAS has set a limit of $m_{\tilde{b}} > 392$ GeV for the same scenario, and $m_{\tilde{b}} > 375$ GeV for $m_{\tilde{\chi}^0_1} < 100$ GeV [84].

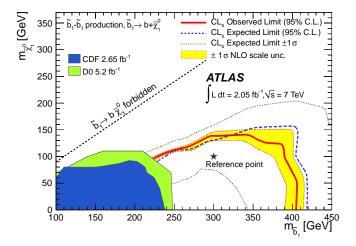

Figure 8: 95% C.L. exclusion contours in the sbottom-neutralino mass plane, for direct bottom squark pair production followed by the decay $\tilde{b} \to b \tilde{\chi}_1^0$.

Gluino pair production followed by $\tilde{g} \to b\tilde{b}$ has been searched for [85–86], and results exclude a gluino with a mass below 920 GeV for sbottom masses below 750 GeV and a light neutralino. Interpreting this search in a simplified model for gluino pair production and $\tilde{g} \to b\bar{b}\chi_1^0$ excludes a gluino with a mass below 900 GeV for neutralino masses below 300 GeV.

II.5. Exclusion limits on slepton masses

In models with slepton and gaugino mass unification at the GUT scale, the right-handed slepton, $\tilde{\ell}_{\rm R}$, is expected to be lighter than the left-handed slepton, $\tilde{\ell}_{\rm L}$. For tau sleptons there may be considerable mixing between the L and R states, leading to a significant mass difference between the lighter $\tilde{\tau}_1$ and the heavier $\tilde{\tau}_2$.

II.5.1. Exclusion limits on the masses of charged sleptons

The cleanest searches for selectrons, smuons and staus originate from the LEP experiments [87]. Smuon production only takes place via s-channel γ^*/Z exchange. Search results are often quoted for $\tilde{\mu}_{\rm R}$, since it is typically lighter than $\tilde{\mu}_{\rm L}$ and has a weaker coupling to the Z boson; limits are therefore conservative. Decays are expected to be dominated by

 $\tilde{\mu}_{\rm R} \to \mu \tilde{\chi}_1^0$, leading to two non-back-to-back muons and missing momentum. Limits are calculated in the MSSM under the assumption of gaugino mass unification at the GUT scale, and depend on the mass difference between the smuon and $\tilde{\chi}_1^0$. A $\tilde{\mu}_{\rm R}$ with a mass below 94 GeV is excluded for $m_{\tilde{\mu}_{\rm R}} - m_{\tilde{\chi}_1^0} > 10$ GeV. The selectron case is similar to the smuon case, except that an additional production mechanism is provided by t-channel neutralino exchange. The $\tilde{e}_{\rm R}$ lower mass limit is 100 GeV for $m_{\tilde{\chi}_1^0} < 85$ GeV. Due to the t-channel neutralino exchange, $\tilde{e}_{\rm R}\tilde{e}_{\rm L}$ pair production was possible at LEP, and a lower limit of 73 GeV was set on the selectron mass regardless of the neutralino mass. The potentially large mixing between $\tilde{\tau}_{\rm L}$ and $\tilde{\tau}_{\rm R}$ not only makes the $\tilde{\tau}_1$ light, but also decreases its coupling to the Z boson. LEP limits range between 87 and 93 GeV depending on the $\tilde{\chi}_1^0$ mass, for $m_{\tilde{\tau}} - m_{\tilde{\chi}_1^0} > 7$ GeV [87].

In gauge-mediated SUSY breaking models, sleptons can be (co-)NLSPs, i.e., the next-to-lightest SUSY particles and almost degenerate in mass, decaying to a lepton and a gravitino. This decay can either be prompt, or the slepton can have a non-zero lifetime. Combining several analyses, lower mass limits on $\tilde{\mu}_{\rm R}$ of 96.3 GeV and on \tilde{e}_{R} of 66 GeV are set for all slepton lifetimes at LEP [88]. In a considerable part of parameter space in these models, the $\tilde{\tau}$ is the NLSP. The LEP experiments have set lower limits on the mass of such a $\tilde{\tau}$ between 87 and 97 GeV, depending on the $\tilde{\tau}$ lifetime. ATLAS has searched for final states with τ s, jets and missing transverse momentum, and has interpreted the results in GMSB models setting limits on the model parameters [89,90]. CMS has interpreted a multilepton analysis in terms of limits on gauge mediation models with slepton (co-)NLSP [91].

Limits also exist on sleptons in R-parity violating models, both from LEP and the Tevatron experiments. From LEP, lower limits on $\tilde{\mu}_R$ and \tilde{e}_R masses in such models are 97 GeV, and the limits on the stau mass are very close: 96 GeV [92].

Charged slepton decays may be kinematically suppressed, for example in the scenario of a NLSP slepton with a very small mass difference to the LSP. Such a slepton may appear to be a stable charged massive particle. Interpretation of searches at LEP for such signatures within GMSB models with stau NLSP or slepton co-NLSP exclude masses up to 99 GeV [93]. Searches of stable charged particles at the Tevatron [80,81] and at the LHC [94,61] are also interpreted in terms of limits on stable charged sleptons. As shown in Fig. 3, CMS excludes stable staus with masses below approximately 300 GeV [61].

II.5.2. Exclusion limits on sneutrino masses

The invisible width of the Z boson puts a lower limit on the sneutrino mass of about 45 GeV. Tighter limits are derived from other searches, notably for gauginos and sleptons, under the assumption of gaugino and sfermion mass universality at the GUT scale, and amount to approximately 94 GeV in the MSSM. It is possible that the lightest sneutrino is the LSP; however, a lefthanded sneutrino LSP is ruled out as a cold dark matter candidate [95,96].

Production of pairs of sneutrinos in R-parity violating models has been searched for at LEP [92]. Assuming fully leptonic decays via λ -type couplings, lower mass limits between 85 and 100 GeV are set. At the Tevatron [97,98] and at the LHC [99], searches have focused on scenarios with resonant production of a sneutrino, decaying to $e\mu$ final states (as well as to $\mu\tau$, and $e\tau$ for CDF). No signal has been seen, and limits have been set on sneutrino masses as a function of the value of relevant RPV couplings. As an example, the ATLAS analysis excludes a resonant tau sneutrino with a mass below 600 GeV for $\lambda_{312} > 0.01$ and $\lambda'_{311} > 0.01$ [99].

II.6. Exclusion limits on the masses of charginos and neutralinos

Charginos and neutralinos result from mixing of the charged wino and higgsino states, and the neutral bino, wino and higgsino states, respectively. The mixing is determined by a limited number of parameters. For charginos these are the wino mass parameter M_2 , the Higgsino mass parameter μ , and $\tan \beta$, and for neutralinos these are the same parameters plus the bino mass parameter M_1 . The mass states are four charginos $\tilde{\chi}_1^{\pm}$ and $\tilde{\chi}_{2}^{\pm}$, and four neutralinos $\tilde{\chi}_{1}^{0}$, $\tilde{\chi}_{2}^{0}$, $\tilde{\chi}_{3}^{0}$ and $\tilde{\chi}_{4}^{0}$, ordered in increasing mass. Depending on the mixing, the chargino and neutralino composition is dominated by specific states, which are referred to as bino-like $(M_1 \ll M_2, \mu)$, wino-like $(M_2 \ll M_1, \mu)$, or Higgsino-like ($\mu \ll M_1, M_2$). If gaugino mass unification at the GUT scale is assumed, a relation between M_1 and M_2 at the electroweak scale follows: $M_1 = 5/3 \tan^2 \theta_W M_2 \approx 0.5 M_2$ (with θ_W the weak mixing angle), with consequences for the chargino-neutralino mass relation after mixing. Charginos and neutralinos carry no color charge, and only have electroweak couplings (neglecting gravity).

II.6.1. Exclusion limits on chargino masses

If kinematically allowed, two body decay modes such as $\tilde{\chi}^{\pm} \to \ell^{\pm} \tilde{\nu}$ are dominant. If not, three body decay $\tilde{\chi}^{\pm} \to f f' \tilde{\chi}^{0}$ are mediated through virtual W bosons or sfermions. If sfermions are heavy, the W mediation dominates, and f f' are distributed with branching fractions similar to W decay products. If, on the other hand, sleptons are light enough to play a significant role in the decay mediation, leptonic final states will be enhanced.

At LEP, charginos have been searched for in fully-hadronic, semi-leptonic and fully leptonic decay modes [100,101]. A general lower limit on the lightest chargino mass of 103.5 GeV is derived, except in corners of phase space with low electron sneutrino mass, where destructive interference in chargino production, or two-body decay modes, play a role. The limit is also affected if the mass difference between $\tilde{\chi}_1^{\pm}$ and $\tilde{\chi}_1^0$ is small; dedicated searches for such scenarios set a lower limit of 92 GeV.

At the Tevatron, charginos are searched for via production of a pair of charginos, or associated production of $\tilde{\chi}_1^{\pm} + \tilde{\chi}_2^0$. Decay modes involving multilepton final states provide the best discrimination against the large multijet background. Analyses

look for at least three charged isolated leptons, or for two leptons with the same charge. Depending on the $\tilde{\chi}_1^\pm - \tilde{\chi}_1^0$ and/or $\tilde{\chi}_2^0 - \tilde{\chi}_1^0$ mass differences, leptons may be soft. In a recent CDF analysis, results are interpreted in CMSSM-inspired scenarios, with $\tan \beta = 3$, $A_0 = 0$ and $\mu > 0$, and assuming $m_{\tilde{\chi}_1^\pm} = m_{\tilde{\chi}_2^0} = 2m_{\tilde{\chi}_1^0}$ [102]. Slepton masses are either assumed to be just above $m_{\tilde{\chi}^\pm}$, maximizing leptonic branching ratios in three-body chargino decays, or to be very large. In the first scenario, charginos with a mass below 168 GeV are excluded. D0 excludes a chargino below 130 GeV for the maximized leptonic branching fraction case for all $\tan \beta < 10$, and sets limits in the CMSSM $m_0 - m_{1/2}$ plane for $\tan \beta = 3$, $A_0 = 0$, and $\mu > 0$ [103].

At the LHC, the search strategy is similar to that at the Tevatron. In an ATLAS analysis of the three lepton final state [104], interpretation of the results is performed in the MSSM as well as using simplified models. In the MSSM, a scan over M_2 and μ is made for $M_1=100$ GeV and $\tan\beta=6$, and M_2 values below 350 GeV are excluded for $|\mu|<190$ GeV. The simplified models assume $\tilde{\chi}_1^{\pm}+\tilde{\chi}_2^0$ production, and $m_{\tilde{\chi}^{\pm}}=m_{\tilde{\chi}_2^0},$ leaving $m_{\tilde{\chi}^{\pm}}$ and $m_{\tilde{\chi}_1^0}$ free. In a scenario that favors leptonic decays of $\tilde{\chi}_1^{\pm}$ and $\tilde{\chi}_2^0$, charginos with masses up to 300 GeV are excluded for massless neutralinos, and charginos up to 250 GeV are excluded for $m_{\tilde{\chi}_1^0}<150$ GeV. More LHC results in these channels based on the 2011 data sample are expected.

In both the wino region (a characteristic of anomaly-mediated SUSY-breaking models) and the higgsino region of the MSSM, the mass splitting between $\tilde{\chi}_1^\pm$ and $\tilde{\chi}_1^0$ is small. In such scenarios, charginos may be long-lived. Charginos decaying in the detectors away from the primary vertex could lead to signatures such as kinked-tracks, or apparently disappearing tracks, since, for example, the pion in $\tilde{\chi}_1^\pm \to \pi^\pm \tilde{\chi}_1^0$ might be too soft to be reconstructed. At the LHC, a search has been performed for such disappearing tracks, and interpreted with anomaly-mediated SUSY breaking models. For specific AMSB parameters, charginos with lifetimes between 0.2 and 90 ns are excluded for chargino masses up to 90 GeV, and limits reach up to 118 GeV for lifetimes around 1 ns [105].

Charginos with a lifetime longer than the time needed to pass through the detector appear as charged stable massive particles. Limits have been derived by the LEP experiments [93] and by D0 at the Tevatron [81]. D0 results exclude higgsinolike stable charginos below 217 GeV, and gaugino-like stable charginos below 267 GeV.

II.6.2. Exclusion limits on neutralino masses

In a considerable part of the MSSM parameter space, and in particular when demanding that the LSP carries no electric or color charge, the lightest neutralino $\tilde{\chi}^0_1$ is the LSP. If R-parity is conserved, such a $\tilde{\chi}^0_1$ is stable. Since it is weakly interacting, it will typically escape detectors unseen. Limits on the invisible width of the Z boson apply to neutralinos with a mass below 45.5 GeV, but depend on the Z-neutralino coupling. Such a coupling could be small or even absent; in such a scenario

Searches Particle Listings Supersymmetric Particle Searches

there is no general lower limit on the mass of the lightest neutralino [106]. In models with gaugino mass unification at high energy scales, a neutralino mass limit is derived from the chargino mass limit, and amounts to 47 GeV. Assuming a constraining model like the CMSSM, this limit increases to 50 GeV at LEP; however the strong constraints now set by the LHC increase such CMSSM-derived $\tilde{\chi}_1^0$ mass limits to well above 100 GeV.

Even though a LSP neutralino is only weakly interacting, collider experiments are not blind to neutralino pair production. Pair production of neutralinos accompanied by initial state radiation could lead to an observable final state. At LEP, final states with only a single isolated photon were studied, but backgrounds from neutrino pair production were too large. At hadron colliders, monojet final states have been used to set limits on the pair production cross section [107,108].

The lightest neutralino can decay in models with R-parity violation, or in cases where it is not the LSP, as in gauge mediation models. In the latter case, a NLSP neutralino will decay to a gravitino and a SM particle whose nature is determined by the neutralino composition. Final states with two high $p_{\rm T}$ photons and missing momentum are searched for, and interpreted in gauge mediation models with bino-like neutralinos [109–113]. Assuming only gluino pair production and a bino-like neutralino produced in gluino decay, limits on gluino masses of about 1 TeV are set for all neutralino masses, as shown in Fig. 9 for the CMS diphoton analysis.

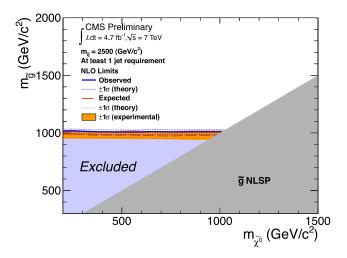

Figure 9: Observed 95% C.L. limits on the gluino mass as a function of the neutralino mass, in general gauge mediation models assuming only gluino pair production, with a bino-like neutralino produced in gluino decay, and a neutralino decay to photon plus gravitino.

Assuming the production of at least two neutralinos per event, neutralinos with large non-bino components can also be searched for in ZZ and γZ final states. Searches for final states with Z ($\rightarrow \ell^+\ell^-$) bosons and missing transverse momentum have been performed at the Tevatron [114] and at the LHC [115], and are interpreted in such models.

In gauge mediation models, NLSP neutralino decay need not be prompt, and experiments have searched for late decays. CDF have searched for delayed $\tilde{\chi}_1^0 \to \gamma Z$ decays using the timing of photon signals in the calorimeter [116], and exclude a neutralino with mass below 101 GeV with a lifetime of 5 ns. CMS has used converted photons to search for photon production away from the primary vertex [117]. Results are given as upper limits on the neutralino production cross section of order 0.12 – 0.24 pb for $c\tau$ between 5 and 25 cm. D0 has looked at the direction of showers in the electromagnetic calorimeter with a similar goal [118].

Heavier neutralinos, in particular $\tilde{\chi}_2^0$, have been searched for in their decays to the lightest neutralino plus a Z boson. Analyses include searches for Z production plus missing energy, Z plus jets plus missing energy, two Z bosons plus missing energy, and Z plus W production plus missing energy [118,119–122]. In $\tilde{\chi}_2^0$ decays to $\tilde{\chi}_1^0$ and a lepton pair, the lepton pair invariant mass distribution may show a structure that can be used to measure the $\tilde{\chi}_2^0 - \tilde{\chi}_1^0$ mass difference in case of a signal [123], but it can also be used in the search itself, in order to suppress background [124].

II.7. Global interpretations

Apart from the interpretation of the direct searches for sparticle production at colliders in terms of limits on masses of individual SUSY particles, model-dependent interpretations of allowed SUSY parameter space are derived from global SUSY fits. Typically these fits combine the results from collider experiments with indirect constraints on SUSY as obtained from low-energy experiments, flavor physics, high-precision electroweak results, and astrophysical data.

In the pre-LHC era these fits were mainly dominated by indirect constraints. Even for very constrained models like the CMSSM, the allowed parameter space, in terms of squark and gluino masses, ranged from several hundreds of GeV to a few TeV. For the theoretically well motivated class of constrained supergravity models like the CMSSM, global fits indicated that squarks and gluino masses in the range of 500 to 1000 GeV were the preferred region of parameter space, although values as high as few TeV were allowed with lower probabilities [125].

With ATLAS and CMS now probing mass scales around 1 TeV and even beyond, the importance of the direct searches for global analyses of allowed SUSY parameter space has significantly increased. For example, imposing the new experimental limits on constrained supergravity models pushes the most likely values of first generation squark and gluino masses beyond 1 TeV, typically resulting in overall values of fit quality

significantly worse than those in the pre-LHC era [126]. Although these constrained models are not yet ruled out, the extended experimental limits impose tight constraints on the allowed parameter space.

For this reason, the emphasis of global SUSY fits has shifted more towards less-constrained SUSY models. Especially interpretations in the pMSSM [48,127,128] and in simplified models have been useful to generalize SUSY searches, for example in order to increase their sensitivity for compressed spectra where the mass of the LSP is much closer to squark and gluino masses than predicted by for example the CMSSM. As shown in Table 2, for neutralino masses above a few hundred GeV the current set of ATLAS and CMS searches cannot exclude the existence of light squarks and gluinos.

II.8. Summary and Outlook

Although the search for SUSY at the LHC has just begun, results of the ATLAS and CMS experiments are already probing direct production of colored SUSY particles at the 1 TeV mass scale. So far no evidence of new particle production has been observed in the data and therefore limits on allowed parameter space in various models have been set. While typically squark and gluino masses around 1 TeV and below are excluded in constrained models, weaker bounds on SUSY particle masses are obtained in less constrained scenarios demonstrating that SUSY below the 1 TeV scale is certainly not ruled out in general. For non-colored sparticles the impact of the LHC is to a large extent yet to come, and limits from LEP and the Tevatron are still competitive. An overview of the current landscape of SUSY searches and corresponding exclusion limits at the LHC is shown in Fig. 10 from the ATLAS experiment [67]. corresponding results of the CMS experiment are similar [66].

Furthermore, the LHC experiments have reported significant constraints on the allowed mass range of a SM-like Higgs boson based on an analysis of 5 fb⁻¹ of data [129,130]. A SM-like Higgs boson is excluded over a large mass range, except in a narrow window around 125 GeV or at a large mass above some 600 GeV. These results impose further tight bounds on the allowed SUSY parameter space, and the first studies of global analyses indicate (see e.g., [131–133]) that the limits on the Higgs boson mass worsen the overall compatibility of the available data with constrained models like the CMSSM. Scenarios of rather light third generation squarks, however, perhaps accompanied with heavy neutralinos as realized in compressed spectra, or first generation squarks and gluinos with masses significantly above 1 TeV are still compatible with the present set of direct and indirect constraints.

Additional searches at the LHC in 2012, at a higher centerof-mass energy of 8 TeV, are expected to make further important steps in the experimental search for SUSY. Once the LHC reaches its full energy after 2013, even higher mass scales will be in reach.

Like the experimental landscape of SUSY searches, the field of global interpretations of allowed SUSY parameters is still rapidly changing. Yet, it seems reasonable to expect that

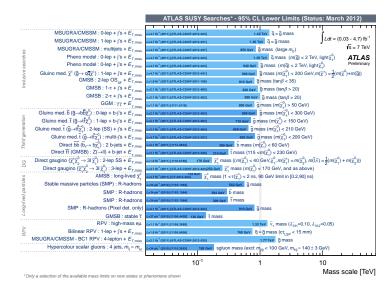

Figure 10: Overview of the current landscape of SUSY searches at the LHC. The plot shows exclusion mass limits of ATLAS for different searches and interpretation assumptions. The corresponding results of CMS are comparable

the emphasis on interpretations in constrained SUSY models is now shifting towards more flexible models, which in turn motivates an even stronger experimental emphasis on searches for direct production of third generation squarks, of electroweak gauginos, or involving compressed $m_{\rm mother}-m_{\tilde{\chi}_1^0}$ mass spectra. An increased emphasis on R-parity violating models and on models with long-lived particles can also be expected.

SUPERSYMMETRIC MODEL ASSUMPTIONS

The exclusion of particle masses within a mass range (m_1, m_2) will be denoted with the notation "none $m_1 - m_2$ " in the VALUE column of the following Listings. The latest unpublished results are described in the "Supersymmetry: Experiment" review.

Most of the results shown below, unless stated otherwise, are based on the Minimal Supersymmetric Standard Model (MSSM), as described in the Note on Supersymmetry. Unless otherwise indicated, this includes the assumption of common gaugino and scalar masses at the scale of Grand Unification (GUT), and use of the resulting relations in the spectrum and decay branching ratios. It is also assumed that R-parity (R) is conserved. Unless otherwise indicated, the results also assume

- 1) The $\tilde{\chi}_1^0$ is the lighest supersymmetric particle (LSP)
- 2) $m_{\widetilde{f}_L} = m_{\widetilde{f}_R}$, where $\widetilde{f}_{L,R}$ refer to the scalar partners of leftand right-handed fermions.

Limits involving different assumptions are identified in the Comments or in the Footnotes. We summarize here the notations used in this Chapter to characterize some of the most common deviations from the MSSM (for further details, see the Note on Supersymmetry).

Theories with R-parity violation (R) are characterized by a superpotential of the form: $\lambda_{ijk}L_iL_je_k^c + \lambda'_{ijk}L_iQ_jd_k^c +$ $\lambda''_{ijk}u_i^c d_i^c d_k^c$, where i,j,k are generation indices. The presence of any of these couplings is often identified in the following by the symbols $LL\overline{E}$, $LQ\overline{D}$, and \overline{UDD} . Mass limits in the presence of R will often refer to "direct" and "indirect" decays. Direct refers to R decays of the particle in consideration. Indirect refers to cases where R appears in the decays of the

In several models, most notably in theories with so-called Gauge Mediated Supersymmetry Breaking (GMSB), the gravitino (G) is the LSP. It is usually much lighter than any other massive particle in the spectrum, and $m_{\widetilde{C}}$ is then neglected in all decay processes involving gravitinos. In these scenarios, particles other than the neutralino are sometimes considered as the next-to-lighest supersymmetric particle (NLSP), and are assumed to decay to their even-R partner plus G. If the lifetime is short enough for the decay to take place within the detector, \widetilde{G} is assumed to be undetected and to give rise to missing energy (E) or missing transverse energy (E_T) signatures.

When needed, specific assumptions on the eigenstate content of $\tilde{\chi}^0$ and $\tilde{\chi}^{\pm}$ states are indicated, using the notation $\tilde{\gamma}$ (photino), \widetilde{H} (higgsino), \widetilde{W} (wino), and \widetilde{Z} (zino) to signal that the limit of pure states was used. The terms gaugino is also used, to generically indicate wino-like charginos and zino-like neutralinos.

$\widetilde{\chi}_1^0$ (Lightest Neutralino) MASS LIMIT

 $\widetilde{\chi_1^0}$ is often assumed to be the lightest supersymmetric particle (LSP). See also the $\widetilde{\chi}_2^0$, $\widetilde{\chi}_3^0$, $\widetilde{\chi}_4^0$ section below.

We have divided the $\widetilde{\chi}_1^0$ listings below into five sections:

- 1) Accelerator limits for stable $\widetilde{\chi}_1^0$,
- 2) Bounds on $\widetilde{\chi}_1^0$ from dark matter searches,
- 3) $\tilde{\chi}_1^0 p$ elastic cross section (spin-dependent, spin-independent interactions),
- 4) Other bounds on $\widetilde{\chi}_1^0$ from astrophysics and cosmology, and
- 5) Unstable $\widetilde{\chi}_1^0$ (Lightest Neutralino) mass limit.

8 ARE

– Accelerator limits for stable $\widetilde{\chi}^0_1$ -

Unless otherwise stated, results in this section assume spectra, production rates, decay modes, and branching ratios as evaluated in the MSSM, with gaugino and sfermion mass unification at the GUT scale. These papers $\,$ generally study production of $\widetilde{\chi}_i^0\,\widetilde{\chi}_i^0$ ($i\ge 1$, $j\ge 2$), $\widetilde{\chi}_1^+\,\widetilde{\chi}_1^-$, and (in the

case of hadronic collisions) $\tilde{\chi}_1^+ \tilde{\chi}_2^0$ pairs. The mass limits on $\tilde{\chi}_1^0$ are either direct, or follow indirectly from the constraints set by the non-observation of $\widetilde{\chi}_1^\pm$ and $\widetilde{\chi}_2^0$ states on the gaugino and higgsino MSSM parameters M_2 and μ . In some cases, information is used from the nonobservation of slepton decays.

Obsolete limits obtained from e^+e^- collisions up to \sqrt{s} =184 GeV have been removed from this compilation and can be found in the 2000 Edition (The European Physical Journal C15 1 (2000)) of this Review. $\Delta m = m_{\widetilde{\chi}^0_2} - m_{\widetilde{\chi}^0_1}$

Searches Particle Listings Supersymmetric Particle Searches

- $^{
 m 1}$ ABBIENDI 04H search for charginos and neutralinos in events with acoplanar leptons+jets and multi-jet final states in the 192–209 GeV data, combined with the results on leptons final states from ABBIENDI 04. The results hold for a scan over the parameter space covering the region $0 < M_2 < 5000$ GeV, $-1000 < \mu < 1000$ GeV and $\tan \beta$ from 1 to 40. This limit supersedes ABBIENDI 00H.
- ²HEISTER 04 data collected up to 209 GeV. Updates earlier analysis of selectrons from HEISTER 02c, includes a new analysis of charginos and neutralinos decaying into stau and uses results on charginos with initial state radiation from HEISTER 02. The limit is based on the direct search for charginos and neutralinos, the constraints from the slepton search and the Higgs mass limits from HEISTER 02 using a top mass of 175 GeV, interpreted in a framework with universal gaugino and sfermion masses. Assuming the mixing in the stau sector to be negligible, the limit improves to 43.1 GeV. Under the assumption of MSUGRA with unification of the Higgs and sfermion masses, the limit improves to 50 GeV, and reaches 53 GeV for $A_0=0$. These limits include and update the results of BARATE 01.
- 3 ABDALLAH 03M uses data from $\sqrt{s}=$ 192–208 GeV. A limit on the mass of $\widetilde{\chi}_1^0$ is derived from direct searches for neutralinos combined with the chargino search. Neutralinos are searched in the production of $\widetilde{\chi}_1^0 \widetilde{\chi}_2^0$, $\widetilde{\chi}_1^0 \widetilde{\chi}_3^0$, as well as $\widetilde{\chi}_2^0 \widetilde{\chi}_3^0$ and $\widetilde{\chi}_2^0 \widetilde{\chi}_4^0$ giving rise to cascade decays, and $\widetilde{\chi}_1^0 \widetilde{\chi}_2^0$ and $\widetilde{\chi}_1^0 \widetilde{\chi}_2^0$, followed by the decay $\widetilde{\chi}_2^0 \to \widetilde{\tau}\tau$. The results hold for the parameter space defined by values of $\mathit{M}_2 < 1$ TeV, $|\mu| \leq 2$ TeV with the $\widetilde{\chi}_1^0$ as LSP. The limit is obtained for $\tan\beta=1$ and large m_0 , where $\widetilde{\chi}_2^0\widetilde{\chi}_4^0$ and chargino pair production are important. If the constraint from Higgs searches is also imposed, the limit improves to 49.0 GeV in the M $_h^{max}$ scenario with $m_t{=}174.3$ GeV. These limits update the results of ABREU 00J.
- 4 ABDALLAH 03M uses data from $\sqrt{s}=1$ 92–208 GeV. An indirect limit on the mass of $\widetilde{\chi}_1^0$ is derived by constraining the MSSM parameter space by the results from direct searches for neutralinos (including cascade decays and $\tilde{\tau}\tau$ final states), for charginos (for all Δm_+) and for sleptons, stop and sbottom. The results hold for the full parameter space defined by values of $M_2 < 1$ TeV, $|\mu| \leq$ 2 TeV with the $\widetilde{\chi}_1^0$ as LSP. Constraints from the Higgs search in the M_h^{max} scenario assuming m_t =174.3 GeV are included. The limit is obtained for $\tan \beta \geq 5$ when stau mixing leads to mass degeneracy between $\widetilde{\tau}_1$ and $\widetilde{\chi}_1^0$ and the limit is based on $\widetilde{\chi}_2^0$ production followed by its decay to $\widetilde{\tau}_1 \tau$. In the pathological scenario where m_0 and $|\mu|$ are large, so that the $\widetilde{\chi}^0_2$ production cross section is negligible, and where there is mixing in the stau sector but not in stop nor sbottom, the limit is based on charginos with soft decay products and an ISR photon. The limit then degrades to 39 GeV. See Figs 40–42 for the dependence of the limit on $\tan \beta$ and $m_{\widetilde{\nu}}$. These limits update the results of ABREU 00w.
- 5 ACCIARRI 00D data collected at $\sqrt{s}{=}189$ GeV. The results hold over the full parameter space defined by $0.7 \le \tan\beta \le 60,~0 \le M_2 \le 2$ TeV, $m_0 \le 500$ GeV, $|\mu| \le 2$ TeV. The minimum mass limit is reached for $\tan\beta{=}1$ and large m_0 . The results of slepton searches from ACCIARRI 99w are used to help set constraints in the region of small m_0 . The limit improves to 48 GeV for $m_0 \gtrsim 200$ GeV and $\tan\beta \gtrsim 10$. See their Figs. 6–8 for the $\tan\beta$ and m_0 dependence of the limits. Updates ACCIARRI 98F.
- ⁶ DREINER 09 show that in the general MSSM with non-universal gaugino masses there exists no model-independent laboratory bound on the mass of the lightest neutralino. An essentially massless χ^0_1 is allowed by the experimental and observational data, imposing some constraints on other MSSM parameters, including M_{2} , μ and the slepton and
- squark masses. 7 ABBOTT 98c searches for trilepton final states $(\ell = e, \mu)$. See footnote to ABBOTT 98c in the Chargino Section for details on the assumptions. Assuming a negligible decay rate of $\tilde{\chi}_1^\pm$ and $\tilde{\chi}_2^0$ to quarks, they obtain $m_{\tilde{\chi}_2^0} \gtrsim 51$ GeV.
- 8 ABE 98J searches for trilepton final states $(\ell\!=\!e,\!\mu).$ See footnote to ABE 98J in the Chargino Section for details on the assumptions. The quoted result corresponds to the best limit within the selected range of parameters, obtained for $m_{\widetilde{q}} > m_{\widetilde{g}}, \tan\beta = 2,$ and $\mu = -600 \text{ GeV}.$

– Bounds on $\widetilde{\chi}^0_1$ from dark matter searches -

These papers generally exclude regions in the M_2 – μ parameter plane assuming that $\tilde{\chi}_1^0$ is the dominant form of dark matter in the galactic halo. These limits are based on the lack of detection in laboratory experiments, telescopes, or by the absence of a signal in underground neutrino detectors. The latter signal is expected if $\widetilde{\chi}_1^0$ accumulates in the Sun or the Earth and annihilates into high-energy ν 's.

- 1 ABRAMOWSKI 11 place upper limits on the annihilation cross section with $\gamma\gamma$ final
- states. 2 ABDO 10 place upper limits on the annihilation cross section with $\gamma\gamma$ or $\mu^+\mu^-$ final
- 3 ACKERMANN 10 place upper limits on the annihilation cross section with $b\overline{b}$ or $\mu^+\,\mu^-$
- main states. 4 ABBASI 09 is based on data collected during 104.3 effective days with the IceCube 22-string detector. They looked for interactions of ν_{μ} 's from neutralino annihilations in the Sun over a background of atmospheric neutrinos and set 90% CL limits on the muon flux. They also obtain limits on the spin dependent neutralino-proton cross section for neutralino masses in the range 250-5000 GeV.
- ⁵ ACHTERBERG 06 is based on data collected during 421.9 effective days with the AMANDA detector. They looked for interactions of ν_{μ} s from the centre of the Earth over a background of atmospheric neutrinos and set 90 % CL limits on the muon flux. Their limit is compared with the muon flux expected from neutralino annihilations into W^+ W^- and $b\,\overline{b}$ at the centre of the Earth for MSSM parameters compatible with the relic dark matter density, see their Fig. 7.
- 6 ACKERMANN 06 is based on data collected during 143.7 days with the AMANDA-II detector. They looked for interactions of $\nu_{\mu} {\rm s}$ from the Sun over a background of atmospheric neutrinos and set 90 % CL limits on the muon flux. Their limit is compared with the muon flux expected from neutralino annihilations into W^{+} W^{-} in the Sun for SUSY model parameters compatible with the relic dark matter density, see their Fig. 3.
- ⁷ DEBOER 06 interpret an excess of diffuse Galactic gamma rays observed with the EGRET Satellite as originating from π^0 decays from the annihilation of neutralinos into quartiets. They analyze the corresponding parameter space in a supergravity inspired MSSM model with radiative electroweak symmetry breaking, see their Fig. 3 for the preferred region in the $(m_0,\,m_{1/2})$ plane of a scenario with large $\tan\beta$.
- 8 AMBROSIO 99 and DESAI 04 set new neutrino flux limits which can be used to limit the parameter space in supersymmetric models based on neutralino annihilation in the
- Sun and the Earth. Sun and the Earth. Sun and the Earth. The Date of the LSP is a photino and 10 GeV if the LSP is a higgsino based on LSP annihilation in the sun producing high-energy neutrinos and the limits on neutrino fluxes from the IMB detector. MORI 93 excludes some region in M_2 - μ parameter space depending on $\tan\beta$ and lightest scalar Higgs mass for neutrinos from neutrino annihilation in the Sun and the Earth. The Date in the IMO 92 excludes some region M_2 - μ parameter space assuming that the lightest contribution of the IMO 92 excludes some region M_2 - μ parameter space assuming that the lightest in the IMO 92 excludes some region M_2 - μ parameter space assuming that the lightest contribution is the IMO 92 excludes some region M_2 - μ parameter space assuming that the lightest contribution is the IMO 92 excludes some region M_2 - μ parameter space assuming that the lightest space assuming that the lightest space assuming that the lightest space assuming that the lightest space assuming that the lightest space assuming that the lightest space assuming that the lightest space assuming that the lightest space assuming that the lightest space assuming that the lightest space assuming that the lightest space assuming that the lightest space assuming that the lightest space assuming that the lightest space assuming that the lightest space assuming that the lightest space assuming that the lightest space assuming that the lightest space assuming that the lightest space assuming that the lightest space as the lightest space as the lightest space as the lightest space as the lightest space as the lightest space as the lightest space as the lightest space as the lightest space as the lightest space as the lightest space as the lightest space as the lightest space as the lightest space as the lightest space as the lightest space as the lightest space as the lightest space as the lightest space as the lightest space as the lightest space as the lightest space as the lightest space as the lightes
- produced by energetic neutrinos from neutralino annihilation in the sun and the Earth. 18 DOTTINO 92 excludes some region M_{2} - μ parameter space assuming that the lightest neutralino is the dark matter, using upgoing muons at Kamiokande, direct searches by Ge detectors, and by LEP experiments. The analysis includes top radiative corrections on Higgs parameters and employs two different hypotheses for nucleon-Higgs coupling. Effects of rescaling in the local neutralino density according to the neutralino relic abundance are taken into account. 18 BOTTINO 91 excluded a region in M_2 - μ plane using upgoing muon data from Kamioka experiment, assuming that the dark matter surrounding us is composed of neutralinos and that the Higgs boson is not too heavy. 13 GET MIMI 91 exclude a region in M_2 - μ plane using dark matter searches.
- 13 GELMINI 91 exclude a region in $\mathit{M}_2 \mu$ plane using dark matter searches.
- 14 KAMIONKOWSKI 91 excludes a region in the $M_2{\rm -}\mu$ plane using IMB limit on upgoing muons originated by energetic neutrinos from neutralino annihilation in the sun, assuming that the dark matter is composed of neutralinos and that $m_{H_1^0}\lesssim$ 50 GeV. See Fig. 8
- 15 MORI 91B exclude a part of the region in the M_2 - μ plane with $m_{\widetilde{\chi}_1^0}\lesssim 80$ GeV using a limit on upgoing muons originated by energetic neutrinos from neutralino annihilation in the earth, assuming that the dark matter surrounding us is composed of neutralinos and that $m_{H_1^0}\lesssim 80$ GeV.
- 16 OLIVE 88 result assumes that photinos make up the dark matter in the galactic halo. Limit is based on annihilations in the sun and is due to an absence of high energy neutrinos detected in underground experiments. The limit is model dependent.

$\widetilde{\chi}_1^0$ -p elastic cross section

Experimental results on the $\widetilde{\chi}_1^0$ -p elastic cross section are evaluated at $m_{\widetilde{\chi}_1^0}$ =100 GeV. The experimental results on the cross section are often mass dependent. Therefore, the mass and cross section results are also mass dependent. Therefore, the mass and cross section results are also given where the limit is strongest, when appropriate. Results are quoted separately for spin-dependent interactions (based on an effective 4-Fermi Lagrangian of the form $\overline{\chi}\gamma^{\mu}\gamma^{5}\chi\overline{q}\gamma_{\mu}\gamma^{5}q$) and spin-independent interactions ($\overline{\chi}\chi\overline{q}q$). For calculational details see GRIEST 88B, ELLIS 88D, BAR-BIERI 89C, DREES 93B, ARNOWITT 96, BERGSTROM 96, and BAER 97 in addition to the theory papers listed in the Tables. For a description of the theoretical assumptions and experimental techniques underlying most of the listed papers, see the review on "Dark matter" in this "Review of Particle Physics," and references therein. Most of the following papers use galactic halo and nuclear interaction assumptions from (LEWIN 96).

- 1 The strongest limit is 0.05 pb and occurs at $m_\chi=$ 55 GeV.
- 2 Predictions for the spin-dependent elastic cross section based on a frequentist approach to electroweak observables in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry.
- 3 The strongest limit is 0.16 pb and occurs at $m_\chi=24$ GeV. The strongest limit for the scattering on neutrons is 2.6 pb, also at $m_\chi=24$ GeV.
- $^4\,\mathrm{The}$ strongest upper limit is 0.76 pb and occurs at $m_\chi\simeq$ 55 GeV. The strongest limit on the neutron spin-dependent cross section is 0.01 pb, also at $m_\chi \simeq$ 55 GeV (the same limit is achieved for $m_\chi=100~{\rm GeV}).$
- 5 The strongest limit is 0.6 pb and occurs at $m_\chi =$ 30 GeV. The limit for scattering on neutrons is 0.01 pb at $m_\chi =$ 100 GeV, and the strongest limit is 0.0045 pb at $m_\chi =$ 30 GeV.
 6 Limit applies to neutron elastic cross section.
- $^7\,\mathrm{The}$ strongest upper limit is 0.25 pb and occurs at $m_\chi \simeq$ 40 GeV.
- 8 The strongest upper limit is 14 pb and occurs at $m_\chi^2 \simeq 65$ GeV. The limit on the neutron spin-dependent cross section is 0.08 pb at $m_\chi = 100$ GeV and the strongest limit for scattering on neutrons is 0.07 pb at $m_\chi = 65$ GeV.
- $^9\,\mathrm{The}$ limit on the neutron spin-dependent cross section is 6 pb at $m_\chi=100$ GeV.
- 10 The strongest upper limit is 4 pb and occurs at $m_{\widetilde{\chi}} \simeq 60$ GeV. The limit on the neutron spin-dependent elastic cross section is 0.07 pb. This latter limit is improved in AHMED 09, where a limit of 0.02 pb is obtained at $m_\chi=100$ GeV. The strongest limit in AHMED 09 is 0.018 pb and occurs at $m_\chi=60$ GeV.
- 11 The strongest upper limit is 1.2 pb and occurs at $m_\chi~\simeq~$ 40 GeV. The limit on the neutron spin-dependent cross section is 35 pb.
- $^{12}\,\mathrm{The}$ strongest upper limit is 0.35 pb and occurs at $m_\chi~\simeq~60$ GeV.
- 13 The strongest upper limit is 1.2 pb and occurs $m_\chi \, \simeq \,$ 30 GeV.
- $^{14}\,\mathrm{The}$ strongest upper limit is 1.2 pb and occurs $m_\chi^{-}\simeq~$ 40 GeV.
- 15 ELLIS 04 calculates the χp elastic scattering cross section in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry, but without universal scalar masses. In the case of universal squark and slepton masses, but non-universal Higgs masses, the limit becomes 2×10^{-4} , see ELLIS 03E.
- 16 The strongest upper limit is 10 pb and occurs at $m_\chi \simeq$ 30 GeV.
- $^{17}\,\mathrm{The}$ strongest upper limit is 0.75 pb and occurs at $m_\chi\approx$ 70 GeV.
- $^{18}\,\mathrm{The}$ strongest upper limit is 30 pb and occurs at $m_\chi^{}\approx~20$ GeV.
- $^{19}\,\mathrm{The}$ strongest upper limit is 8 pb and occurs at $m_\chi \simeq$ 30 GeV.
- 20 ELLIS 01c calculates the $\chi\text{-}p$ elastic scattering cross section in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry. In models with nonuniversal Higgs masses, the upper limit to the cross section is 6×10^{-4} .
- 21 The strongest upper limit is 3 pb and occurs at $m_\chi \simeq$ 60 GeV. The limits are for inelastic
- scattering $X^0 + {}^{129}Xe \rightarrow X^0 + {}^{129}Xe^* (39.58 \text{ keV}).$ $^{22}{\rm The\ strongest\ upper\ limit\ is\ 9\ pb\ and\ occurs\ at\ } m_\chi \simeq 30\ {\rm GeV}.$
- $^{23}\,\mathrm{The}$ strongest upper limit is 4.4 pb and occurs at $m_\chi\simeq$ 60 GeV.
- 24 The strongest upper limit is about 35 pb and occurs at $m_{_Y} \simeq 15$ GeV.

- 1 AHMED 11A gives combined results from CDMS and EDELWEISS. The strongest limit is at $m_\chi=90$ GeV.
- 2 APRILE 11 updates the result of APRILE 10. The strongest upper limit is 2.4 \times 10 $^{-8}$ pb and occurs at $m_\chi~\simeq~50$ GeV. Superseded by APRILE 11B.
- 3 APRILE 11B updates the result of APRILE 10 and APRILE 11. The strongest upper limit is 7 imes 10 $\dot{-}$ 9 pb and occurs at $m_\chi~\simeq~$ 50 GeV.
- $^4\,\mathrm{ARMENGAUD}\,11$ updates result of ARMENGAUD 10. Strongest limit at $m_\chi=$ 85 GeV.
- ⁵ Predictions for the spin-independent elastic cross section based on a frequentist approach to electroweak observables in the framework of $\mathit{N}=1$ supergravity models with radiative
- breaking of the electroweak gauge symmetry.

 6 Predictions for the spin-independent elastic cross section based on a frequentist approach to electroweak observables in the framework of ${\it N}=1$ supergravity models with radiative breaking of the electroweak gauge symmetry.
- ⁷ The strongest upper limit is $< 3.8 \times 10^{-8}$ pb and occurs at $m_{\chi} \simeq 70$ GeV. AHMED 10 updates the results of AHMED 09.
- 8 The strongest upper limit is $< 3.4 \times 10^{-8}$ pb and occurs at $m_V \simeq 55$ GeV. Superseded
- $^9\,\mathrm{The\ strongest\ limit\ is\ at\ }m_\chi=$ 80 GeV. Superseded ARMENGAUD 11.
- $^{10}\,\text{Uses}$ relic density and various collider experiments to set limits on neutralino-nucleon cross section in MSSM models with gaugino mass unification.
- 11 AHMED 09 updates the results of AKERIB 06A. The strongest limit is 4.6 \times 10 $^{-8}$ pb and occurs at $m_\chi=$ 60 GeV. Superseded by AHMED 10.
- 12 The strongest upper limit is 4.8×10^{-7} pb and occurs at $m_\chi = 50$ GeV.
- $^{13}\,\mathrm{BUCHMUELLER}$ 09 makes predictions for the spin-independent elastic cross section based on a frequentist approach to electroweak observables in the framework of N=1supergravity models with radiative breaking of the electroweak gauge symmetry. 14 The strongest upper limit is 8.1×10^{-8} pb and occurs at $m_\chi=60$ GeV.
- ¹⁵ The strongest upper limit is 5.1×10^{-8} pb and occurs at m_{χ} quoted here are based on the analysis performed in ANGLE $\overset{X}{08}$ with the update from SORENSEN 09.
- 16 The strongest upper limit is 6.6×10^{-7} pb and occurs at $m_\chi \simeq 65$ GeV
- $^{17}{\rm The~strongest}$ upper limit is $19\times 10^{-7}~{\rm pb}$ and occurs at $\overset{\cdot \cdot \cdot }{m_\chi} \simeq$ 65 GeV. Supersedes
- LEE 06. $$^{18}\rm{AKERIB}$ 06. Updates the results of AKERIB 05. The strongest upper limit is 1.6 \times $10^{-7}~{\rm pb}$ and occurs at $m_{\chi}~\approx~60~{\rm GeV}$
- $^{
 m 19}$ Predictions for the spin-independent elastic cross section based on a Bayesian approach to electroweak observables in the framework of $\mathit{N}=1$ supergravity models with radiative breaking of the electroweak gauge symmetry. We also show that the strongest upper limit is 8×10^{-6} pb and occurs at $m_\chi\simeq 70$ GeV.
- $^{21}\,\mathrm{A\,KERIB}$ 05 is incompatible with the DAMA most likely value. The strongest upper limit is 4 \times 10 ⁻⁷ pb and occurs at $m_\chi \simeq$ 60 GeV.
- ²²The strongest upper limit is also close to 1.0×10^{-6} pb and occurs at $m_V \simeq 70$ GeV. BENOIT 06 claim that the discrimination power of ZEPLIN-I measurement (ALNER 05A) is not reliable enough to obtain a limit better than $1\times10^{-3}~\text{pb.}$ However, SMITH 06 do not agree with the criticisms of BENOIT 06.
- ²³ The strongest upper limit is also close to 1.4 imes 10⁻⁶ pb and occurs at $m_{\chi} \simeq$ 70 GeV.

- 24 AKERIB 04 is incompatible with BERNABEI 00 most likely value, under the assumption of standard WIMP-halo interactions. The strongest upper limit is 4×10^{-7} pb and occurs at $m_\chi \simeq 60~{\rm GeV}$
- 25 Predictions for the spin-independent elastic cross section in the framework of $N\,=\,1$ supergravity models with radiative breaking of the electroweak gauge symmetry.
- 26 KIM 02 and ELLIS 04 calculate the χp elastic scattering cross section in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry,
- of N=1 Supergravity modes with radiative breaking of the electroscal gasgo symmetry, but without universal scalar masses. 27 in the case of universal squark and slepton masses, but non-universal Higgs masses, the limit becomes 2×10^{-6} (2×10^{-11} when constraint from the BNL g-2 experiment are included), see ELLIS 03z. ELLIS 05 display the sensitivity of the elastic scattering cross ction to the $\pi ext{-Nucleon } \Sigma$ term.
- 28 PIERCE 04A calculates the χp elastic scattering cross section in the framework of models with very heavy scalar masses. See Fig. 2 of the paper. 29 The strongest upper limit is 1.8×10^{-5} pb and occurs at $m_\chi \approx 80$ GeV.
- 30 Under the assumption of standard WIMP-halo interactions, Akerib 03 is incompatible with BERNABEI 00 most likely value at the 99.98% CL. See Fig. 4.
- 31 BAER 03A calculates the χp elastic scattering cross section in several models including the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry. 32 The strongest upper limit is 7 \times 10 $^{-6}$ pb and occurs at $m_\chi \simeq$ 30 GeV.
- 33 ABRAMS 02 is incompatible with the DAMA most likely value at the 99.9% CL. The strongest upper limit is 3×10^{-6} pb and occurs at $m_\chi\simeq 30$ GeV.
- 34 BENOIT 02 excludes the central result of DAMA at the 99.8%CL. 35 The strongest upper limit is 2×10^{-5} pb and occurs at $m_\chi\simeq40$ GeV.
- 36 The strongest upper limit is 7 \times 10 $^{-6}$ pb and occurs at $m_\chi^{\chi} \simeq$ 46 GeV.
- $^{37}\,\mathrm{The}$ strongest upper limit is 1.8×10^{-5} pb and occurs at $\overset{\frown}{m}_{\chi}\simeq32~\mathrm{GeV}$
- 38 BOTTINO 01 calculates the χ-p elastic scattering cross section in the framework of the following supersymmetric models: N=1 supergravity with the radiative breaking of the electroweak gauge symmetry, N=1 supergravity with nonuniversal scalar masses and an effective MSSM model at the electroweak scale.
- 39 Calculates the x-p elastic scattering cross section in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry.
- 40 ELLIS 01c calculates the χ -p elastic scattering cross section in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry. ELLIS 02B find a range 2×10^{-8} – 1.5×10^{-7} at $\tan \beta$ =50. In models with nonuniversal Higgs masses, the upper limit to the cross section is $4\times 10^{-7}\,$
- 41 ACCOMANDO 00 calculate the x-p elastic scattering cross section in the framework of minimal N=1 supergravity models with radiative breaking of the electroweak gauge symmetry. The limit is relaxed by at least an order of magnitude when models nonuniversal scalar masses are considered. A subset of the authors in ARNOWITT 02 updated the limit to $<9\times10^{-8}~(\tan\beta~<55)$.
- 42 BERNABEI 00 search for annual modulation of the WIMP signal. The data favor the hypothesis of annual modulation at 4σ and are consistent, for a particular model framework quoted there, with $m_{\chi 0} = 44 \frac{-12}{19}$ GeV and a spin-independent X^0 -proton cross section of $(5.4 \pm 1.0) \times 10^{-6}$ pb. See also BERNABEI 01 and BERNABEI 00c.
- 43 FENG 00 calculate the χ -p elastic scattering cross section in the framework of $N\!=\!1$ supergravity models with radiative breaking of the electroweak gauge symmetry with a particular emphasis on focus point models. At $\tan\beta$ =50, the range is 8×10^{-8} – 4×10^{-7} .
- 44 BERNABEI 99 search for annual modulation of the WIMP signal. The data favor the hypothesis of annual modulation at 99.6%CL and are consistent, for the particular model framework considered there, with $m_{\chi^0} = 59 ^{+17}_{-14}$ GeV and spin-independent χ^0 -proton cross section of $(7.0^{+0.4}_{-1.2}) \times 10^{-6}$ pb $(1~\sigma$ errors).
- 45 BERNABEI 98 search for annual modulation of the WIMP signal. The data are consistent, for the particular model framework considered there, with m_{χ^0} =59 $^{+36}_{-19}$ GeV and spin-independent X^0 -proton cross section of $(1.0^{+0.1}_{-0.4}) \times 10^{-5}$ pb $(1 \sigma \text{ errors})$.

– Other bounds on $\widetilde{\chi}^0_1$ from astrophysics and cosmology –

Most of these papers generally exclude regions in the \textit{M}_2 – μ parameter plane by requiring that the $\widetilde{\chi}_1^0$ contribution to the overall cosmological density is less than some maximal value to avoid overclosure of the Universe. Those not based on the cosmological density are indicated. Many of these papers also include LEP and/or other bounds.

 1 ELLIS 00 updates ELLIS 98. Uses LEP $e^+\,e^-$ data at $\sqrt{s}{=}202$ and 204 GeV to improve bound on neutralino mass to 51 GeV when scalar mass universality is assumed and 46 GeV when Higgs mass universality is relaxed. Limits on $\tan \beta$ improve to > 2.7 $(\mu > 0), >$ 2.2 $(\mu < 0)$ when scalar mass universality is assumed and > 1.9 (both signs of μ) when Higgs mass universality is relaxed.

 2 AKULA 11a places constraints on the SUSY parameter space in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry using results from 35 pb $^{-1}$ of LHC data.

 3 ALLANACH 11A updates the results of ALLANACH 11 and places constraints on the SUSY parameter space in the framework of ${\it N}=1$ supergravity models with radiative breaking of the electroweak gauge symmetry using results from 35 ${\rm pb}^{-1}$ of LHC data.

⁴ BUCH MUELLER 11 places constraints on the SUSY parameter space in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry using indirect experimental searches and including supersymmetry breaking relations between A and B parameters.

 5 BUCH MUELLER 11a places constraints on the SUSY parameter space in the framework of ${\it N}=1$ supergravity models with radiative breaking of the electroweak gauge symmetry using indirect experimental searches and results from 35 ${
m pb}^{-1}$ of LHC data. Superseded by BUCHMUELLER 11B.

⁶ BUCHMUELLER 11B places constraints on the SUSY parameter space in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry using results from 35 pb $^{-1}$ of LHC data and from XENON100 data as well as indirect experimental searches. See also BUCHMUELLER 11A.

 7 FARINA 11 places constraints on the SUSY parameter space in the framework of N = 1 supergravity models with radiative breaking of the electroweak gauge symmetry using results from 1.1 fb $^{-1}$ of LHC data and from XENON100 data as well as indirect experimental searches.

 $^8\,{\sf PROFUMO}\,\,11$ places constraints on the SUSY parameter space in the framework of N $=\!1$ supergravity models with radiative breaking of the electroweak gauge symmetry using results from 35 pb $^{-1}$ of LHC data and from XENON100.

Places constraints on the SUSY parameter space in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry but non-Universal

- 18 BECHTLE 10 places constraints on the SUSY parameter space in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry.
- 11 ELLIS 10 places constraints on the SUSY parameter space in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry with universality above the GUT scale.
- 12 BUCHMUELLER 09 places constraints on the SUSY parameter space in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry using indirect experimental searches.

Supersymmetric Particle Searches

- $^{13}\,\text{DREINER}$ 09 show that in the general MSSM with non-universal gaugino masses there exists no model-independent laboratory bound on the mass of the lightest neutralino. An essentially massless χ_1^0 is allowed by the experimental and observational data, imposing some constraints on other MSSM parameters, including M_{2} , μ and the slepton and
- 14 BUCHMUELLER 08 places constraints on the SUSY parameter space in the framework of $\mathit{N}=1$ supergravity models with radiative breaking of the electroweak gauge symmetry using indirect experimental searches.
- 15 CALIBBI 07 places constraints on the SUSY parameter space in the framework of $\emph{N}=$ 1 supergravity models with radiative breaking of the electroweak gauge symmetry with universality above the GUT scale including the effects of right-handed neutrinos.
- 16 ELLIS 07 places constraints on the SUSY parameter space in the framework of N = $1\ {\rm supergravity}\ {\rm models}\ {\rm with}\ {\rm radiative}\ {\rm breaking}\ {\rm of}\ {\rm the}\ {\rm electroweak}\ {\rm gauge}\ {\rm symmetry}\ {\rm with}\ {\rm universality}\ {\rm below}\ {\rm the}\ {\rm GUT}\ {\rm scale}.$
- $^{17}\mathrm{ALLA\,NA\,CH}$ 06 places constraints on the SUSY parameter space in the framework of N =1 supergravity models with radiative breaking of the electroweak gauge symmetry. 18 DE-AUSTRI 06 places constraints on the SUSY parameter space in the framework of N
- : 1 supergravity models with radiative breaking of the electroweak gauge symmetry.
- $\frac{19}{8} \text{ALTZ O4 places constraints on the SUSY parameter space in the framework of } N=1$ supergravity models with radiative breaking of the electroweak gauge symmetry.
- 20 HOOPER 03, BOTTINO 03 (see also BOTTINO 03A and BOTTINO 04) , and BE-LANGER 04 do not assume gaugino or scalar mass unification.
- 21 Limit assumes a pseudo scalar mass < 200 GeV. For larger pseudo scalar masses, m_χ >18(29) GeV for an eta = 50(10). Bounds from WMAP, $(g-2)_{\mu}$, $b
 ightarrow s \gamma$, LEP.
- ²² ELLIS 04B places constraints on the SUSY parameter space in the framework of N=1 supergravity models with radiative breaking of the electroweak gauge symmetry including supersymmetry breaking relations between A and B parameters. See also ELLIS 03D.
- 23 PIERCE 04A places constraints on the SUSY parameter space in the framework of models with very heavy scalar masses
- 24 BAER 03, CHATTOPADHYAY 03, ELLIS 03c and LAHANAS 03 place constraints on the SUSY parameter space in the framework of $N\!=\!1$ supergravity models with radiative breaking of the electroweak gauge symmetry based on WMAP results for the cold dark
- $^{25}\, {\sf BOEHM}$ 00B and ELLIS 03 place constraints on the SUSY parameter space in the Framework of minimal M=1 supergravity models with radiative breaking of the electroweak gauge symmetry. Includes the effect of χ - $\bar{\chi}$ co-annihilations. ²⁶ DJOUADI 01, ROSZKOWSKI 01, and BAER 02 place constraints on the SUSY parame-
- ter space in the framework of minimal N=1 supergravity models with radiative breaking of the electroweak gauge symmetry.
- ²⁷ELLIS 02 places constraints on the soft supersymmetry breaking masses in the framework of minimal N=1 supergravity models with radiative breaking of the electroweak gauge symmetry.
- ²⁸LAHA NAS 02 places constraints on the SUSY parameter space in the framework of minimal N=1 supergravity models with radiative breaking of the electroweak gauge symmetry. Focuses on the role of pseudo-scalar Higgs exchange.
- ²⁹BARGER 01c use the cosmic relic density inferred from recent CMB measurements to constrain the parameter space in the framework of minimal $N\!=\!1$ supergravity models with radiative breaking of the electroweak gauge symmetry.
- 30 ELLIS OIB places constraints on the SUSY parameter space in the framework of minimal N=1 supergravity models with radiative breaking of the electroweak gauge symmetry. Focuses on models with large $tan \beta$.
- $^{31}\,\mathsf{FENG}$ 00 explores cosmologically allowed regions of MSSM parameter space with multi-
- $^{
 m 32}$ LAHANAS 00 use the new cosmological data which favor a cosmological constant and its implications on the relic density to constrain the parameter space in the framework of minimal N=1 supergravity models with radiative breaking of the electroweak gauge
- 33 ELLIS 98B assumes a universal scalar mass and radiative supersymmetry breaking with universal gaugino masses. The upper limit to the LSP mass is increased due to the inclusion of $\chi \bar{\tau}_R$ coannihilations.
- ³⁴EDSJO 97 included all coannihilation processes between neutralinos and charginos for any neutralino mass and composition.
- 35 Notes the location of the neutralino Z resonance and h resonance annihilation corridors in minimal supergravity models with radiative electroweak breaking. 36 Mass of the bino (=LSP) is limited to $m_{\widetilde{B}} \lesssim 350$ GeV for $m_t = 174$ GeV.
- $^{
 m 37}$ DREES 93, KELLEY 93 compute the cosmic relic density of the LSP in the framework of minimal N=1 supergravity models with radiative breaking of the electroweak gauge
- 38 FALK 93 relax the upper limit to the LSP mass by considering sfermion mixing in the
- ³⁹ MIZUTA 93 include coannihilations to compute the relic density of Higgsino dark matter.
- 40 LOPEZ 92 calculate the relic LSP density in a minimal SUSY GUT model.
- 41 MCDONALD 92 calculate the relic LSP density in the MSSM including exact tree-level annihilation cross sections for all two-body final states.
- $^{
 m 42}$ GRIEST 91 improve relic density calculations to account for coannihilations, pole effects, and threshold effects.

 43 NOJIRI 91 uses minimal supergravity mass relations between squarks and sleptons to
- 44 Mass of the bino (=LSP) is limited to $m_{\widetilde{H}} \lesssim 350$ GeV for $m_t \leq 200$ GeV. Mass of the higgsino (=LSP) is limited to $m_{\widetilde{H}} \lesssim 1$ TeV for $m_t \leq 200$ GeV.
- 45 ROSZKOWSKI 91 calculates LSP relic density in mixed gaugino/higgsino region. 46 Mass of the bino (=LSP) is limited to $m_{\widetilde{B}}\lesssim 550$ GeV. Mass of the higgsino (=LSP) is limited to $m_{\widetilde{H}} \lesssim$ 3.2 TeV.
- 47 KRAUSS 83 finds $m_{\widetilde{\gamma}}$ not 30 eV to 2.5 GeV. KRAUSS 83 takes into account the gravitino decay. Find that $\lim_{N\to\infty}^{N}$ its depend strongly on reheated temperature. For example a new allowed region $m_{\widetilde{\gamma}}=$ 4–20 MeV exists if $m_{\rm gravitino}$ <40 TeV. See figure 2.

Unstable $\widetilde{\chi}_1^0$ (Lightest Neutralino) MASS LIMIT -

Unless otherwise stated, results in this section assume spectra and production rates as evaluated in the MSSM. Unless otherwise stated, the goldstino or gravitino mass $m_{\widetilde{G}}$ is assumed to be negligible relative to all other masses. In the following, \widetilde{G} is assumed to be undetected and to give rise to a missing energy (₺) signature.

 1 CHATRCHYAN 11B looked in 35 pb $^{-1}$ of pp collisions at \sqrt{s} =7 TeV for events with an isolated lepton (e or μ), a photon and \mathcal{E}_T which may arise in a generalized gauge mediated model from the decay of Wino-like NLSPs. No evidence for an excess over the expected background is observed. Limits are derived in the plane of squark/gluino mass versus Wino mass (see Fig. 4). Mass degeneracy of the produced squarks and gluinos is

 2 AALTONEN 10 searched in 2.6 fb $^{-1}$ of $p \overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for diphoton events with large $ot\!\!E_T$. They may originate from the production of $\widetilde{\chi}^\pm$ in pairs or as-is derived on the $\tilde{\chi}_1^0$ mass of 149 GeV for $\tau_{\tilde{\chi}_1^0}\ll 1$ ns, which improves the results of

 3 ABAZOV 10P looked in 6.3 fb $^{-1}$ of $p\,\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for events with $ilde{\chi}^0_1$ mass range is obtained.

 4 AALTONEN 08u searched in 570 pb $^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for events that contain a time-delayed photon, at least one jet, and large \rlap/E_T . The time-of-arrival is measured for each electromagnetic tower with a resolution of 0.50 ns. The number of observed events in the signal region is consistent with the background estimation. An upper limit on the cross section is derived as a function of the $\widetilde{\chi}^0_1$ mass and lifetime, shown in their Fig. 24. The comparison with the NLO cross section for GMSB yields an exclusion of the $\widetilde{\chi}_1^0$ mass as a function of its lifetime, see Fig. 25. See ABULENCIA 07P

for a previous analysis of the same data set. 5 ABAZOV 08F looked in 1.1 fb $^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for diphoton events with large \wp_T . They may originate from the production of χ^+ in pairs or associated to a $\tilde{\chi}^0_2$, decaying to a $\tilde{\chi}^0_1$ which itself decays promptly in GMSB to $\tilde{\chi}^0_1 \to \gamma \tilde{G}$. No significant excess was found compared to the background expectation. A limit is derived on the masses of SUSY particles in the GMSB framework for $M=2\Lambda$, N=1, $\tan\beta=15$ and $\mu>0$, see Figure 2. It also excludes $\Lambda<91.5$ TeV. Supersedes the results of ABAZOV 05A. Superseded by ABAZOV 10P.

6 ABAZOV 08X searched in 1.1 fb⁻¹ of $p\bar{p}$ collisions at $\sqrt{s}=1.96$ TeV for an excess of events with electron pairs. Their vertex, reconstructed from the directions measured in the segmented electromagnetic calorimeter, is required to be away from the primary interaction point. Such delayed decays might be expected for a Higgsign like $\tilde{\chi}^0$ in

interaction point. Such delayed decays might be expected for a Higgsino-like $\widetilde{\chi}^0_1$ in

Searches Particle Listings Supersymmetric Particle Searches

GMSB. No significant excess was found compared to the background expectation. Upper limits on the cross-section times branching ratio are extracted as a function of the lifetime for several ranges of dielectron invariant masses, see their Fig. 3.

 7 ABULENCIA 07H searched in 346 pb $^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for events with at least three leptons (e or μ) from the decay of $\overline{\chi}_1^0$ via $LL\overline{E}$ couplings. The results are consistent with the hypothesis of no signal. Upper limits on the cross-section are extracted and a limit is derived in the framework of mSUGRA on the masses of $\widetilde{\chi}^0_1$ and

 $\widetilde{\chi}_1^\pm$, see e.g. their Fig. 3 and Tab. II.

 χ_1 , see e.g. their rig. 5 and 1ab. II.

8 ABAZOV 06D looked in 360 pb⁻¹ of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for events with three leptons originating from the pair production of charginos and neutralinos, followed by R decays mediated by $LL\overline{E}$ couplings. One coupling is assumed to be dominant at a time. No significant excess was found compared to the background expectation in the $ee\ell$, $\mu\mu\ell$ nor $ee\tau$ ($\ell=e$, μ) final states. Upper limits on the cross-section are extracted in a specific MSUGRA model and a MSSM model without unification of M_1 and M_2 at the GUT scale. A limit is derived on the masses of charginos and neutralinos for both scenarios assuming λ_{ijk} couplings such that the decay length is less than 1 cm, see their

PABAZOV 06P looked in 380 pb $^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for events with at least 2 opposite sign isolated muons which might arise from the decays of neutralinos into $\mu\mu\nu$ via R couplings $LL\overline{E}$. No events are observed in the decay region defined by a radius between 5 and 20 cm, in agreement with the SM expectation. Limits are set on the cross-section times branching ratio as a function of lifetime, shown in their Fig. 2. This limit availables the SLISV interpretation of the NuTeV excess of dimuon events 3. This limit excludes the SUSY interpretation of the NuTeV excess of dimuon events

reported in ADAMS 01.

 10 ABBIENDI 06B use 600 pb $^{-1}$ of data from \sqrt{s} = 189–209 GeV. They look for events with diphotons + E final states originating from prompt decays of pair-produced neutralinos in a GMSB scenario with $\tilde{\chi}_1^0$ NLSP. Limits on the cross-section are computed as a function of m($\widetilde{\chi}^0_1$), see their Fig. 14. The limit on the $\widetilde{\chi}^0_1$ mass is for a pure Bino state assuming

a prompt decay, with lifetimes up to 10^{-9} s. Supersedes the results of ABBIENDI 04N. ¹¹ ABDALLAH 05B use data from $\sqrt{s} = 180-209$ GeV. They look for events with single photons + E final states. Limits are computed in the plane $(m(\widetilde{G})$, $m(\widetilde{\chi}_1^0))$, shown in their Fig. 9b for a pure Bino state in the GMSB framework and in Fig. 9c for a no-scale

supergravity model. Supersedes the results of ABREU 00z.

12 ABDALLAH 05B use data from $\sqrt{s}=130-209$ GeV. They look for events with diphotons + \$\mathbb{E}\$ final states and single photons not pointing to the vertex, expected in GMSB when the $\widetilde{\chi}^0_1$ is the NLSP. Limits are computed in the plane (m(\widetilde{G}), m($\widetilde{\chi}^0_1$)), see their Fig. 10. The lower limit is derived on the $\widetilde{\chi}_1^0$ mass for a pure Bino state assuming a prompt decay and $m_{\widetilde{e}_R} = m_{\widetilde{e}_L} = 2 \ m_{\widetilde{\chi}_1^0}$. It improves to 100 GeV for $m_{\widetilde{e}_R} = m_{\widetilde{e}_L} = 1.1 \ m_{\widetilde{\chi}_1^0}$. and

- the limit in the plane $(m(\widetilde{\chi}^0_1), m(\overline{e}_R))$ is shown in Fig. 10b. For long-lived neutralinos, cross-section limits are displayed in their Fig 11. Supersedes the results of ABREU 00z. ¹³ ACOSTA 05E looked in 202 pb⁻¹ of $\rho\overline{p}$ collisions at \sqrt{s} =1.96 TeV for diphoton events with large $ot\!\!\!E_T$. They may originate from the production of $\widetilde{\chi}^\pm$ in pairs or associated to a $\widetilde{\chi}_2^0$, decaying to a $\widetilde{\chi}_1^0$ which itself decays promptly in GMSB to $\gamma\,\widetilde{G}$. No events are as A_2 , according to a A_1 minor local according promptly in GMSB to γ 0. No events after the selected at large E_T compared to the background expectation. A limit is derived on the masses of SUSY particles in the GMSB framework for M=2 Λ , N=1, $\tan\beta=15$ and $\mu>0$, see Figure 2. It also excludes $\Lambda<69$ TeV. Supersedes the results of ABE 99. They look for E0 results of E1 and E2 of E3. They look for E3 resonant E3 production via E3 channel exchange of a E4, followed by
- prompt GMSB decay of the $\widetilde{\chi}_1^0$ to $\gamma \widetilde{G}$. Upper limits at 95% on the cross section are derived, see their Figure 4, and compared to two example scenarios. In Figure 5, they display 95% exclusion limits in the plane of $M(\widetilde{\chi}^0_1)$ versus $M(\widetilde{e}_L) - M(\widetilde{\chi}^0_1)$ for the two

scenarios and several values of the λ' Yukawa coupling. ¹⁵ ABBIENDI 04N use data from $\sqrt{s}=189$ –209 GeV, setting limits on $\sigma(e^+e^-\to 189$

 $XX) \times B^2(X \to Y \gamma)$, with Y invisible (see their Fig. 4). Limits on $\widetilde{\chi}_1^0$ masses for a specific model are given. Supersedes the results of ABBIENDI, G 00D. 16 ABDALLAH 04H use data from LEP 1 and $\sqrt{s} = 192-208$ GeV. They re-use results or re-analyze the data from ABDALLAH 03M to put limits on the parameter space of anomaly-mediated supersymmetry breaking (AMSB), which is scanned in the region $1 < m_3/2$ <50 TeV, $0 < m_0 < 1000$ GeV, $1.5 < \tan \beta < 35$, both signs of μ . The constraints are obtained from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the coupled from the cou are obtained from the searches for mass degenerate chargino and neutralino, for SM-like and invisible Higgs, for leptonically decaying charginos and from the limit on non-SM Z width of 3.2 MeV. The limit is for $m_t=174.3$ GeV (see Table 2 for other m_t values).

17 The limit improves to 73 GeV for $m_{\tilde{t}}=174.5$ GeV (see Table 2101 other $m_{\tilde{t}}$ values).
18 ABDALLAH 04M use data from $\sqrt{s}=192-208$ GeV to derive limits on sparticle masses under the assumption of R with $LL\overline{E}$ or \overline{UDD} couplings. The results are valid in the ranges $90 < m_0 < 500$ GeV, $0.7 < \tan \beta < 30$, $-200 < \mu < 200$ GeV, $0 < M_2 < 400$ GeV. Supersedes the result of ABREU 01D and ABREU 00U.

¹⁹ The limit improves to 39.5 GeV for $LL\overline{E}$ couplings.

- 20 ACHARD 04E use data from $\sqrt{s}=189$ – 209 GeV. They look for events with single their Fig. 8c for a no-scale supergravity model, excluding, e.g., Gravitino masses below
- 10^{-5} eV for neutralino masses below 172 GeV. Supersedes the results of ACCIARRI 99R. 21 ACHARD 04E use data from $\sqrt{s}=189$ –209 GeV. They look for events with diphotons The limit on the $\widetilde{\chi}^0_1$ mass is for a pure Bino state assuming a prompt decay, with $m_{\widetilde{e}_l}$ = 1.1 $m_{\widetilde{\chi}_1^0}$ and $m_{\widetilde{e}_R}^{-}=$ 2.5 $m_{\widetilde{\chi}_1^0}.$ Supersedes the results of ACCIARRI 99R.
- ²²ABDALIAH 03D use data from $\sqrt{s}=161$ –208 GeV. They look for 4-tau + \cancel{E} final states, expected in GMSB when the $\widehat{\tau}_1$ is the NLSP, and 4-lepton + \cancel{E} final states, expected in the co-NLSP scenario, and assuming a short-lived $\tilde{\chi}_1^0$ (m(\tilde{G})<1 eV). Limits are computed in the plane $(m(\widetilde{\tau}_1), m(\widetilde{\chi}_1^0))$ from a scan of the GMSB parameters space, after combining these results with the search for slepton production from the same paper to cover prompt decays and for the case of $\widetilde{\chi}_1^0$ NLSP from ABREU 00z. The limit Stronger limits are obtained when more messenger generations are assumed or when the $\widetilde{\tau}_1$ is the NLSP. Stronger limits are obtained when more messenger generations are assumed or when the other sleptons are co-NLSP, see their Fig. 10. Supersedes the results of ABREU 01G.
 23 HEISTER 03C use the data from $\sqrt{s}=189$ -209 GeV to search for $\gamma\not\!\!E_T$ final states with non-pointing photons and $\gamma\gamma\not\!\!E_T$ events. Interpreted in the framework of Minimal

GMSB, a lower bound on the $\widetilde{\chi}^0_1$ mass is obtained as function of its lifetime. For a laboratory lifetime of less than 3 ns, the limit at 95% CL is 98.8 GeV. For other lifetimes, see their Fig. 5. These results are interpreted in a more general GMSB framework in HEISTER 02R.

24 HEISTER 03C use the data from $\sqrt{s}=$ 189–209 GeV to search for $\gamma \not\!\! E_T$ final states. They obtained an upper bound on the cross section for the process $e^+ \, e^-
ightarrow \, \widetilde{G} \, \widetilde{\chi}^0_1$, followed by the prompt decay $\widetilde{\chi}^0_1 \to \gamma \, \widetilde{\mathcal{G}}$, shown in their Fig. 4. These results supersede

BARATE 98H.

- BARATE 98H.
 25 ACHARD 02 searches for the production of sparticles in the case of R prompt decays with $LL\bar{E}$ or $UD\bar{D}$ couplings at \sqrt{s} =189-208 GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The MSUGRA limit results from a scan over the MSSM parameter space with the assumption of gaugino and scalar mass unification at the GUT scale, imposing simultaneously the exclusions from neutralino, chargino, sleptons, and squarks analyses. The limit holds for $UD\bar{D}$ couplings and increases to 40.2 GeV for $LL\bar{E}$ couplings. For L3 limits from $LQ\bar{D}$ couplings, see ACCLARRI 01. ACCIARRI 01.
- 26 HEISTER 02R search for signals of GMSB in the 189–209 GeV data. For the $\widetilde{\chi}_1^0$ NLSP interaction vertex. For the $\widetilde{\ell}$ NLSP case, the topologies consist of $\ell\ell E\!\!\!\!/$ or $4\ell E\!\!\!\!/$ (from $\widetilde{\chi}_1^0\widetilde{\chi}_1^0)$ production), including leptons with large impact parameters, kinks, or stable particles. Limits are derived from a scan over the GMSB parameters (see their Table 5 for the ranges). The limits are valid whichever is the NLSP. The absolute mass bound on the $\tilde{\chi}_1^0$ for any lifetime includes indirect limits from the chargino search, and from the slepton search HEISTER 02E preformed within the MSUGRA framework. A bound for any NLSP and any lifetime of 77 GeV has also been derived by using the constraints from the neutral Higgs search in HEISTER 02. Limits on the universal SUSY mass scale

in the plane $(m_{\widetilde{\chi}_1^0}, m_{\widetilde{\tau}_1})$, see Fig. 6, allowing either the $\widetilde{\chi}_1^0$ or a $\widetilde{\ell}_1$ to be the NLSP. Two scenarios are considered: $\tan\beta = 2$ with the 3 sleptons degenerate in mass and $\tan\beta = 20$ where the $\widetilde{ au}_1$ is lighter than the other sleptons. Data taken at $\sqrt{s}{=}189$ GeV.

28 ACCIARRI 01 searches for multi-lepton and/or multi-jet final states from R prompt decays with $LL\overline{E}$, $LQ\overline{D}$, or \overline{UDD} couplings at \sqrt{s} =189 GeV. The search is performed for direct and indirect decays of neutralinos, charginos, and scalar leptons, with the $\widetilde{\chi}_1^0$ or a $\widetilde{\ell}$ as LSP and assuming one coupling to be nonzero at a time. Mass limits are derived using simultaneously the constraints from the neutralino, chargino, and slepton analyses; and the Z0 width measurements from ACCIARRI 00C in a scan of the parameter space assuming MSUGRA with gaugino and scalar mass universality. Updates and supersedes

the results from ACCIARRI 99.

29 ADAMS 01 looked for neutral particles with mass > 2.2 GeV, produced by 900 GeV ADAMS of lowest of neutral particles with mass 2.2 dev, produced by 900 dev protons incident on a Beryllium oxide target and decaying through weak interactions into $\mu\mu$, μe , or $\mu\pi$ final states in the decay channel of the NuTeV detector (E815) at Fermilab. The number of observed events is $3 \mu\mu$, $0 \mu e$, and $0 \mu\pi$ with an expected background of 0.069 ± 0.010 , 0.13 ± 0.02 , and 0.14 ± 0.02 , respectively. The $\mu\mu$ events are consistent with the R decay of a neutralino with mass around 5 GeV. However, they share several aspects with ν -interaction backgrounds. An upper limit on the differential production for the control of the decay hearth production cross section of neutralinos in pp interactions as function of the decay length

s given in Fig. 3.

30 ABBIENDI 99T searches for the production of neutralinos in the case of R-parity violation with $LL\overline{F}$, $LQ\overline{D}$, or \overline{UDD} couplings using data from \sqrt{s} =183 GeV. They investigate topologies with multiple leptons, jets plus leptons, or multiple jets, assuming one coupling at the time to be non-zero and giving rise to direct or indirect decays. Mixed decays (where one particle has a direct, the other an indirect decay) are also considered for the \overline{UDD} couplings. Upper limits on the cross section are derived which, combined with the constraint from the Z^0 width, allow to exclude regions in the M_2 versus μ plane for

any coupling. Limits on the neutralino mass are obtained for non-zero $LL\overline{E}$ couplings $>10^{-5}$. The limit disappears for $\tan\beta<1.2$ and it improves to 50 GeV for $\tan\beta>20$. ³¹ BARATE 99E looked for the decay of gauginos via R-violating couplings $LQ\overline{D}$. The bound is significantly reduced for smaller values of m_0 . Data collected at \sqrt{s} =130-172

32 ABREU 98 uses data at \sqrt{s} =161 and 172 GeV. Upper bounds on $\gamma\gamma E$ cross section are obtained. Similar limits on γE are also given, relevant for $e^+ \, e^- \to \, \widetilde{\chi}_1^0 \, \widetilde{G}$ production.

33 BARATE 98s looked for the decay of gauginos via R-violating coupling LLE. The bound improves to 25 GeV if the chargino decays into neutralino which further decays into lepton pairs. Data collected at \sqrt{s} =130-172 GeV. 34 ELLIS 97 reanalyzed the LEP2 (\sqrt{s} =161 GeV) limits of $\sigma(\gamma\gamma + E_{miss}) < 0.2$ pb to exclude

 $m_{\widetilde{\chi}_1^0} <$ 63 GeV if $m_{\widetilde{e}_L} = m_{\widetilde{e}_R} <$ 150 GeV and $\widetilde{\chi}_1^0$ decays to $\gamma \widetilde{G}$ inside detector

 $\stackrel{\sim}{}_{35}$ CABIBBO 81 consider $\stackrel{\sim}{\gamma} \rightarrow \gamma +$ goldstino. Photino must be either light enough (<30 eV) to satisfy cosmology bound, or heavy enough (>0.3 MeV) to have disappeared at early universe.

 $\widetilde{\chi}_2^0$, $\widetilde{\chi}_3^0$, $\widetilde{\chi}_4^0$ (Neutralinos) MASS LIMITS Neutralinos are unknown mixtures of photinos, z-inos, and neutral higgsinos (the supersymmetric partners of photons and of Z and Higgs bosons). The limits here apply persymmetric partners of photons and of Z and rings bosons). The limits here apply only to $\tilde{\chi}_2^0$, $\tilde{\chi}_0^0$, and $\tilde{\chi}_4^0$, $\tilde{\chi}_1^0$ is the lightest supersymmetric particle (LSP); see $\tilde{\chi}_1^0$ Mass Limits. It is not possible to quote rigorous mass limits because they are extremely model dependent; i.e. they depend on branching ratios of various $\tilde{\chi}^0$ decay modes, on the masses of decay products ($\tilde{\epsilon}_1$, $\tilde{\gamma}_1$, $\tilde{\epsilon}_2$), and on the $\tilde{\epsilon}_1$ mass exchanged in $e^+e^- o ilde{\chi}^0_i ilde{\chi}^0_i$. Limits arise either from direct searches, or from the MSSM constraints set on the gaugino and higgsino mass parameters M_2 and μ through searches for lighter charginos and neutralinos. Often limits are given as contour plots in the $m_{\widetilde{\chi}^0}-m_{\widetilde{e}}$ plane vs other parameters. When specific assumptions are made, e.g, the neutralino is a pure photino $(\widetilde{\gamma})$, pure z-ino (\widetilde{Z}) , or pure neutral higgsino (\widetilde{H}^0) , the neutralinos will be labelled as such.

Limits obtained from e^+e^- collisions at energies up to 136 GeV, as well as other limits from different techniques, are now superseded and have not been included in

Supersymmetric Particle Searches

this compilation. They can be found in the 1998 Edition (The European Physical Journal **C3** 1 (1998)) of this Review. $\Delta m = m_{\widetilde{\chi}_2^0} - m_{\widetilde{\chi}_1^0}$

- ¹ ABBIENDI 04H search for charginos and neutralinos in events with acoplanar leptons+jets and multi-jet final states in the 192-209 GeV data, combined with the results on leptonic final states from ABBIENDI 04. The results hold for a scan over the parameter space covering the region 0 < M_2 <5000 GeV, -1000 < μ <1000 GeV and tan β from 1 to 40. This limit supersedes ABBIENDI 00H.
- 20. This limit supersects ABBLEUO over the Supersection of Section 1989 and Section 1989. The mass limit is obtained by constraining the MSSM parameter space with gaugino and sfermion mass universality at the GUT scale, using the results of negative direct searches for neutralinos (including cascade decays and \vec{r}_T final states) from ABREU 01, for charginos from ABREU 00J and ABREU 00T (for all Δm_+), and for charged sleptons from ABREU 01B. The results hold for the full parameter space defined by all values of $|M_2|$ and $|\mu| \leq 2$ TeV with the $\widetilde{\chi}_1^0$ as LSP.
- 3 ABULENCIA 07N searched in 1 fb $^{-1}$ of $ho\overline{
 ho}$ collisions at $\sqrt{s}=1.96$ TeV for events with two same sign leptons (e or μ) from the decay of $\tilde{\chi}_1^\pm \tilde{\chi}_2^0 X$ and large E_T . A slight excess of 13 events is observed over a SM background expectation of 7.8 \pm 1.1. However, the kinematic distributions do not show any anomalous deviation from expectations in any
- ABDALLAH 05B use data from $\sqrt{s}=130-209$ GeV, looking for events with diphotons + $\not\!\! E$. Limits on the cross-section are computed in the plane $(\mathsf{m}(\widetilde{\chi}_2^0),\,\mathsf{m}(\widetilde{\chi}_1^0))$, see Fig. 12. Supersedes the results of ABREU 00z.
- 5 ACHARD 04E use data from $\sqrt{s}=$ 189–209 GeV, looking for events with diphotons + $ot\!\!\!E$. Limits are computed in the plane $(\mathsf{m}(\widetilde{\chi}_2^0),\,\mathsf{m}(\widetilde{e}_R))$, for $\Delta m > 10$ GeV, see Fig. 7. Supersedes the results of ACCIARRI 99R.
- ACHARD 02 searches for the production of sparticles in the case of R prompt decays with LLE or \overline{UDD} couplings at \sqrt{s} =189-208 GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The MSUGRA limit results from a scan over the MSSM parameter space with the assumption of gaugino and scalar mass unification at the GUT scale, imposing simultaneously the exclusions from neutralino, chargino, sleptons, and squarks analyses. The limit of $\widetilde{\chi}_2^0$ holds for \overline{UDD} couplings and increases to 84.0 GeV for LLE couplings. The same $\widetilde{\chi}^0_3$ limit holds for both $LL\overline{E}$ and \overline{UDD} couplings. For L3 limits from $LQ\overline{D}$ couplings, see ACCIARRI 01. 7 ABREU 01B used data from \sqrt{s} =189 GeV to search for the production of $\widetilde{\chi}_i^0 \, \widetilde{\chi}_i^0$. They
- looked for di-jet and di-lepton pairs with E for events from $\widetilde{\chi}_i^0 \, \widetilde{\chi}_i^0$ with the decay $\widetilde{\chi}_i^0 \to$ $f\overline{f}\widetilde{\chi}_1^0$; multi-jet and multi-lepton pairs with or without additional photons to cover the cascade decays $\widetilde{\chi}_j^0 \to f \overline{f} \widetilde{\chi}_2^0$, followed by $\widetilde{\chi}_j^0 \to f \overline{f} \widetilde{\chi}_1^0$ or $\widetilde{\chi}_j^0 \to \gamma \widetilde{\chi}_1^0$; multi-tau final states from $\tilde{\chi}^0_2 \to \tilde{\tau} \tau$ with $\tilde{\tau} \to \tau \tilde{\chi}^0_1$. See Figs. 9 and 10 for limits on the (μ, M_2) plane for $\tan \beta = 1.0$ and different values of m_0 .
- 8 ACCIARRI 01 searches for multi-lepton and/or multi-jet final states from R prompt decays with $LL\overline{E}$, $LQ\overline{D}$, or \overline{UDD} couplings at \sqrt{s} =189 GeV. The search is performed for direct and indirect decays of neutralinos, charginos, and scalar leptons, with the $\widetilde{\chi}^0_1$ or a $\widetilde{\ell}$ as LSP and assuming one coupling to be nonzero at a time. Mass limits are derived using simultaneously the constraints from the neutralino, chargino, and slepton analyses; and the Z^0 width measurements from ACCIARRI 00c in a scan of the parameter space assuming MSUGRA with gaugino and scalar mass universality. Updates and supersedes the results from ACCIARRI 991.
- 9 ABREU 000 searches for the production of charginos and neutralinos in the case of R-parity violation with $LL\overline{E}$ couplings, using data from \sqrt{s} =189 GeV. They investigate topologies with multiple leptons or jets plus leptons, assuming one coupling to be nonzero

- at the time and giving rise to direct or indirect decays. Limits are obtained in the M_2 versus μ plane and a limit on the neutralino mass is derived from a scan over the parameters m_0 and $\tan\beta$.
- ABBIENDI 99F looked for γE final states at \sqrt{s} =183 GeV. They obtained an upper bound on the cross section for the production $e^+e^- \to \tilde{\chi}_2^0 \tilde{\chi}_1^0$ followed by the prompt decay $\tilde{\chi}^0_2\to\gamma\tilde{\chi}^0_1$ of 0.075–0.80 pb in the region $m_{\tilde{\chi}^0_2}+m_{\tilde{\chi}^0_1}>m_Z$, $m_{\tilde{\chi}^0_2}=$ 91–183 GeV, and $\Delta m>$ 5 GeV. See Fig. 7 for explicit limits in the $(m_{\tilde{\chi}^0_2},m_{\tilde{\chi}^0_1})$ plane.
- 11 ABBIENDI 99F looked for $\gamma\gamma E$ final states at \sqrt{s} =183 GeV. They obtained an upper bound on the cross section for the production $e^+\,e^-
 ightarrow \, \widetilde{\chi}^0_2 \, \widetilde{\chi}^0_2$ followed by the prompt decay $\widetilde{\chi}_2^0 \to \gamma \widetilde{\chi}_1^0$ of 0.08–0.37 pb for $m_{\widetilde{\chi}_2^0}$ =45–81.5 GeV, and $\Delta m > 5$ GeV. See Fig. 11 for explicit limits in the $(m_{\widetilde{\chi}^0_2}, m_{\widetilde{\chi}^0_1})$ plane.
- 12 ABBOTT 98c searches for trilepton final states (ℓ =e, μ). See footnote to ABBOTT 98c in the Chargino Section for details on the assumptions. Assuming a negligible decay rate of $\widetilde{\chi}_1^\pm$ and $\widetilde{\chi}_2^0$ to quarks, they obtain $m_{\widetilde{\chi}_2^0} \gtrsim$ 103 GeV.
- 13 ABE 98J searches for trilepton final states $(\ell{=}e{,}\mu)$. See footnote to ABE 98J in the Chargino Section for details on the assumptions. The quoted result for $m_{\widetilde{\chi}^0_2}$ corresponds to the best limit within the selected range of parameters, obtained for $m_{\widetilde{q}} > m_{\widetilde{g}}$, $\tan \beta = 2$, and $\mu{=}{-}\,600$ GeV.
- $^{14}\text{ACCIARRI 98F}$ is obtained from direct searches in the $e^+\,e^-\,\to\,\,\widetilde{\chi}^0_{1,2}\,\widetilde{\chi}^0_2$ production channels, and indirectly from $\widetilde{\chi}_1^\pm$ and $\widetilde{\chi}_1^0$ searches within the MSSM. See footnote to ACCIARRI 98F in the chargino Section for further details on the assumptions. Data taken at $\sqrt{s}=130$ –172 GeV.
- 15 ACCIARRI 98V looked for $\gamma(\gamma) E$ final states at \sqrt{s} =183 GeV. They obtained an upper bound on the cross section for the production $e^+e^- \to \widetilde{\chi}_2^0 \widetilde{\chi}_{1,2}^0$ followed by the prompt decay $\widetilde{\chi}^0_2 \to \gamma \widetilde{\chi}^0_1$. See Figs. 4a and 6a for explicit limits in the $(m_{\widetilde{\chi}^0_2}, m_{\widetilde{\chi}^0_1})$ plane.
- 16 BARATE 98H looked for $\gamma\gamma\not\!\! E$ final states at $\sqrt{s}=161,\!172$ GeV. They obtained an upper bound on the cross section for the production $e^+e^- \to \widetilde{\chi}^0_2\widetilde{\chi}^0_2$ followed by the prompt decay $\widetilde{\chi}^0_2 \to \gamma \widetilde{\chi}^0_1$ of 0.4–0.8 pb for $m_{\widetilde{\chi}^0_2}=$ 10–80 GeV. The bound above is for the specific case of $\widetilde{\chi}_1^0=\widetilde{H}^0$ and $\widetilde{\chi}_2^0=\widetilde{\gamma}$ and $m_{\widetilde{e}_R}=100$ GeV. See Fig. 6 and 7 for explicit limits in the $(\widetilde{\chi}^0_2,\widetilde{\chi}^0_1)$ plane and in the $(\widetilde{\chi}^0_2,\widetilde{e}_R)$ plane.
- 17 BARATE 98J looked for $\gamma\gamma\not\!\! E$ final states at $\sqrt{s}=161$ –183 GeV. They obtained an upper bound on the cross section for the production $e^+e^-\to \widetilde{\chi}_2^0\widetilde{\chi}_2^0$ followed by the prompt decay $\tilde{\chi}^0_2 \to \gamma \tilde{\chi}^0_1$ of 0.08–0.24 pb for $m_{\tilde{\chi}^0_2} <$ 91 GeV. The bound above is for the specific case of $\widetilde{\chi}^0_1=\widetilde{H}^0$ and $\widetilde{\chi}^0_2=\widetilde{\gamma}$ and $m_{\widetilde{e}_R}^{\ \ \ }=$ 100 GeV.
- 18 ABACHI 96 searches for 3-lepton final states. Efficiencies are calculated using mass relations and branching ratios in the Minimal Supergravity scenario. Results are presented as lower bounds on $\sigma(\widetilde{\chi}_1^{\pm}\widetilde{\chi}_2^0) \times \mathsf{B}(\widetilde{\chi}_1^{\pm} \to \ell\nu_{\ell}\widetilde{\chi}_1^0) \times \mathsf{B}(\widetilde{\chi}_2^0 \to \ell^+\ell^-\widetilde{\chi}_1^0)$ as a function of $m_{\widetilde{\chi}_1^0}$. Limits range from 3.1 pb ($m_{\widetilde{\chi}_1^0} =$ 45 GeV) to 0.6 pb ($m_{\widetilde{\chi}_1^0} =$ 100 GeV).
- 19 ABE 96K looked for trilepton events from chargino-neutralino production. They obtained lower bounds on $m_{\widetilde{\chi}^0_2}$ as a function of μ . The lower bounds are in the 45–50 GeV range

for gaugino-dominant $ilde{\chi}_2^0$ with negative μ , if $an\!eta <\!10$. See paper for more details of the assumptions

 $\widetilde{\chi}_1^{\pm}$, $\widetilde{\chi}_2^{\pm}$ (Charginos) MASS LIMITS

Charginos are unknown mixtures of w-inos and charged higgsinos (the supersymmetric partners of W and Higgs bosons). A lower mass limit for the lightest chargino $(\widetilde{\chi}_1^{\pm})$ of approximately 45 GeV, independent of the field composition and of the decay mode, has been obtained by the LEP experiments from the analysis of the Z width and decays. These results, as well as other now superseded limits from e^+e^- collisions energies below 136 GeV, and from hadronic collisions, can be found in the 1998 Edition (The European Physical Journal C3 1 (1998)) of this Review

Unless otherwise stated, results in this section assume spectra, production rates, decay modes and branching ratios as evaluated in the MSSM, with gaugino and sfermion mass unification at the GUT scale. These papers generally study production of $\widetilde{\chi}_1^0\widetilde{\chi}_2^0$, $\widetilde{\chi}_1^+\widetilde{\chi}_1^-$ and (in the case of hadronic collisions) $\widetilde{\chi}_1^+\widetilde{\chi}_2^0$ pairs, including the effects of cascade decays. The mass limits on $\widetilde{\chi}_1^\pm$ are either direct, or follow indirectly from the constraints set by the non-observation of $\overline{\chi}_2^0$ states on the gaugino and higgsino MSSM parameters M_2 and μ . For generic values of the MSSM parameters, limits from high-energy e^+e^- collisions coincide with the highest value of the mass allowed by phase-space, namely $m_{\widetilde{\chi}_1^\pm}\lesssim \sqrt{s}/2$. The still unpublished combination of the results of the four LEP collaborations from the 2000 run of LEP2 at \sqrt{s} up to \simeq 209 GeV yields a lower mass limit of 103.5 GeV valid for general MSSM models. The limits become however weaker in certain regions of the MSSM parameter space where the detection efficiencies or production cross sections are suppressed. For example, this may happen when: (i) the mass differences $\Delta m_+ = m_{\widetilde{\chi}_1^\pm} - m_{\widetilde{\chi}_1^0}$ or $\Delta m_\nu = m_{\widetilde{\chi}_1^\pm} - m_{\widetilde{\nu}}$ are very small, and the detection efficiency is reduced; (ii) the electron sneutrino mass is small, and the $\widetilde{\chi}_1^\pm$ production rate is suppressed due to a destructive interference between s and t channel exchange diagrams. The regions of MSSM parameter space where the

following limits are valid are indicated in the comment lines or in the footnotes.

- 1 ABBIENDI 04H search for charginos and neutralinos in events with acoplanar leptons+jets and multi-jet final states in the 192–209 GeV data, combined with the results on leptonic final states from ABBIENDI 04. The results hold for a scan over the parameter space covering the region $0 < M_2 < 5000$ GeV, $-1000 < \mu < 1000$ GeV and $\tan\beta$ from 1 to 40. This limit supersedes ABBIENDI 00H.
- ²ABBIENDI 03H used e^+e^- data at $\sqrt{s}=188$ –209 GeV to search for chargino pair production in the case of small Δm_+ They select events with an energetic photon, large $\not\!\!E$ and little hadronic or leptonic activity. The bound applies to higgsino-like charginos with zero lifetime and a 100% branching ratio $\bar{\chi}_1^+ \to \bar{\chi}_1^0 W^*$. The mass limit for gaugino-like charginos, in case of non-universal gaugino masses, is of 92 GeV for $m_{\widetilde{\nu}}=$ 1000 GeV and is lowered to 74 GeV for $m_{\widetilde{\nu}} \geq 100$ GeV. Limits in the plane $(m_{\widetilde{\chi}_1^+})$

 Δm_+) are shown in Fig. 7. Exclusion regions are also derived for the AMSB scenario in the $(m_{3/2}, \tan \beta)$ plane, see their Fig. 9.

 3 ABDALLAH 03M searches for the production of charginos using data from $\sqrt{s}=192$ to 208 GeV to investigate topologies with multiple leptons, jets plus leptons, multi-jets, or isolated photons. The first limit holds for tan $\beta\geq 1$ and is obtained at $\Delta m_+=3$ GeV in the higgsino region. For $\Delta m_+\geq 10$ (5) GeV and large m_0 , the limit improves to 102.7 (101.7) GeV. For the region of small Δm_+ , all data from $\sqrt{s}=$ 130 to 208 GeV are used to investigate final states with heavy stable charged particles, decay vertices inside the detector and soft topologies with a photon from initial state radiation. The second limit is obtained in the higgsino region, assuming gaugino mass universality at the GUT scale and $1{<}{}$ tan $\beta<$ 50. For the case of non-universality of gaugino masses, the parameter space is scanned in the domain $1{<}{}$ tan $\beta<$ 50 and, for $\Delta m_+<3$ GeV, for values of M_1 , M_2 and μ such that $M_2 \leq 2M_1 \leq 10\,M_2$ and $|\mu| \geq M_2$. The third limit is obtained in the gaugino region. See Fig. 36 for the dependence of the low Δm_+ limits on Δm_+ . These limits include and update the results of ABREU 00J and ABREU 00T.

- 4 ABDALLAH 03M uses data from $\sqrt{s}=1$ 92–208 GeV to obtain limits in the framework of the MSSM with gaugino and sfermion mass universality at the GUT scale. An indirect limit on the mass of charginos is derived by constraining the MSSM parameter space by and for sleptons. These limits are valid for values of $M_2 < 1$ TeV, $|\mu| \le 2$ TeV with the $\tilde{\chi}_1^0$ as LSP. Constraints from the Higgs search in the M_h^{max} scenario assuming $m_t = 174.3$ GeV are included. The quoted limit applies if there is no mixing in the third family or when $m_{\widetilde{\chi}_1} - m_{\widetilde{\chi}_2^0} > 6$ GeV. If mixing is included the limit degrades to 90 GeV. See the results from direct searches for neutralinos (including cascade decays), for charginos
- Fig. 43 for the mass limits as a function of $tan \beta$. These limits update the results of ABREU 00w.
- ABRED 00W. SHEISTER 02J search for chargino production with small Δm_+ in final states with a hard isolated initial state radiation photon and few low-momentum particles, using 189–208 GeV data. This search is sensitive in the intermediate Δm_+ region. Combined with searches for $\not\!\!E$ topologies and for stable charged particles, the above bound is obtained for m_0 larger than few hundred GeV, $1 < \tan \beta < 300$ and holds for any chargino field contents. For light scalars, the general limit reduces to the one from the Z^0 , but under the assumption of gaugino and sfermion mass unification the above bound is recovered. See Figs. 4–6 for the more general dependence of the limits on Δm_+ . Updates BARATE 98x.
- 6 ACCIARRI 00D data collected at $\sqrt{s}{=}189$ GeV. The results hold over the full parameter space defined by $0.7 \leq \tan \beta \leq 60,~0 \leq M_2 \leq 2$ TeV, $|\mu| \leq 2$ TeV $m_0 \leq 500$ GeV. The results of slepton searches from ACCIARRI 99w are used to help set constraints in the region of small m_0 . See their Figs. 5 for the $\tan \beta$ and M_2 dependence on the limits. See the text for the impact of a large B($\tilde{\chi}^{\pm} \to \tau \tilde{\nu}_{\tau}$) on the result. The region of small Δm_{+} is excluded by the analysis of ACCIARRI 00K. Updates ACCIARRI 98F.
- 7 ACCIARRI 00K searches for the production of charginos with small Δm_{\perp} using data from \sqrt{s} =189 GeV. They investigate soft final states with a photon from initial state radiation. The results are combined with the limits on prompt decays from ACCIARRI 00D and from heavy stable charged particles from ACCIARRI 99L (see Heavy Charged Lepton Searches). The production and decay branching ratios are evaluated within the MSSM, assuming heavy sfermions. The parameter space is scanned in the domain $1 < \tan \beta < 50$, $0.3 < M_1/M_2 < 50$, and $0 < |\mu| < 2$ TeV. The limit is obtained in the higgsino region and improves to 78.6 GeV for gaugino-like charginos. The limit is unchanged for light scalar quarks. For light $\bar{\tau}$ or $\bar{\nu}_{\tau}$, the limit is unchanged in the gaugino-like region and is lowered by 0.8 GeV in the higgsino-like case. For light $\bar{\mu}$ or $\bar{\nu}_{\mu}$, the limit is unchanged in the higgsino-like region and is the higgsino-like region and is lowered by 0.9 GeV in the gaugino-like region. No direct
- The higgsino-like region and is lowered by 0.9 GeV in the gaugino-like region. No direct mass limits are obtained for light δ or $\bar{\nu}_{e}$. 8 CHATRCHYAN 11B looked in 35 pb $^{-1}$ of pp collisions at \sqrt{s} =7 TeV for events with an isolated lepton (e or μ), a photon and E_T which may arise in a generalized gauge mediated model from the decay of Wino-like NLSPs. No evidence for an excess over the expected background is observed. Limits are derived in the plane of squark/gluino mass versus Wino mass (see Fig. 4). Mass degeneracy of the produced squarks and gluinos is assumed.
- assumed. 9 CHATRCHYAN 11v looked in $35~{\rm pb}^{-1}$ of pp collisions at $\sqrt{s}=7~{\rm TeV}$ for events with ≥ 3 isolated leptons $(e,~\mu~{\rm or}~\tau)$, with or without jets and $\not\!\!\!E_T$. No evidence for an excess over the expected background is observed. Limits are derived in the CMSSM $(m_0,~m_{1/2})$ plane for $\tan \beta = 3$ (see Fig. 5).
- 10 AALTONEN 09G searched in 976 pb $^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for events with trileptons $(\mu\mu\mu$ or $\mu\mu e)$ with a low, 5 GeV, p_T threshold, and large $\not\!\!E_T$ from the decay of $\tilde{\chi}_1^\pm \tilde{\chi}_2^0 X$. The selected number of events is consistent with the SM background expectation. The results are combined with the analysis of AALTONEN 07J to set a limit on the $\tilde{\chi}_1^{\pm}$ mass for a mSUGRA scenario with no slepton mixing.
- 11 ABAZOV 09T searched in 2.3 fb $^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}=$ 1.96 TeV for events with trileptons (e,μ or hadronically decaying τ) from the decay of $\widetilde{\chi^{+}}\widetilde{\chi}_{2}^{0}X$ and large E_{T} . No evidence for a signal is observed. The data are used to constrain the cross section times branching ratio as a function of the $\widetilde{\chi}_1^\pm$ mass under the assumption that $m_{\widetilde{\chi}_1^\pm}=m_{\widetilde{\chi}_2^0}$

= $2\ m_{\widetilde{\chi}_1^0}$, $\tan\beta=3$, $\mu>0$ and that the sleptons are heavier than the $\widetilde{\chi}_1^{\pm}$, see their Fig. 8. A chargino lighter than 138 GeV is excluded in the "3l-max" scenario. Exclusion regions in the $(m_0,m_{1/2})$ plane are shown in their Fig. 9 for a mSUGRA scenario with $\tan\beta=3$, $A_0=0$ and $\mu>0$. The $\tan\beta$ dependence of this exclusion is illustrated in Fig. 10. Supersedes the results of ABAZOV 050.

 12 AALT ONEN 08AE searched in 2.0 fb $^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for events with trileptons (e, μ or a charged isolated track from au) from the decay of $p\overline{p} \to ~\widetilde{\chi}_1^{\pm} \, \widetilde{\chi}_2^0 X$ and large E_T . The selected number of events is consistent with the SM background expectation. The data are used to constrain the cross section times branching ratio as a function of the $\widetilde{\chi}_1^\pm$ mass. Exclusion regions in the $(m_0, m_{1/2})$ plane are shown in their

Fig. 2 for a mSUGRA scenario. When the $\widetilde{\chi}_1^\pm$ is nearly mass degenerate with the $\widetilde{\tau}_1$ the leptons are too soft and no limit is obtained. For the case $m_0=60$ GeV a lower limit of 145 GeV on the chargino mass is obtained in this mSUGRA scenario. $^{13}\text{AALTONEN 08L searched in 0.7 to 1.0 fb}^{-1} \text{ of } p\overline{p} \text{ collisions at } \sqrt{s}=1.96 \text{ TeV for events with one high}-p_T \text{ electron or muon and two additional leptons } (e \text{ or } \mu) \text{ from the model}$

events with one nigh- p_T electron or muon and two additional leptons (e or μ) from the decay of $\tilde{\chi}_1^\pm \tilde{\chi}_2^0 X$. The selected number of events is consistent with the SM background expectation. The data are used to constrain the cross section times branching ratio as a function of the $\tilde{\chi}_1^\pm$ mass. The results are compared to three MSSM scenarios. An exclusion on chargino and neutralino production is only obtained in a scenario of on mixing between sleptons, yielding nearly equal branching ratios to all three lepton flavors. It amounts to $m_{\tilde{\chi}_2^\pm} > 151$ GeV, while the analysis is not sensitive to chargino masses below about 110 GeV. The analyses have been combined with the analyses of AALTONEN 071 and ABULENCIA 07N. The observed limits for the combination are less stripgent than the one obtained for the high- p_{CT} analysis due to slight excesses in the

other channels. 14 ABAZOV 08F looked in 1.1 fb $^{-1}$ of $p\bar{p}$ collisions at $\sqrt{s}=1.96$ TeV for diphoton events with large \mathcal{L}_T . They may originate from the production of $\tilde{\chi}^{\pm}$ in pairs or associated to a $\tilde{\chi}^0_2$, decaying to a $\tilde{\chi}^0_1$ which itself decays promptly in GMSB to $\tilde{\chi}^0_1 \to \gamma \tilde{G}$. No significant excess was found compared to the background expectation. A limit is derived on the masses of SUSY particles in the GMSB framework for $M=2\Lambda$, N=1, $\tan\beta=15$ and x>0. See Figure 2.1 tags explicitly $\Delta = 0.15$. TeV. Supercodes the scale of $M=2\Lambda$, N=1, $\tan\beta=15$ and x>0. 15 and $\mu>0$, see Figure 2. It also excludes N < 91.5 TeV. Supersedes the results of ABAZOV 05A.

Supersymmetric Particle Searches

- 15 AALTONEN 07J searched in 0.7 to 1.1 fb $^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}=$ 1.96 TeV for events with either two same sign leptons $(e \text{ or } \mu)$ or trileptons from the decay of $\widetilde{\chi}_1^\pm \widetilde{\chi}_2^0 X$ and large E_T . The selected number of events is consistent with the SM background expectation. The data are used to constrain the cross section times branching ratio as a function of the χ_1^\pm mass. The results, shown in their Fig. 2, are compared to several MSSM scenarios. The strongest exclusion is in the case of no mixing between sleptons, yielding nearly equal branching ratios to all three lepton flavors, and amounting to $m_{\tilde{\chi}_1^\pm} > 129$
- GeV. This analysis includes the same sign dilepton analysis of ABULENCIA 07N. 16 ABULENCIA 07H searched in 346 pb $^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for events with at least three leptons (e or μ) from the decay of $\overline{\chi}_1^0$ via $LL\overline{E}$ couplings. The results are consistent with the hypothesis of no signal. Upper limits on the cross-section are extracted and a limit is derived in the framework of mSUGRA on the masses of $\widetilde{\chi}^0_1$ and $\widetilde{\chi}_1^\pm$, see e.g. their Fig. 3 and Tab. II.
- 17 ABULENCIA 07N searched in 1 fb $^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for events with two same sign leptons (e or μ) from the decay of $\tilde{\chi}_1^{\pm}\tilde{\chi}_2^0 X$ and large E_T . A slight excess of 13 events is observed over a SM background expectation of 7.8 \pm 1.1. However, the kinematic distributions do not show any anomalous deviation from expectations in any particular region of parameter space.
- 18 ABAZOV 06 D looked in 360 pb $^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for events with three leptons originating from the pair production of charginos and neutralinos, followed by R decays mediated by LLE couplings. One coupling is assumed to be dominant at a by μ decays interesting to securing is assumed to be dominant at a time. No significant excess was found compared to the background expectation in the $ee\ell$, $\mu\mu\ell$ nor eer ($\ell=e,\mu$) final states. Upper limits on the cross-section are extracted in a specific MSUGRA model and a MSSM model without unification of M_1 and M_2 at the GUT scale. A limit is derived on the masses of charginos and neutralinos for both scenarios assuming λ_{ijk} couplings such that the decay length is less than 1 cm, see their Table III and Fig. 4.
- 19 ABAZOV 05 A looked in 263 pb $^{-1}$ of $^{}$ $^{}$ $^{}$ collisions at $^{}$ $^{}$ $^{}$ $^{}$ TeV for diphoton events with large $ot\!\!E_T$. They may originate from the production of $\widetilde{\chi}^\pm$ in pairs or associated
- $_{20}$ results of ABBOTT 98. $_{20}$ ACOSTA 05E looked in 202 pb $^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}{=}1.96$ TeV for diphoton events with large $ot\!\!\!E_T$. They may originate from the production of $\widetilde{\chi}^\pm$ in pairs or associated to a $\widetilde{\chi}_2^0$, decaying to a $\widetilde{\chi}_1^0$ which itself decays promptly in GMSB to $\gamma\,\widetilde{G}$. No events are
- a χ_2^* , decaying to a χ_1^* winch itself decays promptly in GMSB to γ 6. No events are selected at large E_T compared to the background expectation. A limit is derived on the masses of SUSY particles in the GMSB framework for M=2 A, N=1, $\tan\beta=15$ and $\mu>0$, see Figure 2. It also excludes A<69 TeV. Supersedes the results of ABE 991. 21 ABDALLAH 04H use data from LEP 1 and $\sqrt{s}=192-208$ GeV. They re-use results or re-analyze the data from ABDALLAH 03M to put limits on the parameter space of anomaly-mediated supersymmetry breaking (AMSB), which is scanned in the region $1 < m_{3/2} <$ 50 TeV, $0 < m_0 <$ 1000 GeV, 1.5 < tan $\beta <$ 35, both signs of μ . The constraints are obtained from the searches for mass degenerate chargino and neutralino, for SM-like and invisible Higgs, for leptonically decaying charginos and from the limit on non-SM Z width of 3.2 MeV. The limit is for $m_t=174.3~{\rm GeV}$ (see Table 2 for other m_t values).
- Width of 3.2 MeV. The limit is for $m_L = 177.5$ GeV (see Tebe 1.3 standard) 22 The limit improves to 73 GeV for $\mu < 0$. 23 ABDALLAH 04M use data from $\sqrt{s} = 192-208$ GeV to derive limits on sparticle masses under the assumption of R with $LL\overline{E}$ or \overline{UDD} couplings. The results are valid in the ranges $90 < m_0 < 500$ GeV, $0.7 < \tan \beta < 30$, $-200 < \mu < 200$ GeV, $0 < M_2 < 400$ GeV. Supersedes the result of ABREU 01D and ABREU 00U.
- 24 The limit improves to 103 GeV for LLE couplings. 25 ABDALLAH 03D use data from $\sqrt{s}=183-208$ GeV. They look for final states with two acoplanar leptons, expected in GMSB when the $\tilde{\tau}_1$ is the NLSP and assuming a shortlived $\widetilde{\chi}_1^{\pm}$. Limits are obtained in the plane $(m(\widetilde{\tau}), m(\widetilde{\chi}_1^{\pm}))$ for different domains of $m(\widetilde{G})$, after combining these results with the search for slepton pair production from the same paper. The limit above is valid if the $\widetilde{ au}_1$ is the NLSP for all values of $\mathrm{m}(\widetilde{G})$ provided $\mathsf{m}(\widetilde{\chi}_1^\pm) - \mathsf{m}(\widetilde{\tau}_1) \, \geq \, 0.3$ GeV. For larger $\mathsf{m}(\widetilde{G}) > 100$ eV the limit improves to 102 GeV, see their Fig. 11. In the co-NLSP scenario, the limits are 96 and 102 GeV for all m(\widetilde{G}) and m(\widetilde{G}) > 100 eV, respectively. Supersedes the results of ABREU 01G.
- and m(6) > 100eV, respectively. Superseues the results of ADREO VIS. 26 HEISTER 03G searches for the production of charginos prompt decays. in the case of R prompt decays with $LL\bar{E}$, LQD or UDD couplings at \sqrt{s} =189-209 GeV. The search is performed for indirect decays, assuming one coupling at a time to be non-zero. The limit holds for $\tan \beta$ =1.41. Excluded regions in the (μ,M_2) plane are shown in their Fig. 3.
- noids for tail p=1.41. Excluded regions in the (μ, m_Z) plane are shown in the 1.52 ACHARD 02 searches for the production of sparticles in the case of R prompt decays with LLE or UDD couplings at $\sqrt{s}=189-208$ GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The MSUGRA limit results from a scan over the MSSM parameter space with the assumption of gaugino and scalar mass unification at the GUT scale, imposing simultaneously the exclusions from neutralino, chargino, sleptons, and squarks analyses. The limit of $\widetilde{\chi}_1^\pm$ holds for \overline{UDD} couplings and increases to 103.0 GeV for $LL\overline{E}$ couplings. For L3 limits from $LQ\overline{D}$ couplings, see ACCIARRI 01.
- 28 GHODBANE 02 reanalyzes DELPHI data at \sqrt{s} =189 GeV in the presence of complex phases for the MSSM parameters.
- ²⁹ ABREU 01c looked for au pairs with ot E at \sqrt{s} =183–189 GeV to search for the associated production of charginos, followed by the decay $\bar{\chi}^{\pm} \rightarrow \tau J$, J being an invisible massless particle. See Fig. 6 for the regions excluded in the (μ, M_2) plane. ³⁰ ACCIARRI 01 searches for multi-lepton and/or multi-jet final states from R prompt decays with $LL\bar{E}$, $LQ\bar{D}$, or \overline{UDD} couplings at \sqrt{s} =189 GeV. The search is performed for
- direct and indirect decays of neutralinos, charginos, and scalar leptons, with the $\widetilde{\chi}^0_1$ or a $\widetilde{\ell}$ as LSP and assuming one coupling to be nonzero at a time. Mass limits are derived using simultaneously the constraints from the neutralino, chargino, and slepton analyses; and the Z^0 width measurements from ACCIARRI 00c in a scan of the parameter space assuming MSUGRA with gaugino and scalar mass universality. Updates and supersedes the results from ACCIARRI 991.
- If the results from ACCIANN 271.

 BARATE 01B searches for the production of charginos in the case of R prompt decays with LLE, LQD, or \overline{UDD} couplings at \sqrt{s} =189-202 GeV. The search is performed for indirect decays, assuming one coupling at a time to be nonzero. Updates BARATE 00H.

- 32 ABREU 00v use data from $\sqrt{s}=$ 183–189 GeV. They look for final states with two acoplanar leptons, expected in GMSB when the $\tilde{\tau}_1$ is the NLSP and assuming a shortlived $\widetilde{\chi}_1^\pm$. Limits are obtained in the plane $(m_{\widetilde{\tau}}, m_{\widetilde{\chi}_1^\pm})$ for different domains of $m_{\widetilde{G}}$, after combining these results with the search for slepton pair production in the SUGRA framework from ABREU 01 to cover prompt decays and on stable particle searches from ABREU 00q. The limit above is valid for all values of $m_{\widetilde{G}}$.
- $^{
 m 33}\,\text{CHO}$ 00B studied constraints on the MSSM spectrum from precision EW observables. Global fits favour charginos with masses at the lower bounds allowed by direct searches. Allowing for variations of the squark and slepton masses does not improve the fits.
- Allowing for variations of the squark and stepton masses uses not improve the riss. 34 ABBIENDI 99T searches for the production of neutralinos in the case of R-pairty violation with LLE, LQD, or \overline{UDD} couplings using data from \sqrt{s} =183 GeV. They investigate topologies with multiple leptons, jets plus leptons, or multiple jets, assuming one coupling at the time to be non-zero and giving rise to direct or indirect decays. Mixed decays (where one particle has a direct, the other an indirect decay) are also considered for the \overline{UDD} couplings. Upper limits on the cross section are derived which, combined with the constraint from the Z^0 width, allow to exclude regions in the M_2 versus μ plane for any coupling. Limits on the chargino mass are obtained for non-zero $LL\overline{E}$ couplings $>10^{-5}$ and assuming decays via a W^*
- 35 MALTONI 99B studied the effect of light chargino-neutralino to the electroweak precision data with a particular focus on the case where they are nearly degenerate ($\Delta m_+ \sim 1$ GeV) which is difficult to exclude from direct collider searches. The quoted limit is for higgsino-like case while the bound improves to 56 GeV for wino-like case. The values of the limits presented here are obtained in an update to MALTONI 99B, as described in
- the limits presented here are obtained in an update to main specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific specific speci
- 0.23 pb $(m_{\widetilde{\chi}_1^\pm}=$ 100 GeV) at 95%CL. The gaugino mass unification hypothesis and the assumed mass relation between squarks and gluinos define the value of the leptonic described miss relation between squarks and graines define the value of the leptonic branching ratios. The quoted result corresponds to the best limit within the selected range of parameters, obtained for $m_{\overline{q}} > m_{\overline{g}}$, $\tan \beta = 2$, and $\mu = -600$ GeV. Mass limits for different values of $\tan \beta$ and μ are given in Fig. 2. 37 ACKERSTAFF 98k looked for dilepton+ $\not\!\!E_T$ final states at $\sqrt{s} = 130 - 172$ GeV. Limits on
- $\sigma(e^+e^-\to \widetilde\chi_1^+\widetilde\chi_1^-)\times \mathsf{B}^2(\ell),$ with $\mathsf{B}(\ell)\!=\!\mathsf{B}(\chi^+\to\ell^+\nu_\ell\chi_1^0)$ $(\mathsf{B}(\ell)\!=\!\mathsf{B}(\chi^+\to\ell^+\bar\nu_\ell)),$ are given in Fig. 16 (Fig. 17).
- are given in Fig. 10 (Fig. 17). 38 ACKERSTAFF 98L limit is obtained for $0 < M_2 < 1500$, $|\mu| < 500$ and $\tan\beta > 1$, but remains valid outside this domain. The dependence on the trilinear-coupling parameter A is studied, and found negligible. The limit holds for the smallest value of m_0 consistent with scalar lepton constraints (ACKERSTAFF 97H) and for all values of m_0 where the condition $\Delta m_{\widetilde{\nu}} > 2.0\,\mathrm{GeV}$ is satisfied. $\Delta m_{\nu} > 10\,\mathrm{GeV}$ if $\widetilde{\chi}^{\pm} \to \ell \widetilde{\nu}_{\ell}$. The limit improves to 84.5 GeV for $m_0 = 1\,\mathrm{TeV}$. Data taken at $\sqrt{s} = 130 - 172\,\mathrm{GeV}$.
- ³⁹ ACKERSTAFF 98v excludes the light gluino with universal gaugino mass where charginos, neutralinos decay as $\widetilde{\chi}_1^\pm,\widetilde{\chi}_2^0 \to q \, \overline{q} \, \widetilde{g}$ from total hadronic cross sections at \sqrt{s} =130–172 GeV. See paper for the case of nonuniversal gaugino mass.
- 40 CARENA 97 studied the constraints on chargino and sneutrino masses from muon g-2. The bound can be important for large $\tan\beta$.
- 41 KALINOWSKI 97 studies the constraints on the chargino-neutralino parameter space from limits on $\Gamma(W \to \widetilde{\chi}_1^\pm \widetilde{\chi}_1^0)$ achievable at LEP2. This is relevant when $\widetilde{\chi}_1^\pm$ is "invisible," i.e., if $\widetilde{\chi}_1^\pm$ dominantly decays into $\overline{\nu}_\ell\ell^\pm$ with little energy for the lepton. Small otherwise allowed regions could be excluded.
- 42 ABE 96K looked for trilepton events from chargino-neutralino production. The bound on $m_{\widetilde{\chi}^{\pm}_1}$ can reach up to 47 GeV for specific choices of parameters. The limits on the combined production cross section times 3-lepton branching ratios range between 1.4 and 0.4 pb, for 45</ri> $m_{\widetilde{\chi}_1^+}({\rm GeV}){<}100.$ See the paper for more details on the parameter dependence of the results

- 1 ABAZOV 09M searched in $1.1~{\rm fb^{-1}}$ of $p\overline{p}$ collisions at $\sqrt{s}=1.96~{\rm TeV}$ for events with direct production of a pair of charged massive stable particles identified by their TOF. The number of the observed events is consistent with the predicted background. The $^{-1}$ data are used to constrain the production cross section as a function of the $\widetilde{\chi}_1^\pm$ mass, see their Fig. 2. The quoted limit improves to 206 GeV for gaugino-like charginos
- ABBIENDI 03L used e^+e^- data at $\sqrt{s}=130$ –209 GeV to select events with two high momentum tracks with anomalous dE/dx. The excluded cross section is compared to the theoretical expectation as a function of the heavy particle mass in their Fig. 3. The bounds are valid for colorless fermions with lifetime longer than 10^{-6} s. Supersedes the results from ACKERSTAFF 98P.
- results from ACKERSTAFF 98P. 3 ABREU 00T searches for the production of heavy stable charged particles, identified by their ionization or Cherenkov radiation, using data from \sqrt{s} = 130 to 189 GeV. These limits include and update the results of ABREU 98P. 4 BARATE 97K uses e^+e^- data collected at \sqrt{s} = 130–172 GeV. Limit valid for $\tan\beta = \sqrt{2}$ and $m_{\widetilde{\nu}} > 100$ GeV. The limit improves to 86 GeV for $m_{\widetilde{\nu}} > 250$ GeV.

$\widetilde{\boldsymbol{\nu}}$ (Sneutrino) MASS LIMIT

The limits may depend on the number, $extit{ extit{M}}(\widetilde{
u})$, of sneutrinos assumed to be degenerate in mass. Only $\widetilde{
u}_L$ (not $\widetilde{
u}_R$) is assumed to exist. It is possible that $\widetilde{
u}$ could be the lightest supersymmetric particle (LSP).

We report here, but do not include in the Listings, the limits obtained from the fit of the ... Joseph By the LET Collaborations on the invisible width of the Z boson ($\Delta\Gamma_{\rm inv.} < 2.0$ MeV, LEP-SLC 06): $m_{\widetilde{\nu}} > 43.7$ GeV ($N(\widetilde{\nu}){=}1)$ and $m_{\widetilde{\nu}} > 44.7$ GeV ($N(\widetilde{\nu}){=}3)$.

- 1 ABDALLAH 03M uses data from $\sqrt{s}=192-208$ GeV to obtain limits in the framework of the MSSM with gaugino and sfermion mass universality at the GUT scale. An indirect limit on the mass is derived by constraining the MSSM parameter space by the results from direct searches for neutralinos (including cascade decays) and for sleptons. These limits are valid for values of $\rm M_2 < 1~TeV$, $|\mu| \leq 1~TeV$ with the $\tilde{\chi}_1^0$ as LSP. The quoted limit is obtained when there is no mixing in the third family. See Fig. 43 for the mass imits as a function of aneta. These limits update the results of ABREU 00w.
- 2 HEISTER 02N derives a bound on $m_{\widetilde{
 u}_o}$ by exploiting the mass relation between the $\widetilde{
 u}_e$ and \widetilde{e} , based on the assumption of universal GUT scale gaugino and scalar masses $m_{1/2}$ and m_0 and the search described in the \tilde{e} section. In the MSUGRA framework with at rillnear coupling A_0 =0 at the GUT scale. See Figs. 5 and 7 for the dependence of the
- 3 ADRIANI 93M limit from $\Delta\Gamma(Z)$ (invisible)< 16.2 MeV.
- $^4\,\mathrm{DECA\,MP}$ 92 limit is from $\Gamma(\mathrm{invisible})/\Gamma(\ell\ell)=5.91\pm0.15$ ($\mathit{N}_{\nu}=2.97\pm0.07$).
- 5 ALEXANDER 91F limit is for one species of $\widetilde{
 u}$ and is derived from $\Gamma(\text{invisible, new})/\Gamma(\ell\ell)$
- 6 AAD 11H looked in 35 pb $^{-1}$ of $p\,p$ collisions at $\sqrt{s}=$ 7 TeV for events with one electron and one muon of opposite charge from the production of $\widetilde{
 u}_{ au}$ via an R λ'_{311} coupling and followed by a decay via λ_{312} into $e+\mu$. No evidence for an excess over the SM expectation is observed, and a limit is derived in the plane of λ'_{311} versus $m_{\widetilde{
 u}}$ for several values of $\lambda_{312}\text{, see their Fig. 2. Superseded by AAD 11z.}$

- 7 AAD 11z looked in 1.07 fb $^{-1}$ of $p\,p$ collisions at $\sqrt{s}=$ 7 TeV for events with one electron and one muon of opposite charge from the production of $\widetilde{
 u}_{ au}$ via an R λ'_{311} coupling and followed by a decay via λ_{312} into $e+\mu$. No evidence for an (e,μ) resonance over the SM expectation is observed, and a limit is derived in the plane of λ'_{311} versus $m_{\widetilde{\nu}}$ for three values of λ_{312} , see their Fig. 2. Masses $m_{\widetilde{\nu}} < 1.32$ (1.45) TeV are excluded for
- $\lambda'_{311}=0.10$ and $\lambda_{312}=0.05$ ($\lambda'_{311}=0.11$ and $\lambda_{312}=0.07$). 8 AALTONEN 10z searched in 1 fb $^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for events from the production $d\,\overline{d} \to \widetilde{\nu}_{\mathcal{T}}$ with the subsequent decays $\widetilde{\nu}_{\mathcal{T}} \to e\,\mu,\;\mu\,\tau,\;e\,\tau$ in the MSSM framework with R. Two isolated leptons of different flavor and opposite charges are required, with au s identified by their hadronic decay. No statistically significant excesses are observed over the SM background. Upper limits on χ^2_{311} times the branching ratio are listed in their Table III for various $\widetilde{\nu}_{\tau}$ masses. Limits on the cross section times branching ratio for $\lambda'_{311}=$ 0.10 and $\lambda_{i3k}^{'}=$ 0.05, displayed in Fig. 2, are used to set limits on the $\tilde{\nu}_{\tau}$ mass of 558 GeV for the $e\mu$, 441 GeV for the $\mu\tau$ and 442 GeV for the τ channels
- 9 ABAZOV 10M looked in 5.3 fb $^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for events with exactly one pair of high p_T isolated $e\mu$ and a veto against hard jets. No evidence for an excess over the SM expectation is observed, and a limit at 95% C.L. on the cross section times branching ratio is derived, see their Fig. 3. These limits are translated into limits on couplings as a function of $m_{\widetilde{\nu}_{\tau}}$ as shown on their Fig. 4. As an example, for $m_{\widetilde{\nu}_{\tau}}$
- 100 GeV and $\lambda_{312} \leq$ 0.07, couplings $\lambda_{311}' >$ 7.7 \times 10 $^{-4}$ are excluded.
- 100 GeV and $\lambda_{312} \leq 0.07$, couprings $\lambda_{311} > 1.7$ A $\lambda_{31} > 1.9$ The Section 10 AALTONEN 09V searched in 2.3 fb⁻¹ of $\rho \overline{\rho}$ collisions at $\sqrt{s} = 1.96$ TeV for events with an oppositely charged pair originating from the R production of a sneutrino decaying to dimuons. A limit is derived on the cross section times branching ratio, B, of $\overline{\nu} \rightarrow \mu \mu$ for several values of the coupling λ' , see their Fig. 3. For $\lambda'^2 B = 0.01$, the range 100 GeV $\leq m_{\widetilde{\nu}} \leq$ 810 GeV is excluded.
- 11 ABAZOV 08Q searched in 1.04 fb⁻¹ of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for an excess of events with oppositely charged $e\mu$ pairs. They might be expected in a SUSY model with R where a sneutrino is produced by $LQ\overline{D}$ couplings and decays via $LL\overline{E}$ couplings, focusing on $\bar{\nu}_{\mathcal{T}}$, hence on the λ'_{311} and λ_{312} constants. No significant excess was found compared to the background expectation. Upper limits on the cross-section times branching ratio are extracted and displayed in their Fig. 2. Exclusion regions are determined for the $\bar{\nu}_{\mathcal{T}}$ mass as a function of both couplings, see their Fig. 3. As an indication, for $\widetilde{\nu}_{\tau}$ masses of 100 GeV and $\lambda_{312}=0.01$, values of $\lambda'_{311}\geq 1.6\times 10^{-3}$ are excluded at the 95% C.L. Superseded by ABAZOV 10M.
- 12 SCHAEL 07A searches for the s- or t-channel exchange of sneutrinos in the case of R with LLE couplings by studying di-lepton production at $\sqrt{s}=189-209$ GeV. Limits are obtained on the couplings as a function of the $\widetilde{
 u}$ mass, see their Figs. 22-24. The results of this analysis are combined with BARATE 001.
- 13 ABAZOV 061 looked in 380 pb $^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for events with at least 2 muons and 2 jets for s-channel production of $\widetilde{\mu}$ or $\widetilde{\nu}$ and subsequent decay via R couplings $LQ\overline{D}$. The data are in agreement with the SM expectation. They set limits on resonant slepton production and derive exclusion contours on λ'_{211} in the mass plane of $\widetilde{\ell}$ versus $\widetilde{\chi}_1^0$ assuming a MSUGRA model with $\tan\beta=$ 5, $\mu<0$ and $A_0=0$, see their Fig. 3. For $\lambda'_{211} \geq 0.09$ slepton masses up to 358 GeV are excluded. Supersedes the results of ABAZOV 02H.
- 14 ABDALLAH 06c searches for anomalies in the production cross sections and forward-ABDALEATH of searches of the $\ell^+\ell^-(\gamma)$ final states $(\ell=e,\mu,\tau)$ from 675 pb $^-1$ of e^+e^- data at $\sqrt{s}{=}130{-}207$ GeV. Limits are set on the s- and t-channel exchange of sneutrinos in the presence of R with $\lambda LL\overline{E}$ couplings. For points between the energies at which data were taken, information is obtained from events in which a photon was radiated. Exclusion limits in the $(\lambda, m_{\widetilde{\nu}})$ plane are given in Fig. 16. These limits include and update the results of ABREU 00s.
- the results of ABRED GUS. The results of ABRED GUS. The results of ABRED GUS. The searched in 344 pb $^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for an excess of events with oppositely charged $e\mu$ pairs. They might be expected in a SUSY model with R where a sneutrino is produced by LQD couplings and decays via $LL\overline{E}$ couplings, focusing on $\widetilde{\nu}_{ au}$, hence on the λ'_{311} and λ_{132} constants. No significant excess was found compared to the background expectation. Upper limits on the cross-section times branching ratio are extracted and exclusion regions determined for the $\widetilde{\nu}_T$ mass as a function of both couplings, see their Fig. 3. As an indication, $\widetilde{\nu}_T$ masses are excluded up to 300 GeV for $\lambda'_{311} \geq~0.01$ and $\lambda_{132} \geq~0.02$. Superseded by AALTONEN 10z.
- 16 ABULENCIA 05A looked in \sim 200 pb $^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for dimuon and dielectron events. They may originate from the R production of a sneutrino decaying to dileptons. No significant excess rate was found compared to the background expectation. A limit is derived on the cross section times branching ratio, B, of $\stackrel{\circ}{\nu} \rightarrow e \, e$, $\mu\mu$ of 25 fb at high mass, see their Figure 2. Sneutrino masses are excluded at 95% CL below 680, 620, 460 GeV (ee channel) and 665, 590, 450 GeV ($\mu\mu$ channel) for a λ' coupling
- and branching ratio such that $\lambda^{\prime 2}B=0.01,0.05,0.001$, respectively. 17 ACOSTA 05R looked in 195 pb $^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for ditau events with one identified hadronic tau decay and one other tau decay. They may originate from the R production of a sneutrino decaying to au au. No significant excess rate was found compared to the background expectation, dominated by Drell-Yan. A limit is derived on the cross section times branching ratio, B, of $\tilde{\nu} \to au au$, see their Figure 3. Sneutrino masses below 377 GeV are excluded at 95% CL for a λ' coupling to $d\overline{d}$ and branching ratio such that $\lambda'^2 B = 0.01$.
- 16 ABBIENDI 04F use data from $\sqrt{s}=189-209$ GeV. They derive limits on sparticle masses under the assumption of R with $LL\overline{E}$ or $LQ\overline{D}$ couplings. The results are valid for $\tan\beta=1.5$, $\mu=-200$ GeV, and a BR for the decay given by CMSSM, assuming no sensitivity. to other decays. Limits are quoted for $m_{\widetilde{\chi}^0}=$ 60 GeV and degrade for low-mass $\widetilde{\chi}^0_1$. For $\widetilde{\nu}_e$ the direct (indirect) limits with $LL\overline{E}$ couplings are 89 (95) GeV and with $LQ\overline{D}$ they are 89 (88) GeV. For $\widetilde{
 u}_{\mu, au}$ the direct (indirect) limits with $LL\overline{E}$ couplings are 79 (81) GeV and with $LQ\overline{D}$ they are 74 (no limit) GeV. Supersedes the results of ABBIENDI 00.
- 19 ABDALLAH 04H use data from LEP 1 and $\sqrt{s}=$ 192–208 GeV. They re-use results or re-analyze the data from ABDALLAH 03M to put limits on the parameter space of anomaly-mediated supersymmetry breaking (AMSB), which is scanned in the region $1< m_{3/2} <$ 50 TeV, $0 < m_0 <$ 1000 GeV, 1.5 < tan $\beta <$ 35, both signs of μ . The constraints are obtained from the searches for mass degenerate chargino and neutralino, for SM-like and invisible Higgs, for leptonically decaying charginos and from the limit on non-SM Z width of 3.2 MeV. The limit is for $m_{\tilde{t}}=174.3$ GeV (see Table 2 for other $m_{\tilde{t}}$ values).

 $^{20}\,\text{The limit improves to 114 GeV for }\mu~<0.$

Supersymmetric Particle Searches

- 21 ABDALLAH 04M use data from $\sqrt{s}=189-208$ GeV. The results are valid for $\mu=-200$ GeV, $\tan\beta=1.5$, $\Delta m>5$ GeV and assuming a BR of 1 for the given decay. The limit quoted is for indirect decays using the neutralino constraint of 39.5 GeV, also derived in ABDALLAH 04M. For indirect decays the limit on $\vec{\nu}_e$ decreases to 96 GeV if the constraint from the neutralino is not used and for direct decays the remains 96 GeV. For indirect decays the limit on $\vec{\nu}_e$ decreases to 8.6 GeV if the constraint from the if the constraint from the neutralino is not used and for direct decays it remains 96 GeV. For indirect decays the limit on $\widetilde{\nu}_{\mu}$ decreases to 82 GeV if the constraint from the neutralino is not used and to 83 GeV for direct decays. For indirect decays the limit on $\widetilde{\nu}_{\tau}$ decreases to 82 GeV if the constraint from the neutralino is not used and improves to 91 GeV for direct decays. Supersedes the results of ABREU 000. 2^2 ABDALLAH 03F looked for events of the type $e^+e^- \rightarrow \widetilde{\nu} \rightarrow \widetilde{\chi}^0 \nu$, $\widetilde{\chi}^\pm \ell^\mp$ followed by Barana of the $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi}^0$ via $\widetilde{\chi$
- by R decays of the $\bar{\chi}^0$ via $\lambda_{1|1}$ (j = 2,3) couplings in the data at \sqrt{s} = 183–208 GeV. From a scan over the SUGRA parameters, they derive upper limits on the $\lambda_{1|1}$ couplings
- as a function of the sneutrino mass, see their Figs. 5–8. production cross-section and decay branching ratio for a $\widetilde{
 u}$ in RPV models (see Fig. 3).
- made of the bound $\mathit{m}(\widetilde{\chi}^0_1) >$ 23 GeV from BARATE 98s. Supersedes the results from
- BARATE 01B. 25 ABAZOV 02H looked in 94 pb $^{-1}$ of $p\overline{p}$ collisions at \sqrt{s} =1.8 TeV for events with at least 2 muons and 2 jets for s-channel production of $\overline{\mu}$ or $\overline{\nu}$ and subsequent decay via \overline{R} couplings $LQ\overline{D}$. A scan over the MSUGRA parameters is performed to exclude regions of the $(m_0, m_{1/2})$ plane, examples being shown in Fig. 2.
- 26 ACHARD 02 searches for the associated production of sneutrinos in the case of R prompt decays with $LL\overline{E}$ or \overline{UDD} couplings at \sqrt{s} =189–208 GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The limit holds for direct decays via $LL\overline{E}$ couplings. Stronger limits are reached for $(\overline{\nu}_e, \overline{\nu}_{\mu, \tau})$ for LLE indirect (99,78) GeV and for \(\bar{UDD}\) direct or indirect (99,70) GeV decays. The MSUGRA limit results from a scan over the MSSM parameter space with the assumption of gaugino and scalar mass unification at the GUT scale, imposing simultaneously the exclusions from neutralino, chargino, sleptons, and squarks analyses. The limit holds for \(\bar{UDD}\) couplings and increases to 152.7 GeV for \(LE\) couplings.
- 27 HEISTER 02F searched for single sneutrino production via $e\gamma
 ightarrow ~ \widetilde{
 u}_j \ell_k$ mediated by $\not \! R$ LL \overline{E} couplings, decaying directly or indirectly via a $\widetilde{\chi}_1^0$ and assuming a single coupling to be nonzero at a time. Final states with three leptons and possible $\not\!\!E_T$ due to neutrinos were selected in the 189–209 GeV data. Limits on the couplings λ_{1jk} as function of the sneutrino mass are shown in Figs. 10–14. The couplings λ_{232} and λ_{233} are not accessible and λ_{121} and λ_{131} are measured with better accuracy in sneutrino resonant production. For all tested couplings, except λ_{133} , the limits are significantly improved compared to the law according to compared to the low-energy limits.
- 28 ABBIENDI 00R studied the effect of s- and *t*-channel au or μ sneutrino exchange in $e^+e^- o e^+e^-$ at \sqrt{s} =130–189 GeV, via the R-parity violating coupling $\lambda_{111}L_1L_2$ (i=2 or 3). The limits quoted here hold for λ_{1i1} >0.13, and supersede the results of ABBIENDI 99. See Fig. 11 for limits on $m_{\widetilde{\nu}}$ versus coupling.
- ²⁹ABBIENDI 90. Studied the effect of s-channel τ sneutrino exchange in $e^+e^- \rightarrow \mu^+\mu^-$ at \sqrt{s} =130-189 GeV, in presence of the R-parity violating couplings $\lambda_{i3i}L_iL_3e_i$ (i=1 and 2), with $\lambda_{131}=\lambda_{232}$. The limits quoted here hold for $\lambda_{131}>0.09$, and supersede the results of ABBIENDI 99. See Fig. 12 for limits on $m_{\widetilde{\nu}}$ versus coupling.
- 30 ABREU 00s searches for anomalies in the production cross sections and forwardbackward asymmetries of the $\ell^+\ell^-(\gamma)$ final states $(\ell=e,\mu, au)$ from e^+e^- collisions vacuation asymmetries of the $\ell^+\ell^-(\gamma)$ final states ($\ell=e,\mu,\tau$) from e^+e^- collisions at $\sqrt{s}=130-189$ GeV. Limits are set on the s- and t-channel exchange of sneutrinos in the presence of R with $\lambda L L E$ couplings. For points between the energies at which data were taken, information is obtained from events in which a photon was radiated. Exclusion limits in the $(\lambda,m_{\widetilde{\nu}})$ plane are given in Fig. 5. These limits include and update the results of ABREU 99A.
- 31 ACCIARRI 00P use the dilepton total cross sections and asymmetries at $\sqrt{s} = m_Z$ and \sqrt{s} =130-189 GeV data to set limits on the effect of $RLL\overline{E}$ couplings giving rise to μ or au sneutrino exchange. See their Fig. 5 for limits on the sneutrino mass versus couplings.
- 32 BARATE 001 studied the effect of s-channel and $\it t$ -channel $\it au$ or $\it \mu$ sneutrino exchange in ightarrow $e^+\,e^-$ at \sqrt{s} = 130–183 GeV, via the *R*-parity violating coupling $\lambda_{1j1} L_1 L_j e_1^C$ (i=2 or 3). The limits quoted here hold for $\lambda_{1/1}>0.1$. See their Fig. 15 for limits as a function of the coupling. Superseded by SCHAEL 07A.
- 33 BARATE 001 studied the effect of s-channel au sneutrino exchange in $e^+e^ightarrow \,\mu^+\mu^$ at \sqrt{s} = 130–183 GeV, in presence of the *R*-parity violating coupling $\lambda_{j3j}L_jL_3e_j^C$ (i=1 and 2). The limits quoted here hold for $\sqrt{|\lambda_{131}\lambda_{232}|}>0.2$. See their Fig. 16 for limits as a function of the coupling. Superseded by SCHAEL 07A. ³⁴ ABBIENDI 99 studied the effect of t-channel electron sneutrino exchange in $e^+e^- \rightarrow$
- $au^+\, au^-$ at \sqrt{s} = 130 183 GeV, in presence of the R -parity violating couplings $\lambda_{131} L_1 L_3 e_1^C$. The limits quoted here hold for $\lambda_{131} > 0.6$.
- 35 ACCIARRI 970 studied the effect of the s-channel tau-sneutrino exchange in $e^+e^-\to e^+e^-$ at $\sqrt{s}=m_Z$ and $\sqrt{s}=130$ –172 GeV, via the R-parity violating coupling $\lambda_{131}L_1L_i^ee_1^e$. The limits quoted here hold for $\lambda_{131}>0.05$. Similar limits were studied in $e^+\,e^-\,\rightarrow\,\,\mu^+\,\mu^-$ together with $\lambda_{232} {\it L}_2 \,{\it L}_3 \,e_2^c$ coupling.
- 36 CARENA 97 studied the constraints on chargino and sneutrino masses from muon g-2. The bound can be important for large $\tan\beta$. The bound can be important for large $\tan\beta$. The bound can be important for large $\tan\beta$. Where $\overline{\nu} \to \nu \chi_1^0$ and χ_1^0 decays via R-parity
- violating interactions into two leptons and a neutrino.
- ³⁸ BECK 94 limit can be inferred from limit on Dirac neutrino using $\sigma(\tilde{\nu})=4\sigma(\nu)$. Also private communication with H.V. Klapdor-Kleingrothaus.
- 39 FALK 94 puts an upper bound on $m_{\widetilde{
 u}}$ when $\widetilde{
 u}$ is LSP by requiring its relic density does not overclose the Universe
- 40 SATO 91 search for high-energy neutrinos from the sun produced by annihilation of sneutrinos in the sun. Sneutrinos are assumed to be stable and to constitute dark matter in our galaxy. SATO 91 follow the analysis of NG 87, OLIVE 88, and GAISSER 86.

CHARGED SLEPTONS

This section contains limits on charged scalar leptons $(\bar{\ell},$ with $\ell = e, \mu, \tau)$. Studies of width and decays of the Z boson (use is made here of $\Delta \Gamma_{\rm inV} < 2.0$ MeV, LEP 00) conclusively rule out $m_{\overline{\ell}_R} < 40$ GeV (41

GeV for $\widetilde{\ell}_L$) , independently of decay modes, for each individual slepton. The limits improve to 43 GeV (43.5 GeV for $\widetilde{\ell}_L$) assuming all 3 flavors to be degenerate. Limits on higher mass sleptons depend on model assumptions and on the mass splitting $\Delta \emph{m}=\emph{m}_{\widetilde{\ell}}-\emph{m}_{\widetilde{\chi}_{1}^{0}}$. The mass and composition

of $\tilde{\chi}_1^0$ may affect the selectron production rate in e^+e^- collisions through t-channel exchange diagrams. Production rates are also affected by the potentially large mixing angle of the lightest mass eigenstate $\widetilde{\ell}_1 = \widetilde{\ell}_R \sin \theta_\ell$ + $\widetilde{\ell}_L$ $\cos\! heta_\ell$. It is generally assumed that only $\widetilde{ au}$ may have significant mixing. The coupling to the Z vanishes for $\theta_\ell{=}0.82$. In the high-energy limit of $e^+\,e^-$ collisions the interference between γ and Z exchange leads to a minimal cross section for $\theta_\ell{=}0.91$, a value which is sometimes used in the following entries relative to data taken at LEP2. When limits on $m_{\widetilde{\ell}_{R}}$ are quoted, it is understood that limits on $m_{\widetilde{\ell}_L}$ are usually at least as strong.

Possibly open decays involving gauginos other than $\widetilde{\chi}_1^0$ will affect the detection efficiencies. Unless otherwise stated, the limits presented here result from the study of $\widetilde{\ell}^+\widetilde{\ell}^-$ production, with production rates and decay properties derived from the MSSM. Limits made obsolete by the recent analyses of $e^+\,e^-$ collisions at high energies can be found in previous Editions of this Review.

For decays with final state gravitinos (\widetilde{G}), $m_{\widetilde{G}}$ is assumed to be negligible relative to all other masses.

 1 ABBIENDI 04 search for $\widetilde{e}_R\,\widetilde{e}_R^{}$ production in acoplanar di-electron final states in the 183–208 GeV data. See Fig. 13 for the dependence of the limits on $m_{\widetilde{\chi}_1^0}$ and for the limit at $\tan\beta$ =35 This limit supersedes ABBIENDI 00G.

ACHARD 04 search for $\widetilde{e}_R\widetilde{e}_L$ and $\widetilde{e}_R\widetilde{e}_R$ production in single- and acoplanar di-electron final states in the 192–209 GeV data. Absolute limits on $m_{\widetilde{e}_R}$ are derived from a scan over the MSSM parameter space with universal GUT scale gaugino and scalar masses $m_{1/2}$ and m_0 , $1 \leq \tan\beta \leq 60$ and $-2 \leq \mu \leq 2$ TeV. See Fig. 4 for the dependence of the limits on $m_{\widetilde{\chi}_1^0}$. This limit supersedes ACCIARRI 99w.

 3 ABDALLAH 03M looked for acoplanar dielectron $+
ot \!\!\!E$ final states at $\sqrt{s}=1$ 89–208 GeV. The limit assumes $\mu=-200$ GeV and $\tan\beta=1.5$ in the calculation of the production cross section and $B(\widetilde{e}\to e\chi_1^0)$. See Fig. 15 for limits in the $(m_{\widetilde{e}_R},m_{\chi_1^0})$ plane. These limits include and update the results of ABREU 01

 4 ABDALLAH 03M uses data from $\sqrt{s}=192$ –208 GeV to obtain limits in the framework of the MSSM with gaugino and sfermion mass universality at the GUT scale. An indirect of the MSSM with gaugino and stermion mass universality at the GUT scale. An indirect limit on the mass is derived by constraining the MSSM parameter space by the results from direct searches for neutralinos (including cascade decays) and for sleptons. These limits are valid for values of $M_2 < 1 \text{ TeV}$, $|\mu| \leq 1 \text{ TeV}$ with the $\tilde{\chi}_1^0$ as LSP. The quoted limit is obtained when there is no mixing in the third family. See Fig. 43 for the mass limits as a function of tan β . These limits update the results of ABREU 00w. 5 HEISTER 02E looked for acoplanar dielectron $+ \not\!\! E_T$ final states from e^+e^- interactions between 183 and 209 GeV. The mass limit assumes $\mu < -200$ GeV and $\tan \beta = 2$ for the

production cross section and B($\tilde{e} \rightarrow e \tilde{\chi}_1^0$)=1. See their Fig. 4 for the dependence of the limit on Δm . These limits include and update the results of BARATE 01.

⁶ HEISTER 02N search for \widetilde{e}_R \widetilde{e}_L and \widetilde{e}_R \widetilde{e}_R production in single- and acoplanar di-electron final states in the 183–208 GeV data. Absolute limits on $m_{\widetilde{e}_R}$ are derived from a scan over the MSSM parameter space with universal GUT scale gaugino and scalar masses $m_{1/2}$ and m_0 , $1 \leq \tan\beta \leq 50$ and $-10 \leq \mu \leq 10$ TeV. The region of small $|\mu|$, where cascade decays are important, is covered by a search for $\widetilde{\chi}_1^0\widetilde{\chi}_3^0$ in final states with leptons and possibly photons. Limits on $m_{\widetilde{e}_L}$ are derived by exploiting the mass relation between the \widetilde{e}_L and \widetilde{e}_R , based on universal m_0 and $m_{1/2}$. When the constraint from the mass limit of the lightest Higgs from HEISTER 02 is included, the bounds improve

the mass limit of the lightest Higgs from HEISTER 02 is included, the bounds improve to $m_{\widetilde{e}_R} > 77(75)$ GeV and $m_{\widetilde{e}_L} > 115(115)$ GeV for a top mass of 175(180) GeV. In the MSUGRA framework with radiative electroweak symmetry breaking, the limits improve further to $m_{\widetilde{e}_R} > 95$ GeV and $m_{\widetilde{e}_L} > 152$ GeV, assuming a trilinear coupling $A_0 = 0$ at the GUT scale. See Figs. 4, 5, 7 for the dependence of the limits on tan β . 7 ABBIENDI 04F use data from $\sqrt{s} = 189-209$ GeV. They derive limits on sparticle masses under the assumption of R with $LL\overline{E}$ or $LQ\overline{D}$ couplings. The results are valid for $tan\beta = 1.5$, $\mu = -200$ GeV, with, in addition, $\Delta m > 5$ GeV for indirect decays via $LQ\overline{D}$. The limit quoted applies to direct decays via $LL\overline{E}$ or $LQ\overline{D}$ couplings. For indirect decays, the limits on the \overline{e}_R mass are respectively 99 and 92 GeV for $LL\overline{E}$ and $LQ\overline{D}$ couplings and $m_{\pi^+} = 10$ GeV and degrade slightly for larger \overline{s}^0 mass. Supersedes the results of and $m_{\widetilde{\chi}0}=10$ GeV and degrade slightly for larger $\widetilde{\chi}_1^0$ mass. Supersedes the results of

and $m_{\gamma 0}=10$ GeV and degrade signify for larger χ_1^2 mass. Supersedes the results of ABBIENDI 00. ABDALLAH 04M use data from $\sqrt{s}=192-208$ GeV to derive limits on sparticle masses under the assumption of R with LLE or \overline{UDD} couplings. The results are valid for $\mu=-200$ GeV, $\tan\beta=1.5$, $\Delta m>5$ GeV and assuming a BR of 1 for the given decay. The limit quoted is for indirect \overline{UDD} decays using the neutralino constraint of 39.5 GeV for LLE and of 38.0 GeV for \overline{UDD} couplings, also derived in ABDALLAH 04M. For indirect decays via LLE the limit improves to 95 GeV if the constraint from the neutralino is used and to 94 GeV if it is not used. For indirect decays via \overline{UDD} couplings it remains unchanged when the neutralino constraint is not used. Supersedes the result of ABRELI 0001.

ABREU 00U. HEISTER 03G searches for the production of selectrons in the case of \Re prompt decays with $LL\overline{E}$, $LQ\overline{D}$ or \overline{UDD} couplings at $\sqrt{s}=189$ –209 GeV. The search is performed for direct and indirect decays, assuming one coupling at a time to be non-zero. The limit holds for indirect decays mediated by $LQ\overline{D}$ couplings with $\Delta m>10$ GeV. Limits are also given for $LL\overline{E}$ direct ($m_{\widetilde{e},R}>96$ GeV) and indirect decays ($m_{\widetilde{e},R}>96$ GeV for

 $m(\widetilde{\chi}_1^0) >$ 23 GeV from BARATE 98s) and for $\overline{\mathit{UDD}}$ indirect decays ($m_{\widetilde{e},R} >$ 94 GeV

with $\Delta m~>10$ GeV). Supersedes the results from BARATE 01B.

with $\Delta m > 10$ GeV). Supersedes the results from BARALE ULB. 10 ACHARD 02 searches for the production of selectrons in the case of R prompt decays with $LL\overline{E}$ or \overline{UDD} couplings at \sqrt{s} =189-208 GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The limit holds for direct decays via $LL\overline{E}$ couplings. Stronger limits are reached for $LL\overline{E}$ indirect (79 GeV) and for \overline{UDD} direct or indirect (96 GeV) decays.

GeV) and for UDD direct of indirect (90 GeV) decays. If BARATE 01 looked for acoplanar dielectron $+ E_T$ final states at 189 to 202 GeV. The limit assumes $\mu = -200$ GeV and $\tan \beta = 2$ for the production cross section and 100% branching ratio for $\tilde{e} \to e \tilde{\chi}_1^0$. See their Fig. 1 for the dependence of the limit on Δm . These limits include and update the results of BARATE 990.

These limits include and update the results of BAKALE 370. 12 ABBIENDI 00J looked for acoplanar dielectron + E_T final states at \sqrt{s} = 161–183 GeV. The limit assumes $\mu < -100$ GeV and $\tan \beta$ =1.5 for the production cross section and decay branching ratios, evaluated within the MSSM, and zero efficiency for decays other than $\widetilde{e} \rightarrow e \, \widetilde{\chi}_1^0$. See their Fig. 12 for the dependence of the limit on Δm and $\tan \beta$.

13 ABREU 00u studies decays induced by *R*-parity violating *LLE* couplings, using data from √s=189 GeV. They investigate topologies with multiple leptons, assuming one coupling at the time to be nonzero and giving rise to indirect decays. The limits assume a neutralino mass limit of 30 GeV, also derived in ABREU 00u. Updates ABREU 00u.

Superseded by ABDALLAH 04M. $^{14} ABREU$ 00V use data from $\sqrt{s} = 130 \text{-}189$ GeV to search for tracks with large impact ABREU OW use data from $\sqrt{s}=130$ –189 GeV to search for tracks with large impact parameter or visible decay vertices. Limits are obtained as a function of $m_{\widetilde{G}}$, from a scan of the GMSB parameters space, after combining these results with the search for slepton pair production in the SUGRA framework from ABREU 01 to cover prompt decays and on stable particle searches from ABREU 00Q. For limits at different $m_{\widetilde{G}}$, see their Fig. 12.

15 BARATE 00G combines the search for acoplanar dileptons, leptons with large impact parameters, kinks, and stable heavy-charged tracks, assuming 3 flavors of degenerate sleptons, produced in the schannel. Data collected at \sqrt{s} =189 GeV. 16 ACCIARRI 991 establish indirect limits on $m_{\widetilde{e}_R}$ from the regions excluded in the M_2

versus m_0 plane by their chargino and neutralino searches at \sqrt{s} =130–183 GeV. The situations where the $\widetilde{\chi}^0_1$ is the LSP (indirect decays) and where a $\widetilde{\ell}$ is the LSP (direct decays) were both considered. The weakest limit, quoted above, comes from direct

decays with \overline{UDD} couplings; $LL\overline{E}$ couplings or indirect decays lead to a stronger limit. ACCIARRI 98F looked for acoplanar dielectron+ $\not\!\!E_T$ final states at \sqrt{s} =130–172 GeV. The limit assumes $\mu=-$ 200 GeV, and zero efficiency for decays other than $\widetilde{e}_{R}
ightarrow e\,\widetilde{\chi}_{1}^{0}$

See their Fig. 6 for the dependence of the limit on Δm . 18 BARATE 98k looked for $e^+e^-\gamma\gamma+E$ final states at $\sqrt{s}=$ 161–184 GeV. The limit assumes $\mu=-200$ GeV and $\tan\beta=2$ for the evaluation of the production cross section. See Fig. 4 for limits on the $(m_{\widetilde{e}_R},m_{\widetilde{\chi}_1^0})$ plane and for the effect of cascade decays.

19 BREITWEG 98 used positron+jet events with missing energy and momentum to look for $e^+ q \to \widetilde{e} \widetilde{q}$ via gaugino-like neutralino exchange with decays into $(e \widetilde{\chi}_1^0)(q \widetilde{\chi}_1^0)$. See paper for dependences in $m(\widetilde{q})$, $m(\widetilde{\chi}_1^0)$.

 20 AID 96C used positron+jet events with missing energy and momentum to look for $e^+ q
ightarrow$ $\widetilde{e}\,\widetilde{q}$ via neutralino exchange with decays into $(e\,\widetilde{\chi}^0_1)(q\,\widetilde{\chi}^0_1)$. See the paper for dependences on $m_{\widetilde{q}}$, $m_{\widetilde{\chi}_1^0}$

 1 ABBIENDI 04 search for $\widetilde{\mu}_R\,\widetilde{\mu}_R$ production in acoplanar di-muon final states in the 183–208 GeV data. See Fig. 14 for the dependence of the limits on $m_{\widetilde{\chi}_1^0}$ and for the

limit at $\tan\beta$ =35. Under the assumption of 100% branching ratio for $\overline{\mu}_R \to \mu \overline{\chi}_1^0$, the limit improves to 94.0 GeV for $\Delta m > 4$ GeV. See Fig. 11 for the dependence of the limits on m $\overline{\chi}_1^0$ at several values of the branching ratio. This limit supersedes ABBIENDI 006.

² ACHARD 04 search for $\widetilde{\mu}_R\widetilde{\mu}_R$ production in acoplanar di-muon final states in the 192–209 GeV data. Limits on $m_{\widetilde{\mu}_R}$ are derived from a scan over the MSSM parameter space with universal GUT scale gaugino and scalar masses $m_{1/2}$ and m_0 , $1 \leq m_0$ $aneta \leq$ 60 and $-2 \leq \mu \leq$ 2 TeV. See Fig. 4 for the dependence of the limits on $m_{\widetilde{\chi}^0_+}$. This limit supersedes ACCIARRI 99w.

The limit assumes B($\widetilde{\mu} \to ~\mu \widetilde{\chi}_1^0$) = 100%. See Fig. 16 for limits on the $(m_{\widetilde{\mu}_R}, ~m_{\widetilde{\chi}_1^0})$

plane. These limits include and update the results of ABREU 01. ⁴ ABDALLAH 03M uses data from $\sqrt{s} = 192$ –208 GeV to obtain limits in the framework of the MSSM with gaugino and sfermion mass universality at the GUT scale. An indirect limit on the mass is derived by constraining the MSSM parameter space by the results from direct searches for neutralinos (including cascade decays) and for sleptons. These limits are valid for values of M $_2<1$ TeV, $|\mu|\leq 1$ TeV with the $\tilde{\chi}_1^0$ as LSP. The quoted limit is obtained when there is no mixing in the third family. See Fig. 43 for the mass limits as a function of tan β . These limits update the results of ABREU 00w.

 5 HEISTER 02E looked for acoplanar dimuon $+
ot \!\!\!\!E_T$ final states from $e^+ \, e^-$ interactions between 183 and 209 GeV. The mass limit assumes B($\widetilde{\mu} \to \mu \widetilde{\chi}_1^0$)=1. See their Fig. 4 for the dependence of the limit on Δm . These limits include and update the results of

for the dependence of the limit on Δm . These minits include and appared to example BARATE 01. 6 ABAZOV 06i looked in 380 pb $^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for events with at least 2 muons and 2 jets for s-channel production of $\tilde{\mu}$ or $\tilde{\nu}$ and subsequent decay via R couplings $LQ\overline{D}$. The data are in agreement with the SM expectation. They set limit to the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set of the set o on resonant slepton production and derive exclusion contours on λ'_{211} in the mass plane of $\widetilde{\ell}$ versus $\widetilde{\chi}_1^0$ assuming a MSUGRA model with $\tan\beta=$ 5, $\mu<0$ and $A_0=0$, see their Fig. 3. For $\lambda'_{211} \geq 0.09$ slepton masses up to 358 GeV are excluded. Supersedes the results of ABAZOV 02H.

ABBIENDI 04F use data from $\sqrt{s} = \underline{1}89 - 209$ GeV. They derive limits on sparticle masses ABBLENDI 04F use data from $\sqrt{s} = 169 - 209$ GeV. They derive limits on sparticle masses under the assumption of R with $LL\overline{E}$ or $LQ\overline{D}$ couplings. The results are valid for $\tan\beta$ = 1.5, μ = -200 GeV, with, in addition, $\Delta m > 5$ GeV for indirect decays via $LQ\overline{D}$. The limit quoted applies to direct decays with $LL\overline{E}$ couplings and improves to 75 GeV for $LQ\overline{D}$ couplings. The limits on the $\overline{\mu}_R$ mass for indirect decays are respectively 94 and 87 GeV for $LL\overline{E}$ and $LQ\overline{D}$ couplings and $m_{\widetilde{\chi}^0} = 10$ GeV. Supersedes the results

of ABBIENDI 00. of ABBIENDI 00. 8 ABDALLAH 04M use data from $\sqrt{s}=192-208$ GeV to derive limits on sparticle masses under the assumption of R with LLE or \overline{UDD} couplings. The results are valid for $\mu=-200$ GeV, $\tan\beta=1.5$, $\Delta m > 5$ GeV and assuming a BR of 1 for the given decay. The limit quoted is for indirect \overline{UDD} decays using the neutralino constraint of 39.5 GeV for \overline{UDD} couplings, also derived in ABDALLAH 04M. For indirect decays via LLE the limit improves to 90 GeV if the constraint from the neutralino is used and remains at 87 GeV if it is not used. For indirect decays via \overline{UDD} couplings it decayed to 25 GeV when the neutralino constraint is not used. degrades to 85 GeV when the neutralino constraint is not used. Supersedes the result of ABREU 00u.

ABREU 000.

HEISTER 03G searches for the production of smuons in the case of R prompt decays with LLE, $LQ\overline{D}$ or \overline{UDD} couplings at $\sqrt{s}=189-209$ GeV. The search is performed for direct and indirect decays, assuming one coupling at a time to be non-zero. The limit holds for direct decays mediated by R $LQ\overline{D}$ couplings and improves to 90 GeV for indirect decays (for $\Delta m > 10$ GeV). Limits are also given for $LL\overline{E}$ direct ($m_{\overline{L}R} > 87$ GeV) and indirect Rdecays ($m_{\widetilde{u}R} >$ 96 GeV for $m(\widetilde{\chi}^0_1) >$ 23 GeV from BARATE 98s) and for \overline{UDD} indirect

decays ($m_{\widetilde{\mu}R}^{-}$ > 85 GeV for Δm > 10 GeV). Supersedes the results from BARATE 01B. 10 ABAZOV 02H looked in 94 pb $^{-1}$ of $p\bar{p}$ collisions at $\sqrt{s}{=}1.8$ TeV for events with at least 2 muons and 2 jets for $s{=}$ -channel production of $\bar{\mu}$ or $\bar{\nu}$ and subsequent decay via R couplings $LQ\bar{D}$. A scan over the MSUGRA parameters is performed to exclude regions of the $(m_0,m_{1/2})$ plane, examples being shown in Fig. 2.

11 ACHARD 02 searches for the production of smuons in the case of

R prompt decays with

LLE or UDD couplings at √s=189-208 GeV. The search is performed for direct and
indirect decays, assuming one coupling at the time to be nonzero. The limit holds for
direct decays via LLE couplings. Stronger limits are reached for LLE indirect (87 GeV)
and for UDD direct or indirect (86 GeV) decays.

The limit assumes $B(\widetilde{\mu} \to \mu \widetilde{\chi}_1^0) = 1$. Using decay branching ratios derived from the MSSM, a lower limit of 65 GeV is obtained for $\mu < -100$ GeV and $\tan \beta = 1.5$. See their Figs. 10 and 13 for the dependence of the limit on the branching ratio and on Δm .

14 ABREU 00v use data from \sqrt{s} = 130-189 GeV to search for tracks with large impact parameter or visible decay vertices. Limits are obtained as function of $m_{\widetilde{C}}$, after combining these results with the search for slepton pair production in the SUGRA framework from ABREU 01 to cover prompt decays and on stable particle searches from ABREU 000. For limits at different $m_{\widetilde{\mathbb{Q}}}$, see their Fig. 12.

Supersymmetric Particle Searches

 15 BARATE 98K looked for $\mu^+\mu^-\gamma\gamma+\not\!\!E$ final states at $\sqrt{s}=$ 161–184 GeV. See Fig. 4 for limits on the $(m_{\widetilde{\mu}_R},m_{\widetilde{\chi}_1^0})$ plane and for the effect of cascade decays.

 1 ABBIENDI 04 search for $\widetilde{ au}\widetilde{ au}$ production in acoplanar di-tau final states in the 183–208 GeV data. See Fig. 15 for the dependence of the limits on $m_{\widetilde{\chi}_1^0}$ and for the limit

at $\tan\beta$ =35. Under the assumption of 100% branching ratio for $\tilde{\tau}_R \to \tau \tilde{\chi}_1^0$, the limit improves to 89.8 GeV for $\Delta m >$ 8 GeV. See Fig. 12 for the dependence of the limits on $\tilde{\chi}_1^0$ at level values of the branching ratio and for their dependence on θ_{τ} . This limit supersedes ABBIENDI 00G.

 2 ACHARD 04 search for $\widetilde{\tau\tau}$ production in acoplanar di-tau final states in the 192–209 GeV data. Limits on $m_{\widetilde{\tau}_R}$ are derived from a scan over the MSSM parameter space with universal GUT scale gaugino and scalar masses $m_{1/2}$ and m_0 , $1 \le an\!eta \le 60$ and $-2 \le \mu \le 2$ TeV. See Fig. 4 for the dependence of the limits on $m_{\widetilde{\chi}_1^0}$

 3 ABDALLAH 03M looked for acoplanar ditaus + E final states at $\sqrt{s} = 130$ –208 GeV. A dedicated search was made for low mass $\tilde{\tau}s$ decoupling from the Z^0 . The limit assumes B($\tilde{\tau} \rightarrow ~\tau \tilde{\chi}_1^0) = 100\%$. See Fig. 20 for limits on the $(m_{\widetilde{\tau}}, m_{\widetilde{\chi}_1^0})$ plane and as function

of the $\widetilde{\chi}_1^0$ mass and of the branching ratio. The limit in the loranss region improves to 29.6 and 31.1 GeV for $\widetilde{\tau}_R$ and $\widetilde{\tau}_L$, respectively, at $\Delta m > m_\tau$. The limit in the high-mass region improves to 84.7 GeV for $\widetilde{\tau}_R$ and $\Delta m > 15$ GeV. These limits include and update the results of ABREU 01.

4 HEISTER 02E looked for acoplanar ditau $+ \not\!\!E_T$ final states from e^+e^- interactions between 183 and 209 GeV. The mass limit assumes B($ilde{ au} o au ilde{\chi}_1^0$)=1. See their Fig. 4 for the dependence of the limit on Δm . These limits include and update the results of BARATE 01.

BARATE 01. ABBIENDI 06B use 600 pb $^{-1}$ of data from $\sqrt{s}=189-209$ GeV. They look for events from pair-produced staus in a GMSB scenario with $\tilde{\tau}$ NLSP including prompt $\tilde{\tau}$ decays to ditaus $+\not\!\!E$ final states, large impact parameters, kinked tracks and heavy stable charged particles. Limits on the cross-section are computed as a function of m($\tilde{\tau}$) and the lifetime, see their Fig. 7. The limit is compared to the $\sigma \cdot BR^2$ from a scan over the GMSB parameter space.

GMBB parameter space.

6 ABBIENDI 04F use data from $\sqrt{s} = 189-209$ GeV. They derive limits on sparticle masses under the assumption of R with $LL\overline{E}$ or $LQ\overline{D}$ couplings. The results are valid for $\tan \beta = 1.5$, $\mu = -200$ GeV, with, in addition, $\Delta m > 5$ GeV for indirect decays via $LQ\overline{D}$. The limit quoted applies to direct decays with $LL\overline{E}$ couplings and improves to 75 GeV for $LQ\overline{D}$ couplings. The limit on the T_R mass for indirect decays is 92 GeV for $LL\overline{E}$ couplings at $m_{\sim 0}=10~{
m GeV}$ and no exclusion is obtained for $L\,Q\,\overline{D}$ couplings. Supersedes

the results of ABBIENDI 00. 7 ABDALLAH 04H use data from ABDALLAH 03M to put limits on the parameter space of anomaly-mediated supersymmetry breaking (AMSB), which is scanned in the region $1 < m_{3/2} < 50 \, {\rm TeV}$, $0 < m_0 < 1000 \, {\rm GeV}$, $1.5 < {\tan\beta} < 35$, both signs of μ . The constraints are obtained from the searches for mass degenerate chargino and neutralino, for SM-like and invisible Higgs, for leptonically decaying charginos and from the limit on non-SM Z width of 3.2 MeV. The limit is for $m_t=174.3~{\rm GeV}$ (see Table 2 for other m_t values).

width of 3.2 MeV. The limit is for $m_t=174.3$ GeV (see Table 2 for other m_t values). 8 The limit improves to 75 GeV for $\mu<0$. 9 ABDALLAH 04M use data from $\sqrt{s}=192-208$ GeV to derive limits on sparticle masses under the assumption of R with $LL\overline{E}$ couplings. The results are valid for $\mu=-200$ GeV, $\tan \beta=1.5$, $\Delta m>5$ GeV and assuming a BR of 1 for the given decay. The limit quoted is for indirect decays using the neutralino constraint of 39.5 GeV, also derived in ABDALLAH 04M. For indirect decays via $LL\overline{E}$ the limit decreases to 86 GeV if the constraint from the neutralino is not used. Supersedes the result of ABREU 00u.
10 ABDALLAH 03D use data from $\sqrt{s}=130-208$ GeV to search for tracks with large impact parameter or visible decay vertices and for heavy charged stable particles. Limits are obtained as function of m(\overline{G}), after combining these results with the search for slepton pair production in the SUGRA framework from ABDALLAH 03M to cover prompt decays.
The above limit is reached for the stau decaying promptly, m(\overline{G}) < 6 eV, and is computed

for $LL\overline{E}$ direct $(m_{\widetilde{\tau}_R}~>87~{\rm GeV})$ and indirect decays $(m_{\widetilde{\tau}_R}~>95~{\rm GeV}$ for $m(\widetilde{\chi}^0_1)>23$ GeV from BARATE 985) and for $LQ\overline{D}$ indirect decays $(m_{\widetilde{\tau}_R}~>76~{\rm GeV})$. Supersedes

the results from BARATE 01B. $^{12}\text{ACHARD 02} \text{ searches for the production of staus in the case of } R \text{ prompt decays with } LLE \text{ or } UDD \text{ couplings at } \sqrt{s=189-208} \text{ GeV}. \text{ The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The limit holds for direct decays via LLE couplings. Stronger limits are reached for LLE indirect (86 GeV) and for UDD direct or indirect (75 GeV) decays.$

 13 HEISTER 02R search for signals of GMSB in the 189–209 GeV data. For the $ilde{\chi}^0_1$ NLSP 3 HEISTER 02n search for signals of GMSB in the 189–209 GeV data. For the $\overline{\chi}_1^{\rm M}$ NLSP scenario, they looked for topologies consisting of $\gamma\gamma E$ or a single γ not pointing to the interaction vertex. For the $\bar{\ell}$ NLSP case, the topologies consist of $\ell L E$, including leptons with large impact parameters, kinks, or stable particles. Limits are derived from a scan over the GMSB parameters (see their Table 5 for the ranges). The limit remains valid whichever is the NLSP. The absolute mass bound on the $\bar{\chi}_1^0$ for any lifetime includes indirect limits from the slepton search HEISTER 02E preformed within the MSUGRA framework. A bound for any NLSP and any lifetime of 77 GeV has also been derived by using the constraints from the neutral Higgs search in HEISTER 02. In the co-NLSP scenario, limits $m_{\widetilde{\ell}_R} >$ 83 GeV (neglecting t-channel exchange) and $m_{\widetilde{\mu}_R} >$ 88 GeV are obtained independent of the lifetime. Supersedes the results from BARATE 00G. A slight ABRATE 01 looked for accolance disaute. For final states at 189 to 202 GeV. A slight

 14 BARATE 01 looked for acoplanar ditau + E_T final states at 189 to 202 GeV. A slight excess (with 1.2% probability) of events is observed relative to the expected SM background. The limit assumes 100% branching ratio for $\tilde{\tau} \to \tau \tilde{\chi}_1^0$. See their Fig. 1 for the dependence of the limit on Δm . These limits include and update the results of

15 ABBIENDI 00J looked for acoplanar ditau $+
ot \!\!\!E_T$ final states at \sqrt{s} = 161–183 GeV. The limit assumes B($ilde{ au} o au \widetilde{\chi}_1^0$)=1. Using decay branching ratios derived from the MSSM, a lower limit of 60 GeV at $\Delta m >$ 9 GeV is obtained for $\mu < -100$ GeV and $an \beta$ =1.5. See their Figs. 11 and 14 for the dependence of the limit on the branching ratio and on

 $16\,\Delta m$.

16 ABREU 00v use data from $\sqrt{s}=130-189$ GeV to search for tracks with large impact parameter or visible decay vertices. Limits are obtained as function of $m_{\widetilde{G}}$, after combining these results with the search for slepton pair production in the SUGRA framework from ABREU 01 to cover prompt decays and on stable particle searches from ABREU 00q. The above limit assumes the degeneracy of stau and smuon. For limits at different $m_{\widetilde{G}}$,

17 ABREU 000 used data from \sqrt{s} = 130–189 GeV to search for tracks with large impact parameter or visible decay vertices. Limits are obtained as function of $m_{\widetilde{e}}$, after combining these results with the search for slepton pair production in the SUGRA framework from ABREU 01 to cover prompt decays and on stable particle searches from ABREU 000. The above limit is reached for the stau mixing yielding the minimal cross section and decaying promptly. Stronger limits are obtained for longer lifetimes or for $\widetilde{\tau}_R$; see their Fig. 11. For $10 \le m_{\widetilde{G}} \le 310\,\mathrm{eV}$, the whole range $2 \le m_{\widetilde{\tau}_1} \le 80\,\mathrm{GeV}$ is excluded. Supersedes the results of ABREU 99c and ABREU 99F.

 18 BARATE 98K looked for $au^+ au^-\gamma\gamma+
ot\!\!E$ final states at $\sqrt{s}=$ 161–184 GeV. See Fig. 4 for limits on the $(m_{\widetilde{\tau}_R}, m_{\widetilde{\chi}_1^0})$ plane and for the effect of cascade decays

Degenerate Charged Sleptons

Unless stated otherwise in the comment lines or in the footnotes, the following limits assume 3 families of degenerate charged sleptons.

¹ BARATE 01 looked for acoplanar dilepton $+ \not\!\! E_T$ and single electron (for $\widetilde{e}_R \widetilde{e}_L$) final states at 189 to 202 GeV. The limit assumes $\mu = -200$ GeV and $\tan \beta = 2$ for the production states at 189 to 202 GeV. The limit assumes $\mu=-200$ GeV and $\tan\beta=2$ for the production cross section and decay branching ratios, evaluated within the MSSM, and zero efficiency for decays other than $\ell\to\ell\chi_1^0$. The slepton masses are determined from the GUT relations without stau mixing. See their Fig. 1 for the dependence of the limit on Δm . ² ABBIENDI 06B use 600 pb⁻¹ of data from $\sqrt{s}=189-209$ GeV. They look for events from pair-produced staus in a GMSB scenario with ℓ co-NLSP including prompt ℓ decays to dileptons +E final states, large impact parameters, kinked tracks and heavy stable

charged particles. Limits on the cross-section are computed as a function of $m(\widetilde{\ell})$ and the lifetime, see their Fig. 7. The limit is compared to the $\sigma \cdot BR^2$ from a scan over the GMSB parameter space. The highest mass limit is reached for $\widetilde{\mu}_R$, from which the quoted mass limit is derived by subtracting $m_{\mathcal{T}}$.

quoted mass limit is derived by subtracting $m_{\mathcal{T}}$. 3 ABDALLAH 03D use data from $\sqrt{s}=130$ –208 GeV to search for tracks with large impact parameter or visible decay vertices and for heavy charged stable particles. Limits are obtained as function of m(\widetilde{G}), after combining these results with the search for slepton pair production in the SUGRA framework from ABDALLAH 03M to cover prompt decays The above limit is reached for prompt decays and assumes the degeneracy of the sleptons. For limits at different m(\widetilde{G}), see their Fig. 9. Supersedes the results of ABREU 01G. 4 ACHARD 02 searches for the production of sparticles in the case of R prompt decays with $LL\widetilde{E}$ or \overline{UDD} couplings at \sqrt{s} =189–208 GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The MSUGRA limit results from a scan over the MSSM parameter space with the assumption of gaugino and scalar mass unification at the GUT scale and no mixing in the slepton sector, imposing simultaneously the exclusions from neutralino, chargino, sleptons, and squarks analyses. The limit holds for $LL\widetilde{E}$ couplings, see ACCIARRI 01. L3 limits from $LQ\overline{D}$ couplings, see ACCIARRI 01.

⁵ ABBIENDI 01 looked for final states with $\gamma\gamma E$, $\ell\ell E$, with possibly additional activity and four leptons + E to search for prompt decays of $\widetilde{\chi}_1^0$ or $\overline{\ell}_1$ in GMSB. They derive limits in the plane $(m_{\widetilde{\chi}_1^0}, m_{\widetilde{\tau}_1})$, see Fig. 6, allowing either the $\widetilde{\chi}_1^0$ or a $\overline{\ell}_1$ to be the NLSP.

Two scenarios are considered: $\tan\beta=2$ with the 3 sleptons degenerate in mass and $\tan\beta=20$ where the $\tilde{\tau}_1$ is lighter than the other sleptons. Data taken at $\sqrt{s}=189$ GeV. For $\tan\beta=20$, the obtained limits are $m_{\tilde{\tau}_1}>69$ GeV and $m_{\tilde{e}_1,\tilde{\mu}_1}>88$ GeV.

⁶ ABREU 01 looked for acoplanar dilepton + diphoton + E final states from $\tilde{\ell}$ cascade decays at \sqrt{s} =130–189 GeV. See Fig. 9 for limits on the (μ, M_2) plane for $m_{\tilde{\ell}}$ =80 GeV, _tan β =1.0, and assuming degeneracy of $\tilde{\mu}$ and $\tilde{\epsilon}$.

ACCIARRI 01 searches for multi-lepton and/or multi-jet final states from R prompt decays with LLE, $LQ\overline{D}$, or \overline{UDD} couplings at \sqrt{s} =189 GeV. The search is performed for direct and indirect decays of neutralinos, charginos, and scalar leptons, with the $\overline{\chi}_1^0$ or a $\overline{\ell}$ as LSP and assuming one coupling to be nonzero at a time. Mass limits are derived using simultaneously the constraints from the neutralino, chargino, and slepton analyses; and the Z^0 width measurements from ACCIARRI 00c in a scan of the parameter space assuming MSUGRA with gaugino and scalar mass universality. Updates and supersedes the results from ACCIARRI 90.

the results from ACCIARRI 99. 8 ABREU 000 use data from $\sqrt{s} = 130-189$ GeV to search for tracks with large impact parameter or visible decay vertices. Limits are obtained as function of $m_{\widetilde{G}}$, after combining these results with the search for slepton pair production in the SUGRA framework from ABREU 01 to cover prompt decays and on stable particle searches from ABREU 00Q. For limits at different $m_{\widetilde{G}}$, see their Fig. 12.

⁹The above limit assumes the degeneracy of stau and smuon.

Long-lived $\widetilde{\boldsymbol{\ell}}$ (Slepton) MASS LIMIT

Limits on scalar leptons which leave detector before decaying. Limits from Z decays are independent of lepton flavor. Limits from continuum e^+e^- annihilation are also independent of flavor for smuons and staus. Selectron limits from e^+e^- collisions in the continuum depend on MSSM parameters because of the additional neutralino exchange contribution.

| >136 | 95 | ⁵ AAD | 11P | ATLS | stable $\widetilde{	au}$, GMSB sce- nario, $	aneta=5$ |

 1 ABBIENDI 03L used e^+e^- data at $\sqrt{s}=130\text{--}209$ GeV to select events with two high momentum tracks with anomalous dE/dx. The excluded cross section is compared to the theoretical expectation as a function of the heavy particle mass in their Fig. 3. The limit improves to 98.5 GeV for $\bar{\mu}_L$ and $\bar{\tau}_L$. The bounds are valid for colorless spin 0 particles with lifetimes longer than 10^{-6} s. Supersedes the results from ACKERSTAFF 98P.

 2 ABREU 00Q searches for the production of pairs of heavy, charged stable particles in $e^+\,e^-$ annihilation at $\sqrt{s}{=}\,130{-}189$ GeV. The upper bound improves to 88 GeV for $\widetilde{\mu}_L$, $\widetilde{\tau}_L$. These limits include and update the results of ABREU 98P.

 3 ACCIARRI 99H searched for production of pairs of back-to-back heavy charged particles at \sqrt{s} =130–183 GeV. The upper bound improves to 82.2 GeV for $\widetilde{\mu}_L$, $\widetilde{\tau}_L$

 4 The BARATE 98K mass limit improves to 82 GeV for $\widetilde{\mu}_L,\widetilde{\tau}_L$. Data collected at $\sqrt{s}{=}161{-}184$ GeV.

 \sqrt{s} =161-184 GeV. 5 AAD 11P looked in 37 pb $^{-1}$ of pp collisions at \sqrt{s} = 7 TeV for events with two heavy stable particles, reconstructed in the Inner tracker and the Muon System and identified by their time of flight in the Muon System. No evidence for an excess over the SM expectation is observed. Limits on the mass are derived, see Fig. 3, for \tilde{r} in a GMSB scenario and for sleptons produced by electroweak processes only, in which case the limit degrades to 110 GeV.

q̃ (Squark) MASS LIMIT

For $m_{\widetilde{q}} > 60\text{--}70$ GeV, it is expected that squarks would undergo a cascade decay via a number of neutralinos and/or charginos rather than undergo a direct decay to photinos as assumed by some papers. Limits obtained when direct decay is assumed are usually higher than limits when cascade decays are included.

Limits from $e^+\,e^-$ collisions depend on the mixing angle of the lightest mass eigenstate $\bar{q}_1\!=\!\bar{q}_R\!\sin\!q_q\!+\!\bar{q}_L\!\cos\!q_q$. It is usually assumed that only the sbottom and stop squarks have non-trivial mixing angles (see the stop and sbottom sections). Here, unless otherwise noted, squarks are always taken to be either left/right degenerate, or purely of left or right type. Data from Z decays have set squark mass limits above 40 GeV, in the case of $\bar{q} \to q \bar{\chi}_1$ decays if $\Delta m\!=\!m_{\widetilde{q}}-m_{\widetilde{\chi}_1^0}\!\gtrsim\! 5$ GeV. For smaller values of

 $\Delta m_{\rm r}$ current constraints on the invisible width of the Z ($\Delta \Gamma_{\rm inv} <$ 2.0 MeV, LEP 00) exclude $m_{\widetilde{u}_L,R} <$ 44 GeV, $m_{\widetilde{d}_R} <$ 33 GeV, $m_{\widetilde{d}_L} <$ 44 GeV and, assuming all squarks degenerate, $m_{\widetilde{q}} <$ 45 GeV.

Limits made obsolete by the most recent analyses of e^+e^- , $p\overline{p}$, and ep collisions can be found in previous Editions of this *Review*.

- 1 AAD 11B looked in 35 pb $^{-1}$ of pp collisions at $\sqrt{s}=$ 7 TeV for events with same or opposite charge dileptons (e or μ) and $\not\!\!E_T$ from the production of squarks and gluinos with leptonic decays from $\tilde{\chi}_1^\pm$ or $\tilde{\chi}_2^0$. No evidence for an excess over the SM expectation is observed, and limits are derived in the CMSSM $(m_0, m_{1/2})$ plane (see Fig. 2) and in the $(m_{\widetilde{g}}, m_{\widetilde{q}})$ plane under the assumptions $\tan\beta=4$, $\mu=1.5$ M, $m_{\widetilde{\chi}_2^0}=M$ -100 GeV, $m_{\widetilde{\ell}_L}=\mathrm{M/2}$, $m_{\widetilde{\chi}_1^0}=100$ GeV, where $M=\min(m_{\widetilde{g}}, m_{\widetilde{q}})$ (see Fig. 3). The exclusion limit for a compressed spectrum is 590 GeV for the same charge and 450 GeV for the opposite charge events.
- opposite charge events. 2 AAD 11c looked in 35 pb $^{-1}$ of pp collisions at $\sqrt{s}=7$ TeV for events with jets, same flavor opposite charge dileptons (e or μ) and E_T from the production of squarks and gluinos with decays $\widetilde{q} \to q \widetilde{\chi}_2^0$ and $\widetilde{\chi}_2^0 \to \ell^+\ell^-\widetilde{\chi}_1^0$. No evidence for an excess over the SM expectation is observed, and a limit is derived in the $(m_{\widetilde{q}}, m_{\widetilde{q}})$ plane under the assumptions $\tan\beta = 4$, $\mu = 1.5$ M, $m_{\widetilde{\chi}_2^0} = M 100$ GeV, $m_{\widetilde{\ell}_L^0} = M/2$, $m_{\widetilde{\chi}_1^0} = 100$ GeV, where $M=\min(m_{\widetilde{g}}, m_{\widetilde{q}})$. The excluded mass region is shown in a plane of $(m_{\widetilde{g}}, m_{\widetilde{q}})$, see their Fig. 3. The exclusion limit for a compressed spectrum is 503 GeV.
- 3 AAD 11G looked in 35 pb $^{-1}$ of pp collisions at $\sqrt{s}=$ 7 TeV for events with a single lepton (e or μ), jets and $\not\!\! E_T$ from the production of squarks and gluinos. No evidence for an excess over the SM expectation is observed, and a limit is derived in the CMSSM $(m_0, m_{1/2})$ plane for an eta = 3, see Fig. 2.
- 4 AAD 11N looked in 35 pb $^{-1}$ of ρp collisions at $\sqrt{s}=7$ TeV for events with ≥ 2 jets and $\not\!\!E_T$. Four signal regions were defined, and the background model was found to be in good agreement with the data. Limits are derived in the $(m_{\widetilde{q}}, m_{\widetilde{q}})$ plane (see Fig. 2) for a simplified model where degenerate masses of the squarks of the first two generations are assumed, $m_{\widetilde{\chi}_1^0} = 0$, and all other masses including third generation squarks are set to 5 TeV. Limits are also derived in the CMSSM ($m_0,\,m_{1/2}$) plane (see Fig. 3) for $an\!eta$
- 5 CHATRCHYAN 11w looked in 1.14 fb $^{-1}$ of pp collisions at $\sqrt{s}=7$ TeV for events with ≥ 2 jets, large total jet energy, and E_T . After combining multi-jet events into two pseudo-jets signal events are selected by a cut on $\alpha_T=E_T^{j_2}/M_T$, the transverse energy of the less energetic jet over the transverse mass. Given the lack of an excess over the SM backgrounds, limits are derived in the CMSSM $(m_0, m_{1/2})$ plane (see Fig. 4) for $\tan \beta = 10$. The limits are only weakly dependent on $\tan \beta$ and A_0 .
- tan $\beta=10$. The limits are only weakly dependent on tan β and A_0 . 6 AALTONEN 09s searched in 2 fb⁻¹ of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for events with at least 2 jets and E_T . No evidence for a signal is observed. A limit is derived for a mSUGRA scenario in the $m_{\overline{Q}}$ evenus $m_{\overline{Q}}$ plane, see their Fig. 2. For $m_{\overline{Q}}<340$ GeV the bound increases to 400 GeV. 7 ABAZOV 08G looked in 2.1 fb⁻¹ of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for events with acoplanar jets or multijets with large E_T . No significant excess was found compared to the background expectation. A limit is derived on the masses of squarks and gluinos for specific MSUGRA parameter values, see Figure 3. Similar results would be obtained for a large class of parameter sets. Supersedes the results of ABAZOV 06c. 8 ACHARD 04 search for the production of $\overline{\alpha}$ of the first two generations in acoplanar
- 8 ACHARD 04 search for the production of $q\bar{q}$ of the first two generations in acoplanar di-jet final states in the 192–209 GeV data. Degeneracy of the squark masses is assumed either for both left and right squarks or for right squarks only, as well as $\mathsf{B}(\widetilde{q} o q \, \widetilde{\chi}_1^0) = 1$ See Fig. 7 for the dependence of the limits on $m_{\widetilde{\chi}_1^0}$. This limit supersedes ACCIARRI 99v.
- 9 ABBOTT 01D looked in \sim 108 pb $^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}{=}1.8$ TeV for events with e e, $\mu\mu$, or $e\,\mu$ accompanied by at least 2 jets and E_{T^-} Excluded regions are obtained in the MSUGRA framework from a scan over the parameters 0< m_0 <300 GeV, 10< $m_{1/2}$ <110 GeV, and $1.2 < \tan \beta < 10$.
- 10 BARATE 01 looked for acoplanar dijets $+
 ot\!\!\!E_T$ final states at 189 to 202 GeV. The limit assumes B($\widetilde{q} \to q \widetilde{\chi}_1^0$)=1, with $\Delta m = m_{\widetilde{q}} - m_{\widetilde{\chi}_1^0}$. It applies to tan β =4, μ = -400 GeV. See their Fig. 2 for the exclusion in the $(m_{\widetilde{q}}, m_{\widetilde{g}})^{-1}$ plane. These limits include and update
- the results of BARATE 990. The results of BARATE 990. The results of BARATE 990. The results of searched for production of gluinos and five degenerate squarks in final states containing a pair of leptons, two jets, and missing $E_{\mathcal{T}}$. The two leptons arise from the semileptonic decays of charginos produced in the cascade decays. The limit is derived for

- fixed $\tan\beta=4.0$, $\mu=-400$ GeV, and $m_{H^+}=500$ GeV, and with the cascade decays of the squarks and gluinos calculated within the framework of the Minimal Supergravity
- Scenario. 12 CHATRCHYAN 12 looked in 35 pb $^{-1}$ of pp collisions at $\sqrt{s}=7$ TeV for events with e and/or μ and/or jets, a large total transverse energy, and \rlap/E_T . The event selection is based on the dimensionless razor variable R, related to the \rlap/E_T and M_R , an indicator of the heavy particle mass scale. No evidence for an excess over the expected background is observed. Units are derived in the CMSSM $(m_0, m_1/2)$ plane for $\tan\beta=3$, 10 and
- 50 (see Fig. 7 and 8). Limits are also obtained for Simplified Model Spectra. $^{13}\text{AAD }11\text{AE looked in }34\text{ pb}^{-1}\text{ of }pp\text{ collisions at }\sqrt{s}=7\text{ TeV for events with }\geq2$ same charge isolated leptons (e,μ) and ≥1 jet. They are assumed to come from $\widetilde{q}\widetilde{q}$ production, where the \widetilde{q} decays to $\widetilde{\chi}_1^\pm$ or $\widetilde{\chi}_2^0$ with equal branching ratios, followed by the decays $\tilde{\chi}_1^{\pm} \to W^{\pm} \tilde{\chi}_1^0$ and $\tilde{\chi}_2^0 \to Z^0 \tilde{\chi}_1^0$. No evidence for an excess over the expected background is observed. Limits are derived on the cross sections as a function of the
- masses of the \widetilde{q} , $\widetilde{\chi}_1^{\pm}/\widetilde{\chi}_0^2$ and $\widetilde{\chi}_1^0$ (see Fig. 9 and 10). ¹⁴ AAD 11AF looked in 1.34 fb⁻¹ of pp collisions at $\sqrt{s}=7$ TeV for events with 6 up to 8 jets and \cancel{E}_T . No evidence for an excess over the expected background is observed. Limits are derived in the CMSSM $(m_0, m_{1/2})$ plane for $\tan\beta=10$ (see Fig. 5). The limit improves to $m_{\widetilde{q}}=80$ GeV for $m_{\widetilde{q}}=2$ $m_{\widetilde{g}}=2$.
- 15 AARON 11 looked in 255 pb $^{-1}$ of $e^+ p$ and 183 pb $^{-1}$ of $e^- p$ collisions at $\sqrt{s}=$ 319 GeV for events with at least 1 lepton and jets from R_p violation with $L\,Q\,\overline{D}$ couplings, assuming dominance of a single λ'_{ijk} coupling. No evidence for an excess over the SM expectation is observed, and limits are derived in the $(\lambda', m_{\overline{q}})$ plane for the MSSM with $\tan\beta=6$, see their Figs. 7 and 8. Limits are also derived in a CMSSM-type scenario. ¹⁶ AARON 11c looked in 281 pb $^{-1}$ of e^+p and 165 pb $^{-1}$ of e^-p collisions at $\sqrt{s}=319$
- GeV and \sqrt{s} =301 GeV for contact interactions measured from deviations of the d σ /d Q^2 of neutral current events. They are interpreted in the framework of R-parity violation with $L\,Q\,\overline{D}$ couplings. No evidence for an excess over the SM expectation is observed, and limits are derived for $m_{\widetilde{q}}/\lambda'$, see Table 4.
- 17 CHATRCHYAN 11 AC looked in 36 pb $^{-1}$ of p p collisions at $\sqrt{s}=$ 7 TeV for events with \geq 3 jets, a large total transverse energy, and E_T . No evidence for an excess over the expected background is observed. Limits are derived in the CMSSM $(m_0, m_{1/2})$ plane and the $(m_{\widetilde{g}},m_{\widetilde{q}})$ plane for $\tan\beta=10$ (see Fig. 10). Limits are also obtained for Simplified Model Spectra.
- 18 CHATRCHYAN 11C looked in 34 pb $^{-1}$ of pp collisions at \sqrt{s} =7 TeV for events with opposite charge isolated dileptons (e or μ), jets and E_T from pair production of \tilde{g} and \tilde{q} . No evidence for an excess over the expected background is observed. Limits are derived in the CMSSM $(m_0,\,m_{1/2})$ plane for aneta=3 (see Fig. 4).
- 19 CHATRCHYAN 11G looked in 36 pb $^{-1}$ of pp collisions at $\sqrt{s}=$ 7 TeV for events with \geq 2 isolated photons, 2 1 jet and E_{TP} , which may arise in a generalized gauge mediated model from the decay of a $\widetilde{\chi}_1^0$ NLSP. No evidence for an excess over the expected background is observed. Limits are derived in the plane of squark versus gluino mass (see Fig. 4) for several values of $m_{\widetilde{\chi}_1^0}$.
- 20 CHATRCHYAN 11Q looked in 36 pb $^{-1}$ of pp collisions at $\sqrt{s}=7$ TeV for events with a single isolated lepton (e or μ), \geq 4 jets and \cancel{E}_T . No evidence for an excess over the expected background is observed. Limits are derived in the CMSSM $(m_0,\,m_{1/2})$ plane for $tan \beta = 10$ (see Fig. 7).
- Scenario, 22 CHATRCHYAN 11v looked in 35 pb $^{-1}$ of pp collisions at $\sqrt{s}=7$ TeV for events with ≥ 3 isolated leptons $(e,\mu$ or $\tau)$, with or without jets and E_T . No evidence for an excess over the expected background is observed. Limits are derived in the R framework (see Fig. 4) in the $(m_{\widetilde{g}},m_{\widetilde{q}})$ plane assuming the dominance of a λ_{122} or λ_{123} coupling, $m_{\widetilde{\chi}_1^0}=300$ GeV, $m_{\widetilde{\ell}}=1000$ GeV, and decoupled wino and Higgsino.
- 23 KHACHATRYAN 111 looked in 35 pb $^{-1}$ of pp collisions at $\sqrt{s}=$ 7 TeV for events with \geq 2 jets and $ot\!\!E_T$. After combining multi-jet events into two pseudo-jets signal events are selected by a cut on $\alpha_T=E_T^{j_2}/M_T$, the transverse energy of the less energetic jet over the transverse mass. No evidence for an excess over the expected background is observed. Limits are derived in the CMSSM $(m_0,m_{1/2})$ plane (see Fig. 5) for $\tan\beta=\frac{1}{2}$
- 3. Superseded by CHATRCHYAN 11W. at least 2 jets, a tau decaying hadronically and $\not E_T$ from the production $\vec q_L \vec q_R$, with the taus originating from the decay of a $\vec \chi_2^0$ or $\vec \chi_1^\pm$. The results were combined with ABAZOV 08G which searched for events with jets and $\not E_T$ without requiring taus. No evidence for an excess over the SM expectation is observed. The excluded region is shown for an mSUGRA model in a plane of $m_{1/2}$ versus m_0 in the "tau corridor," see their Figs. 5 and 6. The largest excluded squark mass in the corridor is 340 GeV for the tau analysis only and 410 GeV for the combined analysis.
- 25 SCHAEL 07A studied the effect on hadronic cross sections and charge asymmetries of t-channel down-type squark exchange via R-parity violating couplings $LQ\overline{D}$ at $\sqrt{s}=$ 189–209 GeV. The limit here refers to the case j= 1, 2 and holds for $\lambda^{'}_{1jk}$ of electromagnetic strength. The results of this analysis are combined with BARATE 001.
- 26 CHEKANOV 05A search for lepton flavor violating processes $e^\pm p \to \ell X$, where $\ell=\mu$ or τ with high p_T , in 130 pb $^{-1}$ at 300 and 318 GeV. Such final states may originate from LQD couplings with simultaneously non-zero λ'_{1jk} and λ'_{ijk} (i=2 or 3). The quoted mass bounds hold for a u-type squark, assume a λ' of electromagnetic strength and contributions from only direct squark decays. For d-type squarks the bounds are strengthened to 278 and 275 GeV for the μ and τ final states, respectively. Supersedes
- the results of CHEKANOV 02. 27 AKTAS 04D looked in 77.8 pb $^{-1}$ of $e^\pm p$ collisions at $\sqrt{s}=$ 319 GeV for resonant production of \widetilde{q} by R-parity violating $LQ\overline{D}$ couplings assuming that one of the λ' couplings

Searches Particle Listings Supersymmetric Particle Searches

dominates over all others. They consider final states with or without leptons and/or jets and/or p_T' resulting from direct and indirect decays. They combine the channels to derive limits on $\lambda_{1j1}^{'}$ and $\lambda_{11k}^{'}$ as a function of the squark mass, see their Figs. 8 and 9, from a scan over the parameters 70 < M_2 < 350 GeV, -300 < μ < 300 GeV, $\tan\beta=$ 6, for a fixed mass of 90 GeV for degenerate sleptons and an LSP mass > 30 GeV. The quoted limits refer to $\lambda'=$ 0.3, with U=u,c,t and D=d,s,b. Supersedes the results of ADLOFF 01B. Superseded by AARON 11.

 28 ADLOFF 03 looked for the s-channel production of squarks via R $LQ\overline{D}$ couplings in The comparison of the s-channel production or squarks via k LQD couplings in 117.2 pb $^{-1}$ of e ^+p data at $\sqrt{s}=301$ and 319 GeV and of e ^-p data at $\sqrt{s}=319$ GeV. The comparison of the data with the SM differential cross section allows limits to be set on couplings for processes mediated through contact interactions. They obtain lower bounds on the value of $m_{\overline{q}}/\lambda'$ of 710 GeV for the process $e^+\overline{u}\to \widetilde{a}^k$ (and charge conjugate), mediated by λ'_{11k} , and of 430 GeV for the process $\mathrm{e}^+\,d
ightarrow \, \tilde{u}^j$ (and charge conjugate), mediated by $\lambda_{1j1}^{\prime 110}$. Superseded by AARON 11c.

²⁹ CHEKA NOV 03B used 131.5 pb⁻¹ of e^+p and e^-p data taken at 300 and 318 GeV to look for narrow resonances in the eq or νq final states. Such final states may originate from $LQ\overline{D}$ couplings with non-zero χ'_{1j1} (leading to \overline{u}_j) or χ'_{11k} (leading to \overline{d}_k). See their Fig. 8 and explanations in the text for limits. The quoted mass bound assumes that only direct squark decays contribute. $^{30}\, \rm HEISTER$ 03G searches for the production of squarks in the case of R prompt decays

with \overline{DD} direct couplings at at $\sqrt{s}=189$ –209 GeV. ³¹ ABAZOV 02F looked in 77.5 pb⁻¹ of $p\overline{p}$ collisions at 1.8 TeV for events with $\geq 2\mu + \geq 4$ jets, originating from associated production of squarks followed by an indirect R decay (of the $\tilde{\chi}_1^0$) via $LQ\overline{D}$ couplings of the type λ_{2jk}^{\prime} where j=1,2 and k=1,2,3. Bounds are obtained in the MSUGRA scenario by a scan in the range $0 \leq M_0 \leq 400$ GeV, $60 \leq M_{1/2} \leq 120$ GeV for fixed values $A_0=0$, $\mu<0$, and $\tan\beta=2$ or 6. The bounds are weaker for tan $\beta=6$. See Figs. 2,3 for the exclusion contours in $m_{1/2}$ versus m_0 for tan $\beta=2$ and

³² ABAZOV 02G search for associated production of gluinos and squarks in 92.7 pb $^{-1}$ of $p\overline{p}$ collisions at \sqrt{s} =1.8 TeV, using events with one electron, \geq 4 jets, and large E_T . The results are compared to a MSUGRA scenario with μ <0, A_0 =0, and $\tan \beta$ =3 and allow to exclude a region of the $(m_0,m_{1/2})$ shown in Fig. 11.

 33 ABBIENDI 02 looked for events with an electron or neutrino and a jet in $e^+\,e^-$ at 189 GeV. Squarks (or leptoquarks) could originate from a $LQ\overline{D}$ coupling of an electron with a quark from the fluctuation of a virtual photon. Limits on the couplings $\lambda'_{1j\,k}$ as a function of the squark mass are shown in Figs. 8-9, assuming that only direct squark decays contribute.

 34 ABBIENDI 02B looked for events with an electron or neutrino and a jet in e^+e^- at 189–209 GeV. Squarks (or leptoquarks) could originate from a LQD coupling of an electron with a quark from the fluctuation of a virtual photon. Limits on the couplings λ_{1ik}' as a function of the squark mass are shown in Fig. 4, assuming that only direct squark decays contribute. The quoted limits are read off from Fig. 4. Supersedes the results of ABBIENDI 02.

35 SACHARD 02 searches for the production of squarks in the case of R prompt decays with \overline{UDD} couplings at \sqrt{s} =189-208 GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The limit holds for indirect decays. Stronger limits are reached for $(\widetilde{u}_R,\widetilde{d}_R)$ direct (80,56) GeV and $(\widetilde{u}_L,\widetilde{d}_L)$ direct or indirect (87,86) GeV decays.

36 CHEKA NOV 02 search for lepton flavor violating processes $e^+p \to \ell X$, where $\ell=\mu$ or τ with high p_T , in 47.7 pb $^{-1}$ of e^+p collisions at 300 GeV. Such final states may originate from $LQ\overline{D}$ couplings with simultaneously nonzero λ'_{1jk} and λ'_{ijk} (i=2 or 3). The quoted mass bound assumes that only direct squark decays contribute.

The quoted mass bound assumes that only direct squark decays continuous. $378\,\mathrm{BARATE}$ 01B searches for the production of squarks in the case of R prompt decays with LLE indirect or \overline{UDD} direct couplings at \sqrt{s} =189-202 GeV. The limit holds for direct decays mediated by R \overline{UDD} couplings. Limits are also given for LLE indirect decays $(m_{\widetilde{U}_R} > 90\,\mathrm{GeV}$ and $m_{\widetilde{d}_R} > 89\,\mathrm{GeV})$. Supersedes the results from BARATE 00H.

 38 BREITWEG 01 searches for squark production in 47.7 pb $^{-1}$ of $e^+\,p$ collisions, mediated by R couplings $LQ\overline{D}$ and leading to final states with $\widetilde{
u}$ and ≥ 1 jet, complementing the $e^+ X$ final states of BREITWEG 00E. Limits are derived on $\lambda' \sqrt{\beta}$, where β is the

branching fraction of the squarks into $e^+q+\overline{\nu}q$, as function of the squark mass, see their Fig. 15. The quoted mass limit assumes that only direct squark decays contribute. 39 ABBOTT 00c searched in \sim 94 pb $^{-1}$ of $p\overline{p}$ collisions for events with $\mu\mu$ +jets, originating from associated production of leptoquarks. The results can be interpreted as limits on production of squarks followed by direct R decay via $\lambda'_{2jk}L_2Q_jd_k^C$ couplings. Bounds are obtained on the cross section for branching ratios of 1 and of 1/2, see their Fig. 4. The former yields the limit on the \widetilde{u}_L . The latter is combined with the bound of ABBOTT 99J from the $\mu\nu$ +jets channel and of ABBOTT 98E and ABBOTT 98J from the $\nu \nu + {
m jets}$ channel to yield the limit on $\widetilde{\it d}_R$.

 40 ACCIARRI 00P studied the effect on hadronic cross sections of t-channel down-type squark exchange via R-parity violating coupling $\lambda'_{1jk}L_1Q_jd_k^c$. The limit here refers to the

case j=1,2, and holds for $\chi_{1jk}'=0.3$. Data collected at $\sqrt{s}=130-189$ GeV, superseding the results of ACCIARRI 98J.

41 AFFOLDER 00k searched in $\sim 88\,\mathrm{pb}^{-1}$ of $p\overline{p}$ collisions for events with 2–3 jets, at least one being b-tagged, large E_T and no high p_T leptons. Such $\nu\nu+b$ -jets events would originate from associated production of squarks followed by direct E decay via $V_{ij} = V_{ij} $\lambda_{i\,i\,3}^{\prime}L_{i\,Q_{i}}d_{3}^{c}$ couplings. Bounds are obtained on the production cross section assuming zero branching ratio to charged leptons.

42 BARATE 001 studied the effect on hadronic cross sections and charge asymmetries of t-channel down-type squark exchange via R-parity violating coupling $\lambda_{1jk}' L_1 Q_j d_k^{\mathcal{C}}$. The limit here refers to the case j=1,2, and holds for $\chi_{1jk}'=0.3$. A 50 GeV limit is found for up-type squarks with k=3. Data collected at $\sqrt{s}=130-183$ GeV. Superseded by SCHAEL 07A.

43 BREITWEG 00E searches for squark exchange in e^+p collisions, mediated by R couplings $LQ\overline{D}$ and leading to final states with an identified e^+ and ≥ 1 jet. The limit applies to up-type squarks of all generations, and assumes $B(\widetilde{q} \to qe) = 1$. ⁴⁴ ABBOTT 99 searched for $\gamma \not\!\! E_T + \geq 2$ jet final states, and set limits on $\sigma(\rho \, \overline{\rho} \to 0)$ \widetilde{q} +X)·B($\widetilde{q} \to \gamma \not\!\! E_T$ X). The quoted limits correspond to $m_{\widetilde{g}} \geq m_{\widetilde{q}}$, with B($\widetilde{\chi}_2^0 \to$ $\widetilde{\chi}_1^0\gamma)$ = 1 and B ($\widetilde{\chi}_1^0 o\widetilde{G}\gamma$) = 1, respectively. They improve to 310 GeV (360 GeV in the case of $\gamma \widetilde{G}$ decay) for $m_{\widetilde{g}} = m_{\widetilde{q}}$.

 $^{
m 45}\,{\sf ABBOTT}$ 99K uses events with an electron pair and four jets to search for the decay of the $\widetilde{\chi}_1^0$ LSP via R $LQ\overline{D}$ couplings. The particle spectrum and decay branching ratios are taken in the framework of minimal supergravity. An excluded region at 95% CL is obtained in the $(m_0,m_{1/2})$ plane under the assumption that A_0 =0, μ <0, $\tan\beta$ =2 and

any one of the couplings $\lambda_{1jk}^{-}>10^{-3}~(j=1,2~{\rm and}~k=1,2,3)$ and from which the above limit is computed. For equal mass squarks and gluinos, the corresponding limit is 277 GeV. The results are essentially independent of A_0 , but the limit deteriorates rapidly with increasing aneta or $\mu>$ 0.

46 ABBOTT 99L consider events with three or more jets and large E_T . Spectra and decay rates are evaluated in the framework of minimal Supergravity, assuming five flavors of degenerate squarks, and scanning the space of the universal gaugino $(m_{1/2})$ and scalar (m_0) masses. See their Figs. 2–3 for the dependence of the limit on the relative value of $m_{\widetilde{q}}$ and $m_{\widetilde{g}}$.

47 ABE 99M looked in 107 pb $^{-1}$ of $p\overline{p}$ collisions at \sqrt{s} =1.8 TeV for events with like sign dielectrons and two or more jets from the sequential decays $\widetilde{q} \to q \widetilde{\chi}_1^0$ and $\widetilde{\chi}_1^0 \to e q \overline{q}'$, assuming R coupling $L_1 Q_j D_k^c$, with j=2,3 and k=1,2,3. They assume five degenerate squark flavors, B($\widetilde{q} \to q\widetilde{\chi}_1^0$)=1, B($\widetilde{\chi}_1^0 \to e \, q\overline{q}'$)=0.25 for both e^+ and e^- , and $m_{\widetilde{g}} \geq$ 200 GeV. The limit is obtained for $m_{\widetilde{\chi}_1^0} \ge m_{\widetilde{q}}/2$ and improves for heavier gluinos or

⁴⁸ ABREU 96 looked for events with an electron or neutrino and a jet in e^+e^- at 183 GeV. Squarks (or leptoquarks) could originate from a $LQ\overline{D}$ coupling of an electron with a quark from the fluctuation of a virtual photon. Limits on the couplings λ'_{1jk} as a function of the squark mass are shown in Fig. 4, assuming that only direct squark decays

contribute. 49 ABBOTT 98E searched in $\sim 115 \text{ pb}^{-1}$ of $p\bar{p}$ collisions for events with $e\nu$ +jets, origination. ing from associated production of squarks followed by direct R decay via $\lambda'_{1jk}L_1Q_jd^c_k$ couplings. Bounds are obtained by combining these results with the previous bound of ABBOTT 97B from the ee+jets channel and with a reinterpretation of ABACHI 96B

50 ABE 988 looked in $\sim 110\,\mathrm{pb}^{-1}$ of $p\overline{p}$ collisions at \sqrt{s} =1.8 TeV for events with $\mu\mu$ +jets originating from associated production of squarks followed by direct R decay via λ'_{2ik} L $_2$ Q $_id_k^c$ couplings. Bounds are obtained on the production cross section times the square of the branching ratio, see Fig. 2. Mass limits result from the comparison with theoretical cross sections and branching ratio equal to 1 for \widetilde{u}_L and 1/2 for \widetilde{d}_R

 51 ACKERSTAFF 98v and ACCIARRI 98J studied the interference of *t*-channel squark (\widetilde{d}_R) exchange via R-parity violating $\lambda_{1jk}' L_1 \, Q_j \, d_k^c$ coupling in $e^+ \, e^- \, o \, q \, \overline{q}$. The limit is for $\lambda'_{1jk}\!=\!0.3.$ See paper for related limits on \tilde{u}_L exchange. Data collected at $\sqrt{s}\!=\!130\text{-}172$ GeV.

52 BREITWEG 98 used positron+jet events with missing energy and momentum to look for $e^+ \, q \to \widetilde{e} \, \widetilde{q}$ via gaugino-like neutralino exchange with decays into $(e \, \widetilde{\chi}_1^0)(q \, \widetilde{\chi}_1^0)$. See paper for dependences in $m_{\widetilde{e}}, m_{\widetilde{\chi}_1^0}$.

⁵³DATTA 97 argues that the squark mass bound by ABACHI 95c can be weakened by 10-20 GeV if one relaxes the assumption of the universal scalar mass at the GUT-scale so that the $\widetilde{\chi}_1^\pm,\widetilde{\chi}_2^0$ in the squark cascade decays have dominant and invisible decays to

DERRICK 97 looked for lepton-number violating final states via R-parity violating couplings $\lambda'_{ijk} L_i \ Q_j d_k$. When $\lambda'_{11k} \lambda'_{ijk} \neq 0$, the process $e \ u \to \overline{d}_k^* \to \ell_i \ u_j$ is possible. When $\lambda'_{1j1} \lambda'_{ijk} \neq 0$, the process $e \ \overline{d} \to \overline{u}_j^* \to \ell_i \ \overline{d}_k$ is possible. 100% branching fraction $\overline{q} \to \ell_j$ is assumed. The limit quoted here corresponds to $\overline{t} \to \tau q$ decay, with $t \to t = 0$.

 λ' =0.3. For different channels, limits are slightly better. See Table 6 in their paper. ⁵⁵ HEWETT 97 reanalyzed the limits on possible resonances in di-jet mode $(\tilde{q} \to q\tilde{g})$ from ALITTI 93 quoted in "Limits for Excited q (q^*) from Single Production," ABE 96 in "SCALE LIMITS for Contact Interactions: $\Lambda(q\,q\,q\,q)$," and unpublished CDF, DØ bounds. The bound applies to the gluino mass of 5 GeV, and improves for lighter gluino. The analysis has gluinos in parton distribution function.

56 TEREKHOV 97 improved the analysis of TEREKHOV 96 by including di-jet angular distributions in the analysis.

⁵⁷ AID 96c used positron+jet events with missing energy and momentum to look for $e^+q \to \widetilde{e}\,\widetilde{q}$ via neutralino exchange with decays into $(e\,\widetilde{\chi}^0_1)(q\,\widetilde{\chi}^0_1)$. See the paper for dependences

 58 TEREKHOV 96 reanalyzed the limits on possible resonances in di-jet mode $(\widetilde{u}\to u\widetilde{g})$ from ABE 95N quoted in "MASS LIMITS for g_A (axigluon)." The bound applies only

to the case with a light gluino. 59 ABACHI 95c assume five degenerate squark flavors with $m_{\widetilde{q}_L} = m_{\widetilde{q}_R}$. Sleptons are assumed to be heavier than squarks. The limits are derived for fixed $\tan\beta = 2.0~\mu = -250$ GeV, and $m_{H^+} = 500$ GeV, and with the cascade decays of the squarks and gluinos calculated within the framework of the Minimal Supergravity scenario. The bounds are weakly sensitive to the three fixed parameters for a large fraction of parameter space. No limit is given for $m_{
m gluino}$ >547 GeV.

 60 ABE 95T looked for a cascade decay of five degenerate squarks into $\widetilde{\chi}^0_2$ which further decays into $\widetilde{\chi}_1^0$ and a photon. No signal is observed. Limits vary widely depending on the choice of parameters. For $\mu=-40$ GeV, $\tan\beta=1.5$, and heavy gluinos, the range $50{<}m_{\widetilde{q}}$ (GeV) ${<}110$ is excluded at 90% CL. See the paper for details.

 61 ABE 92L assume five degenerate squark flavors and $m_{\widetilde{q}_L}=m_{\widetilde{q}_R}$. ABE 92L includes the effect of cascade decay, for a particular choice of parameters, $\mu=-250$ GeV, $\tan\beta=2$. Results are weakly sensitive to these parameters over much of parameter space. No limit for $m_{\widetilde{q}} \leq 50$ GeV (but other experiments rule out that region). Limits are 10-20GeV higher if $\mathsf{B}(\widetilde{q} \to q \widetilde{\gamma}) = 1$. Limit assumes GUT relations between gaugino masses

Supersymmetric Particle Searches

and the gauge coupling; in particular that for $|\mu|$ not small, $m_{\widetilde{\chi}_1^0} \approx m_{\widetilde{g}}/6$. This last relation implies that as $m_{\widetilde{g}}$ increases, the mass of $\widetilde{\chi}^0_1$ will eventually exceed $m_{\widetilde{q}}$ so that no decay is possible. Even before that occurs, the signal will disappear; in particular no bounds can be obtained for $m_{\widetilde{g}} >$ 410 GeV. $m_{H^+} =$ 500 GeV.

 62 ROY 92 reanalyzed CDF limits on di-lepton events to obtain limits on squark production in R-parity violating models. The 100% decay $\widetilde{q} \to q \widetilde{\chi}$ where $\widetilde{\chi}$ is the LSP, and the LSP decays either into $\ell q \overline{d}$ or $\ell \ell \overline{\epsilon}$ is assumed.

63 NOJIRI 91 argues that a heavy squark should be nearly degenerate with the gluino in minimal supergravity not to overclose the universe.

Long-lived \tilde{q} (Squark) MASS LIMIT

The following are bounds on long-lived scalar quarks, assumed to hadronise into hadrons with lifetime long enough to escape the detector prior to a possible decay. Limits may depend on the mixing angle of mass eigenstates: $\tilde{q}_1 = \tilde{q}_L \cos\theta_a + \tilde{q}_R \sin\theta_a$. The coupling to the ${\it Z}^0$ boson vanishes for up-type squarks when $\theta_u = 0.98$, and for down type squarks when $\theta_d = 1.17$.

 1 AALTONEN 09z searched in 1 fb $^{-1}$ of $^{}p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for events with direct production of a pair of charged massive stable particles identified by their TOF. No excess of events is observed over the expected background. The data are used to

set a bound on the production cross section, and the result is compared with the pair production cross section of stable stops as a function of the t mass, see their Fig. 2. 2 HEISTER 03H use e^+e^- data at and around the Z^0 peak to look for hadronizing stable squarks. Combining their results on searches for charged and neutral R-hadrons with JANOT 03, a lower limit of 15.7 GeV on the mass is obtained. Combining this further with the centre of the processor of the production of the form of the processor of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the production of the product with the results of searches for tracks with anomalous ionization in data from 183 to 208 GeV yields the quoted bounds.

 3 ABREU 98P assumes that 40% of the squarks will hadronise into a charged hadron, and 60% into a neutral hadron which deposits most of its energy in hadron calorimeter. Data collected at \sqrt{s} =130–183 GeV.

b (Sbottom) MASS LIMIT

Limits in e^+e^- depend on the mixing angle of the mass eigenstate $\tilde{b}_1=\tilde{b}_L\cos\theta_D+$ $\widetilde{b}_R {
m sin} heta_b$. Coupling to the Z vanishes for $heta_b \sim 1.17$. As a consequence, no absolute constraint in the mass region \lesssim 40 GeV is available in the literature at this time from $e^+\,e^-$ collisions. In the Listings below, we use $\Delta m=m_{\widetilde b_1}-m_{\widetilde \chi_1^0}$

 1 AALTONEN 10R searched in 2.65 fb $^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for events with \cancel{E}_T and exactly two jets, at least one of which is b-tagged. The results are in agreement with the SM prediction, and a limit on the cross section of 0.1 pb is obtained for the range of masses 80 $< m_{\widetilde{b}_1} <$ 280 GeV assuming that the sbottom decays exclusively to

 $b\widetilde{\chi}^0_1$. The excluded mass region in the framework of conserved R_p is shown in a plane of $(m_{\widetilde{b}_1}, m_{\widetilde{\chi}_1^0})$, see their Fig. 2.

 2 ABAZOV 10L looked in 5.2 fb $^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for events with ABACOV lot looked in \mathcal{D}_T from the production of $\widetilde{\mathcal{D}_1}$ $\widetilde{\mathcal{D}}_1$. No evidence for an excess over the SM expectation is observed, and a limit on the cross section is derived under the assumption of 100% branching ratio. The excluded mass region in the framework of conserved R_p is shown in a plane of $(m_{\widetilde{\mathcal{D}}_1}, m_{\widetilde{\chi}_1^0})$, see their Fig. 3b. The exclusion also extends to $m_{\widetilde{\chi}_1^0} = 110$ GeV for $160 < m_{\widetilde{\mathcal{D}}_1} < 200$ GeV.

 3 ABULENCIA 06i searched in 156 pb $^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for multijet events with large $\not\!\!E_T$. They request at least 2 b-tagged jets and no isolated leptons. They investigate the production of gluinos decaying into \tilde{b}_1 b followed by $\tilde{b}_1 \to b \tilde{\chi}_1^0$ Both branching fractions are assumed to be 100% and the LSP mass to be 60 GeV. No significant excess was found compared to the background expectation. Upper limits on the cross-section are extracted and a limit is derived on the masses of sbottom and

gluinos, see their Fig.3. 4 ACHARD 04 search for the production of $\widetilde{b}\widetilde{b}$ in acoplanar b-tagged di-jet final states in the 192–209 GeV data. See Fig. 6 for the dependence of the limits on $m_{\widetilde{\chi}0}$. This limit

supersedes ACCIARRI 99v.

 5 JA NOT 04 reanalyzes $e^{+}\,e^{-} \rightarrow \,$ hadrons total cross section data with $\sqrt{s}=$ 20–209 GeV from PEP, PETRA, TRISTAN, SLC, and LEP and constrains the mass of \widetilde{b}_1 assuming it decays quickly to hadrons.

⁶ ABDALLAH 03M looked for \tilde{b} pair production in events with acoplanar jets and E at \sqrt{s} = 189–208 GeV. The limit improves to 87 (98) GeV for all θ_b (θ_b = 0) for $\Delta m > 10$ GeV. See Fig. 24 and Table 11 for other choices of Δm . These limits include and update the results of ABREU, P 000.

The results of ABREU, P volu. TABREU, P volu. TABREUN, P volu. TABREUN, P volu. TABREUN 02H search for events with two acoplanar jets and ψ_T in the 161–209 GeV data. The limit assumes 100% branching ratio and uses the exclusion at large Δm from CDF (AFFOLDER 00D). For $\theta_D = 0$, the bound improves to > 96.9 GeV. See Fig. 4 and Table 6 for the more general dependence on the limits on Δm . These results supersede ABBIENDI 99M.

HEISTER 02k search for bottom squarks in final states with acoplanar jets with b tagging, using 183–209 GeV data. The mass bound uses the CDF results from AFFOLDER 00D. See Fig. 5 for the more general dependence of the limits on Δm . Updates BARATE 01.

9 SAVINOV 01 use data taken at \sqrt{s} =10.52 GeV, below the $B\overline{B}$ threshold. They look for events with a pair of leptons with opposite charge and a fully reconstructed hadronic Dor D^* decay. These could originate from production of a light-sbottom hadron followed by $\widetilde{B} \to D^{(*)} \ell^- \widetilde{\nu}$, in case the $\widetilde{\nu}$ is the LSP, or $\widetilde{B} \to D^{(*)} \pi \ell^-$, in case of R. The mass range $3.5 \le M(\bar{B}) \le 4.5$ GeV was explored, assuming 100% branching ratio reither of the decays. In the $\bar{\nu}$ LSP scenario, the limit holds only for $M(\bar{\nu})$ less than about $1~{\rm GeV}$ and for the D^* decays it is reduced to the range 3.9–4.5 GeV. For the $R\!\!\!/$ decay, the whole range is excluded.

 10 AFFOLDER 00 D search for final states with 2 or 3 jets and $ot\!\!E_T$, one jet with a b tag. See their Fig. 3 for the mass exclusion in the $m_{\widetilde{t}}, \, m_{\widetilde{\chi}_1^0}^+$ plane.

 11 AAD 11K looked in 34 pb $^{-1}$ of pp collisions at $\sqrt{s}=7$ TeV for events with heavy stable particles, identified by their anomalous dE/dx in the tracker or time of flight in the tile calorimeter, from pair production of \widetilde{b} . No evidence for an excess over the SM expectation is observed and limits on the mass are derived for pair production of sbottom,

see Fig. 4. $^{12}\text{AAD 110 looked in 35 pb}^{-1} \text{ of } pp \text{ collisions at } \sqrt{s} = 7 \text{ TeV for events with jets, of which at least one is a } b\text{-jet, and } \cancel{E_T}. \text{ No excess above the Standard Model was found. Limits are derived in the } (m_{\widetilde{g}}, m_{\widetilde{b}_1}) \text{ plane (see Fig. 2) under the assumption of 100% }$

branching ratios and \widetilde{b}_1 being the lightest squark. The quoted limit is valid for $m_{\widetilde{b}_1}$

500 GeV. A similar approach for \widetilde{t}_1 as the lightest squark with $\widetilde{g} \to \widetilde{t}_1 t$ and $\widetilde{t}_1 \to b \widetilde{\chi}_1^\pm$ with 100% branching ratios leads to a gluino mass limit of 520 GeV for 130 $< m_{\widetilde{t}_1} < 1$ 300 GeV. Limits are also derived in the CMSSM (m_0 , $m_{1/2}$) plane for an eta = 40, see

Fig. 4, and in scenarios based on the gauge group SO(1). ^{17/2} CHATRCHYAN 11D looked in 35 pb $^{-1}$ of pp collisions at $\sqrt{s}=7$ TeV for events with \geq 2 jets, at least one of which is b-tagged, and $ot\!\!E_T$, where the b-jets are decay products of \tilde{t} or \tilde{b} . No evidence for an excess over the expected background is observed. Limits are derived in the CMSSM $(m_0, m_{1/2})$ plane for $\tan\beta=50$ (see Fig. 2).

¹⁴ AALTONEN 09R searched in 2.5 fb $^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for events with at least 2 b-tagged jets and $ot\!\!E_T$, originating from the decay $\widetilde{g} \to b\widetilde{b}$ followed by $\widetilde{b} \to b\widetilde{b}$ $b\,\widetilde{\chi}_1^0$. Both decays are assumed to have 100% branching ratio. No significant deviation from the SM prediction is observed. An upper limit on the gluino pair production cross section is calculated as a function of the gluino mass, see their Fig. 2. A limit is derived in the $m_{\widetilde{b}}$ versus $m_{\widetilde{g}}$ plane which improves the results of previous searches, see their

15 15 AALTONEN 07E searched in 295 pb $^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for multijet events with large \cancel{E}_T . They request at least one heavy flavor-tagged jet and no identified leptons. The branching ratio $\vec{b}_1 \to b \, \widetilde{\chi}_1^0$ is assumed to be 100%. No significant excess was found compared to the background expectation. Upper limits on the cross-section are extracted and a limit is derived on the masses of sbottom versus $\tilde{\chi}^0_1$, see their Fig. 5. Superseded by AALTONEN 10R.

- 16 ABAZOV 06R looked in $310~{\rm pb}^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for events with 2 or 3 jets and large E_T with at least 1 b-tagged jet and a veto against isolated leptons. No excess is observed relative to the SM background expectations. Limits are set on the sbottom pair production cross-section under the assumption that the only decay mode is into $b\,\widetilde{\chi}_1^0$. Exclusion contours are derived in the plane of sbottom versus neutralino masses, shown in their Fig. 2. The observed limit is more constraining than the expected one due to a lack of events corresponding to large sbottom masses. Superseded by _ABAZOV 10L.
- ABAZOV 101. 17 ABDALLAH 04M use data from $\sqrt{s}=192-208$ GeV to derive limits on sparticle masses under the assumption of R with \overline{UDD} couplings. The results are valid for $\mu=-200$ GeV, $\tan\beta=1.5$, $\Delta m > 5$ GeV and assuming a BR of 1 for the given decay. The limit quoted is for indirect \overline{UDD} decays using the neutralino constraint of 38.0 GeV, also derived in ABDALLAH 04M, and assumes no mixing. For indirect decays it remains at 78 GeV when the neutralino constraint is not used. Supersedes the result of ABREU 01D. 18 ABDALLAH 03C looked for events of the type $q \overline{q} R^2 + R^2$, $q \overline{q} R^2 R^0$ or e^+e^- interactions at $\sqrt{s}=189-208$ GeV. The R^\pm bound states are identified by anomalous dF/dx in the tracking chambers and the R^0 by missing energy due to their
- 18 ABDALLAH 03c looked for events of the type $q\overline{q}\,R^{\pm}\,R^{\pm}$, $q\overline{q}\,R^{\pm}\,R^{0}$, or $q\overline{q}\,R^{0}\,R^{0}$ in $e^{+}\,e^{-}$ interactions at $\sqrt{s}=189-208$ GeV. The R^{\pm} bound states are identified by anomalous dE/dx in the tracking chambers and the R^{0} by missing energy due to their reduced energy loss in the calorimeters. Excluded mass regions in the $(m(\bar{b}),\,m(\bar{g}))$ plane for $m(\bar{g})>2$ GeV are obtained for several values of the probability for the gluino to fragment into R^{\pm} or R^{0} , as shown in their Fig. 19. The limit improves to 94 GeV for $\theta_{h=0}$.
- 19 BERGER 03 studies the constraints on a \widetilde{b}_1 with mass in the 2.2–5.5 GeV region coming from radiative decays of $\Upsilon({\rm nS})$ into sbottomonium. The constraints apply only if \widetilde{b}_1 lives long enough to permit formation of the sbottomonium bound state. A small region of mass in the $m_{\widetilde{b}_1}-m_{\widetilde{g}}$ plane survives current experimental constraints from CLEO.
- 20 HEISTER 03G searches for the production of \widetilde{b} pairs in the case of R prompt decays with $LL\overline{E}, LQ\overline{D}$ or \overline{UDD} couplings at $\sqrt{s}=189$ –209 GeV. The limit holds for indirect decays mediated by R \overline{UDD} couplings. It improves to 90 GeV for indirect decays mediated by R $LL\overline{E}$ couplings and to 80 GeV for indirect decays mediated by R $LL\overline{E}$ couplings and to 80 GeV for indirect decays mediated by R $LQ\overline{D}$ couplings. Supersedes the results from BARATE 01B.
- 21 HEISTER 03H use their results on bounds on stable squarks, on stable gluinos and on squarks decaying to a stable gluino from the same paper to derive a mass limit on $\overline{b},$ see their Fig. 13. The limit for a long-lived \overline{b}_1 is 92 GeV.
- The limit of a long-model of 1992 across of \$\mathbb{R}\$ prompt decays with \$\frac{UDD}{UDD}\$ couplings at \$\sqrt{\$}\$=189-208 GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The limit is computed for the minimal cross section and holds for indirect decays and reaches 55 GeV for direct decays.
- 23 BAEK 02 studies the constraints on a \tilde{b}_1 with mass in the 2.2–5.5 GeV region coming from precision measurements of Z^0 decays. It is noted that CP-violating couplings in the MSSM parameters relax the strong constraints otherwised derived from CP conservation.
- ²⁴ BECHER 02 studies the constraints on a \widetilde{b}_1 with mass in the 2.2–5.5 GeV region coming from radiative B meson decays, and sets limits on the off-diagonal flavor-changing couplings $q\widetilde{b}\widetilde{g}$ (q=d,s).
- 25 CHEUNG 02B studies the constraints on a \tilde{b}_1 with mass in the 2.2–5.5 GeV region and a gluino in the mass range 12–16 GeV, using precision measurements of Z^0 decays and $e^+\,e^-$ annihilations at LEP2. Few detectable events are predicted in the LEP2 data for the model proposed by BERGER 01.
- 26 CHO 02 studies the constraints on a \widetilde{b}_1 with mass in the 2.2–5.5 GeV region coming from precision measurements of Z^0 decays. Strong constraints are obtained for $\it CP$ -conserving MSSM couplings.
- 27 BERGER of reanalyzed interpretation of Tevatron data on bottom-quark production. Argues that pair production of light gluinos ($m\sim 12\text{--}16$ GeV) with subsequent 2-body decay into a light sbottom ($m\sim 2\text{--}5.5$ GeV) and bottom can reconcile Tevatron data with predictions of perturbative QCD for the bottom production rate. The sbottom must either decay hadronically via a R--pairly-- and B--violating interaction, or be long-lived. Constraints on the mass spectrum are derived from the measurements of time-averaged $B^0\text{--}\overline{B}^0$ mixing.
- 28 ABBOTT 99F looked for events with two jets, with or without an associated muon from b decay, and $\cancel{E}_{\mathcal{T}^-}$ See Fig. 2 for the dependence of the limit on $m_{\widetilde{\chi}_1^0}$. No limit for $m_{\widetilde{\chi}_1^0} >$ 47 GeV. Superseded by ABAZOV 06R.

\widetilde{t} (Stop) MASS LIMIT

Limits depend on the decay mode. In e^+e^- collisions they also depend on the mixing angle of the mass eigenstate $\tilde{t}_1=\tilde{t}_L\cos\theta_t+\tilde{t}_R\sin\theta_t$. The coupling to the Z vanishes when $\theta_t=$ 0.98. In the Listings below, we use $\Delta m\equiv m_{\tilde{t}_1}-m_{\widetilde{\chi}_1^0}$ or $\Delta m\equiv m_{\widetilde{t}_1}-m_{\widetilde{\nu}}$, depending on relevant decay mode. See also bounds in " \tilde{q} (Squark)

MASS LIMIT." Limits made obsolete by the most recent analyses of e^+e^- and $p\overline{p}$ collisions can be found in previous Editions of this *Review*.

- their Fig. 4, under the assumption of 100% branching ratio for $\tilde{t}_1 \to b\ell\bar{\nu}$. 2 AALTONEN 107 searched in 1 fb $^-1$ of $\rho\bar{p}$ collisions at $\sqrt{s}=1.96$ TeV for events with an oppositely charged lepton pair (e or μ), E_T and at least one jet. A limit is derived on the cross section assuming 100% branching ratio of $\tilde{t}_1 \to b\ell\bar{\nu}$ and an invisible $\bar{\nu}$, see their Fig. 10. In Fig. 11, the exclusion contour is shown in the plane of $(m_{\tilde{t}_1}, m_{\tilde{\nu}})$.
- 3 ABAZOV 082 looked in 995 pb $^{-1}$ of $\rho\overline{\rho}$ collisions at $\sqrt{s}=1.96$ TeV for events with exactly 2 jets, at least one being tagged as heavy quark, and \cancel{E}_T , originating from stop pair production. Branching ratios are assumed to be 100% for $\overline{t}_1 \rightarrow c\, \overline{\chi}_1^0$. No evidence for an excess over the SM expectation is observed. The excluded region is shown in a plane of $m_{\overline{t}}$ versus $m_{\overline{\chi}_1^0}$, see their Fig. 5. No limit can be obtained for $m_{\overline{\chi}_1^0} > 70$ GeV. Superseds the results of ABAZOV 078
- Supersedes the results of ABAZOV 07B. ${}^4\text{ABAZOV 04 looked at } 108.3pb^{-1} \text{ of } p\overline{p} \text{ collisions at } \sqrt{s} = 1.8 \text{ TeV for events with } e + \mu + E_T \text{ as signature for the } 3- \text{ and } 4\text{-body decays of stop into } b\ell\nu\overline{\chi}^0 \text{ final states.}$ For the $b\ell\overline{\nu}$ channel they use the results from ABAZOV 02c. No significant excess is observed compared to the Standard Model expectation and limits are derived on the mass of \overline{t}_1 for the 3- and 4-body decays in the $(m_{\widetilde{t}}, m_{\overline{\chi}^0})$ plane, see their Figure 4.
- 5 ACHARD 04 search in the 192–209 GeV data for the production of $\widetilde{t}t$ in acoplanar di-jet final states and, in case of $b\ell\widetilde{\nu}$ ($b\tau\widetilde{\nu}$) final states, two leptons (taus). The limits for $\theta_t=$ 0 improve to 95, 96 and 93 GeV, respectively. All limits assume 100% branching ratio

Supersymmetric Particle Searches

for the respective decay modes. See Fig. 6 for the dependence of the limits on $m_{\widetilde{\chi}^0_+}$ These limits supersede ACCIARRI 99v.

⁶ ABDALLAH 03M looked for t pair production in events with acoplanar jets and E at \sqrt{s} = 189–208 GeV. See Fig. 23 and Table 11 for other choices of Δm . These limits include and update the results of ABREU,P 00D.

 7 ABBIENDI 02H looked for events with two acoplanar jets, p_T , and, in the case of $b\ell ilde{
u}$ final states, two leptons, in the 161–209 GeV data. The bound for $c\widetilde{\chi}^0_1$ applies to the region where $\Delta m < m_W + m_b$, else the decay $\tilde{t}_1 \to b \tilde{\chi}_1^0 W^+$ becomes dominant. The limit for $b \ell \tilde{\nu}$ assumes equal branching ratios for the three lepton flavors and for $b \tau \tilde{\nu}$ 100% for this channel. For θ_t =0, the bounds improve to > 97.6 GeV ($c\,\widetilde{\chi}_1^0$), > 96.0 GeV $(b\ell \overline{\nu})$, and > 95.5 $(b\tau \overline{\nu})$. See Figs. 5–6 and Table 5 for the more general dependence of the limits on Δm . These results supersede ABBIENDI 99M.

⁸ HEISTER 02K search for top squarks in final states with jets (with/without b tagging or leptons) or long-lived hadrons, using 183–209 GeV data. The absolute mass bound is obtained by varying the branching ratio of $\tilde{t} \to c \, \widetilde{\chi}_1^0$ and the lepton fraction in $\tilde{t} \to b \, \widetilde{\chi}_1^0 \, f \, \overline{f}'$ decays. The mass bound for $\widetilde{t} o c \widetilde{\chi}_1^0$ uses the CDF results from AFFOLDER 00D and

for $\widetilde{t} \rightarrow b\ell\widetilde{\nu}$ the DØ results from ABAZOV 02c. See Figs. 2–5 for the more general dependence of the limits on Δm . Updates BARATE 01 and BARATE 00P 9AAD 11k looked in 34 pb⁻¹ of pp collisions at $\sqrt{s}=7$ TeV for events with heavy stable particles, identified by their anomalous dE/dx in the tracker or time of flight in the tile calorimeter, from pair production of \widetilde{t} . No evidence for an excess over the SM expectation is observed and limits on the mass are derived for pair production of stop, see Fig. 4.

 10 KHACHATRYAN 11c looked in 3.1 pb $^{-1}$ of pp collisions at $\sqrt{s}=7$ TeV for events with heavy stable particles, identified by their anomalous dE/dx in the tracker or time of flight in the muon chambers, from pair production of \tilde{t}_1 . No evidence for an excess over the expected background is observed. Limits are derived for pair production of stop as a function of mass, see Fig. 3, and compared to the production cross section in a benchmark scenario.

to the $\widetilde{t}_1\,\widetilde{t}_1$ hypothesis. Assuming a 100% branching ratio of $\widetilde{t}_1 o b\widetilde{\chi}_1^\pm$, the exclusion

is independent of the value of the $\widetilde{\chi}_1^\pm \to \ \ell \widetilde{\chi}_1^0 \, \nu$ branching ratio.

- 12 ABAZOV 09N looked in 0.9 fb $^{-1}$ of $\rho \overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for events with ≥ 3 jets, at least one being b-tagged, one electron or muon and $\not\!\!E_T$ originating from associated production $\widetilde{t}\widetilde{t}$, with one \widetilde{t} decaying leptonically, the other hadronically. The branching ratios for $\bar{t}_1 \to b\bar{\chi}_1^\pm$ and $\bar{\chi}_1^\pm \to \bar{\chi}_1^0$ W^\pm are assumed to be 100%. The separation from the dominant $t\bar{t}$ background is based on a multivariate likelihood discriminant analysis. The tested mass range is 130 GeV $\leq m_{\bar{t}} \leq 190$ GeV, 90 GeV $\leq m_{\bar{\chi}_1^\pm} \leq 150$ GeV and $m_{\bar{\chi}_1^0} = 50$ GeV fixed. The excluded cross section is a factor 2-13 larger than the theoretical expectation in the considered MSSM scenarios, see their
- 13 ABAZOV 090 looked in 1 fb $^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for events with two electrons or one electron and one muon and $\not\!\!\!E_T$ originating from associated production $t\overline{t}$, followed by the three-body decays $\overline{t}\to b\ell\overline{\nu}$. No evidence for an excess over the SM expectation is observed. The excluded region is shown in a plane of $m_{\widetilde{\nu}}$ versus $m_{\widetilde{\tau}}$, see
- expectation is observed. The excluded \widetilde{t} mass is 175 GeV for a $\widetilde{\nu}$ mass of 45 GeV, and the largest excluded $\widetilde{\nu}$ mass is 96 GeV for a \widetilde{t} mass of 140 GeV. Superseded by ABAZOV 11N. 1^4 AALTONEN 08z searched in 322 pb $^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for dijet events with a lepton (e or μ) and a hadronic τ decay produced via R-parity violating couplings $LQ\overline{D}$. No heavy flavour-tagged jets are requested. No significant excess was found compared to the background expectation. Upper limits on the cross-section times the square of the branching ratio $B(\widetilde{t}_1 \to b\tau)$ are extracted, and a limit is derived on the stop mass assuming $B(\widetilde{t}_1 \to b\tau)=1$, see their Fig. 2. Supersedes the results of ACOSTA 04B. ACOSTA 04B.
- 15 ABAZOV 08 looked at approximately 400 pb $^{-1}$ of $p\,\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for events with $b\,\overline{b}\,\ell\ell'\not\!\!E_T$ with $\ell\ell'=e^{\pm}\mu^{\mp}$ or $\ell\ell'=\mu^+\mu^-$, originating from associated production $\widetilde{t}\widetilde{t}$. Branching ratios are assumed to be 100% for both $\widetilde{\chi}_1^\pm \to \ell \widetilde{\nu}$ and $\widetilde{\nu} \to$ $\nu \tilde{\chi}_1^0$. No evidence for an excess over the SM expectation is observed. The excluded region
- $m_{\widetilde{t}}$ so their Fig.3. Superseded by ABAZOV 090. ¹⁶ AALTONEN 07E searched in 295 pb⁻¹ of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for multijet events with large E_T . They request at least one heavy flavor-tagged jet and no identified leptons. The branching ratio $\tilde{t}_1 \to c \tilde{\chi}_1^0$ is assumed to be 100%. No significant excess was found compared to the background expectation. Upper limits on the cross-section are extracted and a limit is derived on the masses of stop versus $\widetilde{\chi}_1^0$, see their Fig. 4.
- 17 ABAZOV 07B looked in 360 pb $^{-1}$ of $p\bar{p}$ collisions at $\sqrt{s}=1.96$ TeV for events with a pair of acoplanar heavy-flavor jets with $ot\!\!E_T$. No excess is observed relative to the SM background expectations. Limits are set on the production of \widetilde{t}_1 under the assumption that the only decay mode is into $c\widetilde{\chi}_1^0$, see their Fig. 4 for the limit in the $(m_{\widetilde{t}}, m_{\widetilde{\chi}_1^0})$ plane. No limit can be obtained for $m_{\widetilde{\chi}_1^0} >$ 54 GeV. Supersedes the results of

 18 CHEKA NOV 07 search for the $^{LQ\overline{D}}$ R-parity violating process $e^+p o \widetilde{t_1}$ in 65 pb $^{-1}$ at 318 GeV. Final states may originate from $LQ\overline{D}$ couplings $\widetilde{t} \rightarrow e^+ d$ and from the R-parity conserving decay $\widetilde{t} \to \widetilde{\chi}^+ b$, giving rise to e+ jet, e+ multi-jet, and $\nu+$ multi-jet. The excluded region in an MSSM scenario is presented for λ_{131} as a function of the stop mass in Fig. 6. Other excluded regions in a more restricted mSUGRA model are shown in Fig. 7 and 8.

19 ABBIENDI 04F use data from $\sqrt{s}=189$ –209 GeV. They derive limits on the stop mass under the assumption of R with $LQ\overline{D}$ or \overline{UDD} couplings. The limit quoted applies to direct decays with $\overline{U}\overline{D}\overline{D}$ couplings when the stop decouples from the Z^0 and improves to 88 GeV for $\theta_{t}=$ 0. For L Q \overline{D} couplings, the limit improves to 98 (100) GeV for $\lambda_{13k}^{'}$ or λ'_{23k} couplings and all θ_t ($\theta_t=0$). For λ'_{33k} couplings it is 96 (98) GeV for all θ_t ($\theta_t=0$). Supersedes the results of ABBIENDI 00. $^{20} \text{ABDALLAH 04M use data from } \sqrt{s}=192-208 \text{ GeV to derive limits on sparticle masses under the assumption of } \mathcal{R} \text{ with } LL\overline{E} \text{ or } \overline{UDD} \text{ couplings. The results are valid for } \mu=$

 $-200~{\rm GeV}$, $\tan \beta = 1.5$, $\Delta m > 5~{\rm GeV}$ and assuming a BR of 1 for the given decay. The limit quoted is for decoupling of the stop from the Z^0 and indirect \overline{UDD} decays using the neutralino constraint of 39.5 GeV for $LL\overline{E}$ and of 38.0 GeV for \overline{UDD} couplings, also derived in ABDALLAH 04M. For no mixing (decoupling) and indirect decays via $LL\overline{E}$ the limit improves to 92 (87) GeV if the constraint from the neutralino is used and to 88 (81) GeV if it is not used. For indirect decays via \overline{UDD} couplings it improves to 87 GeV for no mixing and using the constraint from the neutralino, whereas it becomes 81 GeV (67) GeV for no mixing (decoupling) if the neutralino constraint is not used. Supersedes the result of ABREU 01b.

AKTAS 04B looked in 106 pb $^{-1}$ of $e^{\pm}p$ collisions at $\sqrt{s}=310~{\rm GeV}$ and $320~{\rm GeV}$

21 AKTAS 04B looked in 106 pb^{-1} of $e^{\pm}p$ collisions at $\sqrt{s}=$ 319 GeV and 301 GeV for resonant production of \widetilde{t}_1 by R-parity violating $LQ\overline{D}$ couplings couplings with λ'_{131} , others being zero. They consider the decays $\widetilde{t}_1 \to e^+ d$ and $\widetilde{t}_1 \to W\widetilde{b}$ followed by $b
ightarrow \overline{
u}_e \, d$ and assume gauginos too heavy to participate in the decays. They combine the channels jep_T' , $j\mu p_T'$, $jjjp_T'$ to derive limits in the plane $(m_{\widetilde{t}}$, $\lambda_{131}')$, see their

22 DAS 04 reanalyzes AFFOLDER 00G data and obtains constraints on $m_{\widetilde{t}_1}$ as a function of $\mathsf{B}(\widetilde{t}\to b\ell\nu\chi^0)\times\mathsf{B}(\widetilde{t}\to b\overline{q}\,q'\chi^0)$, $\mathsf{B}(\widetilde{t}\to c\chi^0)$ and m_{χ^0} . Bound weakens for larger B($\widetilde{t} \to c \, \chi^0$) and m_{χ^0} .

- ²³ABDALLAH 03c looked for events of the type $q \, \overline{q} \, R^{\pm} R^{\pm}$, $q \, \overline{q} \, R^{\pm} R^{0}$ or $q \, \overline{q} \, R^{0} \, R^{0}$ in $e^{+} \, e^{-}$ interactions at $\sqrt{s} = 189$ –208 GeV. The R^{\pm} bound states are identified by anomalous dE/dx in the tracking chambers and the $\it R^{0}$ by missing energy, due to their reduced energy loss in the calorimeters. Excluded mass regions in the $(m(\tilde{t}), m(\tilde{g}))$ plane for $m(\tilde{g}) > 2$ GeV are obtained for several values of the probability for the gluino to fragment into R^\pm or R^0 , as shown in their Fig. 18. The limit improves to 90 GeV for
- ²⁴ ACOSTA 03c searched in 107 pb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}=1.8$ TeV for pair production The country of \overline{v} is a searched in 10 $p\bar{p}$ of \bar{p} consists at $\sqrt{s}=1.8$ feV for pair production of \bar{t} followed by the decay $\bar{t} \to b\ell\bar{\nu}$. They looked for events with two isolated leptons (e or μ), at least one jet and E_T . The excluded mass range is reduced for larger $m_{\widetilde{\nu}}$, and no limit is set for $m_{\widetilde{\nu}} > 88.4$ GeV (see Fig. 2). Superseded by AALTONEN 10v. 25 Theoretical analysis of e^+e^-+2 jet final states from the RPV decay of $\bar{t}\,\bar{t}^*$ pairs produced in $p\bar{p}$ collisions at $\sqrt{s}=1.8$ TeV. 95%CL limits of 220 (165) GeV are derived for
- $B(\widetilde{t} \rightarrow eq)=1 (0.5)$
- B($t \to eq f = 1$ (0.3). 26 HEISTER 03G searches for the production of \tilde{t} pairs in the case of R prompt decays with $LL\bar{E}$, $LQ\bar{D}$ or $U\bar{D}\bar{D}$ couplings at $\sqrt{s}=189-209$ GeV. The limit holds for indirect decays mediated by R $U\bar{D}\bar{D}$ couplings. It improves to 91 GeV for indirect decays mediated by R $LL\bar{E}$ couplings, to 97 GeV for direct (assuming $B(\tilde{t}_L \to q\tau)=100\%$) and to 85 GeV for indirect decays mediated by R $LQ\overline{D}$ couplings. Supersedes the results from BARATE 01B. $^{27}\,\mathrm{HEISTER}$ 03H use $e^+\,e^-$ data from 183–208 GeV to look for the production of stop

decaying into a c quark and a stable gluino hadronizing into charged or neutral R-hadrons. Combining these results with bounds on stable squarks and on a stable gluino LSP from the same paper yields the quoted limit. See their Fig. 13 for the dependence

of the mass limit on the gluino mass and on $heta_t$

²⁸ABAZOV 02c looked in 108.3pb $^{-1}$ of $p\overline{p}$ collisions at \sqrt{s} =1.8 TeV for events with $e\mu E_T$, originating from associated production \widetilde{tt} . Branching ratios are assumed to be 100%. The bound for the $b\ell \widetilde{\nu}$ decay weakens for large $\widetilde{\nu}$ mass (see Fig. 3), and no limit is set when $m_{\widetilde{
u}}>$ 85 GeV. See Fig. 4 for the limits in case of decays to a real $\widetilde{\chi}_1^\pm$, followed by $\widetilde{\chi}_1^\pm
ightarrow \ell \widetilde{
u}$, as a function of $m_{\widetilde{\chi}_1^\pm}$

 29 ACHARD 02 searches for the production of squarks in the case of R prompt decays with \overline{UDD} couplings at \sqrt{s} =189-208 GeV. The search is performed for direct and indirect decays, assuming one coupling at the time to be nonzero. The limit is computed for the minimal cross section and holds for both direct and indirect decays

30 AFFOLDER 01B searches for decays of the top quark into stop and LSP, in tT events. Limits on the stop mass as a function of the LSP mass and of the decay branching ratio are shown in Fig. 3. They exclude branching ratios in excess of 45% for SLP masses up

to 40 GeV.

31 ABREU 001 searches for the production of stop in the case of R-parity violation with LLE couplings, for which only indirect decays are allowed. They investigate topologies with jets plus leptons in data from \sqrt{s} =183 GeV. The lower bound on the stop mass assumes a neutralino mass limit of 27 GeV, also derived in ABREU 001.

32 AFFOLDER 00D search for final states with 2 or 3 jets and $\not\!\!E_T$, one jet with a c tag. See their Fig. 2 for the mass exclusion in the $(m_{\widetilde t}, m_{\widetilde \chi_1^0})$ plane. The maximum excluded $\emph{m}_{\widetilde{t}}$ value is 119 GeV, for $\emph{m}_{\widetilde{\chi}_{1}^{0}}{=}$ 40 GeV.

33AFFOLDER 00g searches for $\widetilde{t_1}$ $\widetilde{t_1}^*$ production, with $\widetilde{t_1} \to b\ell\widetilde{\nu}$, leading to topologies with ≥ 1 isolated lepton (e or μ), $\not\!\!\!E_T$, and ≥ 2 jets with ≥ 1 tagged as b quark by a secondary vertex. See Fig. 4 for the excluded mass range as a function of $m_{\widetilde{\nu}}$. Cross-section limits for \tilde{t}_1 \tilde{t}_1^* , with $\tilde{t}_1 \to b \chi_1^\pm (\chi_1^\pm \to \ell^\pm \nu \tilde{\chi}_1^0)$, are given in Fig. 2. Superseded by AALTONEN 10Y.

 34 ABE 99M looked in 107 pb $^{-1}$ of $p\overline{p}$ collisions at \sqrt{s} =1.8 TeV for events with like sign dielectrons and two or more jets from the sequential decays $\widetilde{q} \to ~q \, \widetilde{\chi}^0_1$ and $\widetilde{\chi}^0_1 \to ~e \, q \, \overline{q}'$, assuming R coupling $L_1Q_jD_k^c$, with j=2,3 and k=1,2,3. They assume $\mathrm{B}(\widetilde{t}_1\to c\widetilde{\chi}_1^0)$ =1, ${\sf B}(\widetilde{\chi}_1^0 \to e \, q \, \overline{q}') = 0.25$ for both e^+ and e^- , and $m_{\widetilde{\chi}_1^0} \ge m_{\widetilde{t}_1}/2$. The limit improves for

heavier $\widetilde{\chi}_1^0$. 35 AID 96 considers photoproduction of $\widetilde{t}\,\widetilde{t}$ pairs, with 100% *R*-parity violating decays of \widetilde{t}

to eq, with q=d, s, or b quarks. ³⁶AID 96 considers production and decay of \tilde{t} via the R-parity violating coupling

 37 CHO 96 studied the consistency among the B^0 – $\overline B^0$ mixing, ϵ in K^0 – $\overline K^0$ mixing, and the measurements of $V_{cb},~V_{ub}/V_{cb}.~$ For the range 25.5 GeV<m $_{\widetilde t_1}$ <m $_Z/2$ left by AKERS 94K for $\theta_t=0.98$, and within the allowed range in M_2 - μ parameter space from chargino, neutralino searches by ACCIARRI 95E, they found the scalar top contribution to B^0 - \overline{B}^0 mixing and ϵ to be too large if $\tan\beta < 2$. For more on their assumptions, see the paper and their reference 10.

 38 BUSKULIC 95E looked for $Z o \ \widetilde{t}\, \overline{\widetilde{t}}$, where $\widetilde{t} o c\,\chi_1^0$ and χ_1^0 decays via R-parity violating interactions into two leptons and a neutrino.

 39 SHIRAI 94 bound assumes the cross section without the s-channel Z-exchange and the QCD correction, underestimating the cross section up to 20% and 30%, respectively. They assume $m_{C}\!=\!1.5$ GeV.

Heavy g (Gluino) MASS LIMIT

95

VALUE (GeV)

> 520

For $m_{\widetilde{g}} > 60$ –70 GeV, it is expected that gluinos would undergo a cascade decay via a number of neutralinos and/or charginos rather than undergo a direct decay to photinos as assumed by some papers. Limits obtained when direct decay is assumed are usually higher than limits when cascade decays are included. Limits made obsolete by the most recent analyses of $p\overline{p}$ collisions can be found in previous Editions of this Review.

- 1 AAD 11AF looked in 1.34 fb $^{-1}$ of pp collisions at $\sqrt{s}=7$ TeV for events with 6 up to 8 jets and $\not\!\!\!E_T$. No evidence for an excess over the expected background is observed. Limits are derived in the CMSSM $(m_0,\,m_{1/2})$ plane for $\tan\beta=10$ (see Fig. 5). The limit improves to $m_{\widetilde{g}}>60$ GeV for $m_{\widetilde{q}}=2$ $m_{\widetilde{g}}$.
- 2 AAD 11G looked in 35 pb $^{-1}$ of pp collisions at $\sqrt{s}=7$ TeV for events with a single lepton (e or μ), jets and E_T from the production of squarks and gluinos. No evidence for an excess over the SM expectation is observed, and a limit is derived in the CMSSM $(m_0,\,m_{1/2})$ plane for $\tan\beta=3$, see Fig. 2.
- 3 AAD 11N looked in 35 pb⁻¹ of pp collisions at $\sqrt{s}=7$ TeV for events with ≥ 2 jets and E_T . Four signal regions were defined, and the background model was found to be in good agreement with the data. Limits are derived in the $(m_{\widetilde{g}}, m_{\widetilde{q}})$ plane (see Fig. 2) for a simplified model where degenerate masses of the squarks of the first two generations are assumed, $m_{\widetilde{\chi}_1^0} = 0$, and all other masses including third generation squarks are set to 5 TeV. Limits are also derived in the CMSSM $(m_0, m_{\star}, n_{\star})$ plane (see Fig. 3) for $\tan \beta$
- to 5 TeV. Limits are also derived in the CMSSM (m_0 , $m_{1/2}$) plane (see Fig. 3) for $\tan\beta$ = 3.
- 4 3 3 3 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5
- branching ratios and \widetilde{b}_1 being the lightest squark. The quoted limit is valid for $m_{\widetilde{b}_1} <$
- 500 GeV. A similar approach for \widetilde{t}_1 as the lightest squark with $\widetilde{g} \to \widetilde{t}_1$ t and $\widetilde{t}_1 \to \hat{b} \widetilde{\chi}_1^{\pm}$ with 100% branching ratios leads to a gluino mass limit of 520 GeV for 130 $< m_{\widetilde{t}_1} < 300$ GeV. Limits are also derived in the CMSSM $(m_0, m_{1/2})$ plane for $\tan\beta = 40$, see Fig. 4, and in scenarios based on the gauge group SO(10).
- ⁵ CHATRCHYAN 11Ac looked in 36 pb $^{-1}$ of pp collisions at $\sqrt{s}=7$ TeV for events with ≥ 3 jets, a large total transverse energy, and E_T . No evidence for an excess over the expected background is observed. Limits are derived in the CMSSM $(m_0, m_{1/2})$ plane and the $(m_{\widetilde{g}}, m_{\widetilde{q}})$ plane for $\tan\beta=10$ (see Fig. 10). Limits are also obtained for Simplified Model Spectra.
- Simplified Model Spectra. 6 AALTONEN 09s searched in 2 fb⁻¹ of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for events with at least 2 jets and \cancel{E}_T . No evidence for a signal is observed. A limit is derived for a mSUGRA scenario in the $m_{\widetilde{q}}$ versus $m_{\widetilde{g}}$ plane, see their Fig. 2.
- ⁷ ABAZOV 08G looked in 2.1 fb⁻¹ of $p\bar{p}$ collisions at \sqrt{s} =1.96 TeV for events with acoplanar jets or multijets with large E_T . No significant excess was found compared to the background expectation. A limit is derived on the masses of squarks and gluinos for specific MSUGRA parameter values, see Figure 3. Similar results would be obtained for allowed to the contract of parameters and squares and parameters are supported to the possible of PAZOV.
- a large class of parameter sets. Supersedes the results of ABAZOV 06c.
 8 ABULENCIA 06I searched in 156 pb $^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for multijet events with large E_T . They request at least 2 b-tagged jets and no isolated leptons. They investigate the production of gluinos decaying into \overline{b}_1 b followed by $\overline{b}_1 \rightarrow b \overline{\chi}_1^0$. Both branching fractions are assumed to be 100% and the LSP mass to be 60 GeV. No significant excess was found compared to the background expectation. Upper limits on the cross-section are extracted and a limit is derived on the masses of sbottom and gluinos con their E_1 0.
- affolder of searched in $\sim 84~{\rm pb}^{-1}$ of $p\overline{p}$ collisions for events with ≥ 3 jets and E_{T} , arising from the production of gluinos and/or squarks. Limits are derived by scanning the parameter space, for $m_{\widetilde{q}} \geq m_{\widetilde{g}}$ in the framework of minimal Supergravity, assuming five flavors of degenerate squarks, and for $m_{\widetilde{q}} < m_{\widetilde{g}}$ in the framework of constrained MSSM, assuming conservatively four flavors of degenerate squarks. See Fig. 3 for the variation
- assuming conservatively out havous of degenerate squarks. Supersedes the results of ABE 97K. 10 ABBOTT 01D looked in $\sim 108\,\mathrm{pb}^{-1}$ of $p\overline{p}$ collisions at \sqrt{s} =1.8 TeV for events with $e\,e$, $\mu\mu$, or $e\,\mu$ accompanied by at least 2 jets and E_T . Excluded regions are obtained in the MSUGRA framework from a scan over the parameters $0 < m_0 < 300$ GeV, $10 < m_1/2 < 110$ GeV, and $1.2 < \tan\beta < 10$.
- 11 AFFOLDER 011 searched in $\sim 106~{\rm pb}^{-1}$ of $p\overline{p}$ collisions for events with 2 like-sign leptons (e or μ), ≥ 2 jets and E_T , expected to arise from the production of gluinos and/or squarks with cascade decays into $\overline{\chi}^{\pm}$ or $\overline{\chi}_2^0$. Spectra and decay rates are evaluated in the framework of minimal Supergravity, assuming five flavors of degenerate squarks and a pseudoscalar Higgs mass m_A =500 GeV. The limits are derived for $\tan\beta=2$, $\mu=-800$ GeV, and scanning over $m_{\widetilde{g}}$ and $m_{\widetilde{q}}$. See Fig. 2 for the variation of the limit as function of the squark mass. These limits supersede the results of ABE 96D.
- 12 ABBOTT 99L consider events with three or more jets and large E_T . Spectra and decay rates are evaluated in the framework of minimal Supergravity, assuming five flavors of degenerate squarks, and scanning the space of the universal gaugino $(m_{1/2})$ and scalar (m_0) masses See their Figs. 2–3 for the dependence of the limit on the relative value of m_{π} and m_{π} .
- The following and the second of the following and the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the sec

Supersymmetric Particle Searches

- 14 AAD 11x looked in 36 pb $^{-1}$ of pp collisions at $\sqrt{s}=7$ TeV for events with ≥ 2 photons and E_T from the pair production of gluinos with cascade decays to $\widetilde{\chi}_1^0$ followed by $\widetilde{\chi}_1^0 \to \gamma \widetilde{G}$ prompt decay. No evidence for an excess over the SM expectation is observed, and a limit on the number of new physics events is set. Limits are derived in a Generalized Gauge Mediated model in the $(m_{\widetilde{g}}^{},m_{\widetilde{\chi}_1^0}^0)$ plane (see Fig. 5) under the assumptions $\tan\beta$
 - = 2 and all sparticle masses at 1.5 TeV, except the \widetilde{g} , $\widetilde{\chi}_{1}^{0}$, and $\widetilde{\mathit{G}}$.
- 15 AALTONEN 11Q searched in 3.2 fb⁻¹ of $\rho \overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events with at least 6 jets from the pair production of gluinos and squarks with the subsequent decays $\overline{g} \rightarrow 3$ jets in the MSSM framework with \overline{g} . No statistically significant bumps in the 3-jet systems are observed over the SM background. Limits on the cross section times branching ratio are derived as a function of the gluino mass, displayed in Fig. 3. For decoupled squarks in the range $0.5 < m_{\overline{q}} < 0.7$ TeV gluinos are excluded below 144 GeV. The guided limit is for near degeneracy of squark and gluino masses.
- The quoted limit is for near degeneracy of squark and gluino masses. 16 CHATRCHYAN 11AB looked in 35 pb $^{-1}$ of pp collisions at $\sqrt{s}=7$ TeV for events with ≥ 2 same charge isolated leptons $(e, \mu \text{ or } \tau)$, jets and E_T . Such events might be produced from $\widetilde{g}\widetilde{g}$ or $\widetilde{g}\widetilde{q}$ decaying via charginos into leptons. No evidence for an excess over the expected background is observed. Limits are derived in the CMSSM $(m_0, m_1/2)$ plane for $\tan \beta = 3$ (see Fig. 10).
- 17 CHATRCHYAN 11G looked in 36 pb $^{-1}$ of ρp collisions at $\sqrt{s}=7$ TeV for events with ≥ 2 isolated photons, ≥ 1 jet and E_T , which may arise in a generalized gauge mediated model from the decay of a $\widetilde{\chi}_1^0$ NLSP. No evidence for an excess over the expected background is observed. Limits are derived in the plane of squark versus gluino mass (see Fig. 4) for several values of $m_{\widetilde{\chi}_1^0}$
- 13 CHATRCHYAN 11Q looked in 36 pb $^{-1}$ of pp collisions at $\sqrt{s}=7$ TeV for events with a single isolated lepton (e or μ), \geq 4 jets and \cancel{E}_T . No evidence for an excess over the expected background is observed. Limits are derived in the CMSSM $(m_0,\,m_{1/2})$ plane for $\tan\beta=10$ (see Fig. 7).
- for tan $\beta=10$ (see Fig. 7). 19 CHATRCHYAN 11v looked in 35 pb $^{-1}$ of pp collisions at $\sqrt{s}=7$ TeV for events with ≥ 3 isolated leptons $(e, \mu \text{ or } \tau)$, with or without jets and E_T . Multi-lepton final states originate from $\tilde{q} \to \tilde{\chi}^0 + X$, followed by $\tilde{\chi}^0 \to \tilde{\ell}^\pm \ell^\mp$ and $\tilde{\ell} \to \ell \tilde{G}$. No evidence for an excess over the expected background is observed. Limits are derived (see Fig. 4) for a GMSB-type scenario with mass-degenerate right-handed sleptons (slepton co-NLSP scenario).
- 20 CHATRCHYAN 11w looked in 1.14 fb $^{-1}$ of pp collisions at $\sqrt{s}=7$ TeV for events with ≥ 2 jets, large total jet energy, and \rlap/E_T . After combining multi-jet events into two pseudo-jets signal events are selected by a cut on $\alpha_T=E_T^{j2}/M_T$, the transverse energy of the less energetic jet over the transverse mass. Given the lack of an excess over the SM backgrounds, limits are derived in the CMSSM $(m_0,\,m_1/2)$ plane (see Fig. 4) for $\tan\beta=10$. The limits are only weakly dependent on $\tan\beta$ and A_0 .
- 21 KHACHATRYAN 111 looked in 35 pb⁻¹ of pp collisions at $\sqrt{s}=7$ TeV for events with ≥ 2 Jets and pq. After combining multi-jet events into two pseudo-jets signal events are selected by a cut on $\alpha_T = E_T^{j_2}/M_T$, the transverse energy of the less energetic jet over the transverse mass. No evidence for an excess over the expected background is observed. Limits are derived in the CMSSM $(m_0, m_{1/2})$ plane (see Fig. 5) for $\tan \beta = 3$. Superseded by CHATRCHYAN 11w.
- 3. Superseded by CHATRCHYAN 11w. $^{22}\text{ABAZOV }02\text{F looked in }77.5\text{ pb}^{-1}\text{ of }\rho\overline{\rho}\text{ collisions at }1.8\text{ TeV for events with }\geq 2\mu+\geq 4\text{jets, originating from associated production of squarks followed by an indirect }R\text{ decay (of the }\overline{\chi}_1^0)\text{ via }LQ\overline{\rho}\text{ couplings of the type }\lambda_{2jk}^2\text{ where }j=1,2\text{ and }k=1,2,3\text{. Bounds are obtained in the MSUGRA scenario by a scan in the range }0\leq M_0\leq 400\text{ GeV, }60\leq m_{1/2}\leq 120\text{ GeV for fixed values }A_0=0,\mu<0,\text{ and }\tan\beta=2\text{ or }6\text{. The bounds are weaker for }\tan\beta=6\text{. See Figs. }2,3\text{ for the exclusion contours in }m_{1/2}\text{ versus }m_0\text{ for }\tan\beta=2\text{ and }k=1,2,3\text{ or }k=1,2,3\text{ for the exclusion contours in }m_{1/2}\text{ versus }m_0\text{ for }\tan\beta=2\text{ and }k=1,2,3\text{ for the exclusion contours in }m_{1/2}\text{ versus }m_0\text{ for }\tan\beta=2\text{ and }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{ for }k=1,2,3\text{$
- 23, Respectively. 23 ABAZOV 02G search for associated production of gluinos and squarks in 92.7 pb $^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}{=}1.8$ TeV, using events with one electron, \geq 4 jets, and large E_T . The results are compared to a MSUGRA scenario with μ <0, $A_0{=}0$, and $\tan\beta{=}3$ and allow to exclude a region of the $(m_0,m_{1/2})$ shown in Fig. 11.
- 24 CHEUNG 02B studies the constraints on a \tilde{b}_1 with mass in the 2.2–5.5 GeV region and a gluino in the mass range 12–16 GeV, using precision measurements of Z^0 decays and e^+e^- annihilations at LEP2. Few detectable events are predicted in the LEP2 data for the model proposed by BERGER 01.
- 25 BERGER 01 reanalyzed interpretation of Tevatron data on bottom-quark production. Argues that pair production of light gluinos ($m \sim 12$ –16 GeV) with subsequent 2-body decay into a light sbottom ($m \sim 2$ –5.5 GeV) and bottom can reconcile Tevatron data with predictions of perturbative QCD for the bottom production rate. The sbottom must either decay hadronishly via a Parity and P. Widshiring interaction or belong lived.
- either decay hadronically via a R-parity- and B-violating interaction, or be long-lived. 26 ABBOTT 99 searched for $\gamma \not\!\! E_T + \geq 2$ jet final states, and set limits on $\sigma(\rho \overline{\rho} \to \overline{g} + X) \cdot B(\overline{g} \to \gamma \not\!\! E_T X)$. The quoted limits correspond to $m_{\widetilde{q}} \geq m_{\widetilde{g}}$, with $B(\widetilde{\chi}_2^0 \to \widetilde{\chi}_1^0 \gamma) = 1$ and $B(\widetilde{\chi}_1^0 \to \overline{G} \gamma) = 1$, respectively. They improve to 310 GeV (360 GeV in the case of γG decay) for $m_{\widetilde{g}} = m_{\widetilde{q}}$.
- 27 ABBOTT 99K uses events with an electron pair and four jets to search for the decay of the $\tilde{\chi}_1^0$ LSP via R $LQ\overline{D}$ couplings. The particle spectrum and decay branching ratios are taken in the framework of minimal supergravity. An excluded region at 95% CL is obtained in the $(m_0,m_{1/2})$ plane under the assumption that A_0 =0, μ <0, $\tan \beta$ =2 and
- any one of the couplings $\lambda'_{1jk} > 10^{-3}$ (j=1,2 and k=1,2,3) and from which the above limit is computed. For equal mass squarks and gluinos, the corresponding limit is 277 GeV. The results are essentially independent of A_0 , but the limit deteriorates rapidly with increasing $\tan\beta$ or μ >0.
- 28 ABACHI 95c assume five degenerate squark flavors with with $m_{\widetilde{q}_1}=m_{\widetilde{q}_{\widetilde{B}}}$. Sleptons are assumed to be heavier than squarks. The limits are derived for fixed $\tan\beta=2.0~\mu=-250~{\rm GeV}$, and $m_{H^+}=500~{\rm GeV}$, and with the cascade decays of the squarks and gluinos calculated within the framework of the Minimal Supergravity scenario. The bounds are weakly sensitive to the three fixed parameters for a large fraction of parameter space.
- 29 ABE 95T looked for a cascade decay of gluino into $\widetilde{\chi}_2^0$ which further decays into $\widetilde{\chi}_1^0$ and a photon. No signal is observed. Limits vary widely depending on the choice of parameters. For $\mu=-40$ GeV, $\tan\beta=1.5$, and heavy squarks, the range $50 < m_{\widetilde{g}}$ (GeV)<140 is excluded at 90% CL. See the paper for details.

- 30 HEBBEKER 93 combined jet analyses at various $e^+\,e^-$ colliders. The 4-jet analyses at TRISTAN/LEP and the measured $\alpha_{\rm S}$ at PEP/PETRA/TRISTAN/LEP are used. A constraint on effective number of quarks ${\it N}{=}6.3\pm1.1$ is obtained, which is compared to that with a light gluino, ${\it N}{=}8$.
- 31 ABE 92L bounds are based on similar assumptions as ABACHI 95C. Not sensitive to $m_{\rm gluino}$ <40 GeV (but other experiments rule out that region).
- 32 ROY 92 reanalyzed CDF limits on di-lepton events to obtain limits on gluino production in R-parity violating models. The 100% decay $\tilde{g} \to q \overline{q} \, \tilde{\chi}$ where $\tilde{\chi}$ is the LSP, and the LSP decays either into $\ell q \, \overline{d}$ or $\ell \ell \overline{e}$ is assumed.
- 33 NOJIRI 91 argues that a heavy gluino should be nearly degenerate with squarks in minimal supergravity not to overclose the universe.
- ³⁴ The limits of ALBAJAR 87D are from $p\overline{p}\to \widetilde{g}\widetilde{g}$ X $(\widetilde{g}\to q\overline{q}\widetilde{\gamma})$ and assume $m_{\widetilde{q}}>m_{\widetilde{g}}$. These limits apply for $m_{\widetilde{\gamma}}\lesssim$ 20 GeV and $\tau(\widetilde{g})<10^{-10}$ s.
- 35 The limit of ANSARI 87D assumes $m_{\widetilde{q}} > m_{\widetilde{g}}$ and $m_{\widetilde{\gamma}} \approx 0$.

Long-lived/light \widetilde{g} (Gluino) MASS LIMIT

Limits on light gluinos ($m_{\widetilde{g}}~<5$ GeV), or gluinos which leave the detector before decaying.

Searches Particle Listings Supersymmetric Particle Searches

- 1 AAD 1 K looked in 34 pb $^{-1}$ of p p collisions at $\sqrt{s}=7$ TeV for events with heavy stable particles, identified by their anomalous dE/dx in the tracker or time of flight in the tile calorimeter, from pair production of \tilde{g} . No evidence for an excess over the SM expectation is observed. Limits are derived for pair production of gluinos as a function of mass (see Fig. 4), for a fraction, f=10%, of formation of $\tilde{g}-g$ (R-gluonball) if instead of a phase space driven approach for the hadronic scattering of the R-hadrons, a triple-Regge model or a bag-model is used, the limit degrades to 566 and 562 GeV, respectively.
- 2 AAD 11P looked in 37 pb $^{-1}$ of pp collisions at $\sqrt{s}=$ 7 TeV for events with heavy stable particles, reconstructed and identified by their time of flight in the Muon System. There is no requirement on their observation in the tracker to increase the sensitivity to cases where gluinos have a large fraction, f, of formation of neutral $\widetilde{g}-g$ (R-gluonball). No evidence for an excess over the SM expectation is observed. Limits are derived as a function of mass (see Fig. 4), for f=0.1. For fractions f = 0.5 and 1.0 the limit degrades to 537 and 530 GeV, respectively.
- 3 KHACHATRYAN 11 looked in 10 pb $^{-1}$ of pp collisions at $\sqrt{s}=7$ TeV for events with pair production of long-lived gluinos. The hadronization of the gluinos leads to R-hadrons pan production long-invasions and intermediate in the games test of the which may stop inside the detector and later decay via $\tilde{g} \to g \tilde{\chi}_1^0$ during gaps between the proton bunches. No significant excess over the expected background is observed. From a counting experiment, a limit at 95% C.L. on the cross section times branching ratio is derived for $m_{\widetilde{g}}-m_{\widetilde{\chi}_1^0}>100$ GeV, see their Fig. 2. Assuming 100% branching

ratio, lifetimes between 75 ns and 3×10^5 s are excluded for $m_{\widetilde{g}}=300$ GeV. The \widetilde{g} mass exclusion is obtained with the same assumptions for lifetimes between $10~\mu s$ and mass exclusion is obtained with the same assumptions for interactions with matter, illustrated in Fig. 3. From a time-profile analysis, the mass exclusion is 382 GeV for a lifetime of $10~\mu s$ under the same assumptions as above. ⁴ KHACHATRYAN 11c looked in 3.1 pb⁻¹ of pp collisions at $\sqrt{s}=7$ TeV for events with heavy stable particles, identified by their anomalous dE/dx in the tracker or additionally

- requiring that it be identified as muon in the muon chambers, from pair production of \widetilde{g} . No evidence for an excess over the expected background is observed. Limits are derived for pair production of gluinos as a function of mass (see Fig. 3), depending on the fraction, f, of formation of g-g (R-gluonball). The quoted limit is for f=0.1, while for f=0.5 it degrades to 357 GeV. In the conservative scenario where every hadronic interaction causes it to become neutral, the limit decreases to 311 GeV for f=0.1.
- BERGER 10 updated the results of BERGER 05. They fit parton distribution functions including the effects of a light gluino as an extra parton. Different data on α_S is also included. A fit for $\alpha_S(M_Z)$ is performed as a function of the gluino mass. The bound is determined by comparing the quality of the fit to the CT10 fit, and the CT10 tolerance criterion is used to define the significance. The lower bound is 25 GeV for fixed $\alpha_S(M_Z)$
- 6 KAPLAN 08 reanalysed jet event shape data from LEP 1 and LEP 2 using soft collinear effective theory methods. These data are sensitive to the effects of new degrees of freedoms, including a relatively light gluino, at different energy scales, roughly between 5 and 50 GeV. The analysis relies on theoretical modeling of and approximations for non-perturbative effects and matching between different scales.

 7 ABAZOV 07L looked in approximately 410 pb $^{-1}$ of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV for events with a long-lived gluino from split supersymmetry, decaying after stopping in the detector into $g\,\tilde{\chi}^0_1$ with lifetimes from 30 μ s to 100 h. The signal signature is a largely empty event with a single large transverse energy deposit in the calorimeter. The main background is due to cosmic muons interacting in the calorimeter. The data agree with the estimated background and allow the authors to estimate a limit on the rate of an out-of-time monoiet signal of a given energy. Assuming the branching ratios $\tilde{\sigma} = \sigma\,\tilde{\sigma}^0$ out-of-time monojet signal of a given energy. Assuming the branching ratios $\tilde{g} \to g \tilde{\chi}_1^0$ to be 100% the results can be translated to limits on the gluino cross section versus the gluino mass for fixed $\tilde{\chi}^0_1$ mass. After comparing to the expected gluino cross sections, the excluded region of gluino masses can be obtained, see examples in their Fig. 3.
- ⁸ BERGER 05 include the light gluino in proton PDF and perform global analysis of hadronic data. Effects on the running of α_S also included. Strong dependency on $\alpha_S(m_Z)$. Bound quoted for $\alpha_S(m_Z)=0.118$. Superseded by BERGER 10.
- ASDALLAH 03c looked for events of the type $q \overline{q} R^{\pm} R^{\pm}$, $q \overline{q} R^{\pm} R^{0}$ or $q \overline{q} R^{0} R^{0}$ in $e^{+}e^{-}$ interactions at 91.2 GeV collected in 1994. The R^{\pm} bound states are identified by anomalous dE/dx in the tracking chambers and the R^{0} by missing energy, due to their reduced energy loss in the calorimeters. The upper value of the excluded range depends on the probability for the gluino to fragment into R^{\pm} or R^{0} , see their Fig. 17. It improves to 23 GeV for 100% fragmentation to R^{\pm} .
- 10 ABDALLAH 03G used e^+e^- data at and around the Z^0 peak, above the Z^0 up to $\sqrt{s}=202$ GeV and events from radiative return to cover the low energy region. They perform a direct measurement of the QCD beta-function from the means of fully inclusive event observables. Compared to the energy range, gluinos below 5 GeV can be considered massless and are firmly excluded by the measurement.
- 11 HEISTER 03 use e^+e^- data from 1994 and 1995 at and around the Z^0 peak to measure the 4-jet rate and angular correlations. The comparison with QCD NLO calculations allow $\alpha_S(M_Z)$ and the color factor ratios to be extracted and the results are in a greement with the expectations from QCD. The inclusion of a massless gluino in the beta functions yields $T_R / C_F = 0.15 \pm 0.06 \pm 0.06$ (expectation is $T_R / C_F = 3.8$), excluding a massless gluino at more than 95% C.L. As no NLO calculations are available for massive gluinos, the earlier LO results from BARATE 97L for massive gluinos remain valid.
- guinos, the earlier LO Tesuis from BARATE 97L for massive guinos remain valid.

 12 HEISTER 03H use e^+e^- data at and around the Z^0 peak to look for stable gluinos hadronizing into charged or neutral R-hadrons with arbitrary branching ratios. Combining these results with bounds on the Z^0 hadronic width from electroweak measurements (JANOT 03) to cover the low mass region the quoted lower limit on the mass of a lengthing blaine is obtained. long-lived gluino is obtained.
- $^{13}\,\mathsf{JANOT}\,\,^{\circ}\!\!^{\circ}\!\!^{\circ}$ excludes a light gluino from the upper limit on an additional contribution to the Z hadronic width. At higher confidence levels, $m_{\widetilde{g}} > 5.3(4.2)$ GeV at $3\sigma(5\sigma)$ level.
- 14 MAFI 00 reanalyzed CDF data assuming a stable heavy gluino as the LSP, with model for R-hadron-nucleon scattering. Gluino masses between 35 GeV and 115 GeV are excluded based on the CDF Run I data. Combined with the analysis of BAER 99, this allows a LSP gluino mass between 25 and 35 GeV if the probability of fragmentation into charged *R*-hadron P>1/2. The cosmological exclusion of such a gluino LSP are assumed to be avoided as in BAER 99. Gluino could be NLSP with $au_{\widetilde{g}} \sim 100$ yrs, and decay to gluon
- 15 ALAVI-HARATI 99E looked for R0 bound states, yielding $\pi^+\pi^-$ or π^0 in the final state. The experiment is sensitive to values of $\Delta m = m_{R^0} - m_{\widetilde{\gamma}}$ larger than 280 MeV and 140 MeV for the two decay modes, respectively, and to R^0 mass and lifetime in the ranges 0.8–5 GeV and 10^{-10} – 10^{-3} s. The limits obtained depend on $B(R^0 \to 0.00)$

- $\pi^+\pi^-$ photino) and B($R^0 o\pi^0$ photino) on the value of $m_{R^0}/m_{\widetilde{\gamma}}$, and on the ratio of production rates $\sigma(R^0)/\sigma(K_I^0)$. See Figures in the paper for the excluded R^0 production rates as a function of $\Delta D_A M_c^0$ mass and lifetime. Using the production rates expected from perturbative QCD, and assuming dominance of the above decay channels over the suitable phase space, R^0 masses in the range 0.8–5 GeV are excluded at 90%CL for a large fraction of the sensitive lifetime region. ALAVI-HARATI 99E updates and supersedes
- 16 BAER 99 set constraints on the existence of stable \widetilde{g} hadrons, in the mass range $m_{\widetilde{g}} > 3$ GeV. They argue that strong-interaction effects in the low-energy annihilation rates could leave small enough relic densities to evade cosmological constraints up to $m_{\widetilde{g}} < 10$ TeV. They consider jet+ $\not\!\!E_T$ as well as heavy-ionizing charged-particle signatures from production of stable \widetilde{g} hadrons at LEP and Tevatron, developing modes for the energy loss production of stable \widetilde{g} nations at LEP and revarion, developing modes for the energy loss of \widetilde{g} hadrons inside the detectors. Results are obtained as a function of the fragmentation probability P of the \widetilde{g} into a charged hadron. For P<1/2, and for various energy-loss models, OPAL and CDF data exclude gluinos in the $3 < m_{\widetilde{g}}(\text{GeV}) < 130$ mass range. For P>1/2, gluinos are excluded in the mass ranges $3 < m_{\widetilde{g}}(\text{GeV}) < 23$ and $50 < m_{\widetilde{g}}({
 m GeV}) < 200.$
- 17 FANTI 99 looked for 0 bound states yielding high 0 0 0 decays. The experiment is sensitive to a region of R^0 mass and lifetime in the ranges of 1–5 GeV and 10^{-10} – 10^{-3} s. The limits obtained depend on $B(R^0\to\eta\tilde{\gamma})$, on the value of $m_{R^0}/m_{\widetilde{\gamma}}$, and on the ratio of production rates $\sigma(R^0)/\sigma(K_I^0)$. See Fig. 6–7 for the excluded production rates as a function of R^0 mass and lifetime.
- 18 ACKERSTAFF 98v excludes the light gluino with universal gaugino mass where charginos, neutralinos decay as $\widetilde{\chi}_1^{\pm},\widetilde{\chi}_2^0 \to q \overline{q} \widetilde{g}$ from total hadronic cross sections at \sqrt{s} =130–172
- GeV. See paper for the case of nonuniversal gaugino mass. ¹⁹ ADAMS 97B looked for $\rho^0 \to \pi^+\pi^-$ as a signature of $R^0 = (\tilde{g} \, g)$ bound states. The experiment is sensitive to an R^0 mass range of 1.2-4.5 GeV and to a lifetime range of 10^{-10} - 10^{-3} sec. Precise limits depend on the assumed value of $m_{R^0}/m_{\widetilde{\gamma}^*}$. See Fig. 7 for the excluded mass and lifetime region.
- for the excluded mass and interime region.

 20 ALBUQUERQUE 97 looked for weakly decaying baryon-like states which contain a light gluino, following the suggestions in FARRAR 96. See their Table 1 for limits on the production fraction. These limits exclude gluino masses in the range 100-600 MeV for the predicted lifetimes (FARRAR 96) and production rates, which are assumed to be comparable to those of strange or charmed baryons.
- $^{21}\,\mathrm{BARATE}$ 97L studied the QCD color factors from four-jet angular correlations and the differential two-jet rate in Z decay. Limit obtained from the determination of $n_f=4.24\pm0.29\pm1.15$, assuming $T_F/C_F=3/8$ and $C_A/C_F=9/4$.
- 22 CSIKOR 97 combined the α_S from $\sigma(e^+e^-\to hadron),~\tau$ decay, and jet analysis in Z decay. They exclude a light gluino below 5 GeV at more than 99.7%CL.
- Z decay. They exclude a light guillo below 5 dev at more than 27.74c.

 32 DEGOUVEA 97 reanalyzed AKERS 95A data on Z decay into four jets to place constraints on a light stable gluino. The mass limit corresponds to the pole mass of 2.8 GeV. The analysis, however, is limited to the leading-order QCD calculation.
 24 FARRAR 96 studied the possible $R^0 = (\tilde{g} \, g)$ component in Fermilab E799 experiment and used its bound $B(K_L^0 \to \pi^0 \nu \overline{\nu}) \le 5.8 \times 10^{-5}$ to place constraints on the combination of \mathbb{R}^0 production cross section and its lifetime.
- 25 AKERS 95R looked for Z decay into $q\overline{q}\,\widetilde{g}\,\widetilde{g}$, by searching for charged particles with dE/dx consistent with \widetilde{g} fragmentation into a state ($\widetilde{g}\,q\overline{q})^{\pm}$ with lifetime $\tau>10^{-7}$ sec. The fragmentation probability into a charged state is assumed to be 25%.
- 26 CLAVELLI 95 updates the analysis of CLAVELLI 93, based on a comparison of the hadronic widths of charmonium and bottomonium S-wave states. The analysis includes a parametrization of relativistic corrections. Claims that the presence of a light gluino with the data by claving days the unning of control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the control of the contr improves agreement with the data by slowing down the running of $lpha_{S}$.
- improves agreement with the data by slowing down the running or α_S . 27 CAKIR 94 reanalyzed TUTS 87 and later unpublished data from CUSB to exclude pseudo-scalar gluinonium $\eta_{\widetilde{g}}(\widetilde{g})$ of mass below 7 GeV. It was argued, however, that the perturbative QCD calculation of the branching fraction $T \to \eta_{\widetilde{g}} \gamma$ is unreliable for $m_{\eta_{\widetilde{g}}} < 3$ GeV. The gluino mass is defined by $m_{\widetilde{g}} = (m_{\eta_{\widetilde{q}}})/2$. The limit holds for any gluino lifetime. 28 LOPEZ 93c uses combined restraint from the radiative symmetry breaking scenario within the minimal supergrayity model, and the LEP bounds on the $(M_{\Omega,U})$ plane. Claims that
- the minimal supergravity model, and the LEP bounds on the (M_2,μ) plane. Claims that the light gluino window is strongly disfavored.
- 29 CLAVELLI 92 claims that a light gluino mass around 4 GeV should exist to explain the discrepancy between $\alpha_{\rm S}$ at LEP and at quarkonia (\varUpsilon) , since a light gluino slows the running of the QCD coupling.
- 30 ANTONIADIS 91 argue that possible light gluinos (< 5 GeV) contradict the observed running of $\alpha_{\rm S}$ between 5 GeV and m_Z . The significance is less than 2 s.d. 31 ANTONIADIS 91 interpret the search for missing energy events in 450 GeV/c pN colli-
- sions, AKESSON 91, in terms of light gluinos. 32 NAKAMURA 89 searched for a long-lived ($au\gtrsim 10^{-7}$ s) charge-(± 2) particle with mass
- $\lesssim 1.6$ GeV in proton-Pt interactions at 12 GeV and found that the yield is less than \sim 10^{-8} times that of the pion. This excludes R- Δ^{++} (a $\widetilde{g}\,u\,u\,u$ state) lighter than 1.6
- GeV. 33 The limits assume $m_{\widetilde{q}}=100$ GeV. See their figure 3 for limits vs. $m_{\widetilde{q}}$.
- 34 The gluino mass is defined by half the bound $\widetilde{g}\widetilde{g}$ mass. If zero gluino mass gives a $\widetilde{g}\widetilde{g}$ of mass about 1 GeV as suggested by various glueball mass estimates, then the low-mass bound can be replaced by zero. The high-mass bound is obtained by comparing the data with nonrelativistic potential-model estimates.
- 35 ALBRECHT 86c search for secondary decay vertices from $\chi_{b1}(1P) \to \widetilde{g}\,\widetilde{g}\,g$ where \widetilde{g} 's make long-lived hadrons. See their figure 4 for excluded region in the $m_{\widetilde{g}}-m_{\widetilde{g}}$ and $m_{\widetilde{g}} - m_{\widetilde{q}}$ plane. The lower $m_{\widetilde{g}}$ region below \sim 2 GeV may be sensitive to fragmentation effects. Remark that the \widetilde{g} -hadron mass is expected to be ~ 1 GeV (glueball mass) in the zero \widetilde{g} mass limit.
- 36 BADIER 86 looked for secondary decay vertices from long-lived \widetilde{g} -hadrons produced at 300 GeV π^- beam dump. The quoted bound assumes \widetilde{g} -hadron nucleon total cross section of $10\mu b$. See their figure 7 for excluded region in the $m_{\widetilde{g}}-m_{\widetilde{q}}$ plane for several assumed total cross-section values.
- 37 BARNETT 86 rule out light gluinos (m=3–5 GeV) by calculating the monojet rate from gluino gluino gluon events (and from gluino gluino events) and by using UA1 data from $p\overline{p}$ collisions at CERN.

Supersymmetric Particle Searches

- 38 VOLOSHIN 86 rules out stable gluino based on the cosmological argument that predicts too much hydrogen consisting of the charged stable hadron \tilde{g} uud. Quasi-stable $(\tau>1.\times 10^{-7}\text{s})$ light gluino of $m_{\widetilde{g}}<3$ GeV is also ruled out by nonobservation of the stable charged particles, \tilde{g} uud, in high energy hadron collisions.
- 39 COOPER-SARKAR 85B is BEBC beam-dump. Gluinos decaying in dump would yield $\tilde{\gamma}$'s in the detector giving neutral-current-like interactions. For $m_{\widetilde{q}} > 330$ GeV, no limit
- 40 DAWSON 85 first limit from neutral particle search. Second limit based on FNAL beam
- 41 FARRAR 85 points out that BALL 84 analysis applies only if the \widetilde{g} 's decay before interacting, i.e. $m_{\widetilde{q}} < 80 m_{\widetilde{g}}^{-1.5}$. FARRAR 85 finds $m_{\widetilde{g}} < 0.5$ not excluded for $m_{\widetilde{q}} = 30$ –1000 GeV and $m_{\widetilde{g}} < 1.0$ not excluded for $m_{\widetilde{q}} = 100$ –500 GeV by BALL 84 experiment.
- 42 GOLDMAN $^{"}$ 85 use nonobservation of a pseudoscalar \widetilde{g} - \widetilde{g} bound state in radiative ψ
- $^{43}\,\text{HABER}$ 85 is based on survey of all previous searches sensitive to low mass $\widetilde{\textit{g}}$'s. Limit makes assumptions regarding the lifetime and electric charge of the lightest supersym-
- 44 BALL 84 is FNAL beam dump experiment. Observed no interactions of $\widetilde{\gamma}$ in the calorimeter, where $\widetilde{\gamma}$'s are expected to come from pair-produced \widetilde{g} 's. Search for long-lived $\widetilde{\gamma}$ interacting in calorimeter 56m from target. Limit is for $m_{\widetilde{q}}=40$ GeV and production
- cross section proportional to A $^{0.72}$. BALL 84 find no \widetilde{g} allowed below 4.1 GeV at CL = 90%. Their figure 1 shows dependence on $m_{\widetilde{q}}$ and A. See also KANE 82.
- 45 BRICK 84 reanalyzed FNAL 147 GeV HBC data for R- Δ (1232) $^{++}$ with au $\,>$ 10^{-9} s and $\rho_{\mathsf{lab}} > 2$ GeV. Set CL = 90% upper limits 6.1, 4.4, and 29 microbarns in ρp , $\pi^+ p$, K+p collisions respectively. $R-\Delta ++$ is defined as being \tilde{g} and 3 up quarks. If mass = 1.2–1.5 GeV, then limits may be lower than theory predictions.
- 46 FARRAR 84 argues that $m_{\widetilde{g}} < 100$ MeV is not ruled out if the lightest R-hadrons are long-lived. A long lifetime would occur if R-hadrons are lighter than $\widetilde{\gamma}$'s or if $m_{\overline{g}} > 100$
- 47 BERGSMA 83c is reanalysis of CERN-SPS beam-dump data. See their figure 1.
- 48 CHANOWITZ 83 find in bag-model that charged s-hadron exists which is stable against strong decay if $m_{\widetilde{g}}$ <1 GeV. This is important since tracks from decay of neutral shadron cannot be reconstructed to primary vertex because of missed $\tilde{\gamma}$. Charged s-hadron leaves track from vertex.
- 49 KANE 82 inferred above \widetilde{g} mass limit from retroactive analysis of hadronic collision and beam dump experiments. Limits valid if \widetilde{g} decays inside detector.

LIGHT \tilde{G} (Gravitino) MASS LIMITS FROM COLLIDER EXPERIMENTS

The following are bounds on light ($\ll 1\,\mathrm{eV}$) gravitino indirectly inferred from its coupling to matter suppressed by the gravitino decay constant.

Unless otherwise stated, all limits assume that other supersymmetric particles besides the gravitino are too heavy to be produced. The gravitino is assumed to be undetected and to give rise to a missing energy (₺) signature.

- 1 ABDALLAH 05B use data from $\sqrt{s}=180$ –208 GeV. They look for events with a single photon $+ \not\!\!E$ final states from which a cross section limit of $\sigma < 0.18 \ pb$ at 208 GeV is
- photon $+\not$ \not mind states from which a closs section limit of x < 0.10 pb at 200 GeV is obtained, allowing a limit on the mass to be set. Supersedes the results of ABREU 00z. ² ACHARD 04E use data from $\sqrt{s} = 189$ –209 GeV. They look for events with a single photon $+\not$ \not final states from which a limit on the Gravitino mass is set corresponding to $\sqrt{F} > 238$ GeV. Supersedes the results of ACCIARRI 99R.
- to $\sqrt{F} > 238$ GeV. Supersedes the results of ACCIARKI 99K.

 ³ HEISTER 03C use the data from $\sqrt{s} = 189-209$ GeV to search for $\gamma \not\!\!E_T$ final states.

 ⁴ ACOSTA 02H looked in 87 pb^{-1} of $\rho \overline{\rho}$ collisions at $\sqrt{s} = 1.8$ TeV for events with a high- E_T photon and $\not\!\!E_T$. They compared the data with a GMSB model where the final state could arise from $q\overline{q} \to \widetilde{G}\ \widetilde{G}\ \gamma$. Since the cross section for this process scales as $1/|F|^4$, a limit at 95% CL is derived on $|F|^{1/2} > 221$ GeV. A model independent limit for the above topology is also given in the paper.

 ⁵ ARRIENDI G 000 searches for γE final states from $\sqrt{s} = 189$ GeV.
- ⁵ ABBIENDI,G 00D searches for γE final states from \sqrt{s} =189 GeV.
- ⁶ ABREU 00Z search for γE final states using data from \sqrt{s} =189 GeV. Superseded by ABDALLAH 05B
- AFFOLDER 00J searches for final states with an energetic jet (from quark or gluon) and large $ot\!\!E_T$ from undetected gravitinos
- 8 ACCIARRI 99R search for γE final states using data from \sqrt{s} =189 GeV. Superseded by 9 Searches for γE final states at \sqrt{s} =183 GeV.

- jets originating from pair production of scalar gluons, each decaying to two gluons. No two-jet resonances are observed over the SM background. Limits are derived on the cross section times branching ratio (see Fig. 3). Assuming 100% branching ratio for the decay to two gluons, the quoted exclusion range is obtained, except for a 5 GeV mass window around 140 GeV. ${}^2\text{CHATRCHYAN 11E looked in 35 pb}^{-1} \text{ of } pp \text{ collisions at } \sqrt{s} = 7 \text{ TeV for events with collimated } \mu \text{ pairs (leptonic jets) from the decay of hidden sector states. No evidence for new resonance production is found. Limits are derived and compared to various SUSY models (see Fig. 4) where the LSP, either the <math>\tilde{v}^0$ or a \tilde{a} , decays to dark sector particles.
- models (see Fig. 4) where the LSP, either the $\widetilde{\chi}_1^0$ or a \widetilde{q} , decays to dark sector particles.
- ³ ABAZOV 10N looked in 5.8 fb⁻¹ of $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV for events from ABACOV for looked in 8.6 in on pp consisting at $\sqrt{s} \equiv 1.96$ feV for events from hidden valley models in which a $\overline{\chi}_1^0$ decays into a dark photon, γ_D , and the unobservable lightest SUSY particle of the hidden sector. As the γ_D is expected to be light, it may decay into a tightly collimated lepton pair, called lepton jet. They searched for events with E_T and two isolated lepton jets observable by an opposite charged lepton pair e_E . $e\,\mu$ or μ . No significant excess over the SM expectation is observed, and a limit at 95% C.L. on the cross section times branching ratio is derived, see their Table I. They also examined the invariant mass of the lepton jets for a narrow resonance, see their Fig. 4, but found no evidence for a signal.
- ⁴ LOVE 08A searched for decays of Y(nS) with n = 1, 2, 3 into $\mu\tau$ in 1.1, 1.3, 1.4 fb⁻¹, respectively, in the CLEO III detector at CESR. The signature is a muon with \approx 97 % of the beam energy and an electron from the decay of τ . No evidence for lepton flavour violation is found and 95% CL limits on the branching ratio are estimated to be 6.0, 14.4 and 20.3 \times 10⁻⁶ for n = 1, 2, 3, respectively. Shall be a substitution of proposition of pr
- of events with $\ell\gamma E_T$ and $\ell\ell\gamma$ ($\ell=e,\mu$). No significant excess was found compared to the background expectation. No events are found such as the $e\,e\,\gamma\gamma E_T$ event observed
- 6 ACOSTA 04E looked in $107~pb^{-1}$ of $p\overline{p}$ collisions at $\sqrt{s}=1.8$ TeV for events with two same sign leptons without selection of other objects nor E_T . No significant excess is observed compared to the Standard Model expectation and constraints are derived on the parameter space of MSUGRA models, see Figure 4.
- 7 Looked for the scalar partner of a goldstino in decays $\,{\it K}^-
 ightarrow \,\, \pi^- \pi^0 \, P$ from a 25 GeV K^- beam produced at the IHEP 70 GeV proton synchrotron. The sgoldstino is assumed to be sufficiently long-lived to be invisible. A 90% CL upper limit on the decay branching ratio is set at $\sim 9.0 \times 10^{-6}$ for a sgoldstino mass range from 0 to 200 MeV, excluding the interval near $m(\pi^0)$, where the limit is $\sim 3.5 \times 10^{-5}$
- ⁸ AFFOLDER 02D looked in 85 pb $^{-1}$ of $\rho\overline{p}$ collisions at \sqrt{s} =1.8 TeV for events with a high- E_T photon, and a b-tagged jet with or without E_T . They compared the data with models where the final state could arise from cascade decays of gluinos and/or squarks into $\widetilde{\chi}^\pm$ and $\widetilde{\chi}^0_2$ or direct associated production of $\widetilde{\chi}^0_2\widetilde{\chi}^\pm_2$, followed by $\widetilde{\chi}^0_2 \to \gamma\widetilde{\chi}^0_1$ or
- a GMSB model where $\tilde{\chi}_1^0 \to \gamma \tilde{G}$. It is concluded that the experimental sensitivity is insufficient to detect the associated production or the GMSB model, but some sensitivity may exist to the cascade decays. A model independent limit for the above topology is
- 9 AFFOLDER 01H searches for $p\overline{p}\to\gamma\gamma$ X events, where the di-photon system originates from sgoldstino production, in $100\,\mathrm{pb}^{-1}$ of data. Upper limits on the cross section times branching ratio are shown as function of the di-photon mass >70 GeV in Fig. 5. Excluded regions are derived in the plane of the sgoldstino mass versus the supersymmetry breaking scale for two representative sets of parameter values, as shown in Figs. 6 and 7.
- 10 ABBOTT 00G searches for trilepton final states $(\ell = e, \mu)$ with $ot\!\!E_T$ from the indirect decay of gauginos via $LL\overline{E}$ couplings. Efficiencies are computed for all possible production and decay modes of SUSY particles in the framework of the Minimal Supergravity scenario. See Figs. 1–4 for excluded regions in the $m_{1/2}$ versus m_0 plane.
- 11 ABREU,P 00c look for the *CP*-even (*S*) and *CP*-odd (*P*) scalar partners of the goldstino, expected to be produced in association with a photon. The S/P decay into two photons or into two gluons and both the tri-photon and the photon + two jets topologies are investigated. Upper limits on the production cross section are shown in Fig. 5 and the excluded regions in Fig. 6. Data collected at $\sqrt{s} = 189-202$ GeV.
- To a BACH 197 searched for $p\bar{p}\to\gamma\gamma$ $E\gamma+X$ as supersymmetry signature. It can be caused by selectron, sneutrino, or neutralino production with a radiative decay of their decay products. They placed limits on cross sections.
- 13 BARBER 84B consider that $\widetilde{\mu}$ and \widetilde{e} may mix leading to $\mu \to e \, \widetilde{\gamma} \widetilde{\gamma}$. They discuss massmixing limits from decay dist. asym. in LBL-TRIUMF data and e^+ polarization in SIN
- spin-1 partner of Goldstone fermions with 140 < m <160 MeV decaying $\rightarrow e^+e^-$ pair.

Technicolor

DYNAMICAL ELECTROWEAK SYMMETRY BREAKING

Revised April 2012 by R.S. Chivukula (Michigan State University), M. Narain (Brown University), and J. Womersley (STFC, Rutherford Appleton Laboratory).

In theories of dynamical electroweak symmetry breaking, the electroweak interactions are broken to electromagnetism by the vacuum expectation value of a fermion bilinear. These theories may thereby avoid the introduction of fundamental scalar particles, of which we have no examples in nature. In this note, we review the status of experimental searches for the particles predicted in technicolor, topcolor, and related models. The limits from these searches are summarized in Table 1.

I. Technicolor

The earliest models [1,2] of dynamical electroweak symmetry breaking [3] include a new asymptotically free non-abelian gauge theory ("technicolor") and additional massless fermions ("technifermions" transforming under a vectorial representation of the gauge group) which feel this new force. The global chiral symmetry of the fermions is spontaneously broken by the formation of a technifermion condensate, just as the approximate chiral $SU(2) \times SU(2)$ symmetry in QCD is broken down to SU(2) isospin by the formation of a quark condensate. If the quantum numbers of the technifermions are chosen correctly (e.g., by choosing technifermions in the fundamental representation of an SU(N) technicolor gauge group, with the left-handed technifermions being weak doublets and the right-handed ones weak singlets), this condensate can break the electroweak interactions down to electromagnetism.

The breaking of the global chiral symmetries implies the existence of Goldstone bosons, the "technipions" (π_T) . Through the Higgs mechanism, three of the Goldstone bosons become the longitudinal components of the W and Z, and the weak gauge bosons acquire a mass proportional to the technipion decay constant (the analog of f_{π} in QCD). The quantum numbers and masses of any remaining technipions are model-dependent. There may be technipions which are colored (octets and triplets), as well as those carrying electroweak quantum numbers, and some color-singlet technipions are too light [4,3] unless additional sources of chiral-symmetry breaking are introduced. The next lightest technicolor resonances are expected to

Table 1: Summary of the mass limits. Symbols are defined in the text.

| Process | Excluded mass range | Decay channels | Ref. |

| $pp \to \text{Coloron}$ | $320 < m_{Coloron} < 580 \text{ GeV}$ | $Coloron \to q\overline{q}$ | [63] |

be the analogs of the vector mesons in QCD. The technivector mesons can also have color and electroweak quantum numbers and, for a theory with a small number of technifermions, are expected to have a mass in the TeV range [5].

While technicolor chiral symmetry breaking can give mass to the W and Z particles, additional interactions must be introduced to produce the masses of the standard model fermions. The most thoroughly studied mechanism for this invokes "extended technicolor" (ETC) gauge interactions [4,6]. In ETC, technicolor and flavor are embedded into a larger gauge group, which is broken at a sequence of mass scales down to the residual, exact technicolor gauge symmetry. The massive gauge bosons associated with this breaking mediate

Technicolor

transitions between quarks/leptons and technifermions, giving rise to the couplings necessary to produce fermion masses. The ETC gauge bosons also mediate transitions among technifermions themselves, leading to interactions which can explicitly break unwanted chiral symmetries and raise the masses of any light technipions. The ETC interactions connecting technifermions to quarks/leptons also mediate technipion decays to ordinary fermion pairs. Since these interactions are responsible for fermion masses, one generally expects technipions to decay to the heaviest fermions kinematically allowed (though this need not hold in all models).

In addition to quark masses, ETC interactions must also give rise to quark mixing. One expects, therefore, that there are ETC interactions coupling quarks of the same charge from different generations. A stringent limit on these flavor-changing neutral current interactions comes from $K^0 - \overline{K}^0$ mixing [4]. These force the scale of ETC breaking and the corresponding ETC gauge boson masses to be in the 100-1000 TeV range (at least insofar as ETC interactions of first two generations are concerned). To obtain quark and technipion masses that are large enough then requires an enhancement of the technifermion condensate over that expected naively by scaling from QCD. Such an enhancement can occur if the technicolor gauge coupling runs very slowly, or "walks" [7]. Some theories of walking technicolor incorporate many technifermions, implying that the technicolor scale and, in particular, the technivector mesons may be much lighter than 1 TeV [3,8].

It should be noted that there are no reliable analytical calculation techniques to analyze the properties of strongly-coupled gauge theories. Recently, however, progress has been made in simulating these theories using lattice gauge theory [9], including preliminary studies of condensate enhancement [10], precision electroweak parameters and parity doubling [11,12,13], and vector-boson scattering [14]. Progress has also been made in constructing a complete theory of fermion masses (including neutrino masses) in the context of extended technicolor [15].

In existing colliders, technivector mesons are dominantly produced when an off-shell standard model gauge boson "resonates" into a technivector meson with the same quantum numbers [16]. The technivector mesons may then decay, in analogy with $\rho \to \pi\pi$, to pairs of technipions. However, in walking technicolor the technipion masses may be increased to the point that the decay of a technirho to pairs of technipions is kinematically forbidden [8]. In this case the decay to a technipion and a longitudinally polarized weak boson (an "eaten" Goldstone boson) may be preferred, and the technivector meson would be very narrow. Alternatively, the technivector may also decay, in analogy with the decay $\rho \to \pi \gamma$, to a technipion plus a photon, gluon, or transversely polarized weak gauge boson. Finally, in analogy with the decay $\rho \to e^+e^-$, the technivector meson may resonate back to an off-shell gluon or electroweak gauge boson, leading to a decay into a pair of leptons, quarks, or gluons.

When comparing the various results presented in this review, one should be aware that the more recent analyses [23,24,27,29] make use of newer calculations [17] of technihadron production and decay, as implemented in PYTHIA [19] version 6.126 and higher [20]. The LHC analyses use the calculations given in reference [18] and PYTHIA [19] version 6.4. The results obtained with older cross section calculations are not generally directly comparable, and have only been listed in Table 1 when newer results are not available.

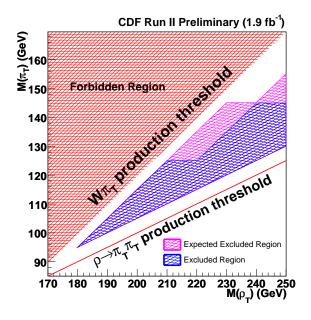

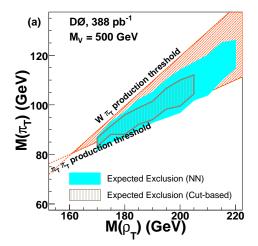

Figure 1: Search for a light technirho decaying to W^{\pm} and a π_T , and in which the π_T decays to two jets including at least one b quark [23]. Exclusion region at the 95% C.L. in the $M(\rho_T), M(\pi_T)$ plane for $\rho_T \to W \pi_T \to e \nu \ b \bar{b}(\bar{c})$ production. Kinematic thresholds from $W \pi_T$ and $\pi_T \pi_T$ are shown on the figure.

If the dominant decay mode of the technirho is $W_L\pi_T$, promising signal channels [21] are $\rho_T^\pm \to W^\pm\pi_T^0$ and $\rho_T^0 \to W^\pm\pi_T^\mp$. If we assume that the technipions decay to $b\overline{b}$ (neutral) and $b\overline{c}$ (charged), then both channels yield a signal of $W(\ell\nu)+2$ jets, with one or more heavy flavor tags. The CDF collaboration carried out a search in this final state [22] based on Run I data and using PYTHIA version 6.1 for the signal simulation. Using 1.9 fb⁻¹ of data from Run II, CDF [23] has published an update of this analysis. A large region of $M(\rho_T)=180-250$ GeV and $M(\pi_T)=95-145$ GeV are excluded at 95% CL, with the exact exclusion region displayed in Fig. 1.

The DØ [24] collaboration published an analysis based on 388 pb⁻¹ of data from Run II and PYTHIA 6.22. The searches are sensitive to $\sigma \cdot B \gtrsim 4$ pb and DØ finds mass combinations up to $m_{\rho_T}=215$ GeV, $m_{\pi_T}=115$ GeV to be excluded for certain values of the model parameters. The expected sensitivity and the region excluded at 95% C.L. by the DØ analysis for $M_V=500$ GeV is shown in Fig. 2. For $M_V=100$ GeV, only a

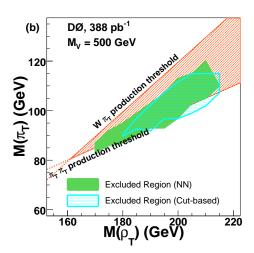

Figure 2: Search for a light technirho decaying to W^{\pm} and a π_T , and in which the π_T decays to two jets including at least one b quark [24]. Expected region of exclusion (a) and excluded region (b) at the 95% C.L. in the $M(\rho_T), M(\pi_T)$ plane for $\rho_T \to W \pi_T \to e \nu \ b \bar{b}(\bar{c})$ production with $M_V = 500$ GeV. Kinematic thresholds from $W \pi_T$ and $\pi_T \pi_T$ are shown on the figures.

small region around $M(\rho_T)=190$ GeV and $M(\pi_T)=95$ GeV can be excluded. For an integrated luminosity of 2 fb⁻¹, the 5σ discovery reach is expected to extend to $m_{\rho_T}=210$ GeV and $m_{\pi_T}=110$ GeV, while the 95% exclusion sensitivity will extend to $m_{\rho_T}=250$ GeV and $m_{\pi_T}=145$ GeV.

DØ has also performed a search for technihadrons decaying to WZ [25]. These decays can be searched in the tri-lepton final state, where the W decays into a lepton and neutrino and the accompanying Z decays to dileptons. With a dataset corresponding to a 4.1 fb⁻¹ of integrated luminosity, DØ excludes ρ_T with mass between 208 and 408 GeV at 95% C.L. for $M(\rho_T) < M(\pi_T) + M(W)$ as displayed in Fig. 4.

CDF also searched [26] in Run I for the process $\omega_T^0 \to \gamma \pi_T^0$, yielding a signal of a hard photon plus two jets, with one or

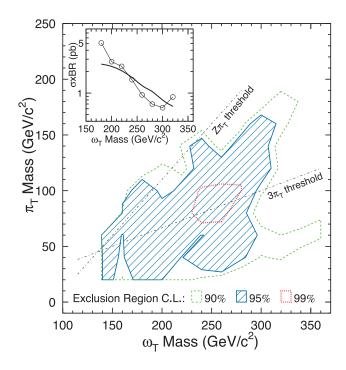

Figure 3: 95% CL exclusion region [26] for a light techniomega decaying to γ and a π_T , and in which the π_T decays to two jets, including at least one b quark. (Inset: cross section limit for $m_{\pi_T} = 120$ GeV.)

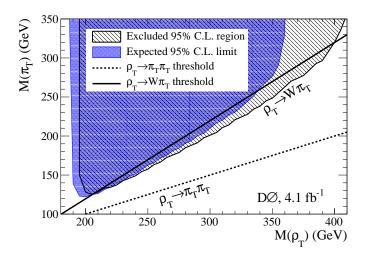

Figure 4: 95% CL exclusion region by the DØ experiment [25] in the $M(\rho_T)$, $M(\pi_T)$ plane for $\rho_T \to WZ \to lll\nu$ (with $l=e,\mu$) final state.

more heavy flavor tags. The sensitivity to $\sigma \cdot B$ is of order 1 pb. The excluded region is shown in Fig. 3 and is roughly $140 < m_{\omega_T} < 290$ GeV at the 95% level, for $m_{\pi_T} \approx m_{\omega_T}/3$.

Technicolor

The analysis assumes four technicolors, $Q_D = Q_U - 1 = \frac{1}{3}$ and $M_T = 100 \text{ GeV}/c^2$. Here Q_U and Q_D are the charges of the lightest technifermion doublet, and M_T is a dimensionful parameter, of order 100 GeV/ c^2 , which controls the rate of $\rho_T, \omega_T \to \gamma \pi_T$.

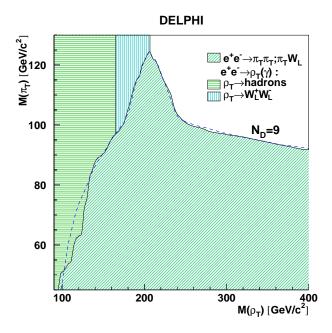

Figure 5: 95% CL exclusion region [29] in the technirho-technipion mass plane obtained from searches by the DELPHI collaboration at LEP 2, for nine technifermion doublets. The dashed line shows the expected limit for the 4-jet analysis.

The DØ experiment has searched [27] for low-scale technicolor resonances ρ_T and ω_T decaying to dileptons, using an inclusive e^+e^- sample from Run I. In the search, the ρ_T and ω_T are assumed to be degenerate in mass. The absence of structure in the dilepton invariant mass distribution is then used to set limits. Masses $m_{\rho_T}=m_{\omega_T}\lesssim 200$ GeV are excluded, provided either $m_{\rho_T}< m_{\pi_T}+m_W$, or $M_T>200$ GeV. The CDF experiment also performed a similar search with 200 pb⁻¹ of Run II data, and excluded equal $m_{\rho_T}=m_{\omega_T}$ masses below 280 GeV for $M_V=500$ GeV and $m_{\rho_T}< m_{\pi_T}+m_W$ at 95% C.L. [28]. With 2 fb⁻¹ of data, the sensitivity will extend to $m_{\rho_T}=m_{\omega_T}\approx 500$ GeV.

DELPHI [29] has reported a search for technicolor production in 452 pb⁻¹ of e^+e^- data taken between 192 and 208 GeV. The analysis combines searches for $e^+e^- \to \rho_T(\gamma)$ with $\rho_T \to W_L W_L$, $\rho_T \to$ hadrons $(\pi_T \pi_T \text{ or } q\overline{q})$, $\rho_T \to \pi_T \gamma$, and $e^+e^- \to \rho_T^* \to W_L \pi_T$ or $\pi_T \pi_T$. Technirho masses in the range $90 < m_{\rho_T} < 206.7$ GeV are excluded, while technipion masses $m_{\pi_T} < 79.8$ GeV are ruled out independent of the parameters of the technicolor model.

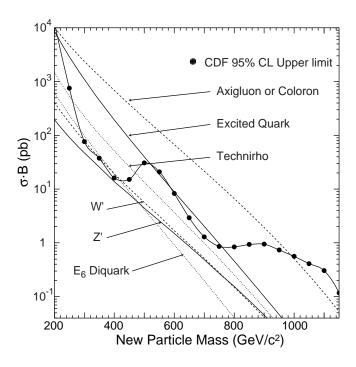

Figure 6: 95% CL Cross-section limits [31] for a technirho decaying to two jets at the Tevatron.

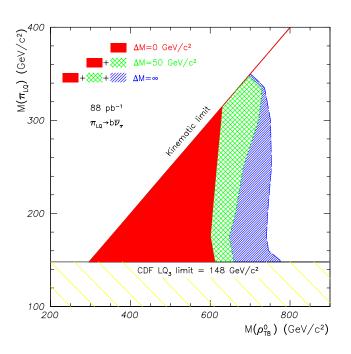

Figure 7: 95% CL exclusion region [34] in the technirho-technipion mass plane for pair produced technipions, with leptoquark couplings, decaying to $b\nu$.

Searches have also been carried out at the Tevatron for colored technihadron resonances [30,31]. CDF has used a search for structure in the dijet invariant mass spectrum to set limits on a color-octet technirho ρ_{T8} produced by an off-shell gluon, and decaying to two real quarks or gluons. As shown in Fig. 6, masses $260 < m_{\rho_{T8}} < 480$ GeV are excluded; in Run II the limits will improve to cover the whole mass range up to about 0.8 TeV [32].

The CDF second- and third-generation leptoquark searches (see Refs. [33,34]) have also been interpreted in terms of the complementary ρ_{T8} decay mode: $p\overline{p} \to \rho_{T8} \to \pi_{LQ}\pi_{LQ}$. Here π_{LQ} denotes a color-triplet technipion carrying both color and lepton number, assumed to decay to $b\nu$ or $c\nu$ [34], or to a τ plus a quark [33]. The searches exclude technirho masses $m_{\rho_{T8}}$ less than 510 GeV ($\pi_{LQ} \to c\nu$), 600 GeV ($\pi_{LQ} \to b\nu$), and 465 GeV ($\pi_{LQ} \to \tau q$) for technipion masses up to $m_{\rho_{T8}}/2$. Figure 7 shows the $\pi_{LQ} \to b\nu$ exclusion region. (Leptoquark masses $m_{\pi_{LQ}}$ less than 123 GeV ($c\nu$), 148 GeV ($b\nu$), and 99 GeV (τq) are already ruled out by standard continuum-production leptoquark searches).

It has been demonstrated that there is substantial uncertainty in the theoretical estimate of the ρ_{T8} production cross section at the Tevatron and that the cross section may be as much as an order of magnitude lower than the naive vector meson dominance estimate [35]. To establish the range of allowed masses, these limits will need to be redone with a reduced theoretical cross section.

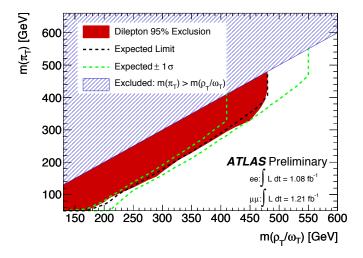

Figure 8: 95% CL excluded region by the ATLAS experiment [36] in the $M(\rho_T), M(\pi_T)$ plane for $\rho_T/\omega_T \to ll \ (l=e,\mu)$.

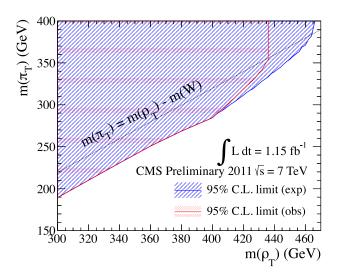

Figure 9: 95% CL Exclusion contour in the $M(\rho_T), M(\pi_T)$ plane for $\rho_T/a_T \to WZ \to lll\nu$ (with $l=e,\mu$) final state by the CMS experiment [37].

Within the context of the model in reference [18], both the ATLAS and CMS experiments have carried out searches for technihadron production in proton-proton collisions at $\sqrt{s} = 7$ TeV LHC running during 2011. An analysis of the process ρ_T and ω_T decaying to $\mu^+\mu^-$ and e^+e^- has been carried out by the ATLAS experiment [36]. This analysis based on 1.08 fb⁻¹ (1.21 fb⁻¹) of integrated luminosity, for the e^+e^- ($\mu^+\mu^-$) channel, as shown in Fig. 8, excludes ρ_T and ω_T with masses in the range 130–480 GeV at 95% CL for π_T masses between 50–480 GeV. The CMS experiment has searched for ρ_T and its axial-vector partner, a_T production at $\sqrt{s} = 7$ TeV using the $\rho_T/a_T \to WZ \to lll\nu$ (with $l = e, \mu$) final state [37]. Using a sample of 1.15 fb⁻¹ of data, CMS excludes ρ_T with masses below 382 GeV in the parameter space $M(\pi_T) = \frac{3}{4}M(\rho_T) - 25$ GeV. If $M(\rho_T) < M(\pi_T) + M_W$, then ρ_T with masses below 436 GeV are excluded. The exclusion contour in the ρ_T vs. π_T mass plane is shown in Fig. 9.

LHC searches for Higgs Bosons in di-photon [40,41] or di-tau [42] decay modes place strong constraints [43] on the light top-pion state predicted in technicolor models that include colored technifermions. Compared with the standard Higgs Boson, the top-pions have an enhanced production rate (largely because the technipion decay constant is smaller than the weak scale) and also enhanced branching ratios into di-photon and di-tau final states (largely due to the suppression of WW decays of the technipions). These factors combine to make such technipions more visible in both channels than a standard model Higgs would be, though the precise bounds are model-dependent.

Technicolor

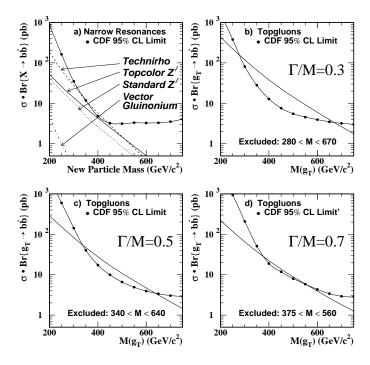

Figure 10: Tevatron limits [47] on new particles decaying to $b\overline{b}$: narrow resonances and topgluons for various widths.

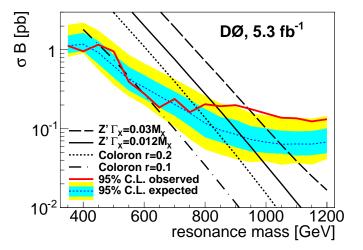

Figure 11: 95% CL exclusion limit on a narrow $t\bar{t}$ resonance as a function of the resonance mass by the DØ experiment [49].

II. Top Condensate, Higgsless, and Related Models

The top quark is much heavier than other fermions and must be more strongly coupled to the symmetry-breaking sector. It is natural to consider whether some or all of electroweaksymmetry breaking is due to a condensate of top quarks [3,44]. Top quark condensation alone, without additional fermions, seems to produce a top quark mass larger [45] than observed experimentally, and is therefore not favored. Topcolor-assisted technicolor [46] combines technicolor and top condensation. In addition to technicolor, which provides the bulk of electroweak symmetry breaking, top condensation and the top quark mass arise predominantly from "topcolor," a new QCD-like interaction which couples strongly to the third generation of quarks. An additional, strong, U(1) interaction (giving rise to a topcolor Z') precludes the formation of a b-quark condensate.

CDF has searched [47] for the "topgluon," a massive coloroctet vector which couples preferentially to the third generation, in the mode $p\overline{p} \to g_t \to b\overline{b}$. The results are shown in Fig. 10. Topgluon masses from approximately 0.3 to 0.6 TeV are excluded at 95% confidence level, for topgluon widths in the range $0.3m_{g_t} < \Gamma < 0.7m_{g_t}$. Results have also been reported by CDF [48] on a search for narrow resonances in the $t\bar{t}$ invariant mass distribution. Using a data sample corresponding to 4.8 fb⁻¹ integrated luminosity, CDF excludes a leptophobic topcolor Z' with masses less than 900 GeV, for the case where its width $\Gamma = 0.012m_{Z'}$. DØ has carried out a similar search, with greater sensitivity [49], and excludes a leptophobic topcolor Z'bosons at the 95% confidence level for masses below 835 GeV (940 GeV) if its width is 1.2% (3%) of its mass (see Fig. 11). A similar study by ATLAS searches for $Z' \to t\bar{t}$ events, excludes leptophobic topcolor Z' with a width of 1.2% in the mass region 500-860 GeV [50]. The CMS experiment [51] quotes a 95% CL upper limit on the $\sigma(pp \to Z') \times Z' \to t\bar{t}$ as a function of the invariant mass of the resonance. A limit of 2.51 pb is set for Z'mass of 1 TeV, resonance width 1%, and 0.62 pb or below for Z' mass above 2 TeV. A broad topgluon could also be detected in the same final state, though no results are yet available. In Run II, the Tevatron [32] should be sensitive to topgluon and topcolor Z' masses up to of order 1 TeV in $b\overline{b}$ and $t\overline{t}$ final states. A detailed theoretical analysis of $B-\overline{B}$ mixing and light quark mass generation in top-color-assisted technicolor shows that, at least in some models, the topgluon and Z' boson masses must be greater than about 5 TeV [53].

The top quark seesaw model of electroweak symmetry breaking [54] is a variant of the original top condensate idea which reconciles top condensation with a lighter top quark mass. Such a model can easily be consistent with precision electroweak tests, either because the spectrum includes a light composite Higgs [55], or because additional interactions allow for a heavier Higgs [56]. Such theories may arise naturally from gauge fields propagating in compact extra spatial dimensions [57].

A variant of topcolor-assisted technicolor is flavor-universal, in which the topcolor SU(3) gauge bosons, called colorons, couple equally to all quarks [58]. Flavor-universal versions of the seesaw model [59] incorporating a gauged flavor symmetry are also possible. In these models all left-handed quarks (and possibly leptons as well) participate in electroweak-symmetry-breaking condensates with separate (one for each flavor) right-handed weak singlets, and the different fermion masses arise by adjusting the parameters which control the mixing of each fermion with the corresponding condensate.

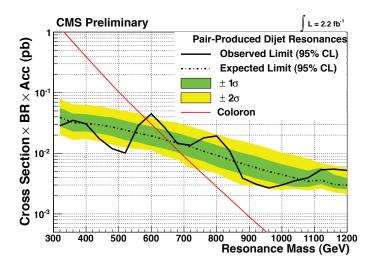

Figure 12: 95% CL exclusion limit on pair production cross section of colorons by the CMS experiment [63]. Colorons with mass in the range 320-580 GeV are excluded.

A prediction of these flavor-universal models is the existence of new heavy gauge bosons, coupling to color or flavor, at relatively low mass scales. The absence of an excess of high- E_T jets in DØ data [60] has been used to constrain strongly coupled flavor-universal colorons (massive color-octet bosons coupling to all quarks). A mass limit of between 0.8 and 3.5 TeV is set [61] depending on the coloron-gluon mixing angle. Precision electroweak measurements constrain [62] the masses of these new gauge bosons to be greater than 1-3 TeV in a variety of models, for strong couplings. A direct search for colorons has been performed in the proton-proton collisions at $\sqrt{s} = 7$ TeV, during the 2011 running of the LHC. From analysis of dijet events, the CMS experiment excludes pair production of colorons with mass between 320 and 580 GeV at 95% CL, as shown in Fig. 12 [63]. A recent DØ analysis [49] of a resonance decaying to $t\bar{t}$ can also be interpreted to search for colorons which would decay to $t\bar{t}$ with a branching fraction of about 1/6 and have a width substantially below 1% of its mass. This study is performed for for different values of the coupling to light quarks r=0.1 and 0.2 [64]. This DØ analysis can exclude such a coloron for r=0.2 with masses below 775 GeV (displayed in Fig. 11).

LHC searches for the standard model Higgs Boson in WW or ZZ decay modes [65,66] place strong constraints [67] on the top-Higgs state predicted in top-color models. Such a state couples strongly to top-quarks, and is therefore produced through gluon fusion at a rate enhanced relative to the rate for the standard model Higgs boson. A top-Higgs state with mass less than 300 GeV is excluded at 95% CL if the associated top-pion has a mass of 150 GeV, and the constraint is even stronger if the mass of the top-pion state exceeds the top-quark

mass or if the top-pion decay constant is a substantial fraction of the weak scale.

A class [68] of composite Higgs model [69], dubbed "Little Higgs Theory," has been developed which gives rise to naturally light Higgs bosons without supersymmetry [70]. Inspired by discretized versions of higher-dimensional gauge theory [71], these models are based on the chiral symmetries of "theory space." The models involve extended gauge groups and novel gauge symmetry-breaking patterns [72]. The new chiral symmetries prevent large corrections to the Higgs boson mass, and allow the scale (Λ) of the underlying strong dynamics giving rise to the composite particles to be as large as 10 TeV. These models typically require new gauge bosons and fermions, and possibly additional composite scalars beyond the Higgs, in the TeV mass range [73].

Finally, "Higgsless" models [74] provide electroweak symmetry breaking, including unitarization of the scattering of longitudinal W and Z bosons, without employing a scalar Higgs boson. The most extensively studied models [75] are based on a five-dimensional $SU(2) \times SU(2) \times U(1)$ gauge theory in a slice of Anti-deSitter space, and electroweak symmetry breaking is encoded in the boundary conditions of the gauge fields. Using the AdS/CFT correspondence [76], these theories may be viewed as "dual" descriptions of walking technicolor the-In addition to a massless photon and near-standard W and Z bosons, the spectrum includes an infinite tower of additional massive vector bosons (the higher Kaluza-Klein or KK excitations), whose exchange is responsible for unitarizing longitudinal W and Z boson scattering [77]. Depending on how these KK bosons couple to fermions, searches for the W'bosons decaying to WZ [37] may be used to place bonds in these theories.

Using deconstruction it has been shown [78] that a Higgsless model whose fermions are localized (i.e., derive their electroweak properties from a single site on the deconstructed lattice) cannot simultaneously satisfy unitarity bounds and precision electroweak constraints. The [79] size of corrections to electroweak processes in Higgsless models may be reduced, however, by considering delocalized fermions, i.e., considering the effect of the distribution of the wavefunctions of ordinary fermions in the fifth dimension (corresponding, in the deconstruction language, to allowing the fermions to derive their electroweak properties from several sites on the lattice). It has been shown [80] that, in an arbitrary Higgsless model, if the probability distribution of the delocalized fermions is related to the W wavefunction (a condition called "ideal" delocalization), then deviations in precision electroweak parameters are minimized. Phenomenological limits on delocalized Higgsless models may be derived [81] from limits on the deviation of the triple-gauge boson (WWZ) vertices from the standard model, and current constraints allow for the lightest KK resonances (which tend to be fermiophobic in the case of ideal fermion delocalization) to have masses of only a few hundred

Technicolor

GeV. Such resonances would have to be studied using WW scattering [82].

An alternative approach to "Higgsless" models, dubbed "holographic technicolor" [83], incorporates a generalized extradimensional framework and allows for arbitrary couplings of the vector mesons to the light fermions, resulting in a wide variety of potential signatures at the LHC [84].

Acknowledgments

 1 AALTONEN 11AD and AALTONEN 11AE search for top-color Z' decaying to $t\,\overline{t}$. The quoted limit is for Z'_{top} with decay width $\Gamma = 0.012 \text{ M}_{Z'}$

Using the LHC limit on the Higgs boson production cross section, CHIVUKULA 11 obtain a limit on the top-Higgs mass > 300 GeV at 95% CL assuming 150 GeV top-pion mass. Using the LHC limit on the Higgs boson production cross section, CHIVUKULA 11A obtain a limit on the techinipion mass ruling out the region 110 GeV $< m_P < 2m_t$. Existence of color techni-fermions, top-color mechanism, and $N_{TC} \geq 3$ are assumed.

 4 AALTONEN 101 search for the vector techni-resonances $(
ho_T, \omega_T)$ decaying into $W\pi_T$ with $W \to \ell \nu$ and $\pi_T \to b\,\overline{b}$, $b\,\overline{c}$, or $b\,\overline{u}$. See their Fig. 3 for the exclusion plot in $M_{\pi_T} - M_{\rho_T}$ plane.

 5 ABAZOV 10 A search for a vector techni-resonance decaying into WZ. The limit assumes $M_{\rho\tau} < M_{\pi\tau} + M_W$

 6 ABAZOV 071 search for the vector techni-resonances $(
ho_T,\omega_T)$ decaying into $W\pi_T$ with $W \to e \nu$ and $\pi_T \to b \, \overline{b}$ or $b \, \overline{c}$. See their Fig. 2 for the exclusion plot in $M_{\pi_T} - M_{\rho_T}$

7 ABULENCIA 05A search for resonances decaying to electron or muon pairs in $p\overline{p}$ collisions. at $\sqrt{s}=1.96$ TeV. The limit assumes Technicolor-scale mass parameters $M_V=M_A=500$ GeV.

8 $^{\prime\prime}A^{\prime\prime}$ CHEKANOV 02B search for color octet techni- π $^{\prime\prime}P$ decaying into dijets in $^{\prime\prime}e$ collisions. See their Fig. 5 for the limit on $\sigma(ep\rightarrow ePX)$ ·B($P\rightarrow 2j$). 9 ABAZOV 01B searches for vector techni-resonances (ρ_T,ω_T) decaying to e^+e^- . The

limit assumes $M_{
ho_T} = M_{\omega_T} < M_{\pi_T} + M_W$.

 10 The limit is independent of the π_T mass. See their Fig. 9 and Fig. 10 for the exclusion plot in the $M_{\rho_T}-M_{\pi_T}$ plane. ABDALLAH 01 limit on the techni-pion mass is $M_{\pi_T}>79.8$ GeV for $N_D=2$, assuming its point-like coupling to gauge bosons.

 11 AFFOLDER 00F search for ho_T decaying into $W\pi_T$ or $\pi_T\pi_T$ with $W o \ell
u$ and $\pi_T o$ $\overline{b}b,\overline{b}c$. See Fig. 1 in the above Note on "Dynamical Electroweak Symmetry Breaking" for the exclusion plot in the $M_{\rho_T}-M_{\pi_T}$ plane.

 12 AFFOLDER 00K search for the ρ_{TB} decaying into $\pi_{LQ}\pi_{LQ}$ with $\pi_{LQ}\to b\nu.$ For $\pi_{LQ}\to c\nu$, the limit is $M_{\rho_{TB}}>$ 510 GeV. See their Fig. 2 and Fig. 3 for the exclusion plot in the $M_{\rho_{TB}}-M_{\pi_{LQ}}$ plane.

13 ABE 99F search for a new particle X decaying into $b\,\overline{b}$ in $p\,\overline{p}$ collisions at $E_{\rm CM}=1.8$ TeV. See Fig. 7 in the above Note on "Dynamical Electroweak Symmetry Breaking" for the upper limit on $\sigma(p\,\overline{p}\to X)\times B(X\to b\,\overline{b})$. ABE 99F also exclude top gluons of width $\Gamma=0.3M$ in the mass interval 280 < M < 670 GeV, of width $\Gamma=0.5\,M$ in the mass interval 340 < M < 640 GeV, and of width $\Gamma=0.7\,M$ in the mass interval 375 < M < 560 GeV.

340 < M/< 640 GeV, and or width 1 = 0.7 M in the mass interval 373 < M/> 300 GeV. 14 ABE 99N search for the technical decaying into $\gamma \pi_T$. The technipion is assumed to decay $\pi_T \to b\overline{b}$. See Fig. 2 in the above Note on "Dynamical Electroweak Symmetry Breaking" for the exclusion plot in the $M_{\omega_T} - M_{\pi_T}$ plane.

 15 ABE 976 search for a new particle X decaying into dijets in $p\overline{p}$ collisions at $E_{\rm cm}=1.8$ TeV. See Fig. 5 in the above Note on "Dynamical Electroweak Symmetry Breaking" for the upper limit on $\sigma(p\overline{p}\to X)\times {\rm B}(X\to 2j)$.

Quark and Lepton Compositeness, Searches for

The latest unpublished results are described in the "Quark and Lepton Compositeness" review.

SEARCHES FOR QUARK AND LEPTON COMPOSITENESS

Revised 2001 by K. Hagiwara (KEK), and K. Hikasa and M. Tanabashi (Tohoku University).

If quarks and leptons are made of constituents, then at the scale of constituent binding energies, there should appear new interactions among quarks and leptons. At energies much below the compositeness scale (Λ), these interactions are suppressed by inverse powers of Λ . The dominant effect should come from the lowest dimensional interactions with four fermions (contact terms), whose most general chirally invariant form reads [1]

$$L = \frac{g^2}{2\Lambda^2} \left[\eta_{LL} \, \overline{\psi}_L \, \gamma_\mu \psi_L \, \overline{\psi}_L \, \gamma^\mu \psi_L + \eta_{RR} \, \overline{\psi}_R \, \gamma_\mu \psi_R \, \overline{\psi}_R \, \gamma^\mu \psi_R \right.$$
$$\left. + 2\eta_{LR} \, \overline{\psi}_L \, \gamma_\mu \psi_L \, \overline{\psi}_R \, \gamma^\mu \psi_R \right] . \tag{1}$$

Chiral invariance provides a natural explanation why quark and lepton masses are much smaller than their inverse size Λ . We may determine the scale Λ unambiguously by using the above form of the effective interactions; the conventional method [1] is to fix its scale by setting $g^2/4\pi = g^2(\Lambda)/4\pi = 1$ for the new strong interaction coupling and by setting the largest magnitude of the coefficients $\eta_{\alpha\beta}$ to be unity. In the following, we denote

$$\begin{split} & \Lambda = \Lambda_{LL}^{\pm} \ \, \text{for} \ \, (\eta_{LL},\, \eta_{RR},\, \eta_{LR}) = (\pm 1,\, 0,\, 0) \,\,, \\ & \Lambda = \Lambda_{RR}^{\pm} \ \, \text{for} \ \, (\eta_{LL},\, \eta_{RR},\, \eta_{LR}) = (0,\, \pm 1,\, 0) \,\,, \\ & \Lambda = \Lambda_{VV}^{\pm} \ \, \text{for} \ \, (\eta_{LL},\, \eta_{RR},\, \eta_{LR}) = (\pm 1,\, \pm 1,\, \pm 1) \,\,, \\ & \Lambda = \Lambda_{AA}^{\pm} \ \, \text{for} \ \, (\eta_{LL},\, \eta_{RR},\, \eta_{LR}) = (\pm 1,\, \pm 1,\, \mp 1) \,\,, \end{split} \label{eq:lambda}$$

as typical examples. Such interactions can arise by constituent interchange (when the fermions have common constituents, e.g., for $ee \rightarrow ee$) and/or by exchange of the binding quanta (whenever binding quanta couple to constituents of both particles).

Another typical consequence of compositeness is the appearance of excited leptons and quarks (ℓ^* and q^*). Phenomenologically, an excited lepton is defined to be a heavy lepton which shares leptonic quantum number with one of the existing leptons (an excited quark is defined similarly). For example, an excited electron e^* is characterized by a nonzero transition-magnetic coupling with electrons. Smallness of the lepton mass

and the success of QED prediction for g–2 suggest chirality conservation, *i.e.*, an excited lepton should not couple to both left- and right-handed components of the corresponding lepton.

Excited leptons may be classified by $SU(2)\times U(1)$ quantum numbers. Typical examples are:

1. Sequential type

$$\begin{pmatrix} \nu^* \\ \ell^* \end{pmatrix}_L$$
, $[\nu_R^*]$, ℓ_R^* .

 ν_R^* is necessary unless ν^* has a Majorana mass.

2. Mirror type

$$[
u_L^*], \qquad \ell_L^*, \qquad \begin{pmatrix}
u^* \\ \ell^* \end{pmatrix}_R.$$

3. Homodoublet type

$$\begin{pmatrix} \nu^* \\ \ell^* \end{pmatrix}_L \,, \qquad \begin{pmatrix} \nu^* \\ \ell^* \end{pmatrix}_R \,.$$

Similar classification can be made for excited quarks.

Excited fermions can be pair produced via their gauge couplings. The couplings of excited leptons with Z are listed in the following table (for notation see Eq. (1) in "Standard Model of Electroweak Interactions"):

| | Sequential type | Mirror type | Homodoublet type |
|-----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|-------------------------------------------|
| V^{ℓ^*} A^{ℓ^*} $V^{\nu_D^*}$ $A^{\nu_D^*}$ $V^{\nu_M^*}$ $A^{\nu_M^*}$ | $ \begin{array}{r} -\frac{1}{2} + 2\sin^2\theta_W \\ -\frac{1}{2} \\ +\frac{1}{2} \\ +\frac{1}{2} \\ 0 \\ +1 \end{array} $ | $ \begin{array}{r} -\frac{1}{2} + 2\sin^2 \theta_W \\ +\frac{1}{2} \\ +\frac{1}{2} \\ -\frac{1}{2} \\ 0 \\ -1 \end{array} $ | $-1 + 2\sin^2\!\theta_W$ 0 $+1$ 0 $-$ |

Here ν_{D}^{*} (ν_{M}^{*}) stands for Dirac (Majorana) excited neutrino. The corresponding couplings of excited quarks can be easily obtained. Although form factor effects can be present for the gauge couplings at $q^{2} \neq 0$, they are usually neglected.

In addition, transition magnetic type couplings with a gauge boson are expected. These couplings can be generally parameterized as follows:

$$\mathcal{L} = \frac{\lambda_{\gamma}^{(f^{*})} e}{2m_{f^{*}}} \overline{f}^{*} \sigma^{\mu\nu} (\eta_{L} \frac{1-\gamma_{5}}{2} + \eta_{R} \frac{1+\gamma_{5}}{2}) f F_{\mu\nu}
+ \frac{\lambda_{Z}^{(f^{*})} e}{2m_{f^{*}}} \overline{f}^{*} \sigma^{\mu\nu} (\eta_{L} \frac{1-\gamma_{5}}{2} + \eta_{R} \frac{1+\gamma_{5}}{2}) f Z_{\mu\nu}
+ \frac{\lambda_{W}^{(\ell^{*})} g}{2m_{\ell^{*}}} \overline{\ell}^{*} \sigma^{\mu\nu} \frac{1-\gamma_{5}}{2} \nu W_{\mu\nu}
+ \frac{\lambda_{W}^{(\nu^{*})} g}{2m_{\nu^{*}}} \overline{\nu}^{*} \sigma^{\mu\nu} (\eta_{L} \frac{1-\gamma_{5}}{2} + \eta_{R} \frac{1+\gamma_{5}}{2}) \ell W_{\mu\nu}^{\dagger}
+ \text{h.c.},$$
(3)

where $g = e/\sin\theta_W$, $F_{\mu\nu} = \partial_{\mu}A_{\nu} - \partial_{\nu}A_{\mu}$ is the photon field strength, $Z_{\mu\nu} = \partial_{\mu}Z_{\nu} - \partial_{\nu}Z_{\mu}$, etc. The normalization of the coupling is chosen such that

$$\max(|\eta_L|, |\eta_R|) = 1.$$

Chirality conservation requires

$$\eta_L \eta_R = 0. (4)$$

Some experimental analyses assume the relation $\eta_L = \eta_R = 1$, which violates chiral symmetry. We encode the results of such analyses if the crucial part of the cross section is proportional to the factor $\eta_L^2 + \eta_R^2$ and the limits can be reinterpreted as those for chirality conserving cases $(\eta_L, \eta_R) = (1, 0)$ or (0, 1)after rescaling λ .

These couplings in Eq. (3) can arise from $SU(2)\times U(1)$ invariant higher-dimensional interactions. A well-studied model is the interaction of homodoublet type ℓ^* with the Lagrangian [2,3]

$$\mathcal{L} = \frac{1}{2\Lambda} \overline{L}^* \sigma^{\mu\nu} (g f \frac{\tau^a}{2} W_{\mu\nu}^a + g' f' Y B_{\mu\nu}) \frac{1 - \gamma_5}{2} L + \text{h.c.} , \quad (5)$$

where L denotes the lepton doublet (ν, ℓ) , Λ is the compositeness scale, g, g' are SU(2) and U(1)_Y gauge couplings, and $W_{\mu\nu}^a$ and $B_{\mu\nu}$ are the field strengths for SU(2) and U(1)_Y gauge fields. The same interaction occurs for mirror-type excited leptons. For sequential-type excited leptons, the ℓ^* and ν^* couplings become unrelated, and the couplings receive the extra suppression of $(250 \,\mathrm{GeV})/\Lambda$ or m_{L^*}/Λ . In any case, these couplings satisfy the relation

$$\lambda_W = -\sqrt{2}\sin^2\theta_W(\lambda_Z \cot\theta_W + \lambda_\gamma) \ . \tag{6}$$

Additional coupling with gluons is possible for excited quarks:

$$\mathcal{L} = \frac{1}{2\Lambda} \overline{Q}^* \sigma^{\mu\nu} \left(g_s f_s \frac{\lambda^a}{2} G^a_{\mu\nu} + g f \frac{\tau^a}{2} W^a_{\mu\nu} + g' f' Y B_{\mu\nu} \right)$$

$$\times \frac{1 - \gamma_5}{2} Q + \text{h.c.} , \qquad (7)$$

where Q denotes a quark doublet, g_s is the QCD gauge coupling, and $G_{\mu\nu}^a$ the gluon field strength.

It should be noted that the electromagnetic radiative decay of $\ell^*(\nu^*)$ is forbidden if f = -f' (f = f'). These two possibilities (f = f') and f = -f' are investigated in many analyses of the LEP experiments above the Z pole.

Several different conventions are used by LEP experiments on Z pole to express the transition magnetic couplings. To facilitate comparison, we re-express these in terms of λ_Z and λ_{γ} using the following relations and taking $\sin^2 \theta_W = 0.23$. We assume chiral couplings, i.e., |c| = |d| in the notation of Ref. 2.

1. ALEPH (charged lepton and neutrino)

$$\lambda_Z^{\text{ALEPH}} = \frac{1}{2} \lambda_Z \quad (1990 \text{ papers})$$
 (8a)

$$\frac{2c}{\Lambda} = \frac{\lambda_Z}{m_{\ell^*}[\text{or } m_{\nu^*}]} \quad \text{(for } |c| = |d|)$$
(8b)

2. ALEPH (quark)

$$\lambda_u^{\text{ALEPH}} = \frac{\sin \theta_W \cos \theta_W}{\sqrt{\frac{1}{4} - \frac{2}{3} \sin^2 \theta_W + \frac{8}{9} \sin^4 \theta_W}} \lambda_Z = 1.11 \lambda_Z \quad (9)$$

3. L3 and DELPHI (charged lepton)

$$\lambda^{\text{L3}} = \lambda_Z^{\text{DELPHI}} = -\frac{\sqrt{2}}{\cot \theta_W - \tan \theta_W} \lambda_Z = -1.10\lambda_Z$$
 (10)

4. L3 (neutrino)

$$f_Z^{\text{L3}} = \sqrt{2}\lambda_Z \tag{11}$$

5. OPAL (charged lepton)

$$\frac{f^{\mathrm{OPAL}}}{\Lambda} = -\frac{2}{\cot \theta_W - \tan \theta_W} \frac{\lambda_Z}{m_{\ell^*}} = -1.56 \frac{\lambda_Z}{m_{\ell^*}}$$
(12)

6. OPAL (quark)

$$\frac{f^{\mathrm{OPAL}}c}{\Lambda} = \frac{\lambda_Z}{2m_{q^*}} \quad (\text{for } |c| = |d|)$$
 (13)

7. DELPHI (charged lepton)

$$\lambda_{\gamma}^{\text{DELPHI}} = -\frac{1}{\sqrt{2}} \lambda_{\gamma}$$
 (14)

If leptons are made of color triplet and antitriplet constituents, we may expect their color-octet partners. Transitions between the octet leptons (ℓ_8) and the ordinary lepton (ℓ) may take place via the dimension-five interactions

$$\mathcal{L} = \frac{1}{2\Lambda} \sum_{\ell} \left\{ \overline{\ell}_8^{\alpha} \; g_S \, F_{\mu\nu}^{\alpha} \, \sigma^{\mu\nu} \left(\eta_L \; \ell_L + \eta_R \; \ell_R \right) + h.c. \right\} \eqno(15)$$

where the summation is over charged leptons and neutrinos. The leptonic chiral invariance implies $\eta_L^{}$ $\eta_R^{}=0$ as before.

⁷ ABBIENDI 04G limits are from $e^+e^- \rightarrow au au$ cross section at $\sqrt{s}=130$ –207 GeV.

 $^{^8}$ SCHAEL 07A limits are from $R_c,\,Q_{FB}^{depl}$, and hadronic cross section measurements. 9 ABBIENDI 04G limits are from $\mathrm{e^+\,e^-} \to \ell^+\ell^-$ cross section at $\sqrt{s}=130$ –207 GeV. 10 BABICH 03 obtain a bound -0.175 TeV $^{-2}$ $<1/\Lambda_{LL}^2<0.095$ TeV $^{-2}$ (95%CL) in a model independent analysis allowing all of $\Lambda_{LL},\Lambda_{LR},\Lambda_{RL},\Lambda_{RR}$ to coexist.

 $^{^{12}}$ SCHAEL 07A limits are from R_c , Q_{FB}^{depl} , and hadronic cross section measurements.

¹³ CHEUNG 01B is an update of BARGER 98E.

 $^{^{14}}$ AARON 11c limits are from Q^2 spectrum measurements of $e^\pm p
ightarrow e^\pm X$.

 $^{^{15}}$ ABDALLAH 11 limit is from e $^+$ e $^ \to$ $\,$ t \overline{c} cross section. $\Lambda_{LL}=\Lambda_{LR}=\Lambda_{RL}=\Lambda_{RR}$ is assumed.

16 SCHAEL 07A limit assumes quark flavor universality of the contact interactions.

 $^{^{17}}$ ABULENCIA 06L limits are from $ho \, \overline{
ho}$ collisions at $\sqrt{s} = 1.96$ TeV.

²¹ DIAZCRUZ 94 limits are from $\Gamma(au o e
u
u)$ and assume flavor-dependent contact interactions with $\Lambda(\tau \nu_{\tau} e \nu_{e}) \ll \Lambda(\mu \nu_{\mu} e \nu_{e})$.

 $^{^{22}}$ DIAZCRUZ 94 limits are from $\Gamma(au
ightarrow$ $\mu
u
u$) and assume flavor-dependent contact interactions with $\Lambda(\tau \nu_{\tau} \mu \nu_{\mu}) \ll \Lambda(\mu \nu_{\mu} e \nu_{e})$.

 $^{^{25}}$ AAD 11 limit is from dijet angular distribution and dijet centrality ratio in pp collisions

²⁶ The quoted limit is from dijet centrality ratio measurement in pp collisions at \sqrt{s} =7 TeV.

 $^{^{27}\,\}mathrm{ABAZOV}$ 09AE also obtain $\Lambda_{LL}^{-}~>$ 2.96 TeV.

Searches Particle Listings **Quark and Lepton Compositeness**

MASS LIMITS for Excited e (e*)

Most e^+e^- experiments assume one-photon or Z exchange. The limits experiments which depend on λ have assumed transition couplings which are chirality violating $(\eta_L=\eta_R)$. However they can be interpreted as limits for chirality-conserving interactions after multiplying the coupling value λ by $\sqrt{2}$; see Note.

Excited leptons have the same quantum numbers as other ortholeptons. See also the searches for ortholeptons in the "Searches for Heavy Leptons" section.

Limits for Excited e (e*) from Pair Production

These limits are obtained from $e^+\,e^ightarrow\,e^{*+}\,e^{*-}$ and thus rely only on the (electroweak) charge of e^* . Form factor effects are ignored unless noted. For the case of limits from Z decay, the e^{*} coupling is assumed to be of sequential type. Possible t channel contribution from transition magnetic coupling is neglected. All limits assume a dominant $e^* \to e \gamma$ decay except the limits from $\Gamma(Z)$.

For limits prior to 1987, see our 1992 edition (Physical Review D45 S1 (1992)).

 29 From $e^+\,e^-$ collisions at $\sqrt{s}=183$ –209 GeV. f=f' is assumed.

Limits for Excited $e(e^*)$ from Single Production

These limits are from $e^+e^-\to e^*e$, $W\to e^*\nu$, or $ep\to e^*X$ and depend on transition magnetic coupling between e and e^* . All limits assume $e^*\to e\gamma$ decay except as noted. Limits from LEP, UA2, and H1 are for chiral coupling, whereas all other limits are for nonchiral coupling, $\eta_L=\eta_R=1$. In most papers, the limit is expressed in the form of an excluded region in the $\lambda-m_{e^+}$ plane. See the original

For limits prior to 1987, see our 1992 edition (Physical Review D45 S1 (1992)).

 31 CHATRCHYAN 11 X search for single e^* production in pp collisions with the decay $e^*
ightarrow$ $e\gamma$. $f=f'=\Lambda/m_{
ho^*}$ is assumed. See their Fig. 2 for the exclusion plot in the mass-

 32 AARON 08A search for single e^* production in ep collisions with the decays $e^*
ightarrow e\gamma$, $e\,Z$, $\nu\,W$. The quoted limit assumes $f=\,f'=\,\Lambda/m_{\,e^*}$. See their Fig. 3 and Fig. 4 for the exclusion plots in the mass-coupling plane.

 33 ABAZOV 08H search for single e^* production in $ho\,\overline{
ho}$ collisions with the decays $e^*
ightarrow e\,\gamma$. The e^* production is assumed to be described by an effective four-fermion interaction. See their Fig. 5 for the exclusion plot in the mass-coupling plane.

 34 ACOSTA 05B search for single e^* production in $ho \overline{
ho}$ collisions with the decays $e^*
ightarrow e \gamma$. $f=f'=\Lambda/m_{
ho^*}$ is assumed for the e^* coupling. See their Fig.3 for the exclusion limit in the mass-coupling plane.

35 ACHARD 03B result is from e^+e^- collisions at $\sqrt{s}=189$ –209 GeV. See their Fig. 4 for the exclusion plot in the mass-coupling plane.

³⁶ ABBIENDI 02G result is from e^+e^- collisions at $\sqrt{s}=183$ –209 GeV. $f=f'=\Lambda/m_{e^*}$ is assumed for e^* coupling. See their Fig. 4c for the exclusion limit in the mass-coupling

 37 CHEKA NOV 02D search for single e^* production in ep collisions with the decays $e^*
ightarrow$ $e\gamma$, eZ, vW. $f=f'=\Lambda/m_{e^*}$ is assumed for the e^* coupling. See their Fig. 5a for the exclusion plot in the mass-coupling plane.

Limits for Excited e (e^*) from $e^+e^- \rightarrow \gamma \gamma$

These limits are derived from indirect effects due to e^* exchange in the t channel and depend on transition magnetic coupling between e and e^* . All limits are for $\lambda_{\gamma}=1$. All limits except ABE 89J and ACHARD 02D are for nonchiral coupling with η_L = 1. We choose the chiral coupling limit as the best limit and list it in the Summary

For limits prior to 1987, see our 1992 edition (Physical Review D45 S1 (1992)).

 39 DORENBOSCH 89 obtain the limit $\lambda_{\gamma}^2 \Lambda_{\rm Cut}^2/m_{e^*}^2 < 2.6$ (95% CL), where $\Lambda_{\rm cut}$ is the cutoff scale, based on the one-loop calculation by GRIFOLS 86. If one assumes that $\Lambda_{\rm Cut}=1$ TeV and $\lambda_{\gamma}=1$, one obtains $m_{e^*}>620$ GeV. However, one generally expects $\lambda_{\gamma} \approx m_{e^*}/\Lambda_{\text{cut}}$ in composite models.

 40 GRIFOLS 86 uses $\nu_{\mu}e \rightarrow \; \nu_{\mu}e$ and $\overline{\nu}_{\mu}e \rightarrow \; \overline{\nu}_{\mu}e$ data from CHARM Collaboration to derive mass limits which depend on the scale of compositeness.

 41 RENARD 82 derived from g-2 data limits on mass and couplings of e^* and μ^* . See figures 2 and 3 of the paper

MASS LIMITS for Excited μ (μ *)

Limits for Excited μ (μ^*) from Pair Production

These limits are obtained from $e^+\,e^-\,
ightarrow\,\mu^{*+}\,\mu^{*-}$ and thus rely only on the (electroweak) charge of μ^* . Form factor effects are ignored unless noted. For the case of limits from Z decay, the μ^* coupling is assumed to be of sequential type. All limits assume a dominant $\mu^*
ightarrow \; \mu \gamma$ decay except the limits from $\Gamma(Z)$

For limits prior to 1987, see our 1992 edition (Physical Review D45 S1 (1992)).

 59 CHEKA NOV 02D search for single ν^* production in ep collisions with the decays $\nu^* \rightarrow \nu \gamma, \, \nu Z, \, eW. \, f = -f' = \Lambda/m_{\nu^*}$ is assumed for the e^* coupling. CHEKA NOV 02D also obtain limit for $f=f'=\Lambda/m_{\nu^*}$ in $m_{\nu^*}>135\,$ GeV. See their Fig. 5c and Fig. 5d for the exclusion plot in the mass-coupling plane.

 60 ACCIARRI 01D search for $\nu\nu^*$ production in e^+e^- collisions at $\sqrt{s}=192-202$ GeV with decays $\nu^*\to\nu\gamma,\,\nu^*\to e\,W.\,\,f=-f'=\Lambda/m_{\nu^*}$ is assumed for the ν^* coupling. See their Fig. 4 for limits in the mass-coupling plane.

Limits for Excited $q(q^*)$ from Pair Production

These limits are mostly obtained from $e^+e^- \to q^*\overline{q}^*$ and thus rely only on the (electroweak) charge of the q^* . Form factor effects are ignored unless noted. Assumptions about the q^* decay are given in the comments and footnotes.

Extra Dimensions

For explanation of terms used and discussion of significant model dependence of following limits, see the "Extra Dimensions" review. Footnotes describe originally quoted limit. δ indicates the number of extra dimensions.

Limits not encoded here are summarized in the "Extra Dimensions" review, where the latest unpublished results are also described.

EXTRA DIMENSIONS

Updated November 2011 by John Parsons (Columbia University) and Alex Pomarol (Universitat Autònoma de Barcelona).

$I\ Introduction$

Proposals for a spacetime with more than three spatial dimensions date back to the 1920s, mainly through the work of Kaluza and Klein, in an attempt to unify the forces of nature [1]. Although their initial idea failed, the formalism that they and others developed is still useful nowadays. Around 1980, string theory proposed again to enlarge the number of space dimensions, this time as a requirement for describing a consistent theory of quantum gravity. The extra dimensions were supposed to be compactified at a scale close to the Planck scale, and thus not testable experimentally in the near future.

A different approach was given by Arkani-Hamed, Dimopoulos and Dvali (ADD) in their seminal paper in 1998 [2]. They showed that the weakness of gravity could be explained by postulating two or more extra dimensions in which only gravity could propagate. The size of these extra dimensions should range between roughly a millimeter and $\sim 1/\text{TeV}$, leading to possible observable consequences in current and future experiments. A year later, Randall and Sundrum (RS) [3] found a new possibility using a warped geometry. They postulated a five-dimensional Anti-de Sitter (AdS) spacetime with a compactification scale of order TeV. The origin of the smallness of the electroweak scale versus the Planck scale was explained by the gravitational redshift factor present in the warped AdS metric. As in the ADD model, originally only gravity was assumed to propagate in the extra dimensions, although it was soon clear that this was not necessary in the RS model and also the SM gauge fields [4] and SM fermions [5,6] could propagate in the five-dimensional space.

The physics of warped extra-dimensional models have an alternative interpretation by means of the AdS/CFT correspondence [7]. Models with warped extra dimensions are related to four-dimensional strongly-interacting theories, allowing an understanding of the properties of five-dimensional fields as those of four-dimensional (4D) composite states [8]. This has opened new directions for tackling outstanding questions in particle physics, such as the flavor problem, grand unification, and the origin of electroweak symmetry breaking or supersymmetry breaking.

I.1 Kaluza-Klein Theories

Theories with compact extra dimensions can be written as theories in ordinary four dimensions by performing a Kaluza-Klein (KK) reduction. As an illustration, consider a simple example, namely a field theory of a complex scalar in flat five-dimensional (5D) spacetime. The action will be given by †

$$S_5 = -\int d^4x \, dy \, M_5 \left[|\partial_\mu \phi|^2 + |\partial_y \phi|^2 + \lambda_5 |\phi|^4 \right] \,, \tag{1}$$

where y refers to the extra (fifth) dimension. A universal scale M_5 has been extracted in front of the action in order to keep the 5D field with the same mass-dimension as in four dimensions. This theory is perturbative for energies $E \lesssim \ell_5 M_5/\lambda_5$ where $\ell_5 = 24\pi^3$ [9].

 $^{^{75}}$ BARGER 89 used ABE 89B limit for events with large missing transverse momentum. Two-body decay $\nu_8 \to ~\nu g$ is assumed.

 $^{^{76}\,\}rm KIM$ 90 is at $E_{\rm CM} = 50\text{-}60.8$ GeV. The same assumptions as in BARTEL 87B are used.

 $^{^{77}}$ BARTEL 87B is at $E_{\rm CM}=46.3$ –46.78 GeV. The limit assumes the ν_8 pair production cross section to be eight times larger than that of the corresponding heavy neutrino pair production. This assumption is not valid in general for the weak couplings, and the limit can be sensitive to its ${\rm SU}(2)_L\times {\rm U}(1)_Y$ quantum numbers.

[†] Our convention for the metric is $\eta_{MN} = \text{Diag}(-1, 1, 1, 1, 1)$.

Extra Dimensions

Let us now consider that the fifth dimension is compact with the topology of a circle S^1 of radius R, which corresponds to the identification of y with $y+2\pi R$. In such a case, the 5D complex scalar field can be expanded in a Fourier series:

$$\phi(x,y) = \frac{1}{\sqrt{2\pi R M_5}} \sum_{n=-\infty}^{\infty} e^{iny/R} \phi^{(n)}(x) ,$$

that, inserted in Eq. (1) and integrating over y, gives

$$S_5 = S_4^{(0)} + S_4^{(n)} \,,$$

where

$$S_4^{(0)} = -\int d^4x \left[|\partial_\mu \phi^{(0)}|^2 + \lambda_4 |\phi^{(0)}|^4 \right], \text{ and } (2)$$

$$S_4^{(n)} = -\int d^4\!x\, \sum_{n\neq 0} \left[|\partial_\mu \phi^{(n)}|^2 + \left(\frac{n}{R}\right)^2 |\phi^{(n)}|^2 \right] + \text{quartic int}. \label{eq:S4n}$$

The n = 0 mode self-coupling is given by

$$\lambda_4 = \frac{\lambda_5}{2\pi R M_5} \,. \tag{3}$$

The above action corresponds to a 4D theory with a massless scalar $\phi^{(0)}$, referred to as the zero-mode, and an infinite tower of massive modes $\phi^{(n)}$, known as KK modes. The KK reduction thus allows a treatment of 5D theories as 4D field theories with an infinite number of fields. At energies smaller than 1/R, the KK modes can be neglected, leaving the zero-mode action of Eq. (2). The strength of the interaction of the zero-mode, given by Eq. (3), decreases as R increases. Thus, for a large extra dimension $R \gg 1/M_5$, the massless scalar is weakly coupled.

II Large Extra Dimensions for Gravity

II.1 The ADD Scenario

The ADD scenario [2,10,11] assumes a $D=4+\delta$ dimensional spacetime, with δ compactified spatial dimensions. The weakness of gravity arises since it propagates in the higher-dimensional space. The SM is assume to be localized in a 4D subspace, a 3-brane, as can be found in certain string constructions [12]. Gravity is described by the Einstein-Hilbert action in $D=4+\delta$ spacetime dimensions

$$S_D = -\frac{\bar{M}_D^{2+\delta}}{2} \int d^4x d^\delta y \sqrt{-g} \mathcal{R} + \int d^4x \sqrt{-g_{\rm ind}} \mathcal{L}_{\rm SM} , \quad (4)$$

where x labels the ordinary four coordinates, y the δ extra coordinates, g refers to the determinant of the D-dimensional metric whose Ricci scalar is defined by \mathcal{R} , and \bar{M}_D is the reduced Planck scale of the D-dimensional theory. In the second term of Eq. (4), which gives the gravitational interactions of SM fields, the D-dimensional metric reduces to the induced metric on the 3-brane where the SM fields propagate. The extra dimensions are assumed to be flat and compactified in a volume V_{δ} . As an example, consider a toroidal compactification of equal radii R and volume $V_{\delta} = (2\pi R)^{\delta}$. After a KK reduction, one finds that the fields that couple to the SM are the spin-2 gravitational field $G_{\mu\nu}(x,y)$ and a tower of spin-1 KK graviscalars [13]. The

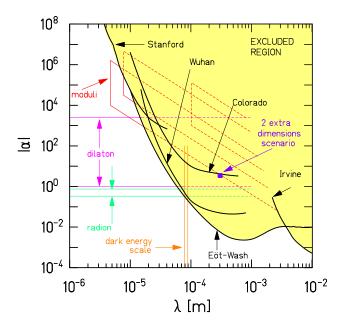

Figure 1: Experimental limits (from Ref. [15]) on α and λ of Eq. (8), which parametrize deviations from Newton's law of gravitation.

graviscalars, however, only couple to SM fields through the trace of the energy-momentum tensor, resulting in weaker couplings to the SM fields. The Fourier expansion of the spin-2 field is given by

$$G_{\mu\nu}(x,y) = G_{\mu\nu}^{(0)}(x) + \frac{1}{\sqrt{V_{\delta}}} \sum_{\vec{n} \neq 0} e^{i\vec{n} \cdot \vec{y}/R} G_{\mu\nu}^{(\vec{n})}(x) , \qquad (5)$$

where $\vec{y} = (y_1, y_2, ..., y_{\delta})$ are the extra-dimensional coordinates and $\vec{n} = (n_1, n_2, ..., n_{\delta})$. Eq. (5) contains a massless state, the 4D graviton, and its KK tower with masses $m_{\vec{n}}^2 = |\vec{n}|^2/R^2$. At energies below 1/R the action is that of the zero-mode

$$S_4^{(0)} = -\frac{\bar{M}_D^{2+\delta}}{2} \int d^4x \, V_\delta \sqrt{-g^{(0)}} \mathcal{R}^{(0)} + \int d^4x \sqrt{-g_{\mathrm{ind}}^{(0)}} \, \mathcal{L}_{\mathrm{SM}} \,,$$

where we can identify the 4D reduced Planck mass, $M_P \equiv G_N/\sqrt{8\pi} \simeq 2.4 \times 10^{18}$ GeV, as a function of the *D*-dimensional parameters:

$$M_P^2 = V^{\delta} \bar{M}_D^{2+\delta} \equiv R^{\delta} M_D^{2+\delta} \,. \tag{6}$$

Fixing M_D at around the electroweak scale $M_D \sim \text{TeV}$ to avoid introducing a new mass-scale in the model, Eq. (6) gives a prediction for R:

$$\delta = 1, 2, ..., 6 \rightarrow R \sim 10^9 \text{ km}, 0.5 \text{ mm}, ..., 0.1 \text{ MeV}^{-1}.$$
 (7)

The option $\delta=1$ is clearly ruled out. However this is not the case for $\delta\geq 2$, and possible observable consequences can be sought in present and future experiments.

Consistency of the model requires a stabilization mechanism for the radii of the extra dimensions, to the values shown in Eq. (7). The fact that we need $R\gg 1/M_D$ leads to a new hierarchy problem, the solution of which might require imposing supersymmetry in the extra-dimensional bulk [14].

Searches Particle Listings Extra Dimensions

II.2 Tests of the Gravitational Force Law at Sub-mm Distances

The KK modes of the graviton give rise to deviations from Newton's law of gravitation for distances $\lesssim R$. Such deviations are usually parametrized by a modified Newtonian potential of the form

$$V(r) = -G_N \frac{m_1 m_2}{r} \left[1 + \alpha e^{-r/\lambda} \right].$$
 (8)

For a 2-torus compactification, $\alpha=16/3$ and $\lambda=R$. Searches for deviations from Newton's law of gravitation have been performed in several experiments. Fig. 1, taken from Ref. [15], gives the present constraints. We find $R<37\mu{\rm m}$ at 95% CL for $\delta=2$, corresponding to $M_D>3.6$ TeV.

II.3 Astrophysical and Cosmological Constraints

The light KK gravitons could be copiously produced in stars, carrying away energy. Ensuring that the graviton luminosity is low enough to preserve the agreement of stellar models with observations provides powerful bounds on the scale M_D . The most stringent arises from supernova SN1987A, giving $M_D > 27$ (2.4) TeV for $\delta = 2$ (3) [16]. After a supernova explosion, most of the KK gravitons stay gravitationally trapped in the remnant neutron star. The requirement that neutron stars are not excessively heated by KK decays into photons leads to $M_D > 1700$ (76) TeV for $\delta = 2$ (3) [17].

Cosmological constraints are also quite stringent [18]. To avoid overclosure of the universe by relic gravitons one needs $M_D > 7$ TeV for $\delta = 2$. Relic KK gravitons decaying into photons contribute to the cosmic diffuse gamma radiation, from which one can derive the bound $M_D > 100$ TeV for $\delta = 2$.

We must mention however that bounds coming from the decays of KK gravitons into photons can be reduced if we assume that KK gravitons decay mainly into other non-SM states. This could happen, for example, if there are other 3-branes with hidden sectors residing on them [10].

II.4 Collider Signals

II.4a Graviton and Other Particle Production

Although each KK graviton has a purely gravitational coupling, suppressed by $1/M_P$, inclusive processes in which one sums over the almost continuous spectrum of available gravitons have cross sections suppressed only by powers of M_D . Processes involving gravitons are therefore detectable in collider experiments if $M_D \sim \text{TeV}$. A number of experimental searches for evidence of large extra dimensions have been performed at colliders, and interpreted in the context of the ADD model.

One signature arises from direct graviton emission. By making a derivative expansion of Einstein gravity, one can construct an effective theory, valid for energies much lower than M_D , and use it to make predictions for graviton-emission processes at colliders [13,19,20]. Gravitons produced in the final state would escape detection, giving rise to missing transverse energy $(\not\!E_T)$. The results quoted below are 95% CL lower limits on M_D for a range of values of δ between 2 and 6, with more stringent limits corresponding to lower δ values.

A combined $\gamma + \not\!\!E_T$ result from LEP yields limits of $M_D > 0.66 - 1.60$ TeV [21], and less stringent results also exist from LEP for the $Z + \cancel{E}_T$ final state. At hadron colliders, experimentally sensitive channels include the $j + \not\!\!E_T$ and $\gamma + \not\!\!E_T$ final states. The most stringent limits from the Tevatron include CDF results of $M_D > 0.94 - 1.94$ TeV [22], using the combined $j/\gamma + \not\!\!E_T$ final state. DØ results limit $M_D > 0.80$ – 0.88 TeV [23] from $\gamma + \not\!\!E_T$, and $M_D > 0.63 - 0.89$ TeV [24] from $j + \not\!\!E_T$. At the LHC, using a dataset of 1 fb⁻¹ and assuming leading order (LO) signal cross sections, CMS sets limits of $M_D > 2.25 - 3.67$ TeV [25] from analyzing the $j + \not\!\!E_T$ final state, and $M_D > 1.03 - 1.21 \text{ TeV } [26] \text{ from } \gamma + E_T$. To account for next-to-leading order (NLO) signal enhancements, sizeable k-factors, in the range 1.3-2 depending on δ , would increase these limits by typically $\approx 10\%$ if applied. ATLAS $j + E_T$ results with 1 fb⁻¹ provide limits of $M_D > 1.68 - 3.16$ TeV [27], using LO cross sections. For the $j + E_T$ analyses, the LHC experiments handle somewhat differently the issue that the effective theory is only valid for energies much less than M_D : CMS suppresses the graviton cross section by a factor M_D^2/\hat{s} for $\sqrt{\hat{s}} > M_D$, where $\sqrt{\hat{s}}$ is the parton-level center-of-mass energy of the hard collision. ATLAS simply truncates the differential cross section to remove the contribution from events where $\sqrt{\hat{s}} > M_D$, and points out that the effect of the truncation grows with δ , from a negligible impact for $\delta = 2$ up to a 16% reduction in the limit for $\delta = 6$.

In models in which the ADD scenario is embedded in a string theory at the TeV scale [12], we expect the string scale M_s to be smaller than M_D , and therefore production at the LHC of string resonances [28]. Analysis of the dijet invariant mass distribution have been interpreted by CMS for a 1 fb⁻¹ dataset to exclude at 95% CL string excitations of quarks and gluons that decay predominantly to q + g with masses less than 4 TeV [29].

II.4b Virtual graviton effects

One can also search for virtual graviton effects, the calculation of which however depends on the ultraviolet cut-off of the theory and is therefore very model dependent. In the literature, several different formulations exist [13,20,30] for the dimension-eight operator for gravity exchange at tree level:

$$\mathcal{L}_8 = \pm \frac{4}{M_{TT}^4} \left(T_{\mu\nu} T^{\mu\nu} - \frac{1}{\delta + 2} T^{\mu}_{\mu} T^{\nu}_{\nu} \right), \tag{9}$$

where $T_{\mu\nu}$ is the energy-momentum tensor and M_{TT} is related to M_D by some model-dependent coefficient [31]. The relations with the parametrizations of Refs. [30] and [13] are, respectively, $M_{TT}=M_S$ and $M_{TT}=(2/\pi)^{1/4}\Lambda_T$. The experimental results below are given as 95% CL lower limits on M_{TT} , including in some cases the possibility of both constructive or destructive interference, depending on the sign chosen in Eq. (9). Results from $e^{\pm}p \rightarrow e^{\pm}X$ at HERA limit $M_{TT} \gtrsim 800$ GeV [32]. The most sensitive limits from LEP arise from the $e^+e^- \rightarrow ee$ and $e^+e^- \rightarrow \gamma\gamma$ final states, with limits for the case of constructive (destructive) interference corresponding

Extra Dimensions

to $M_{TT}>1.1$ (1.0) TeV [33] and $M_{TT}>1.0$ (0.9) TeV [34], respectively. The most stringent results, for constructive (destructive) interference, from the Tevatron include limits of $M_{TT}>1.48$ (1.37) TeV [35] from $p\bar{p}\to ee/\gamma\gamma+X$, and $M_{TT}>1.48$ (1.34) TeV [36] from an analysis of the angular distributions in dijet events. Results from the LHC extend the sensitivity to higher scales. CMS has reported 1 fb⁻¹ results in the diphoton and dimuon final states. For constructive interference and using NLO cross sections, the CMS $\gamma\gamma$ and $\mu\mu$ results correspond approximately to limits of $M_{TT}>2.8$ TeV [37] and 2.4 TeV [38], respectively. A 2 fb⁻¹ update of the ATLAS $\gamma\gamma$ analysis in Ref. [39] provides limits of $M_{TT}>2.7$ TeV (2.3 TeV) for constructive (destructive) interference.

At the one-loop level, gravitons can also generate dimensions six operators with coefficients that are also model dependent. Experimental bounds on these operators can also give stringent constraints on M_D [31].

II.4c Black Hole Production

The physics at energies $\sqrt{s} \sim M_D$ is sensitive to the details of the quantum theory of gravity. Nevertheless, in the transplanckian regime, $\sqrt{s} \gg M_D$, one can rely on a semiclassical description of gravity to obtain predictions. An interesting feature of transplanckian physics is the creation of black holes [40]. A black hole is expected to be formed in a collision in which the impact parameter is smaller than the Schwarzschild radius [41]:

$$R_S = \frac{1}{M_D} \left[\frac{2^{\delta} \pi^{(\delta - 3)/2}}{\delta + 2} \Gamma\left(\frac{\delta + 3}{2}\right) \frac{M_{BH}}{M_D} \right]^{1/(\delta + 1)}, \tag{10}$$

where M_{BH} is the mass of the black hole, which would roughly correspond to the total energy in the collision. The cross section for black hole production can be estimated to be of the same order as the geometric area $\sigma \sim \pi R_S^2$. For $M_D \sim \text{TeV}$, this gives a production of $\sim 10^7$ black holes at the $\sqrt{s} = 14$ TeV LHC with an integrated luminosity of 30 fb⁻¹ [40]. A black hole would provide a striking experimental signature since it is expected to thermally radiate with a Hawking temperature $T_H = (\delta + 1)/(4\pi R_S)$, and therefore would evaporate democratically into all SM states.

At the LHC, one starts to be able to access a regime where the energies are large compared to (or at least comparable to) M_D values in the TeV range. However, given the present constraints on M_D , the LHC will not be able to reach energies much above M_D . This implies that predictions based on the semiclassical approximation could receive sizeable modifications from model-dependent quantum-gravity effects.

The LHC experiments have performed searches for microscopic black holes by looking for excesses above the SM background in final states with multiple high $p_{\rm T}$ objects [42,43], high $p_{\rm T}$ jets [44], high $p_{\rm T}$ leptons and jets [45], and in same-sign dimuon events [46]. No excesses have been observed. The results are usually quoted as model-independent limits on the cross section for new physics in the final state and kinematic region analyzed. These results can then be used to provide

constraints on models of low-scale gravity and weakly-coupled string theory. In addition, limits are sometimes quoted on particular implementations of models, which are used as benchmarks to illustrate the sensitivity. For example, using 1 fb⁻¹, CMS provides limits in the mass range of 4-5 TeV [42] for semiclassical black holes, and ATLAS gets similar results [45]. ATLAS have also searched for black holes via a 36 pb⁻¹ analysis of the invariant mass and angular distributions in dijet events, excluding M_D values in the range from 0.75 up to 3.26 (3.69) TeV [47] for the case of 2 (6) extra dimensions.

In weakly-coupled string models the semiclassical description of gravity fails in the energy range between M_s and M_s/g_s^2 since stringy effects are important. In this regime one expects, instead of black holes, the formation of string balls, made of highly excited long strings, that could be copiously produced at the LHC for $M_s \sim \text{TeV}$ [48], and would evaporate thermally at the Hagedorn temperature giving rise to high-multiplicity events. CMS has interpreted their 1 fb⁻¹ multi-object search to exclude the production of string balls with a minimum mass in the range of 4.1-4.5 TeV [42], depending on the details of the model. ATLAS gets similar results [45] for their 1 fb⁻¹ search for an excess of events with high p_T leptons and jets.

III TeV-Scale Extra Dimensions

III.1 Warped Extra Dimensions

The RS model [3] is the most attractive setup of warped extra dimensions at the TeV scale, since it provides an alternative solution to the hierarchy problem. The RS model is based on a 5D theory with the extra dimension compactified on an orbifold, S^1/Z_2 , a circle S^1 with the extra identification of y with -y. This corresponds to the segment $y \in [0, \pi R]$, a manifold with boundaries at y = 0 and $y = \pi R$. Let us now assume that this 5D theory has a cosmological constant in the bulk Λ , and on the two boundaries Λ_0 and $\Lambda_{\pi R}$:

$$S_{5} = -\int d^{4}x \, dy \left\{ \sqrt{-g} \left[\frac{1}{2} M_{5}^{3} \mathcal{R} + \Lambda \right] + \sqrt{-g_{0}} \delta(y) \Lambda_{0} + \sqrt{-g_{\pi R}} \delta(y - \pi R) \Lambda_{\pi R} \right\},$$
(11)

where g_0 and $g_{\pi R}$ are the values of the determinant of the induced metric on the two respective boundaries. Einstein's equations can be solved, giving in this case the metric

$$ds^2 = a(y)^2 dx^{\mu} dx^{\nu} \eta_{\mu\nu} + dy^2 , \quad a(y) = e^{-ky} ,$$
 (12)

where $k=\sqrt{-\Lambda/(6M_5^3)}$. Consistency of the solution requires $\Lambda_0=-\Lambda_{\pi R}=-\Lambda/k$. The metric in Eq. (12) corresponds to a 5D AdS space. The factor a(y) is called the "warp" factor and determines how 4D scales change as a function of the position in the extra dimension. In particular, this implies that energy scales for 4D fields localized at the boundary at $y=\pi R$ are red-shifted by a factor $e^{-k\pi R}$ with respect to those localized at y=0. For this reason, the boundaries at y=0 and $y=\pi R$ are usually referred to as the ultraviolet (UV) and infrared (IR) boundaries, respectively.

As in the ADD case, we can perform a KK reduction and obtain the low-energy effective theory of the 4D massless graviton. In this case we obtain

$$M_P^2 = \int_0^{\pi R} dy \, e^{-2ky} M_5^3 = \frac{M_5^3}{2k} \left(1 - e^{-2k\pi R} \right) \,.$$
 (13)

Taking $M_5 \sim k \sim M_P$, we can generate an IR-boundary scale of order $ke^{-k\pi R} \sim \text{TeV}$ for an extra dimension of radius $R \simeq 11/k$. Mechanisms to stabilize R to this value have been proposed [49] that, contrary to the ADD case, do not require introducing any new small or large parameter. Therefore a natural solution to the hierarchy problem can be achieved in this framework if the Higgs field, whose vacuum expectation value (VEV) is responsible for electroweak symmetry breaking, is localized at the IR-boundary where the effective mass scales are of order TeV.

In the original RS model [3], all the SM fields were assumed to be localized on the IR-boundary. Nevertheless, for the hierarchy problem, only the Higgs field has to be localized there. SM gauge bosons and fermions can propagate in the 5D bulk [4,5,6,50]. By performing a KK reduction from the 5D action of a gauge boson, we find [4]

$$\frac{1}{g_4^2} = \int_0^{\pi R} dy \, \frac{1}{g_5^2} = \frac{\pi R}{g_5^2} \,,$$

where g_D (D=4,5) is the gauge coupling in D-dimensions. Therefore the 4D gauge couplings can be of order one, as is the case of the SM, if we demand $g_5^2 \sim \pi R$. Using $kR \sim 10$ and $g_4 \sim 0.5$, we obtain the 5D gauge coupling

$$g_5 \sim 4/\sqrt{k} \,. \tag{14}$$

Boundary kinetic terms for the gauge bosons can modify this relation, allowing for larger values of $g_5\sqrt{k}$.

Fermions propagating in the RS extra dimension have 4D massless zero-modes with wavefunctions which vary as $f_0 \sim Exp[(1/2 - c_f)ky]$, where $c_f k$ is their 5D mass [51,6]. Depending on the free parameter $c_f k$, fermions can be localized either towards the UV-boundary ($c_f > 1/2$) or IR-boundary $(c_f < 1/2)$. Since the Higgs is localized on the IR-boundary, we can generate exponentially suppressed Yukawa couplings by having the fermion zero-modes localized towards the UVboundary, generating naturally the light SM fermion spectrum [6]. A large overlap with the wavefunction of the Higgs is needed for the top quark, in order to generate its large mass, thus requiring it to be localized towards the IR-boundary. In conclusion, the large mass hierarchies present in the SM fermion spectrum can be easily obtained in warped models via suitable choices of the order-one parameters c_f [52]. In these scenarios deviations in flavor physics from the SM predictions are expected to arise from flavor-changing KK gluon couplings [53]. These put certain constraints on the parameters of the models and predicts new physics effects to be observed in B-physics processes [54].

The masses of the KK states can also be calculated. One finds [6]

$$m_n \simeq \left(n + \frac{\alpha}{2} - \frac{1}{4}\right) \pi k e^{-\pi kR},$$
 (15)

where n=1,2,... and $\alpha=\{|c_f-1/2|,0,1\}$ for KK fermions, KK gauge bosons and KK gravitons, respectively. Their masses are of order $ke^{-\pi kR}\sim$ TeV; the first KK state of the gauge bosons would be the lightest, while gravitons are expected to be the heaviest.

III.1a Models of Electroweak Symmetry Breaking

Theories in warped extra dimensions can be used to implement symmetry breaking at low energies by boundary conditions [55]. For example, for a U(1) gauge symmetry in the 5D bulk, this can be easily achieved by imposing a Dirichlet boundary condition on the IR-boundary, $A_{\mu}|_{y=\pi R} = 0$. This makes the zero-mode gauge boson get a mass, given by $m_A = g_4 \sqrt{2k/g_5^2} e^{-\pi kR}$, that can be smaller than the KK masses for $g_5^2 \gg 1/k$. A very different situation occurs if the Dirichlet boundary condition is imposed on the UV-boundary, $A_{\mu}|_{\nu=0}=0$. In this case the zero-mode gauge boson disappears from the spectrum. Finally, if a Dirichlet boundary condition is imposed on the two boundaries, we obtain a massless 4D scalar corresponding to the fifth component of the 5D gauge boson, A_5 . Thus, different scenarios can be implemented by appropriately choosing the 5D bulk gauge symmetry, \mathcal{G}_5 , and the symmetries to which it reduces on the UV and IR-boundary, \mathcal{H}_{UV} and \mathcal{H}_{IR} respectively. In all cases the KK spectrum comes in representations of the group \mathcal{G}_5 .

Higgsless models: One of the most interesting applications of warped extra dimensions is for models of electroweak symmetry breaking. To guarantee the relation $M_W^2 \simeq M_Z^2 \cos^2 \theta_W$, a custodial $SU(2)_V$ symmetry in needed in the bulk and IR-boundary [56]. For this reason the minimal symmetry pattern is [57]

$$\mathcal{G}_5 = SU(3)_c \times SU(2)_L \times SU(2)_R \times U(1)_X$$

$$\mathcal{H}_{IR} = SU(3)_c \times SU(2)_V \times U(1)_X$$

$$\mathcal{H}_{UV} = G_{SM}$$

where $G_{SM} \equiv SU(3)_c \times SU(2)_L \times U(1)_Y$ is the SM gauge group with the identification of hypercharge as $Y = T_3^R + X$. In this theory the W and Z bosons are massive, there is no Higgs boson, and the first KK mode associated to the W boson has a mass given by

$$m_{KK} \simeq \frac{3\pi g_5 \sqrt{k}}{4q_4} M_W \,. \tag{16}$$

Using Eq. (14), one obtains $m_{KK} \simeq 1.2$ TeV.

Composite Higgs models: Alternatively, warped extra dimensions can give rise to scenarios, often called gauge-Higgs unified models, where the Higgs appears as the fifth component of a 5D gauge boson, A_5 . The Higgs mass is protected by the

Extra Dimensions

5D gauge invariance and can only get a nonzero value from non-local one-loop effects [58]. As in the Higgsless case, a custodial symmetry is needed. The simplest realization [59] has

$$\mathcal{G}_5 = SU(3)_c \times SO(5) \times U(1)_X$$

 $\mathcal{H}_{IR} = SU(3)_c \times SO(4) \times U(1)_X$
 $\mathcal{H}_{UV} = G_{SM}$

The Higgs gets a potential at the one-loop level that triggers a VEV, breaking the electroweak symmetry. In these models there is a light Higgs with mass 100 - 200 GeV that, as will be explained in Sec. III.3, behaves as a composite state. The lightest KK modes of the model are color fermions with charges Q = -1/3, 2/3 and 5/3 [60].

$III.1b\ Constraints\ from\ Electroweak\ Precision\ Tests$

Models in which the SM gauge bosons propagate in 1/TeV-sized extra dimensions give generically large corrections to electroweak observables. When the SM fermions are confined on a boundary these corrections are universal and can be parametrized by four quantities: \hat{S} , \hat{T} , W and Y, as defined in Ref. [61]. For warped models, where the 5D gauge coupling of Eq. (14) is large, the most relevant parameter is \hat{T} , which gives the bound $m_{KK} \gtrsim 10$ TeV [50]. When a custodial symmetry is imposed [56], the main constraint comes from the \hat{S} parameter, requiring $m_{KK} \gtrsim 3$ TeV independently of the value of g_5 . Notice that this bound, when applied to 5D Higgsless models where Eq. (16) holds, constrains the coupling g_5^2k to be close to its nonperturbative value [62]. Also corrections to the $Zb_L\bar{b}_L$ coupling can be important [50], especially in warped models for electroweak symmetry breaking as the ones described above.

III.1c Kaluza-Klein Searches

The main prediction of 1/TeV-sized extra dimensions is the presence of a discretized KK spectrum, with masses around the TeV scale, associated with the SM fields that propagate in the extra dimension.

In the original RS model, only gravity propagates in the 5D bulk. Experimental searches have been performed for the lightest RS graviton through its decay to a variety of SM particle-antiparticle pairs. The results are usually interpreted in the plane of the dimensionless coupling k/M_P versus m_1 , where M_P is the reduced Planck mass defined previously and m_1 is the mass of the lightest KK excitation of the graviton. Since the AdS curvature $\sim k$ cannot exceed the cut-off scale of the model, which is estimated to be $\ell_5^{1/3}M_5$ [31], we must demand $k \ll \sqrt{2\ell_5}M_P$. The results quoted below are 95% CL lower limits on the KK graviton mass for a coupling $k/M_P = 0.1$.

Tevatron limits exist for the diphoton, dielectron and dimuon final states, and are typically near the kinematic limit of order 1 TeV. The most stringent results from the Tevatron are the CDF limit of $m_1 > 1.11$ TeV [64] from combining $G \to \gamma \gamma / ee/\mu \mu$, and the DØ limit of $m_1 > 1.05$ TeV [65] using $G \to \gamma \gamma / ee$. The LHC experiments can probe higher masses, with recent results available using ≈ 1 fb⁻¹ of 7 TeV data. No published predictions exist for NLO cross sections for 7 TeV pp

collisions, and CMS and ATLAS adopted different conventions with regard to k-factors, meaning some care is required when comparing their results. CMS used a k-factor value of ≈ 1.6 for their combined $ee/\mu\mu$ result of $m_1 > 1.78$ TeV [66], and for their preliminary result of $m_1 > 1.72$ TeV [37] using the $\gamma\gamma$ final state. The ATLAS limit of $m_1 > 1.63$ TeV [67] from the $ee/\mu\mu$ final state combination assumes the signal cross section as obtained with LO* PDFs; this choice corresponds to an effective k-factor of ≈ 1.1 for masses near the obtained limit. A 2 fb⁻¹ update of the ATLAS $\gamma\gamma$ analysis in Ref. [39] assumes a k-factor of 1.75 and provides a limit of $m_1 > 1.95$ TeV when combined with the 1 fb⁻¹ $ee/\mu\mu$ results.

Less stringent limits on the KK graviton mass come from the WW/ZZ final states at the Tevatron. By combining searches with one, two, or three charged leptons, DØ sets a limit in the WW final state of $m_1 > 754$ GeV [68]. An earlier CDF result in the $e + \not\!\!E_T + jj$ final state limits $m_1 > 606$ GeV [69]. A preliminary ZZ result from CDF [70] reports 4 events compatible with a mass of ≈ 325 GeV in the final state with four charged leptons (electrons or muons), and they state that the probability to observe such a distribution of events given the SM background lies in the range $(2.7 - 10.5) \times 10^{-5}$. However, CDF analyses with two charged leptons and either a pair of jets or E_T do not confirm a signal for a new heavy particle decaying to a pair of Z bosons. The combined result is quoted as a limit of 0.26 pb on the production cross section of a 325 GeV RS Graviton decaying to ZZ. A DØ measurement of the ZZ production cross section in the four charged lepton final state [71] also shows no evidence of an enhancement at a ZZinvariant mass near 325 GeV.

If the SM fields propagate in the 5D bulk, the couplings of the KK graviton to $ee/\mu\mu/\gamma\gamma$ are suppressed [72], the above bounds would not apply. In this case the graviton is the heaviest KK state, so experimental searches for KK gauge bosons and fermions are more appropriate discovery channels in these scenarios. For the scenarios discussed above in which only the Higgs and the top quark are localized towards the IRboundary, the KK gauge bosons mainly decay into top quarks, longitudinal W/Z bosons, and Higgs bosons. Couplings to light SM fermions are suppressed by a factor $g_4/\sqrt{g_5^2k} \sim 0.2$ [6]. Searches have been made for evidence of the lightest KK excitation of the gluon, through its decay to $t\bar{t}$ pairs. An ATLAS analysis of the lepton-plus-jets final state using 0.2 fb^{-1} of data excludes KK gluons with masses below 650 GeV [73], while a 1 fb⁻¹ analysis of the dilepton final state yields a lower limit of 0.84 TeV [74]. A 0.9 fb⁻¹ CMS analysis of the fully hadronic final state searches uses "top tagging" techniques to identify events where one or both of the top quarks is highly boosted and reconstructed as a single merged jet; this analysis claims to exclude KK gluons with a mass lying between 1 and 1.5 TeV [75], though the paper states that the large width expected for the KK gluon was not taken into account in determining the result. A gauge KK excitation could be also sought through its decay to longitudinal W/Z bosons. While, as

Searches Particle Listings Extra Dimensions

reported elsewhere in this volume, searches for WZ resonances have been used to set limits on sequential SM W' bosons or other models, as yet no WZ experimental results have been interpreted in the context of warped extra-dimensions.

The lightest KK states are usually the partners of the top quark. In warped models of electroweak symmetry breaking, these are color states with charges Q = -1/3, 2/3 and 5/3, and masses between 0.5 and 1.5 TeV [60]. They can be either singly- or pair-produced, and mainly decay into a combination of W/Z with top/bottom. Of particular note, the Q=5/3 state decays mainly into $W^+t \to W^+W^+b$, giving a pair of samesign leptons in the final state [76]. $D\emptyset$ searched with 5.4 fb⁻¹ for single production of heavy vector-like quarks decaying to W/Z + i [77], and set limits on their production cross sections that could be reinterpreted to provide some exclusion on KK fermions decaying to W/Z + b, though the sensitivity might be less than optimal since b-tagging was not used in the analysis. CMS performed a 1 fb⁻¹ search for pair-production of heavy vector-like quarks T, which excludes such quarks with masses below 475 GeV [78], assuming a 100% branching ratio for the decay $T \to tZ$.

$III. 2\ Connection\ with\ Strongly-Coupled\ Models\ via\ the$ $AdS/CFT\ Correspondence$

The AdS/CFT correspondence [7] provides a connection between warped extra-dimensional models and strongly-coupled theories in ordinary 4D. Although the exact connection is only known for certain cases, the AdS/CFT techniques have been very useful to obtain, at the qualitative level, a 4D holographic description of the various phenomena in warped extra-dimensional models [8].

The connection goes as follows. The physics of the bulk AdS₅ models can be interpreted as that of a 4D conformal field theory (CFT) which is strongly-coupled. The extra-dimensional coordinate y plays the role of the renormalization scale μ of the CFT by means of the identification $\mu \equiv ke^{-ky}$. Therefore the UV-boundary corresponds in the CFT to a UV cut-off scale at $\Lambda_{UV} = k \sim M_P$, breaking explicitly conformal invariance, while the IR-boundary can be interpreted as a spontaneous breaking of the conformal symmetry at energies $ke^{-k\pi R} \sim \text{TeV}$. Fields localized on the UV-boundary are elementary fields external to the CFT, while fields localized on the IR-boundary and KK states corresponds to composite resonances of the CFT. Furthermore, local gauge symmetries in the 5D models, \mathcal{G}_5 , correspond to global symmetries of the CFT, while the UV-boundary symmetry can be interpreted as a gauging of the subgroup \mathcal{H}_{UV} of \mathcal{G}_5 in the CFT. Breaking gauge symmetries by IR-boundary conditions corresponds to the spontaneous breaking $\mathcal{G}_5 \to \mathcal{H}_{IR}$ in the CFT at energies $\sim ke^{-k\pi R}$. Using this correspondence we can easily derive the 4D massless spectrum of the compactified AdS₅ models. We also have the identification $k^3/M_5^3 \approx 16\pi^2/N^2$ and $g_5^2k \approx 16\pi^2/N^r$ (r=1 or 2for CFT fields in the fundamental or adjoint representation of the gauge group, respectively), where N plays the role of the

number of colors of the CFT. Therefore the weak-coupling limit in AdS_5 corresponds to a large-N expansion in the CFT.

Following the above AdS/CFT dictionary we can understand the RS solution to the hierarchy problem from a 4D viewpoint. The equivalent 4D model is a CFT with a TeV mass-gap and a Higgs emerging as a composite state. The AdS/CFT correspondence also shows that the 5D Higgsless models described above should share similar physics as Technicolor models [79]. Indeed, the lowest KK $SU(2)_L$ -gauge boson behaves as the Techni-rho ρ_T with a coupling to longitudinal W/Z bosons given by $g_5\sqrt{k}\approx g_{\rho_T}$, while the coupling to elementary fermions is $g_4^2/\sqrt{g_5^2k}\approx g^2F_{\rho_T}/M_{\rho_T}$. Also, models with the Higgs identified as A_5 correspond to models, similar to those proposed in Ref. [80], where the Higgs is a composite pseudo-Goldstone boson arising from the spontaneous breaking $\mathcal{G}_5\to\mathcal{H}_{IR}$ in the CFT.

Fermions in compactified AdS₅ also have a simple 4D holographic interpretation. The 4D massless mode described in sec. III.1 corresponds to an external fermion ψ_i linearly coupled to a fermionic CFT operator \mathcal{O}_i : $\mathcal{L}_{\text{int}} = \lambda_i \bar{\psi}_i \mathcal{O}_i + h.c.$. The dimension of the operator \mathcal{O}_i is related to the 5D fermion mass according to $\text{Dim}[\mathcal{O}_i] = |c_f + 1/2| - 1$. Therefore, by varying c_f we vary $\text{Dim}[\mathcal{O}_i]$, making the coupling λ_i irrelevant $(c_f > 1/2)$, marginal $(c_f = 1/2)$ or relevant $(c_f < 1/2)$. When irrelevant, the coupling is exponentially suppressed at low energies, and then the coupling of ψ_i to the CFT (and eventually to the composite Higgs) is very small. When relevant, it grows towards the IR and become as large as g_5 (in units of k), meaning that the fermion is as strongly coupled as the CFT states [59]. In this latter case ψ_i behaves as a composite fermion.

III.3 Flat Extra Dimensions

Models with quantum-gravity at the TeV scale, as in the ADD scenario, can have extra (flat) dimensions of 1/TeV size, as it happens in string scenarios [81]. All SM fields may propagate in these extra dimensions, leading to the possibility of observing their corresponding KK states.

A simple example is to assume that the SM gauge bosons propagate in a flat five-dimensional orbifold S^1/Z_2 of radius R, with the fermions localized on a 4D boundary. The KK gauge bosons behave as sequential SM gauge bosons with a coupling to fermions enhanced by a factor $\sqrt{2}$ [81]. The experimental limits on such sequential gauge bosons could therefore be recast as limits on KK gauge bosons. Bounds from LEP2 require $1/R \gtrsim 6$ TeV [61].

An alternative scenario, known as Universal Extra Dimensions (UED) [82], assumes that all SM fields propagate universally in a flat orbifold S^1/Z_2 with an extra Z_2 parity, called KK-parity, that interchanges the two boundaries. In this case, the lowest KK state is stable becoming a Dark Matter candidate. At colliders, the KK particles would have to be created in pairs, and would then cascade decay to the lightest KK particle (LKP), which would be stable and escape detection. Experimental signatures, such as jets or leptons and

Extra Dimensions

 E_T , would be similar to those of typical R-parity conserving SUSY searches. However, few experimental searches have as yet been interpreted in the UED scenario. DØ and ATLAS have both examined a specific UED model in which the KK parity is violated by gravitational interactions [83]. In this case the LKP can decay via $\gamma^* \to \gamma + G$, where G represents one of a tower of eV-spaced KK graviton states. Beginning with strong production of a pair of KK quarks and/or gluons [84], the final state would be $\gamma \gamma + \not\!\!E_T + X$, where $\not\!\!E_T$ results from the escaping gravitons and X represents SM particles emitted during the cascade decays. The experimental analyses treat R, the UED compactification radius, as a free parameter and follow the theory calculation [85] that sets Λ , the cut-off used in the calculation of radiative corrections to the KK masses, such that $\Lambda R = 20$. The gravitational decay widths of the KK particles are set by the values of δ and of M_D , the Planck scale in the $(4+\delta)$ -dimensional theory. Setting $\delta = 6$ and $M_D = 5$ TeV, and provided 1/R < 2 TeV, only the LKP has an appreciable gravitational decay, with a sizeable branching ratio for $\gamma^* \to \gamma + G$. In this scenario, DØ set a 95% CL limit that 1/R > 477 GeV [86]. The initial ATLAS result used only 3 pb⁻¹ to increase this limit to 1/R > 729 GeV; a recent ATLAS 1 fb⁻¹ update extends it further to 1/R > 1.23 TeV [87].

Finally, realistic models of electroweak symmetry breaking can also be constructed with flat extra spatial dimensions, similarly to those in the warped case, requiring, however, the presence of sizeable boundary kinetic terms [88]. There is also the possibility of breaking supersymmetry by boundary conditions [89]. Models of this type could explain naturally the presence of a Higgs boson lighter than M_D [90].

Direct Limits on Gravitational or String Mass Scale

Limits on $1/R=M_{C}$ Limits on Kaluza-Klein Gravitons in Warped Extra Dimensions

Limits on Mass of Radion

Limits on R from Deviations in Gravitational Force Law

This section includes limits on the size of extra dimensions from deviations in the Newtonian $\left(1/r^2\right)$ gravitational force law at short distances. Deviations are parametrized by a gravitational potential of the form V=-(G m m'/r) $[1+\alpha \exp(-r/R)]$. For δ toroidal extra dimensions of equal size, $\alpha=8\delta/3$. Quoted bounds are for $\delta=2$ unless otherwise noted.

- 1 BEZERRA 11 obtain constraints on non-Newtonian forces with strengths $10^{11}\lesssim |lpha|\lesssim$ 10^{18} and length scales R=30–1260 nm. See their Fig. 2 for more details. These constraints do not place limits on the size of extra flat dimensions.
- 2 SUSHKOV 11 obtain improved limits on non-Newtonian forces with strengths $10^7\lesssim$ $|\alpha|\lesssim 10^{11}$ and length scales 0.4 $\mu\mathrm{m}< R<4~\mu\mathrm{m}$ (95% CL). See their Fig. 2. These bounds do not place limits on the size of extra flat dimensions. However, a model dependent bound of $M_*>70~\mathrm{TeV}$ is obtained assuming gauge bosons that couple to baryon number also propagate in $(4 + \delta)$ dimensions.
- $^3\,\mathrm{BEZERRA}$ 10 obtain improved constraints on non-Newtonian forces with strengths $10^{19} \lesssim |\alpha| \lesssim 10^{29}$ and length scales R=1.6-14 nm (95% CL). See their Fig. 1. This bound does not place limits on the size of extra flat dimensions.
- 4 MASUDA 09 obtain improved constraints on non-Newtonian forces with strengths $10^9 \lesssim$ $|lpha|\lesssim 10^{11}$ and length scales R= 1.0–2.9 μm (95% CL). See their Fig. 3. This bound es not place limits on the size of extra flat dimensions.
- 5 GERACI 08 obtain improved constraints on non-Newtonian forces with strengths $|\alpha|>14,000$ and length scales $R=5-15~\mu\mathrm{m}$. See their Fig. 9. This bound does not place limits on the size of extra flat dimensions.
- 6 TRENKEL 08 uses two independent measurements of Newton's constant G to constrain new forces with strength $|\alpha| \simeq 10^{-4}$ and length scales R=0.02–1 m. See their Fig. 1. This bound does not place limits on the size of extra flat dimensions.
- 7 DECCA 07A search for new forces and obtain bounds in the region with strengths $|lpha| \simeq$ 10^{13} and length scales R=20-86 nm. See their Fig. 6. This bound does not place limits on the size of extra flat dimensions.
- 8 KAPNER 07 search for new forces, probing a range of $\alpha\simeq 10^{-3}$ –10 5 and length scales $R\simeq 10$ –1000 $\mu\mathrm{m}$. For $\delta=1$ the bound on R is 44 $\mu\mathrm{m}$. For $\delta=2$, the bound is expressed in terms of M_{*} , here translated to a bound on the radius. See their Fig. 6 for details on the bound.
- gettails on the bound. 9 TU 07 search for new forces probing a range of $|\alpha| \simeq 10^{-1}$ – 10^5 and length scales $R \simeq 20$ – $1000~\mu m$. For $\delta = 1$ the bound on R is 53 μm . See their Fig. 3 for details on the
- $10\,\mathrm{SMULLIN}$ 05 search for new forces, and obtain bounds in the region with strengths $lpha \simeq 10^3$ – 10^8 and length scales R= 6–20 $\mu{\rm m}$. See their Figs. 1 and 16 for details on
- the bound. This work does not place limits on the size of extra flat dimensions. 11 HOYLE 04 search for new forces, probing α down to 10^{-2} and distances down to $10\mu m$. Quoted bound on R is for $\delta=2$. For $\delta=1$, bound goes to $160~\mu m$. See their Fig. 34 for details on the bound.
- 12 CHIAVERINI 03 search for new forces, probing α above 10^4 and λ down to 3μ m, finding no signal. See their Fig. 4 for details on the bound. This bound does not place limits on the size of extra flat dimensions.
- 13 LONG 03 search for new forces, probing lpha down to 3, and distances down to about
- $10\mu\text{m}$. See their Fig. 4 for details on the bound. 14 HOYLE 01 search for new forces, probing α down to 10^{-2} and distances down to $20\mu\text{m}$. See their Fig. 4 for details on the bound. The quoted bound is for $lpha \, \geq \, 3$.
- 15 HOSKINS 85 search for new forces, probing distances down to 4 mm. See their Fig. 13 for details on the bound. This bound does not place limits on the size of extra flat

Limits on R from On-Shell Production of Gravitons: $\delta = 2$

This section includes limits on on-shell production of gravitons in collider and astrophysical processes. Bounds quoted are on R, the assumed common radius of the flat extra dimensions, for $\delta=2$ extra dimensions. Studies often quote bounds in terms of derived parameter; experiments are actually sensitive to the masses of the KK gravitons: $m_{\vec{n}} = |\vec{n}|/R$. See the Review on "Extra Dimensions" for details. Bounds are given in μ m for $\delta=2$.

Limits on R from On-Shell Production of Gravitons: $\delta \geq 3$

This section includes limits similar to those in the previous section, but for $\delta=3$ extra dimensions. Bounds are given in nm for $\delta=3$. Entries are also shown for papers examining models with $\delta > 3$.

- 16 AAD 11s search for $pp \to jG$, using 33 pb⁻¹ of data at $\sqrt{s}=7$ TeV, to place bounds on M_D for two to four extra dimensions, from which these bounds on R are derived. See their Table 3 for bounds on all $\delta \leq 4$. 17 CHATRCHYAN 11u search for $pp \to jG$, using 36 pb⁻¹ of data at $\sqrt{s}=7$ TeV, to place bounds on M_D for two to six extra dimensions, from which these bounds on R are derived. See their Table 3 for bounds on all $\delta \leq 6$. 18 AALTONEN 08AC search for $p\overline{p} \to \gamma G$ and $p\overline{p} \to jG$ at $\sqrt{s}=1.96$ TeV with 2.0

- size of the extra dimensions. See their Table III for limits on all $\delta \leq 6$.

 19 ABAZOV 08s search for $p\overline{p} \to \gamma G$, using 1 fb⁻¹ of data at $\sqrt{s} = 1.96$ TeV with 2.0 bounds on M_D for two to eight extra dimensions, from which these bounds on R are derived. See their paper for intermediate values of δ .
- ²⁰ DAS 08 obtain a limit on R from Kaluza-Klein graviton cooling of SN1987A due to plasmon-plasmon annihilation.
- 21 ABULENCIA,A 06 search for $p\,\overline{p} o j\,G$ using 368 pb $^{-1}$ of data at $\sqrt{s}=1$.96 TeV. See
- 22 ABDALLAH 058 search for $e^+e^- o \gamma G$ at $\sqrt{s}=189$ –209 GeV to place bounds on the size of extra dimensions and the fundamental scale. Limits for all $\delta \leq 6$ are given in their Table 6. These limits supersede those in ABREU 002.

 23 ACHARD 04E search for $e^+e^- o \gamma G$ at $\sqrt{s}=189$ –209 GeV to place bounds on the size of extra dimensions and the fundamental scale. See their Table 8 for limits with $\delta \leq 8$. There limits supersede those in AGREU 07.
- $\delta \leq 8$. These limits supersede those in ACCIARRI 99R. 24 ACOSTA 04C search for $\overline{\rho}p \to jG$ at $\sqrt{s}=1.8$ TeV to place bounds on the size of extra dimensions and the fundamental scale. See their paper for bounds on $\delta=4$, 6.
- ²⁵ CASSE 04 obtain a limit on R from the gamma-ray emission of point γ sources that arises from the photon decay of gravitons around newly born neutron stars, applying the technique of HANNESTAD 03 to neutron stars in the galactic bulge. Limits for all $\delta \leq$ 7 are given in their Table I.
- 26 ABAZOV 03 search for $p\overline{p}\to jG$ at $\sqrt{s}{=}1.8$ TeV to place bounds on M_D for 2 to 7 extra dimensions, from which these bounds on R are derived. See their paper for bounds on intermediate values of δ . We quote results without the approximate NLO scaling introduced in the paper.
- 27 HANNESTAD 03 obtain a limit on R from graviton cooling of supernova SN1987a Limits for all $\delta \leq 7$ are given in their Tables V and VI.
- 28 HANNESTAD 03 obtain a limit on R from gravitons emitted in supernovae and which subsequently decay, contaminating the diffuse cosmic γ background. Limits for all $\delta \leq 7$ are given in their Tables V and VI. These limits supersede those in HANNESTAD 02.
- 29 HANNESTAD 03 obtain a limit on R from gravitons emitted in two recent supernovae and which subsequently decay, creating point γ sources. Limits for all $\delta \leq 7$ are given in their Tables V and VI. These limits are corrected in the published erratum.
- 30 HANNESTAD 03 obtain a limit on R from the heating of old neutron stars by the surrounding cloud of trapped KK gravitons. Limits for all $\delta \leq 7$ are given in their Tables V and VI. These limits supersede those in HANNESTAD 02.

- 31 HEISTER 03c use the process $e^+e^-
 ightarrow \gamma \mathit{G}$ at $\sqrt{s}=$ 189–209 GeV to place bounds on the size of extra dimensions and the scale of gravity. See their Table 4 for limits with $\delta \leq$ 6 for derived limits on M_D .
- 32 FAIRBAIRN 01 obtains bounds on R from over production of KK gravitons in the early universe. Bounds are quoted in paper in terms of fundamental scale of gravity. Bounds depend strongly on temperature of QCD phase transition and range from $R < 0.13~\mu m$ to 0.001 μ m for δ =2; bounds for δ =3,4 can be derived from Table 1 in the paper.
- 33 HANHART 01 obtain bounds on *R* from limits on graviton cooling of supernova SN 1987a using numerical simulations of proto-neutron star neutrino emission.
- 34 CASSISI 00 obtain rough bounds on M_D (and thus R) from red giant cooling for $\delta{=}2,3$.
- See their paper for details. See Their paper for details. See Their paper for details. See Their paper for $e^+e^- \rightarrow ZG$ at \sqrt{s} =189 GeV. Limits on the gravity scale are found in their Table 2, for $\delta \leq 4$.

Mass Limits on M_{TT}

This section includes limits on the cut-off mass scale, M_{TT} , of dimension-8 operators from KK graviton exchange in models of large extra dimensions. Ambiguities in the UV-divergent summation are absorbed into the parameter λ , which is taken to be $\lambda=$ ± 1 in the following analyses. Bounds for $\lambda = -1$ are shown in parenthesis after the bound for $\lambda=\pm 1$, if appropriate. Different papers use slightly different definitions of the mass scale. The definition used here is related to another popular convention by $M_{TT}^4=(2/\pi)~\Lambda_T^4$, as discussed in the above Review on "Extra Dimensions."

- 36 AARON 11c search for deviations in the differential cross section of $e^{\pm} p
 ightarrow e^{\pm} X$ in
- 4460 b⁻¹ of data taken at $\sqrt{s}=301$ and 319 GeV to place a bound on M_{TT} . 37 CHATRCHYAN 11A use 36 pb⁻¹ of data from pp collisions at $\sqrt{s}=7$ TeV to place lower limits on Λ_T , here converted to M_{TT} .
- 38 ABAZOV 09AE use dijet angular distributions in 0.7 fb $^{-1}$ of data from $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV to place lower bounds on Λ_T (equivalent to their M_S), here converted to M_{TT}
- 39 ABAZOV 09D use 1.05 fb $^{-1}$ of data from $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV to place lower
- bounds on Λ_T (equivalent to their M_S), here converted to M_{TT} .

 40 SCHAEL 07A use e^+e^- collisions at $\sqrt{s}=189$ –209 GeV to place lower limits on Λ_T . here converted to limits on M_{TT} .
- 41 ABDALLAH 06c use $e^+\,e^-$ collisions at $\sqrt{s}\sim 130$ –207 GeV to place lower limits on M_{TT} , which is equivalent to their definition of M_S . Bound shown includes all possible final state leptons, $\ell=e,\,\mu,\,\tau.$ Bounds on individual leptonic final states can be found in the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state of the state
- In their label 51. 42 GERDES 06 use 100 to 110 pb $^{-1}$ of data from $p\overline{p}$ collisions at $\sqrt{s}=1.8$ TeV, as recorded by the CDF Collaboration during Run I of the Tevatron. Bound shown includes a K-factor of 1.3. Bounds on individual e^+e^- and $\gamma\gamma$ final states are found in their Table I.
- 43 ABAZOV 05v use 246 pb $^{-1}$ of data from $ho \overline{
 ho}$ collisions at $\sqrt{s}=1.96$ TeV to search for deviations in the differential cross section to $\mu^+\mu^-$ from graviton exchange.
- ⁴⁴ CHEKANOV 04B search for deviations in the differential cross section of $e^{\pm} p
 ightarrow e^{\pm} X$ with 130 pb^{-1} of combined data and Q^2 values up to 40,000 GeV² to place a bound on M_{TT}
- 45 ABBIENDI 03D use e^+e^- collisions at \sqrt{s} =181-209 GeV to place bounds on the ultraviolet scale M_{TT} , which is equivalent to their definition of M_S .
- ⁴⁶ ACHARD 03D look for deviations in the cross section for $e^+e^-
 ightarrow ZZ$ from $\sqrt{s}=$ 200–209 GeV to place a bound on M_{TT} .
- 47 ADLOFF 03 search for deviations in the differential cross section of $e^\pm p \to e^\pm X$ at \sqrt{s} =301 and 319 GeV to place bounds on M_{TT} .

- 48 GIUDICE 03 review existing experimental bounds on M_{TT} and derive a combined limit.
- $^{49}\,\text{GIUDICE}$ 03 place bounds on Λ_6 , the coefficient of the gravitationally-induced dimension-6 operator $(2\pi/\Lambda \Lambda_0^2)(\sum \overline{I}\gamma_\mu \gamma^5 f)(\sum \overline{I}\gamma^\mu \gamma^5 f)$, using data from a variety of experiments. Results are quoted for $\lambda = \pm 1$ and are independent of δ .
- $50\,\mathrm{HEISTER}$ 03c use e^+e^- collisions at $\sqrt{s}=$ 189–209 GeV to place bounds on the scale of dim-8 gravitational interactions. Their M_S^{\pm} is equivalent to our M_{TT} with $\lambda = \pm 1$.
- 51 ACHARD 02 search for s-channel graviton exchange effects in $e^+\,e^-
 ightarrow \, \gamma\gamma$ at $E_{
 m cm}=$
- 192–209 GeV. 192–209 GeV. 192–209 GeV. 192–209 GeV. 192–209 GeV. 193–309 GeV. 193–309 GeV. 193–309 GeV. 193–309 GeV. 193–309 GeV. 193–309 GeV. 193–309 GeV.
- 54 ABREU 00A search for s-channel graviton exchange effects in $e^+\,e^-\,
 ightarrow\,\gamma\gamma$ at $E_{
 m Cm}=$
- 55 ABREU 00s uses e^+e^- collisions at \sqrt{s} =183 and 189 GeV. Bounds on μ and au individual final states given in paper.
- 56 CHANG 008 derive 37 limit on M T of (28,19,15) TeV for 5 =(2,4,6) respectively assuming the presence of a torsional coupling in the gravitational action. Highly model
- ⁵⁷ CHEUNG 00 obtains limits from anomalous diphoton production at OPAL due to graviton exchange. Original limit for δ =4. However, unknown UV theory renders δ dependence unreliable. Original paper works in HLZ convention.
- ⁵⁸ GRAESSER 00 obtains a bound from graviton contributions to g-2 of the muon through loops of 0.29 TeV for δ =2 and 0.38 TeV for δ =4,6. Limits scale as $\lambda^{1/2}$. However calculational scheme not well-defined without specification of high-scale theory. See the "Extra Dimensions Review."
- Taxtra Dimensions review. The Air No calculates corrections to gauge boson self-energies from KK graviton loops and constrain them using S and T. Bounds on M_{TT} range from 0.5 TeV (δ =6) to 1.1 TeV (δ =2); see text. Limits have strong dependence, $\lambda^{\delta+2}$, on unknown λ coefficient.
- 60 (0-2), see text. Elimina have strong appearance of MATHEWS 00 search for evidence of graviton exchange in CDF and DØ dijet production data. See their Table 2 for slightly stronger δ-dependent bounds. Limits expressed in terms of $\widetilde{M}_S^4 = M_{TT}^4/8$.
- 61 MELE 00 obtains bound from KK graviton contributions to ${
 m e^+\,e^-}
 ightarrow~V~V~(V=\gamma,W,Z)$
- at LEP. Authors use Hewett conventions. 62 ABBIENDI 99P search for s-channel graviton exchange effects in $e^+e^- \to \gamma \gamma$ at $E_{\rm cm}$ =189 GeV. The limits $G_+ >$ 660 GeV and $G_- >$ 634 GeV are obtained from combined $E_{\rm cm}$ =183 and 189 GeV data, where G_\pm is a scale related to the fundamental
- 63 ACCIARRI 99M search for the reaction $e^+\,e^-\,
 ightarrow\,\gamma\,{\it G}$ and s-channel graviton exchange effects in $e^+e^-\to\gamma\gamma$, W^+W^- , Z, e^+e^- , $\mu^+\mu^-$, $\tau^+\tau^-$, $q\overline{q}$ at $E_{\rm cm}=$ 183 GeV. Limits on the gravity scale are listed in their Tables 1 and 2.
- ⁶⁴ ACCIARRI 99s search for the reaction $e^+e^- \to ZG$ and s-channel graviton exchange effects in $e^+e^- \to \gamma\gamma$, W^+W^- , ZZ, e^+e^- , $\mu^+\mu^-$, $\tau^+\tau^-$, $q\overline{q}$ at $E_{\rm cm}=189$ GeV. Limits on the gravity scale are listed in their Tables 1 and 2.
- 65 BOURLIKOV 99 performs global analysis of LEP data on $e^+\,e^-$ collisions at $\sqrt{s}{=}183$ and 189 GeV. Bound is on Λ $_T$.

Direct Limits on Gravitational or String Mass Scale

This section includes limits on the fundamental gravitational scale and/or the string scale from processes which depend directly on one or the other of these scales.

| VALUE (TeV) | DO CUMENT ID | TECN | COMMENT | |
|-------------------------|-----------------------------------|-----------|------------|--|
| • • • We do not use the | following data for averages, fits | , limits, | etc. • • • | |

| \n 10 | 67 ACCIARRI NOD | 13 | a+ a a+ a- | |

- 66 ANCHORDOQUI 02B derive bound on M_D from non-observation of black hole production in high-energy cosmic rays. Bound is stronger for larger δ , but depends sensitively on threshold for black hole production.
- on the short of productions of N_S from massive string modes. N_S is defined in hep-ph/0001166 by $M_{\rm S}(1/\pi)^{1/8}\alpha^{-1/4} = M \text{ where } (4\pi G)^{-1} = M^{n+2}R^n.$

Limits on $1/R = M_c$

This section includes limits on $1/R=M_{\rm C}$, the compactification scale in models with TeV extra dimensions, due to exchange of Standard Model KK excitations. Bounds assume fermions are not in the bulk, unless stated otherwise. See the "Extra Dimensions" review for discussion of model dependence.

- 68 AAD 11F use diphoton events with large missing transverse energy in 3.1 pb $^{-1}$ of data produced from pp collisions at $\sqrt{s}=7$ TeV to place a lower bound on the compactifiance. cation scale in a universal extra dimension model with gravitational decays. The bound assumes that the cutoff scale Λ , for the radiative corrections to the Kaluza-Klein masses, satisfies $\Lambda/{\rm M}_c=$ 20. The model parameters are chosen such that the decay γ^* occurs with an appreciable branching fraction.
- ⁶⁹ AAD 11x use diphoton events with large missing transverse energy in 36 pb $^{-1}$ of data produced from pp collisions at $\sqrt{s}=7$ TeV to place a lower bound on the compactification scale in a universal extra dimension model with gravitational decays. The bound assumes that the cutoff scale Λ , for the radiative corrections to the Kaluza-Klein masses, satisfies $\Lambda/M_C=20$. The model parameters are chosen such that the decay $\gamma^*\to G\gamma$ occurs with an appreciable branching fraction.

- 70 ABAZOV 10P use diphoton events with large missing transverse energy in 6.3 fb $^{-1}$ of data produced from $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV to place a lower bound on the compactification scale in a universal extra dimension model with gravitational decays. The bound assumes that the cutoff scale Λ , for the radiative corrections to the Kaluza-Viai process at 16 fb. ALM. 30 The scale Λ are produced by the contraction of the scale Λ and Λ are produced by the scale Λ and Λ are produced by the scale Λ . Klein masses, satisfies $\Lambda/\mathrm{M}_c{=}20$. The model parameters are chosen such that the decay
- $\gamma^*
 ightarrow G \, \gamma$ occurs with an appreciable branching fraction. ^1 ABAZOV 09AE use dijet angular distributions in 0.7 fb $^{-1}$ of data from $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV to place a lower bound on the compactification scale.
- $72\,\mathrm{HAISCH}$ 07 use inclusive \overline{B} -meson decays to place a Higgs mass independent bound on the compactification scale 1/R in the minimal universal extra dimension model.
- 73 GOGOLADZE 06 use electroweak precision observables to place a lower bound on the compactification scale in models with universal extra dimensions. Bound assumes a 115 GeV Higgs mass. See their Fig. 3 for the bound as a function of the Higgs mass.
- 74 CORNET 00 translates a bound on the coefficient of the 4-fermion operator $(\overline{\ell}\gamma_{\mu}\tau^a\ell)(\overline{\ell}\gamma^{\mu}\tau^a\ell)$ derived by Hagiwara and Matsumoto into a limit on the mass scale of KK W bosons.
- 75 RIZZO 00 obtains limits from global electroweak fits in models with a Higgs in the bulk (3.8 TeV) or on the standard brane (3.3 TeV).

Limits on Kaluza-Klein Gravitons in Warped Extra Dimensions

This sections places limits on the mass of the first Kaluza-Klein (KK) excitation of the graviton in the warped extra dimension model of Randall and Sundrum. Experimental bounds depend strongly on the warp parameter, k. See the "Extra Dimensions" review for a full discussion

Here we list limits for the value of the warp parameter $k/\overline{M}_P=0.1$.

- 76 AAD 11AD use 1.08 and 1.21 fb $^{-1}$ of data from $p\,p$ collisions at $\sqrt{s}=7$ TeV in the dielectron and dimuon channels, respectively, to place a lower bound on the mass of the lightest graviton. For warp parameter values k/\overline{M}_P between 0.01 to 0.1 the lower limit on the mass of the lightest graviton is between 0.71 and 1.63 TeV. See their Table IV for more details
- To more decials. To more decials, $\sqrt{s}=1.96~{\rm TeV}$ to fata from $p\overline{p}$ collisions at $\sqrt{s}=1.96~{\rm TeV}$ to search for KK gravitons in a warped extra dimension decaying to ZZ dibosons via the eeee, ee $\mu\mu$, $\mu\mu\mu\mu$, eejj, and $\mu\mu$ jj channels. See their Fig. 20 for limits on the cross
- e eee, ee μ i, μ μ μ i, ee jj, and μ μ j channels. See their Fig. 20 for limits on the cross section σ ($G \rightarrow ZZ$) as a function of the graviton mass. 78 AALTONEN 11R uses 5.7 fb⁻¹ of data from $p\bar{p}$ collisions at $\sqrt{s}=1.96$ TeV in the dielectron channel to place a lower bound on the mass of the lightest graviton. It provides combined limits with the diphoton channel analysis of AALTONEN 11U. For warp parameter values $k/\overline{M}p$ between 0.01 to 0.1 the lower limit on the mass of the lightest graviton is between 612 and 1058 GeV. See their Table I for more details. 79 ABAZOV 11H use 5.4 fb⁻¹ of data from $p\bar{p}$ collisions at $\sqrt{s}=1.96$ TeV to place a lower bound on the mass of the lightest graviton. Their 95% C.L. exclusion limit does not include masses less than 300 GeV.
- not include masses less than 300 GeV. 80 CHATRCHYAN 11 use 35 and 40 pb $^{-1}$ of data from pp collisions at $\sqrt{s}=$ 7 TeV in the dielectron and dimuon channels, respectively, to place a lower bound on the mass of the lightest graviton. For a warp parameter value $k/\overline{M}_P=0.05$, the lower limit on the
- mass of the lightest graviton is 0.855 TeV. 81 AALTONEN 10N use 2.9 fb $^{-1}$ of data from $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV to place a lower bound on the mass of the lightest graviton.
- 82 ABAZOV 10F use 5.4 fb $^{-1}$ of data from $p\overline{p}$ collisions at $\sqrt{s}=$ 1.96 TeV to place lower bound on the mass of the lightest graviton. For warp parameter values of k/Mp between 0.01 and 0.1 the lower limit on the mass of the lightest graviton is between 560 and 1050 GeV. See their Fig. 3 for more details.
- 83 AALTONEN 08s use $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV to search for KK gravitons in warped extra dimensions. They search for graviton resonances decaying to four electrons via two Z bosons using 1.1 fb $^{-1}$ of data. See their Fig. 8 for limits on $\sigma \cdot B(G \to ZZ)$ versus the graviton mass.
- ABAZOV 08J use $p T_0$ collisions at $\sqrt{s}=1.96$ TeV to search for KK gravitons in warped extra dimensions. They search for graviton resonances decaying to electrons and photons using 1 fb $^{-1}$ of data. For warp parameter values of k/\overline{M}_P between 0.01 and 0.1 the lower limit on the mass of the lightest excitation is between 300 and 900 GeV. See their Fig. 4 for more details.
- Fig. 4 for more details. 85 AALTONEN 076 use $p\bar{p}$ collisions at $\sqrt{s}=1.96$ TeV to search for KK gravitons in warped extra dimensions. They search for graviton resonances decaying to photons using 1.2 fb^{-1} of data. For warp parameter values of $k/M_P=0.1$, 0.05, and 0.01 the bounds on the graviton mass are 850, 694, and 230 GeV, respectively. See their Fig. 3 for more details. See also AALTONEN 07H.
- details. See also AALTONEN 0/H. 86 AALTONEN 0/H. 86 AALTONEN 07H use $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV to search for KK gravitons in warped extra dimensions. They search for graviton resonances decaying to electrons using $1.3~{\rm fb}^{-1}$ of data. For a warp parameter value of $k/\overline{M}_P=0.1$ the bound on the graviton mass is 807 GeV. See their Fig. 4 for more details. A combined analysis with the diphoton data of AALTONEN 07G yields for $k/\overline{M}_P=0.1$ a graviton mass lower bound of 880 GeV.
- the diphoton data of AALTONEN ore yields for k/mp=0.1 a graviton mass combound of 889 GeV. 87 ABAZOV 05N use $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV to search for KK gravitons in warped extra dimensions. They search for graviton resonances decaying to muons, electrons or photons, using 260 pb $^{-1}$ of data. For warp parameter values of $k/\overline{M}p=0.1,\,0.05,\,\mathrm{and}$

Extra Dimensions, WIMPs and Other Particle Searches

0.01, the bounds on the graviton mass are 785, 650 and 250 GeV respectively. See their Fig. 3 for more details.

88 $^{18}_{18}$. So limited secans. ABULENCIA 05A use $p_{\overline{p}}$ collisions at $\sqrt{s}=1.96$ TeV to search for KK gravitons in warped extra dimensions. They search for graviton resonances decaying to muons or electrons, using 200 pb $^{-1}$ of data. For warp parameter values of $k/\overline{M}_{p}=0.1$, 0.05, and 0.01, the bounds on the graviton mass are 710, 510 and 170 GeV respectives.

Limits on Mass of Radion

This section includes limits on mass of radion, usually in context of Randall-Sundrum models. See the "Extra Dimension Review" for discussion of model dependence.

| VALUE (GeV) | DO CUMENT ID | | TECN | COMMENT |
|-------------------------|----------------------------|-----------|---------|---------------------------------------------------------------------|

WIMPs and Other Particles Searches for

OMITTED FROM SUMMARY TABLE

WIMPS AND OTHER PARTICLE SEARCHES

Revised March 2012 by K. Hikasa (Tohoku University).

We collect here those searches which do not appear in any of the above search categories. These are listed in the following order:

- Galactic WIMP (weakly-interacting massive particle) searches
- 2. Concentration of stable particles in matter
- 3. General new physics searches
- 4. Limits on jet-jet resonance in hadron collisions
- 5. Limits on neutral particle production at accelerators
- 6. Limits on charged particles in e^+e^- collisions
- 7. Limits on charged particles in hadron reactions
- 8. Limits on charged particles in cosmic rays

Note that searches appear in separate sections elsewhere for Higgs bosons (and technipions), other heavy bosons (including W_R , W', Z', leptoquarks, axigluons), axions (including pseudo-Goldstone bosons, Majorons, familons), heavy leptons, heavy neutrinos, free quarks, monopoles, supersymmetric particles, and compositeness. We include specific WIMP searches in the appropriate sections when they yield limits on hypothetical particles such as supersymmetric particles, axions, massive neutrinos, monopoles, etc.

We omit papers on CHAMP's, millicharged particles, and other exotic particles. We no longer list for limits on tachyons and centauros. See our 1994 edition for these limits.

GALACTIC WIMP SEARCHES

Cross-Section Limits for Dark Matter Particles (X^0) on Nuclei

These limits are for weakly-interacting stable particles that may constitute the invisible mass in the galaxy. Unless otherwise noted, a local mass density of 0.3 GeV/cm 3 is assumed; see each paper for velocity distribution assumptions. In the papers the limit is given as a function of the X^0 mass. Here we list limits only for typical mass values of 20 GeV, 100 GeV, and 1 TeV. Specific limits on supersymmetric dark matter particles may be found in the Supersymmetry section.

For $m_{\chi^0}=20~{\rm GeV}$

- ross

- 5 AHMED 11A combine CDMS and EDELWEISS data and give $\sigma < 2.7 imes 10^{-7}$ pb (90% CL) for spin-independent X^0 -nucleon cross section.
- 6 AHMED 11B give limits on spin-independent X^0 -nucleon and spin-dependent X^0 -neutron cross section for $m_{\chi 0}=4$ –12 GeV in the range 10^{-5} – 10^{-3} pb and 10– 10^3 pb, respectively. See their Fig. 3.
- 7 ANGLE 11 give σ < 5×10^{-7} pb (90% CL) for spin-independent X^0 -nucleon cross section. See their Fig. 3 for limits down to $m_{X^0}=4$ GeV.
- 8 APRILE 11 reanalyze APRILE 10 data and give $\sigma~<~7 \times 10^{-8}$ pb (90% CL) for spin-independent X^0 -nucleon cross section.
- 9 APRILE 11B give $\sigma < 2 \times 10^{-8}$ pb (90% CL) for spin-independent X^0 -nucleon cross
- 10 BEHNKE 11 give $\sigma < 0.1$ pb (90% CL) for spin-dependent X^0 -proton cross section with a direction sensitive detector.

 11 HORN 11 perform detector calibration by neutrons. Earlier results are only marginally
- 12 TANAKA 11 search for neutrinos produced by X^0 annihilation in the Sun and give $\sigma~<~1.5\times10^{-2}~{\rm pb}$ (90% CL) (for $m_{\chi^{\,0}}=10~{\rm GeV})$ for spin-dependent $\chi^{\,0}-{\rm proton}$
- cross section, assuming that X^0 pairs annihilate to $b\overline{b}$. 13 AKERIB 10 give $\sigma < 1 \times 10^{-5}$ pb (90% CL) for spin-independent X^0 -nucleon cross section. See their Figs. 10 and 12 for limits extending to X^0 mass of 1 GeV.
- 14 APRILE 10 give $\sigma < 1 imes 10^{-7}$ pb (90% CL) for spin-independent X^0 -nucleon cross
- 15 ARMENGAUD 10 give $\sigma < 2 \times 10^{-6}$ pb (90% CL) for spin-independent X^0 -nucleon cross section.
- 16 FELIZARDO 10 give $\sigma < 4 imes 10^{-5}$ pb (90% CL) for spin-independent X^0 -nucleon
- 17 AHMED 09 give $\sigma < 0.06$ pb (90% CL) for spin-dependent X^0 -neutron cross section.
- 18 ARCHAMBAULT 09 give $\sigma < 0.2$ pb (90% CL) for spin-dependent X^0 -proton cross
- 19 LEBEDENKO 09A give $\sigma <$ 4 (0.04) pb (90% CL) for spin-dependent X^0 -proton (neutron) cross section.
- 20 See their Fig. 6(b) for limits on spin-dependent 0 -neutron cross section for m_{χ^0}
- between 2 and 10 GeV. 21 See their Fig. 2 for cross section limits for $m_{\mbox{$\chi$}0}$ between 4 and 10 GeV.
- $^{22}\,\mathrm{A\,NGLE}$ 08A give $\sigma\,<$ 0.6 (0.007) pb (90% CL) for spin-dependent $\,\mathrm{X}^{\,0}\text{-proton}$ (neutron)
- 23 ALNER 07 give $\sigma < 100$ (0.5) pb (90% CL) for spin-dependent χ^0 -proton (neutron)
- 24 LEE 07A give $\sigma < 1$ (25) pb (90% CL) for spin-dependent $^{\prime}$ 0-proton (neutron) cross
- Section. See also AKERIB 06 give $\sigma <$ 20 (0.3) pb (90% CL) for spin-dependent X^0 -proton (neutron) cross section. See also AKERIB 05. 26 SHIMIZU 06A give $\sigma <$ 2 (30) pb (90% CL) for spin-dependent X^0 -proton (neutron)
- cross section. 27 ALNER 05 give σ < 0.5 (60) pb (90% CL) for spin-dependent X^0 -proton (neutron) cross section

- 28 BARNABE-HEIDER 05 give $\sigma~<$ 1.5 (20) pb (90% CL) for spin-dependent X^0 -proton (neutron) cross section.
- $^{29}\, {\rm BENOIT}$ 05 give $\sigma~<$ 10 pb (90% CL) for spin-dependent X^0 -neutron cross section.
- 30 GIRARD 05 give $\sigma < 1.5$ pb (90% CL) for spin-dependent X^0 -proton cross section.
- 31 KLAPDOR-KLEINGROTHAUS 05 give σ $\,<$ 4 pb (90% CL) for spin-dependent X^0 neutron cross section.
- 32 MIUCHI 03 give model-independent limit σ <35 pb (90% CL) for spin-dependent X^0 proton cross section.
- 33 TAKEDA 03 give model-independent limit $\sigma < 0.03~(0.6)\,\mathrm{nb}~(90\%$ CL) for spindependent X^0 -proton (neutron) cross section.
- ³⁴ ANGLOHER 02 limit is for spin-dependent WIMP-Aluminum cross section.
- $^{35}\,\mathrm{BENOIT}$ 00 find four event categories in Ge detectors and suggest that low-energy surface nuclear recoils can explain anomalous events reported by UKDMC and Saclay
- ³⁶ KLIMENKO 98 limit is for inelastic scattering X^0 ⁷³ Ge $\to X^0$ ⁷³ Ge* (13.26 keV). ³⁷ BELLI 96 limit for inelastic scattering X^0 ¹²⁹Xe $\to X^0$ ¹²⁹Xe*(39.58 keV).
- 38 BELLI 96c use background subtraction and obtain $\sigma <$ 150 pb (< 1.5 fb) (90% CL) for spin-dependent (independent) X^0 -proton cross section. The confidence level is from R. Bernabei, private communication, May 20, 1999.
- 39 BERNABEI 96 use pulse shape discrimination to enhance the possible signal. The limit here is from R. Bernabei, private communication, September 19, 1997.
- $^{
 m 40}\,{\rm SARSA}$ 96 search for annual modulation of WIMP signal. See SARSA 97 for details of the analysis. The limit here is from M.L. Sarsa, private communication, May 26, 1997.
- 41 SMITH 96 use pulse shape discrimination to enhance the possible signal. A dark matter density of 0.4 GeV cm⁻³ is assumed.
- 42 GARCIA 95 limit is from the event rate. A weaker limit is obtained from searches for
- diurnal and annual modulation.

 43 SNOWDEN-IFFT 95 look for recoil tracks in an ancient mica crystal. Similar limits are also given for ²⁷Al and ²⁸Si. See COLLAR 96 and SNOWDEN-IFFT 96 for discussion on potential backgrounds.
- on potential absorptions.

 44 REUSSER 91 limit here is changed from published (0.04) after reanalysis by authors.

 J.L. Vuilleumier, private communication, March 29, 1996.

- 1 AALSETH 11 give $\sigma < 2 \times 10^{-4}$ pb (90% CL) for spin-independent X^0 -nucleon cross
- 2 AHLEN 11 give $\sigma <~2 \times 10^3$ pb (90% CL) for spin-dependent $\it X^0$ -proton cross section.
- 3 AHMED 11 search for X^0 inelastic scattering. See their Figs. 8–10 for limits
- 4 AHMED 11A combine CDMS and EDELWEISS data and give $\sigma~<~3.3\times10^{-8}$ pb (90% CL) for spin-independent X^0 -nucleon cross section.
- 5 AJELLO 11 search for e^\pm flux from X^0 annihilations in the Sun. Models in which X^0 annihilates into an intermediate long-lived weakly interacting particles or X^0 scatters inelastically are constrained. See their Figs. 6–8 for limits.
- 6 APRILE 11 reanalyze APRILE 10 data and give $\sigma~<~3 imes 10^{-8}$ pb (90% CL) for spin-independent x^0 -nucleon cross section.
- $^7\mathrm{APRILE}\ 11\mathrm{A}$ search for X^0 inelastic scattering. See their Figs. 2 and 3 for limits.
- ⁸APRILE 11B give $\sigma < 1 \times 10^{-8}$ pb (90% CL) for spin-independent X^0 -nucleon cross
- section. 9 ARMENGAUD 11 give $\sigma < 5 \times 10^{-8}$ pb (90% CL) for spin-independent X^0 -nucleon cross section. Supersedes ARMENGAUD 10. A limit on inelastic cross section is also
- 10 BEHNKE 11 give $\sigma < 0.07$ pb (90% CL) for spin-dependent X^0 -proton cross section
- with a direction sensitive detector.

 11 HORN 11 perform detector calibration by neutrons. Earlier results are only marginally
- σ = 2.7 × 10⁻⁴ (4.5 × 10⁻³) pb (90% CL) for spin-dependent X^0 -proton cross section, if X^0 pairs annihilate to $W^+W^-(b\overline{b})$.
- 13 AKERIB 10 give $\sigma < 9 \times 10^{-6}$ pb (90% CL) for spin-independent X^0 -nucleon cross
- section. $^{14}{\rm A\,KIMOV}$ 10 give cross section limits for inelastically scattering dark matter. See their
- 15 APRILE 10 give $\sigma < 5 imes 10^{-8}$ pb (90% CL) for spin-independent X^0 -nucleon cross
- 16 ARMENGAUD 10 give $\sigma < 1 \times 10^{-7}$ pb (90% CL) for spin-independent X^0 -nucleon
- 17 FELIZARDO 10 give $\sigma < 3 imes 10^{-5}$ pb (90% CL) for spin-independent X^0 -nucleon cross section. See their Fig. 3 for limits on spin-dependent proton/neutron couplings for X^0 mass of 50 GeV.
- 18 MIUCHI 10 give $\sigma < ~6 imes 10^3$ pb (90% CL) for spin-dependent X^0 -proton cross section
- with a direction sensitive detector. $^{19}{\rm AHMED}$ 09 give $\sigma <$ 0.02 pb (90% CL) for spin-dependent $\it X^0$ -neutron cross section.
- 20 ANGLE 09 search for X^0 inelastic scattering. See their Fig. 4 for limits.
- $^{21}\,\mathrm{ARCHAMBAULT}$ 09 give $\sigma<$ 0.4 pb (90% CL) for spin-dependent $X^0\mathrm{-proton}$ cross
- 22 LEBEDENKO 09A give $\sigma < 0.8~(0.01)$ pb (90% CL) for spin-dependent X^0 -proton (neutron) cross section.
- 23 ANGLE 08A give σ < 0.9 (0.01) pb (90% CL) for spin-dependent X^0 -proton (neutron) cross section. 24 BEDNYAKOV 08 reanalyze KLAPDOR-KLEINGROTHAUS 05 and BAUDIS 01 data and
- give $\sigma < 0.05$ pb (90% CL) for spin-dependent X^0 -neutron cross section.
- 25 ALNER 07 give $\sigma < 15$ (0.08) pb (90% CL) for spin-dependent X^0 -proton (neutron)
- 26 LEE 07A give $\sigma < 0.2$ (6) pb (90% CL) for spin-dependent X^0 -proton (neutron) cross 27 section. Or give $\sigma <~1\times 10^4~{\rm pb}$ (90% CL) for spin-dependent $X^0\text{-proton}$ cross section
- with a direction-sensitive detector. with a direction-sensitive detector.

 28 AKERIB 80 6 give $\sigma < 5$ (0.07) pb (90% CL) for spin-dependent X^0 -proton (neutron)

 across section. See also AKERIB 05.
- ²⁹ SHIMIZU 06A give $\sigma < 2$ (30) pb (90% CL) for spin-dependent X^0 -proton (neutron)
- $_{30}$ cross section. $_{30}$ ALNER 05 give σ $\,<$ 0.3 (10) pb (90% CL) for spin-dependent X^0 -proton (neutron)
- 31 BARNABE-HEIDER 05 give σ < 2 (30) pb (90% CL) for spin-dependent X^0 -proton (neutron) cross section.
- 32 BENOIT 05 give σ < 100 (0.7) pb (90% CL) for spin-dependent X^0 -proton (neutron)
- cross section. $^{33}\,\rm GIRARD$ 05 give $\sigma < 1.5$ pb (90% CL) for spin-dependent X^0 -proton cross section.
- 34 GIULIANI 05 analyzes the spin-independent X^0 -nucleon cross section limits with both isoscalar and isovector couplings. See Figs. 3 and 4 for limits on the couplings.
- 35 GIULIANI 05A analyze available data and give combined limits $\sigma~<$ 0.7 (0.2) pb for spin-dependent X^0 -proton (neutron) cross section.
- 36 KLAPDOR-KLEINGROTHAUS 05 give $\sigma~<$ 1.5 pb (90% CL) for spin-dependent $\,X^0$ neutron cross section.
- 37 GIULIANI 04 reanalyze COLLAR 00 data and give limits for spin-dependent 30 -proton and neutron couplings.

- 38 GIULIANI 04A gives limits for spin-dependent X^0 -proton and neutron couplings from existing data. $^{\rm 39}\,\rm MIUCHI$ 03 give model-independent limit for spin-dependent $X^0\text{-proton}$ and neutron
- cross sections. See their Fig. 5.
- 40 MIUCHI 03 give model-independent limit σ <35 pb (90% CL) for spin-dependent X 0 proton cross section.
- 41 TAKEDA 03 give model-independent limit σ < 0.04 (0.8) nb (90% CL) for spindependent X^0 -proton (neutron) cross section.
- ⁴² ANGLOHER 02 limit is for spin-dependent WIMP-Aluminum cross section.
- 43 BELLI 02 discuss dependence of the extracted WIMP cross section on the assumptions of the galactic halo structure.
- 44 BERNABEI 02c analyze the DAMA data in the scenario in which χ^0 scatters into a slightly heavier state as discussed by SMITH 01.
- 45 GREEN 02 discusses dependence of extracted WIMP cross section limits on the assumptions of the galactic halo structure.
- 46 ULLIO 01 disfavor the possibility that the BERNABEI 99 signal is due to spin-dependent WIMP coupling.
- 47 BENOIT 00 find four event categories in Ge detectors and suggest that low-energy surface nuclear recoils can explain anomalous events reported by UKDMC and Saclay
- ⁴⁸BERNABEI 00D limit is for inelastic scattering X^{0129} Xe $\rightarrow X^{0129}$ Xe (39.58 keV).
- 49 A MBROSIO 99 search for upgoing muon events induced by neutrinos originating from WIMP annihilations in the Sun and Earth.
- 50 BRHLIK 99 discuss the effect of astrophysical uncertainties on the WIMP interpretation of the BERNABEI 99 signal.
- ⁵¹ KLIMENKO 98 limit is for inelastic scattering $X^{0.73}$ Ge $\rightarrow X^{0.73}$ Ge* (13.26 keV).
- 52 KLIMENKO 98 limit is for inelastic scattering X^0 73 Ge \rightarrow X^0 73 Ge* (66.73 keV). 53 BELLI 96 limit for inelastic scattering X^0 129 Xe \rightarrow X^0 129 Xe*(39.58 keV).
- 54 BELLI 96c use background subtraction and obtain $\sigma <$ 0.35 pb (< 0.15 fb) (90% CL) for spin-dependent (independent) X^0 -proton cross section. The confidence level is from R. Bernabei, private communication, May 20, 1999.
- $^{55}\,\mathrm{BERNABEI}$ 96 use pulse shape discrimination to enhance the possible signal. The limit here is from R. Bernabei, private communication, September 19, 1997.
- ⁵⁶ SARSA 96 search for annual modulation of WIMP signal. See SARSA 97 for details of the analysis. The limit here is from M.L. Sarsa, private communication, May 26, 1997
- 57 SMITH 96 use pulse shape discrimination to enhance the possible signal. A dark matter density of 0.4 GeV cm⁻³ is assumed.
- 58 GARCIA 95 limit is from the event rate. A weaker limit is obtained from searches for diurnal and annual modulation.
- 59 SNOWDEN-IFFT 95 look for recoil tracks in an ancient mica crystal. Similar limits are also given for ²⁸ Si. See COLLAR 96 and SNOWDEN-IFFT 96 for discussion on potential backgrounds.
- 60 BECK 94 uses enriched 76 Ge (86% purity).
- 61 REUSSER 91 limit here is changed from published (0.3) after reanalysis by authors. J.L. Vuilleumier, private communication, March 29, 1996.

For $m_{\chi^0} = 1 \text{ TeV}$

- ¹ AHLEN 11 give $\sigma < 8 \times 10^3$ pb (90% CL) for spin-dependent X^0 -proton cross section. ²AHMED 11 search for X^0 inelastic scattering. See their Figs. 8–10 for limits.
- 3 AHMED 11A combine CDMS and EDELWEISS data and give $\sigma < 1.5 \times 10^{-7}$ pb (90% CL) for spin-independent X^0 -nucleon cross section.
- $^4\,\mathrm{APRILE}$ 11 reanalyze APRILE 10 data and give $\sigma~<~2\times10^{-7}$ pb (90% CL) for spin-independent x^0 -nucleon cross section.
- 5 APRILE 11A search for $X^{\,0}$ inelastic scattering. See their Figs. 2 and 3 for limits.
- 6 APRILE 11B give $\sigma < 8 \times 10^{-8}$ pb (90% CL) for spin-independent X^0 -nucleon cross
- 7 ARMENGAUD 11 give $\sigma < 2 imes 10^{-7}$ pb (90% CL) for spin-independent X^0 -nucleon cross section. Supersedes ARMENGAUD 10. A limit on inelastic cross section is also given.
- 8 BEHNKE 11 give $\sigma <$ 0.4 pb (90% CL) for spin-dependent X^0 -proton cross section with a direction sensitive detector.

 9 HORN 11 perform detector calibration by neutrons. Earlier results are only marginally
- affected. $^{10}\,\mathrm{TANAKA}$ 11 search for neutrinos produced by $\mathrm{X}^{\,0}$ annihilation in the Sun and give TAINWALL 1 section in the solin and give $\sigma < 2 \times 10^{-3} \ (2 \times 10^{-2})$ pb (90% CL) for spin-dependent X^0 -proton cross section, if X^0 pairs annihilate to W^+W^- ($b\bar{b}$).
- 11 ABBASI 10 search for u_{μ} from annihilations of Kaluza-Klein photon dark matter in the Sun and give $\sigma < 1 \times 10^{-3}$ pb (90% CL) for spin-dependent X^0 -proton cross section. ¹²APRILE 10 give $\sigma < 4 \times 10^{-7}$ pb (90% CL) for spin-independent X^0 -nucleon cross
- 13 ARMENGAUD 10 give $\sigma < 6 \times 10^{-7}$ pb (90% CL) for spin-independent X^0 -nucleon
- cross section. 14 MIUCHI 10 give $\sigma<~2\times10^4$ pb (90% CL) for spin-dependent X^0 -proton cross section
- with a direction sensitive detector. 15 ABBASI 09B search for neutrinos produced by X^0 annihilation in the Sun and give $\sigma < 8.7 \times 10^{-4}~(2.2 \times 10^{-2})$ pb (90% CL) for spin-dependent X^0 -proton cross section, if X^0 pairs annihilate to $W^+W^-(b\overline{b})$.
- $^{10}\rm AHMED$ 09 give $\sigma < 0.2$ pb (90% CL) for spin-dependent X^0 -neutron cross section. Superseded by AHMED 10.
- 17 ARCHAMBAULT 09 give $\sigma <$ 3 pb (90% CL) for spin-dependent X^0 -proton cross sec-
- 18 LEBEDENKO 09A give $\sigma <$ 6 (0.1) pb (90% CL) for spin-dependent X 0 -proton (neutron)
- 19 ANGLE 08A give σ < 8 (0.1) pb (90% CL) for spin-dependent X^0 -proton (neutron) cross section 20 BEDNYAKOV 08 reanalyze KLAPDOR-KLEINGROTHAUS 05 and BAUDIS 01 data and
- give $\sigma < 0.25$ pb (90% CL) for spin-dependent X^0 -neutron cross section. 21 ALNER 07 give σ < 100 (0.6) pb (90% CL) for spin-dependent X^0 -proton (neutron)
- cross section. 22 LEE 07A give $\sigma < 0.8$ (30) pb (90% CL) for spin-dependent X^0 -proton (neutron) cross
- 2section. 23 MIUCHI 07 give $\sigma < 4 \times 10^4$ pb (90% CL) for spin-dependent X^0 -proton cross section with a direction-sensitive detector. 24 AKERIB 06 give $\sigma < 30$ (0.5) pb (90% CL) for spin-dependent X^0 -proton (neutron) cross section. See also AKERIB 05.
- 25 ALNER 05 give σ < 1.5 (40) pb (90% CL) for spin-dependent X^0 -proton (neutron) cross section
- 26 BARNABE-HEIDER 05 give $\sigma < 15$ (200) pb (90% CL) for spin-dependent X^0 -proton (neutron) cross section.
- 27 BENOIT 05 give σ < 600 (4) pb (90% CL) for spin-dependent X^0 -proton (neutron) cross section. ²⁸ GIRARD 05 give $\sigma < 10$ pb (90% CL) for spin-dependent X^0 -proton cross section.
- 29 KLAPDOR-KLEINGROTHAUS 05 give $\sigma < 10$ pb (90% CL) for spin-dependent X^0 -
- neutron cross section. 30 MIUCHI 03 give model-independent limit σ <260 pb (90% CL) for spin-dependent X^0 -proton cross section.
- 31 TAKEDA 03 give model-independent limit $\sigma < 0.15$ (4) nb (90% CL) for spin-dependent X^0 -proton (neutron) cross section.
- 32 ANGLOHER 02 limit is for spin-dependent WIMP-Aluminum cross section.
- 33 BENOIT 00 find four event categories in Ge detectors and suggest that low-energy surface nuclear recoils can explain anomalous events reported by UKDMC and Saclay Nal experiments.
- 34 BERNABEI 99D search for SIMPs (Strongly Interacting Massive Particles) in the mass range $10^3 - 10^{16}$ GeV. See their Fig. 3 for cross-section limits.
- 35 DERBIN 99 search for SIMPs (Strongly Interacting Massive Particles) in the mass range $10^2 - 10^{14}$ GeV. See their Fig. 3 for cross-section limits. ³⁶ KLIMENKO 98 limit is for inelastic scattering χ^0 73 Ge $\to \chi^0$ 73 Ge* (13.26 keV).
- 37 KLIMENKO 98 limit is for inelastic scattering $X^{0.73}$ Ge $\rightarrow X^{0.73}$ Ge* (66.73 keV).

- ³⁸BELLI 96 limit for inelastic scattering X_0^0 ¹²⁹Xe $\rightarrow X_0^0$ ¹²⁹Xe*(39.58 keV).
- ³⁹BELLI 96 limit for inelastic scattering X^0 ¹²⁹Xe $\rightarrow X^0$ ¹²⁹Xe*(236.14 keV).
- 40 BELLI 96c use background subtraction and obtain $\sigma <$ 0.7 pb (< 0.7 fb) (90% CL) for spin-dependent (independent) χ^0 -proton cross section. The confidence level is from R. Bernabei, private communication, May 20, 1999.
- $^{
 m 41}$ BERNABEI 96 use pulse shape discrimination to enhance the possible signal. The limit
- here is from R. Bernabei, private communication, September 19, 1997. 42 SARSA 96 search for annual modulation of WIMP signal. See SARSA 97 for details of the analysis. The limit here is from M.L. Sarsa, private communication, May 26, 1997.
- 43 SMITH 96 use pulse shape discrimination to enhance the possible signal. A dark matter density of 0.4 GeV cm $^{-3}$ is assumed.
- 44 GARCIA 95 limit is from the event rate. A weaker limit is obtained from searches for
- 45 SNOWDEN-IFFT 95 look for recoil tracks in an ancient mica crystal. Similar limits are also given for ²⁷Al and ²⁸Si. See COLLAR 96 and SNOWDEN-IFFT 96 for discussion on potential backgrounds.

 46 BECK 94 uses enriched 76 Ge (86% purity).
- TREUSER 91 limit here is changed from published (5) after reanalysis by authors. J.L. Vuilleumier, private communication, March 29, 1996.

- X^0 Annihilation Cross Section -

Limits are on σv for X^0 pair annihilation at threshold.

- 1 AAD 11AG search for dijet resonances in $\it pp$ collisions at $\it E_{\rm cm}=$ 7 TeV with L $_{\rm =36\,pb^{-1}}.$ Limits on number of events for $\it m=0.6$ –4 TeV are given in their Table 3.
- ²AALTONEN 11M find a peak in two jet invariant mass distribution around 140 GeV in W + 2 jet events in $ho \overline{
 ho}$ collisions at $E_{
 m cm} =$ 1.96 TeV with L = 4.3 fb $^{-1}$
- 3 ABAZOV 111 search for two-jet resonances in W+2 jet events in $p\overline{p}$ collisions at $E_{\rm cm}$ = 1.96 TeV with L = 4.3 fb $^{-1}$ and give limits $\sigma < (2.6-1.3)$ pb (95% CL) for m=110-170 GeV. The result is incompatible with AALTONEN 11M.
- ⁴ AAD 10 search for narrow dijet resonances in pp collisions at $E_{cm} = 7$ TeV with L = 315 nb $^{-1}$. Limits on the cross section in the range 10–10 3 pb is given for m=
- 5 KHACHATRYAN 10 search for narrow dijet resonances in pp collisions at $E_{\rm cm}=7\,{\rm TeV}$ with L = $2.9~{\rm pb}^{-1}$. Limits on the cross section in the range 1–300 pb is given for m=0.5–2.6 TeV separately in the final states qq, qg, and gg.
- 6 ABE 99F search for narrow $b\,\overline{b}$ resonances in $p\,\overline{p}$ collisions at $E_{\rm cm}{=}1.8$ TeV. Limits on $\sigma(p\overline{p}\to X+ \text{ anything})\times \text{B}(X\to b\overline{b})$ in the range 3–10 3 pb (95%CL) are given for $m_X=$ 200–750 GeV. See their Table I.
- ⁷ABE 97G search for narrow dijet resonances in $p\overline{p}$ collisions with 106 pb⁻¹ of data at $E_{\rm cm}=1.8\,{\rm TeV}$. Limits on $\sigma(p\,\overline{p}\to X+{\rm anything})\cdot{\rm B}(X\to jj)$ in the range $10^4-10^{-1}\,{\rm pb}$ (95 %CL) are given for dijet mass m=200–1150 GeV with both jets having $|\eta| <$ 2.0 and the dijet system having $|\cos\theta^*| < 0.67$. See their Table I for the list of limits. Supersedes
- ABE 93G. 8 ABE 93G gives cross section times branching ratio into light (d, u, s, c, b) quarks for Γ = 0.02 M. Their Table II gives limits for M = 200–900 GeV and Γ = (0.02–0.2) M.

- $^{
 m 1}$ ADAMS 97B search for a hadron-like neutral particle produced in p N interactions, which decays into a ho^0 and a weakly interacting massive particle. Upper limits are given for the ratio to K_L production for the mass range 1.2–5 GeV and lifetime 10^{-9} – 10^{-4} s. See also our Light Gluino Section.
- 2 GALLAS 95 limit is for a weakly interacting neutral particle produced in 800 GeV/c ρ N interactions decaying with a lifetime of 10^{-4} – 10^{-8} s. See their Figs. 8 and 9. Similar limits are obtained for a stable particle with interaction cross section 10^{-29} – 10^{-33} cm².
- 3 AKESSON 91 limit is from weakly interacting neutral long-lived particles produced in pN reaction at 450 GeV/c performed at CERNSPS. Bourquin-Gaillard formula is used as the production model. The above limit is for $\tau>10^{-7}$ s. For $\tau>10^{-9}$ s, $\sigma<10^{-30}$ cm $^{-2}$ /nucleon is obtained.
- 4 BADIER 86 looked for long-lived particles at 300 GeV π^- beam dump. The limit applies for nonstrongly interacting neutral or charged particles with mass >2 GeV. The limit applies for particle modes, $\mu^+\pi^-$, $\mu^+\mu^-$, $\pi^+\pi^-X$, $\pi^+\pi^-\pi^\pm$ etc. See their figure 5 for the contours of limits in the mass- τ plane for each mode.
- 5 GUSTAFSON 76 is a 300 GeV FNAL experiment looking for heavy ($m>\!\!2$ GeV) long-lived neutral hadrons in the M4 neutral beam. The above typical value is for m=3 GeV and assumes an interaction cross section of 1 mb. Values as a function of mass and interaction cross section are given in figure 2

Production of New Penetrating Non- ν Like States in Beam Dump

- 1 SAITO 90 candidates carry about 450 MeV/nucleon. Cannot be accounted for by conventional backgrounds. Consistent with strange quark matter hypothesis. 2 MINCER 85 is high statistics study of calorimeter signals delayed by 20–200 ns. Cali-
- bration with AGS beam shows they can be accounted for by rare fluctuations in signals from low-energy hadrons in the shower. Claim that previous delayed signals including BJORNBOE 68, DARDO 72, BHAT 82, SAKUYAMA 83B below may be due to this fake
- effect.

 3 SAKUYAMA 83B analyzed 6000 extended air shower events. Increase of delayed particles and change of lateral distribution above 10¹⁷ eV may indicate production of very heavy parent at top of atmosphere.
- A BHAT 82 observed 12 events with delay $> 2.\times 10^{-8}$ s and with more than 40 particles. 1 eV has good hadron shower. However all events are delayed in only one of two detectors in cloud chamber, and could not be due to strongly interacting massive particle.
- MARINI 82 applied PEP-counter for TOF. Above limit is for velocity = 0.54 of light. Limit is inconsistent with YOCK 80 YOCK 81 events if isotropic dependence on zenith angle is assumed.
- 6 YOCK 81 saw another 3 events with $\mathit{Q}=\pm 1$ and m about 4.5 m_{p} as well as 2 events with m>5.3 m_p , $Q=\pm0.75\pm0.05$ and m>2.8 m_p , $Q=\pm0.70\pm0.05$ and 1 event with $m=(9.3\pm3.)m_p$, $Q=\pm0.89\pm0.06$ as possible heavy candidates.
- ⁷ YOCK 80 events are with charge exactly or approximately equal to unity.
- 8 BHAT 78 is at Kolar gold fields. Limit is for $au > 10^{-6}$ s
- ⁹YOCK 74 events could be tritons.

- $^{1}\,\mathrm{A\,MBROSIO}$ 00B searched for quark matter ("nuclearites") in the velocity range $(10^{-5}-1)$ c. The listed limit is for 2×10^{-3} c.
- 2 ASTONE 93 searched for quark matter ("nuclearites") in the velocity range ($^{10-3}$ -1) c. Their Table 1 gives a compilation of searches for nuclearites.
- Their fable I gives a compliation of searches for necessities. 3 AHLEN 92 searched for quark matter ("nuclearites"). The bound applies to velocity $< 2.5 \times 10^{-3} c$. See their Fig. 3 for other velocity/c and heavier mass range. 4 NAKAMURA 91 searched for quark matter in the velocity range $(4 \times 10^{-5} 1) c$.
- 5 ORITO 91 searched for quark matter. The limit is for the velocity range $(10^{-4}-10^{-3})$ c.
- 6 kHO 83 searched for quark matter. The limit is not the velocity range (10 $^{-10}$) c. 6 kHO 88 searched for quark matter ("nuclearites") in the velocity range (2.5 \times 10 $^{-3}$ -1) c. A less stringent limit of 5.8 \times 10 $^{-11}$ applies for (1–2.5) \times 10 $^{-3}$ c.

- 7 BARISH 87 searched for quark matter ("nuclearites") in the velocity range (2.7 imes $10^{-4} - 5 \times 10^{-3}$) c.
- 8 NAKAMURA 85 at KEK searched for quark-matter. These might be lumps of strange quark matter with roughly equal numbers of $u,\,d,\,s$ quarks. These lumps or nuclearites were assumed to have velocity of $(10^{-4}-10^{-3})\,c$.
- $^9\,\text{ULLMA\,N}$ 81 is sensitive for heavy slow singly charge particle reaching earth with vertical velocity 100-350 km/s.
