LIGHT UNFLAVORED MESONS (S=C=B=0)

For I = 1 (π, b, ρ, a) : $u\overline{d}$, $(u\overline{u} - d\overline{d})/\sqrt{2}$, $d\overline{u}$; for I = 0 $(\eta, \eta', h, h', \omega, \phi, f, f')$: $c_1(u\overline{u} + d\overline{d}) + c_2(s\overline{s})$

$$I^{G}(J^{P}) = 1^{-}(0^{-})$$

We have omitted some results that have been superseded by later experiments. The omitted results may be found in our 1988 edition Physics Letters **B204** 1 (1988).

π^{\pm} MASS

The most accurate charged pion mass measurements are based upon xray wavelength measurements for transitions in π^- -mesonic atoms. The observed line is the blend of three components, corresponding to different K-shell occupancies. JECKELMANN 94 revisits the occupancy question, with the conclusion that two sets of occupancy ratios, resulting in two different pion masses (Solutions A and B), are equally probable. We choose the higher Solution B since only this solution is consistent with a positive mass-squared for the muon neutrino, given the precise muon momentum measurements now available (DAUM 91, ASSAMAGAN 94, and ASSAM-AGAN 96) for the decay of pions at rest. Earlier mass determinations with pi-mesonic atoms may have used incorrect K-shell screening corrections.

Measurements with an error of $> 0.005\,$ MeV have been omitted from this Listing

- 1 LENZ 98 result does not suffer K-electron configuration uncertainties as does JECKEL-
- ² JECKELMANN 94 Solution B (dominant 2-electron K-shell occupancy), chosen for consistency with positive $m_{
 u_{\mu}}^2$
- $^3 \, {\rm ASSAMAGAN}$ 96 measures the μ^+ momentum p_μ in $\pi^+ \to \ \mu^+ \, \nu_\mu$ decay at rest to be 29.79200 \pm 0.00011 MeV/c. Combined with the μ^+ mass and the assumption $m_{
 u_{\mu}}$
- = 0, this gives the π^+ mass above; if $\textit{m}_{\nu_{\mu}}>$ 0, \textit{m}_{π^+} given above is a lower limit.
- Combined instead with m_{μ} and (assuming $^{'}\mathit{CPT})$ the π^- mass of JECKELMANN 94,
- p_{μ} gives an upper limit on $m_{\nu_{\mu}}$ (see the ν_{μ}). 4 JECKELMANN 94 Solution A (small 2-electron K-shell occupancy) in combination with either the DAUM 91 or ASSAMAGAN 94 pion decay muon momentum measurement yields a significantly negative $m_{
 u_{\mu}}^2$. It is accordingly not used in our fits.
- 5 The DAUM 91 value includes the ABELA 84 result. The value is based on a measurement of the μ^+ momentum for π^+ decay at rest, $\rho_\mu=$ 29.79179 \pm 0.00053 MeV, uses $m_\mu=$ 105.658389 \pm 0.000034 MeV, and assumes that $m_{\nu_\mu}=$ 0. The last assumption means that in fact the value is a lower limit.
- that in fact the value is a lower limit. 6 JECKELMANN 868 gives $m_{e}/m_{e}=273.12677(71)$. We use $m_{e}=0.51099906(15)$ MeV from COHEN 87. The authors note that two solutions for the probability distribution of K-shell occupancy fit equally well, and use other data to choose the lower of the two
- possible π^\pm masses. 7 These values are scaled with a new wavelength-energy conversion factor $\textit{V}\lambda =$ $1.23984244(37) imes 10^{-6}$ eV m from COHEN 87. The LU 80 screening correction relies upon a theoretical calculation of inner-shell refilling rates.
- 8 This MARUSHENKO 76 value used at the authors' request to use the accepted set of calibration γ energies. Error increased from 0.0017 MeV to include QED calculation error of 0.0017 MeV (12 ppm).

Lepton Family number (LF) or Lepton number (L) violating modes

- [a] Measurements of $\Gamma(e^+\nu_e)/\Gamma(\mu^+\nu_\mu)$ always include decays with γ 's, and measurements of $\Gamma(e^+\nu_e\,\gamma)$ and $\Gamma(\mu^+\nu_\mu\,\gamma)$ never include low-energy γ 's. Therefore, since no clean separation is possible, we consider the modes with γ 's to be subreactions of the modes without them, and let $[\Gamma(e^+
 u_e)$ + $\Gamma(\mu^+ \nu_\mu)]/\Gamma_{\text{total}} = 100\%$.
- [b] See the Particle Listings below for the energy limits used in this measurement; low-energy γ 's are not included.
- [c] Derived from an analysis of neutrino-oscillation experiments.

FORM FACTORS FOR RADIATIVE PION AND KAON DECAYS

Updated August 2009 by W. Bertl (Paul Scherrer Inst.)

The radiative decays, $\pi^{\pm} \to l^{\pm} \nu \gamma$ and $K^{\pm} \to l^{\pm} \nu \gamma$, with l standing for an e or a μ , and γ for a real or virtual photon (e^+e^-) pair), provide a powerful tool to investigate the hadronic structure of pions and kaons. The structure-dependent part SD_i of the amplitude describes the emission of photons from virtual hadronic states, and is parametrized in terms of form factors F_i , with i = V, A (vector, axial vector), in the standard description [1,2]. Exotic, non-standard contributions like i = T, S (tensor, scalar) have also been considered, and we shall discuss them below. Apart from the SD terms, the decay amplitude depends also on Inner Bremsstrahlung IB from the weak decay $\pi^{\pm}(K^{\pm}) \to l^{\pm}\nu$ accompanied by the photon radiated from the external charged particles. Naturally, experiments try to optimize their kinematics so as to minimize the "trivial" IB part of the amplitude.

The SD amplitude in its standard form is given as

$$M(SD_V) = \frac{-eG_F V_{qq'}}{\sqrt{2}m_P} \epsilon^{\mu} l^{\nu} F_V^P \epsilon_{\mu\nu\sigma\tau} k^{\sigma} q^{\tau}$$
 (1)

$$M(SD_A) = \frac{-ieG_F V_{qq'}}{\sqrt{2}m_P} \epsilon^{\mu} l^{\nu} \{ F_A^P [(qk - k^2)g_{\mu\nu} - q_{\mu}k_{\nu}] + R^P k^2 g_{\mu\nu} \},$$
 (2)

which contains an additional axial form factor \mathbb{R}^P which only can be accessed if the photon remains virtual. $V_{qq'}$ is the Cabibbo-Kobayashi-Maskawa mixing-matrix element; ϵ^{μ} is the polarization vector of the photon (or the effective vertex, ϵ^{μ} $(e/k^2)\overline{u}(p_-)\gamma^{\mu}v(p_+)$, of the e^+e^- pair); $\ell^{\nu}=\overline{u}(p_{\nu})\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}(1-e^+k^2)\overline{u}(p_-)\gamma^{\nu}$ $\gamma_5)v(p_\ell)$ is the lepton-neutrino current; q and k are the meson

and photon four-momenta ($k = p_+ + p_-$ for virtual photons); and P stands for π or K.

The pion vector form factor, F_V^π , is related via CVC (Conserved Vector Current) to the $\pi^0 \to \gamma \gamma$ decay width by $|F_V^\pi| = (1/\alpha) \sqrt{2\Gamma_{\pi^0 \to \gamma \gamma}/\pi m_{\pi^0}}$ [3]. The resulting value, $F_V^\pi(0) = 0.0259(9)$, has been confirmed by calculations based on chiral perturbation theory (χPT) [4], and by two experiments given in the Listings below. A recent experiment by the PIBETA collaboration [5] obtained an F_V that is in excellent agreement with the CVC hypothesis. It also measured the slope parameter a in $F_V^\pi(s) = F_V^\pi(0)(1+a\cdot s)$, where $s = (1-2E_\gamma/m_\pi)$, and E_γ is the gamma energy in the pion rest frame: $a = 0.095 \pm 0.058$. A functional dependence on s is expected for all form factors. It becomes non-negligible in the case of $F_V^\pi(s)$ when a wide range of photon momenta is recorded; proper treatment in the analysis of K decays is mandatory.

The form factor, R^P , can be related to the electromagnetic radius, r_P , of the meson [2]: $R^P = \frac{1}{3} m_P f_P \langle r_P^2 \rangle$ using PCAC (Partial Conserved Axial vector Current; f_P is the meson decay constant). In lowest order χPT , the ratio F_A/F_V is related to the pion electric polarizability $\alpha_E = [\alpha/(8\pi^2 m_\pi f_\pi^2)] \times F_A/F_V$ [6]. The calculation of the other form factors, F_A^π, F_V^K , and F_A^K , is model-dependent [1,2,4].

For decay processes where the photon is real, the partial decay width can be written in analytical form as a sum of IB, SD, and IB/SD interference terms INT [1,4]:

$$\frac{d^{2}\Gamma_{P\to\ell\nu\gamma}}{dxdy} = \frac{d^{2}\left(\Gamma_{\rm IB} + \Gamma_{\rm SD} + \Gamma_{\rm INT}\right)}{dxdy}
= \frac{\alpha}{2\pi}\Gamma_{P\to\ell\nu}\frac{1}{(1-r)^{2}} \left\{ IB(x,y) + \frac{1}{r}\left(\frac{m_{P}}{2f_{P}}\right)^{2} \left[(F_{V} + F_{A})^{2}SD^{+}(x,y) + (F_{V} - F_{A})^{2}SD^{-}(x,y) \right] + \frac{m_{P}}{f_{P}} \left[(F_{V} + F_{A})S_{\rm INT}^{+}(x,y) + (F_{V} - F_{A})S_{\rm INT}^{-}(x,y) \right] \right\}.$$
(3)

Here

$$IB(x,y) = \left[\frac{1-y+r}{x^2(x+y-1-r)}\right]$$

$$\left[x^2 + 2(1-x)(1-r) - \frac{2xr(1-r)}{x+y-1-r}\right]$$

$$SD^+(x,y) = (x+y-1-r)\left[(x+y-1)(1-x) - r\right]$$

$$SD^-(x,y) = (1-y+r)\left[(1-x)(1-y) + r\right]$$

$$S_{INT}^+(x,y) = \left[\frac{1-y+r}{x(x+y-1-r)}\right]\left[(1-x)(1-x-y) + r\right]$$

$$S_{INT}^-(x,y) = \left[\frac{1-y+r}{x(x+y-1-r)}\right]\left[x^2 - (1-x)(1-x-y) - r\right]$$

$$(4)$$

where $x = 2E_{\gamma}/m_P$, $y = 2E_{\ell}/m_P$, and $r = (m_{\ell}/m_P)^2$. Recently, formulas (3) and (4) have been extended to describe polarized distributions in radiative meson and muon decays [7].

The "helicity" factor r is responsible for the enhancement of the SD over the IB amplitude in the decays $\pi^{\pm} \to e^{\pm}\nu\gamma$, while $\pi^{\pm} \to \mu^{\pm}\nu\gamma$ is dominated by IB. Interference terms are important for the decay $K^{\pm} \to \mu^{\pm}\nu\gamma$ [8], but contribute only a few percent correction to pion decays. However, they provide the basis for determining the signs of F_V and F_A . Radiative corrections to the decay $\pi^+ \to e^+\nu\gamma$ have to be taken into account in the analysis of the precision experiments. They make up to 4% corrections in the total decay rate [9]. In $\pi^{\pm} \to e^{\pm}\nu e^+e^-$ and $K^{\pm} \to \ell^{\pm}\nu e^+e^-$ decays, all three form factors, F_V^P , F_A^P , and R^P , can be determined [10,11].

We give the experimental π^{\pm} form factors F_V^{π} , F_A^{π} , and R^{π} in the Listings below. In the K^{\pm} Listings, we give the extracted sum $F_A^K + F_V^K$ and difference $F_A^K - F_V^K$, as well as F_V^K , F_A^K and R^K .

Several searches for the exotic form factors F_T^{π} , F_T^K (tensor), and F_S^K (scalar) have been pursued in the past, some of them claiming non-zero results [12,13]. In particular, F_T^{π} has been brought into focus by experimental as well as theoretical work. It was shown that a tensor contribution could destructively interfere with the inner bremsstrahlung amplitude, leading to a substantial reduction of the branching ratio as compared with standard V-A calculations [14]. In addition, a tensor contribution as large as $F_T = -(5.6\pm1.7)\times10^{-3}$ could not be completely ruled out by constraints from other measurements [15]. New high-statistics data from the PIBETA collaboration have been re-analyzed together with an additional data set optimized for low backgrounds in the radiative pion decay. In particular, lower beam rates have been used in order to reduce the accidental background, thereby making the treatment of systematic uncertainties easier and more reliable. The PIBETA analysis now restricts F_T to the range $-5.2 \times 10^{-4} < F_T < 4.0 \times 10^{-4}$ at a 90% confidence limit [5]. This result is in excellent agreement with the most recent theoretical work [4].

Precision measurements of radiative pion and kaon decays are effective tools to study QCD in the non-perturbative region. The structure-dependent form factors have direct relations to (renormalized) coupling constants of chiral perturbation theories. Therefore, they are of interest beyond the scope of radiative decays. On the other hand, the interest in searching for new physics manifesting in exotic form factors F_T or F_S has weakened over the last years mainly for two reasons: (i) on the experimental side, the lack of results confirming the non-zero findings; (ii) on the theoretical side, numerical uncertainties are still too large to allow a clear distinction of exotic and standard contributions at the currently required level. Likely this will change in the future, but meanwhile other processes such as $\pi^+ \to e^+ \nu$ seem to be better suited to search for new physics at the precision frontier, because of the very accurate and reliable theoretical predictions and the more straightforward experimental analysis.

π^0 MEAN LIFE

Most experiments measure the π^0 width which we convert to a lifetime. ATHERTON 85 is the only direct measurement of the π^0 lifetime. Our average based only on indirect measurement yields $(8.30\pm0.19)\times10^{-17}\,\mathrm{s}$. The two Primakoff measurements from 1970 have been excluded from our average because they suffered model-related systematics unknown at the time. More information on the π^0 lifetime can be found in BERN-

[a] Astrophysical and cosmological arguments give limits of order 10^{-13} ; see the Particle Listings below.

CONSTRAINED FIT INFORMATION

An overall fit to 2 branching ratios uses 6 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 =$ 4.6 for 4 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv$ $\Gamma_i/\Gamma_{\mathrm{total}}$. The fit constrains the x_i whose labels appear in this array to sum to

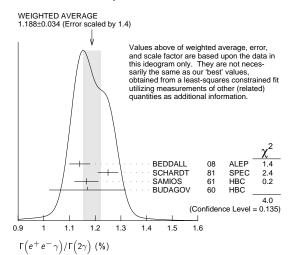

$$\begin{array}{c|cccc}
x_2 & -100 & \\
x_4 & 0 & -1 \\
\hline
& x_1 & x_2
\end{array}$$

| 3.18 ± 0.30 | 146 | 8 SAMIOS | 62B | нвс | L | DD |

 7 This ABOUZAID 08D value includes all radiative final states. The error includes both statistical and systematic errors. The correlation between the Dalitz-pair planes gives a direct measurement of the π^0 parity. The π^0 $2\gamma^*$ form factor is measured and limits are placed on a scalar contribution to the decay.

8 SAMIOS 62B value uses a Panofsky ratio = 1.62

 $\Gamma(e^+e^-)/\Gamma_{total}$ Experimental results are listed; branching ratios corrected for radiative effects are given in the footnotes. BERMAN 60 found $B(\pi^0 \to e^+e^-) \ge 4.69 \times 10^{-8}$ via an exact OFD calculation.

 9 ABOUZAID 07 result is for $m_{e^+\,e^-}/m_{\pi^0}>$ 0.95. With radiative corrections the result becomes (7.48 \pm 0.29 \pm 0.25) \times 10 $^{-8}$.

 10 The DESHPANDE 93 result with bremsstrahlung radiative corrections is (8.0 \pm 2.6 \pm 0.6) \times 10–8.

11 The MCFARLAND 93 result is for B[$\pi^0 \rightarrow e^+e^-$, $(m_{e^+e^-}/m_{\pi^0})^2 > 0.95$]. With radiative corrections it becomes $(8.8^{+4.5}_{-3.2} \pm 0.6) \times 10^{-8}$.

 12 ALAVI-HARATI 99c quote result for B| $_{170}^{0} \rightarrow e^{+}e^{-}$, ($m_{e^{+}e^{-}}/m_{\pi^{0}})^{2} > 0.95$] to minimize radiative contributions from $\pi^{0} \rightarrow e^{+}e^{-}\gamma$. After radiative corrections they obtain (7.04 \pm 0.46 \pm 0.28) \times 10 $^{-8}$.

π^0 ELECTROMAGNETIC FORM FACTOR

The amplitude for the process $\pi^0\to e^+e^-\gamma$ contains a form factor ${\sf F}(x)$ at the $\pi^0\,\gamma\gamma$ vertex, where $x=[m_{e^+e^-}/m_{\pi^0}]^2$. The parameter a in the linear expansion ${\sf F}(x)=1+ax$ is listed below.

All the measurements except that of BEHREND 91 are in the time-like region of momentum transfer.

η MASS

The new measurements from CLEO-c and KLOE seem to resolve the obvious inconsistency of the previously available high-precision η mass measurements by NA48 (LAI 02) and GEM (ABDEL-BARY 05) in favor of the higher η mass from NA48. Therefore we now use only the results from LAI 02, MILLER 07, and AMBROSINO 07B for our η mass average.

[a] C parity forbids this to occur as a single-photon process.

CONSTRAINED FIT INFORMATION

An overall fit to a decay rate and 19 branching ratios uses 49 measurements and one constraint to determine 9 parameters. The overall fit has a $\chi^2=$ 56.4 for 41 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\left\langle \delta x_i \delta x_j \right\rangle/(\delta x_i \cdot \delta x_j),$ in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}.$ The fit constrains the x_i whose labels appear in this array to sum to one.

²RODRIGUES 08 uses a more sophisticated calculation for the inelastic background due to incoherent photoproduction to reanalyze the η photoproduction data on Be and Cu at 9 GeV from BROWMAN 74B. This brings the value of $\Gamma(\eta \to 2\gamma)$ in line with direct measurements of the width. The error here is only statistical.

³BEMPORAD 67 gives $\Gamma(2\gamma) = 1.21 \pm 0.26$ keV assuming $\Gamma(2\gamma)/\Gamma(\text{total}) = 0.314$.

 3 BEMPORAD 67 gives $\Gamma(2\gamma)=1.21\pm0.26$ keV assuming $\Gamma(2\gamma)/\Gamma(\text{total})=0.314$. Bemporad private communication gives $\Gamma(2\gamma)^2/\Gamma(\text{total})=0.380\pm0.083$. We evaluate this using $\Gamma(2\gamma)/\Gamma(\text{total})=0.38\pm0.01$. Not included in average because the uncertainty resulting from the separation of the coulomb and nuclear amplitudes has apparently been underestimated.

| 0.12 ± 0.06 | | ²⁶ THALER | 72 | A SP K | |

 $^{^{26}\,\}mathrm{The}$ authors don't believe this indicates D-wave because the dependence of β on the γ energy is inconsistent with the theoretical prediction. A $\cos^2 \theta$ dependence can also come from P- and F-wave interference.

η CP-NONCONSERVING DECAY PARAMETER

$\pi^+\pi^-e^+e^-$ DECAY-PLANE ASYMMETRY PARAMETER A_ϕ

In the η rest frame, the total momentum of the e^+e^- pair is equal and opposite to that of the $\pi^+\pi^-$ pair. Let \hat{z} be the unit vector along the momentum of the e^+e^- pair; let \hat{n}_{ee} and $\hat{n}_{\pi\pi}$ be the unit vectors normal to the e^+e^- and $\pi^+\pi^-$ planes; and let ϕ be the angle between the two normals. Then

$$\sin\!\phi\,\cos\!\phi = [(\,\hat{n}_{ee}\times\hat{n}_{\pi\,\pi})\,\cdot\hat{z}\,]\,(\,\hat{n}_{ee}\cdot\hat{n}_{\pi\,\pi})$$
 ,

$$A_{\phi} \equiv \frac{\textit{N}_{\sin\phi\cos\phi>0} - \textit{N}_{\sin\phi\cos\phi<0}}{\textit{N}_{\sin\phi\cos\phi>0} + \textit{N}_{\sin\phi\cos\phi<0}}$$

NOTE ON SCALAR MESONS BELOW 2 GEV

Revised September 2011 by C. Amsler (University of Zurich), S. Eidelman (Budker Institute of Nuclear Physics, Novosibirsk), T. Gutsche (University of Tübingen), C. Hanhart (Forschungszentrum Jülich), S. Spanier (University of Tennessee), and N.A. Törnqvist (University of Helsinki)

I. Introduction: In contrast to the vector and tensor mesons, the identification of the scalar mesons is a long-standing puzzle. Scalar resonances are difficult to resolve because some of them have large decay widths which cause a strong overlap between resonances and background. In addition, several decay channels sometimes open up within a short mass interval (e.g. at the $K\bar{K}$ and $\eta\eta$ thresholds), producing cusps in the line shapes of the near-by resonances. Furthermore, one expects non- $q\bar{q}$ scalar objects, such as glueballs and multiquark states in the mass range below 2 GeV (for reviews see, e.g., Refs. [1–4]) .

Scalars are produced, for example, in πN scattering on polarized/unpolarized targets, $p\bar{p}$ annihilation, central hadronic production, J/Ψ , B-, D- and K-meson decays, $\gamma\gamma$ formation, and ϕ radiative decays. Especially for the lightest scalar mesons simple parameterizations fail and more advanced theory tools are necessary to extract the resonance parameters from data. In the analyses available in the literature fundamental properties of the amplitudes such as unitarity, analyticity, Lorentz invariance, chiral and flavor symmetry are implemented at different levels of rigor. Especially, chiral symmetry implies the appearance of zeros close to the threshold in elastic S-wave scattering amplitudes involving soft pions [5,6], which may be shifted or removed in associated production processes [7]. The methods employed are the K-matrix formalism, the N/D-method, the

Meson Particle Listings $f_0(500)$

Dalitz Tuan ansatz, unitarized quark models with coupled channels, effective chiral field theories and the linear sigma model, etc. Dynamics near the lowest two-body thresholds in some analyses are described by crossed channel (t, u) meson exchange or with an effective range parameterization instead of, or in addition to, resonant features in the s-channel. Recent dispersion theoretical approaches made it possible to accurately pin down the location of resonance poles for the low lying states [8–11].

The mass and width of a resonance are found from the position of the nearest pole in the process amplitude (T-matrix or S-matrix) at an unphysical sheet of the complex energy plane, traditionally labeled as

$$\sqrt{s_{\text{Pole}}} = M - i \Gamma/2$$
.

It is important to note that the Breit-Wigner parameterization agrees with this pole position only for narrow and well–separated resonances, far away from the opening of decay channels.

In this note, we discuss the light scalars below 2 GeV organized in the listings under the entries $(I=1/2)~K_0^*(800)$ (or κ , currently omitted from the summary table), $K_0^*(1430)$, $(I=1)~a_0(980),~a_0(1450)$, and $(I=0)~f_0(500)$ (or σ), $f_0(980)$, $f_0(1370),~f_0(1500)$, and $f_0(1710)$. This list is minimal and does not necessarily exhaust the list of actual resonances. The $(I=2)~\pi\pi$ and $(I=3/2)~K\pi$ phase shifts do not exhibit any resonant behavior. See also our notes in previous issues for further comments on, e.g., scattering lengths and older papers.

II. The I=1/2 States: The $K_0^*(1430)$ [12] is perhaps the least controversial of the light scalar mesons. The $K\pi$ S-wave scattering has two possible isospin channels, I = 1/2and I = 3/2. The I = 3/2 wave is elastic and repulsive up to 1.7 GeV [13] and contains no known resonances. The $I = 1/2 K\pi$ phase shift, measured from about 100 MeV above threshold in Kp production, rises smoothly, passes 90° at 1350 MeV, and continues to rise to about 170° at 1600 MeV. The first important inelastic threshold is $K\eta'(958)$. In the inelastic region the continuation of the amplitude is uncertain since the partial-wave decomposition has several solutions. The data are extrapolated towards the $K\pi$ threshold using effective range type formulas [12,14] or chiral perturbation predictions [15,16]. From analyses using unitarized amplitudes there is agreement on the presence of a resonance pole around 1410 MeV having a width of about 300 MeV. With reduced model dependence, Ref. 17 finds a larger width of 500 MeV.

Similar to the situation for the $f_0(500)$, discussed in the next section, the presence and properties of the light $K_0^*(800)$ (or κ) meson in the 700-900 MeV region are difficult to establish since it appears to have a very large width ($\Gamma \approx 500$ MeV) and resides close to the $K\pi$ threshold. Hadronic *D*-meson decays provide additional data points in the vicinity of the $K\pi$ threshold - experimental results from E791, e.g., Ref. [18,19], FOCUS [17,20], CLEO [21], and BaBar [22] are discussed in the Review of Charm Dalitz Plot Analyses. Precision information

from semileptonic D decays avoiding theoretically ambiguous three-body final state interactions is not available. BES II [23] (re-analyzed in [24]) finds a $K_0^*(800)$ -like structure in J/ψ decays to $\bar{K}^{*0}(892)K^+\pi^-$ where $K_0^*(800)$ recoils against the $K^*(892)$. Also clean with respect to final state interaction is the decay $\tau^- \to K_S^0\pi^-\nu_\tau$ studied by Belle [25], with $K_0^*(800)$ parameters fixed to Ref. 23.

Some authors find a $K_0^*(800)$ pole in their phenomenological analysis (see, e.g., [21,26–36]), while others do not need to include it in their fits (see, e.g., [16,22,37–39]). Similarly to the case of the $f_0(500)$ discussed below, all works including constraints from chiral symmetry at low energies naturally seem to find a light $K_0^*(800)$ below 800 MeV, see, e.g., [40-44]. In these works the $K_0^*(800)$, $f_0(500)$, $f_0(980)$ and $a_0(980)$ appear to form a nonet [41,42]. Additional evidence for this assignment is presented in Ref. 11, where the couplings of the nine states to $\bar{q}q$ sources were compared. The same low lying scalar nonet was also found earlier in the unitarized quark model of Ref. 43. The analysis of Ref. 45 is based on the Roy-Steiner equations, which include analyticity and crossing symmetry. It establishes the existence of a light $K_0^*(800)$ pole in the $K\pi \to K\pi$ amplitude on the second sheet.

III. The I=1 States: Two isovector states are known, the established $a_0(980)$ and the $a_0(1450)$. Independent of any model, the KK component in the $a_0(980)$ wave function must be large: it lies just below the opening of the $K\bar{K}$ channel to which it strongly couples [14,46]. This generates an important cusp-like behavior in the resonant amplitude. Hence, its mass and width parameters are strongly distorted. To reveal its true coupling constants, a coupled channel model with energy-dependent widths and mass shift contributions is necessary. All listed $a_0(980)$ measurements agree on a mass position value near 980 MeV, but the width takes values between 50 and 100 MeV, mostly due to the different models. For example, the analysis of the $p\bar{p}$ -annihilation data [14] using a unitary K-matrix description finds a width as determined from the T-matrix pole of 92 ± 8 MeV, while the observed width of the peak in the $\pi\eta$ mass spectrum is about 45 MeV.

The relative coupling $K\bar{K}/\pi\eta$ is determined indirectly from $f_1(1285)$ [47–49] or $\eta(1410)$ decays [50–52], from the line shape observed in the $\pi\eta$ decay mode [54–57], or from the coupled-channel analysis of the $\pi\pi\eta$ and $K\bar{K}\pi$ final states of $p\bar{p}$ annihilation at rest [14].

The $a_0(1450)$ is seen in $p\bar{p}$ annihilation experiments with stopped and higher momenta antiprotons, with a mass of about 1450 MeV or close to the $a_2(1320)$ meson which is typically a dominant feature. A contribution from $a_0(1450)$ is also found in the analysis of the $D^\pm \to K^+K^-\pi^\pm$ decay [58]. The broad structure at about 1300 MeV observed in $\pi N \to K\bar{K}N$ reactions [59] needs still further confirmation in its existence and isospin assignment.

IV. The I = 0 States: The I = 0, $J^{PC} = 0^{++}$ sector is the most complex one, both experimentally and theoretically. The

 $f_0(500)$

data have been obtained from $\pi\pi$, $K\bar{K}$, $\eta\eta$, 4π , and $\eta\eta'$ (958) systems produced in S-wave. Analyses based on several different production processes conclude that probably four poles are needed in the mass range from $\pi\pi$ threshold to about 1600 MeV. The claimed isoscalar resonances are found under separate entries $f_0(500)$ (or σ), $f_0(980)$, $f_0(1370)$, and $f_0(1500)$.

For discussions of the $\pi\pi$ S wave below the $K\bar{K}$ threshold and on the long history of the $f_0(500)$, which was suggested in linear sigma models more than 50 years ago, see our reviews in previous editions and the conference proceedings [60].

Information on the $\pi\pi$ S-wave phase shift $\delta_I^I = \delta_0^0$ was already extracted many years ago from πN scattering [61–63], and near threshold from the K_{e4} -decay [64]. The kaon decays were later revisited leading to consistent data, however, with very much improved statistics [65,66]. The reported $\pi\pi \to K\bar{K}$ cross sections [67–70] have large uncertainties. The πN data have been analyzed in combination with highstatistics data (see entries labeled as RVUE for re-analyses of the data). The $2\pi^0$ invariant mass spectra of the $p\bar{p}$ annihilation at rest [71-73] and the central collision [74] do not show a distinct resonance structure below 900 MeV, but these data are consistently described with the standard solution for πN data [62,75], which allows for the existence of the broad $f_0(500)$. An enhancement is observed in the $\pi^+\pi^-$ invariant mass near threshold in the decays $D^+ \to \pi^+\pi^-\pi^+$ [76–103] and $J/\psi \to \omega \pi^+ \pi^-$ [79,100], and in $\psi(2S) \to J/\psi \pi^+ \pi^-$ with very limited phase space [81,82].

The precise $f_0(500)$ (or σ) pole is difficult to establish because of its large width, and because it can certainly not be modeled by a naive Breit-Wigner resonance. For the same reason a splitting in background and resonance contributions is not possible in a model-independent way. The $\pi\pi$ scattering amplitude shows an unusual energy dependence due to the presence of a zero in the unphysical regime close to the threshold [5–6], required by chiral symmetry, and possibly due to crossed channel exchanges, the $f_0(1370)$, and other dynamical features. However, most of the analyses listed under $f_0(500)$ agree on a pole position near (500 - i 250 MeV). In particular, analyses of $\pi\pi$ data that include unitarity, $\pi\pi$ threshold behavior, strongly constrained by the K_{e4} data, and the chiral symmetry constraints from Adler zeroes and/or scattering lengths find a light $f_0(500)$, see, e.g., [83,84].

Precise pole positions with an uncertainty of less than 20 MeV (see our table for T-matrix pole) were extracted by use of Roy equations, which are twice subtracted dispersion relations derived from crossing symmetry and analyticity. In Ref. [9] the subtraction constants were fixed to the S-wave scattering lengths a_0^0 and a_0^2 derived from matching Roy equations and two-loop chiral perturbation theory [8]. The only additional relevant input to fix the $f_0(500)$ pole turned out to be the $\pi\pi$ -wave phase shifts at 800 MeV. The analysis was improved further in Ref. 11. Alternatively, in Ref. 10 only data was used as input inside Roy equations. In that reference also once-subtracted Roy-like equations, called GKPY equations,

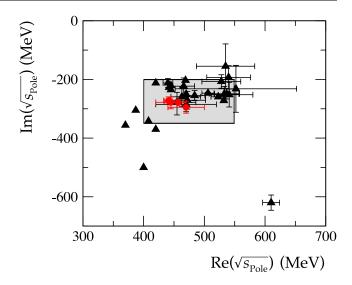

Figure 1: Location of the $f_0(500)$ (or σ) poles in the complex energy plane. Circles denote the recent analyses based on Roy(-like) dispersion relations [8–11], while all other analyses are denoted by triangles. The corresponding references are given in the listing.

were used, since the extrapolation into the complex plane based on the twice subtracted equations leads to larger uncertainties mainly due to the limited experimental information on the isospin 2 $\pi\pi$ scattering length. All these extractions find consistent results. Using analyticity and unitarity only to describe data from $K_{2\pi}$ and K_{e4} decays, Ref. 85 finds consistent values for pole position and scattering length a_0^0 . The importance of the $\pi\pi$ scattering data for fixing the $f_0(500)$ pole is nicely illustrated by comparing analyses of $\bar{p}p \to 3\pi^0$ omitting [71,86] or including [72,87] information on $\pi\pi$ scattering: while the former analyses find an extremely broad structure above 1 GeV, the latter find $f_0(500)$ masses of the order of 400 MeV.

As a result of the sensitivity of the extracted $f_0(500)$ pole position on the high accuracy low energy $\pi\pi$ scattering data [65,66], the currently quoted range of pole positions for the $f_0(500)$, namely

$$\sqrt{s_{\text{Pole}}^{\sigma}} = (400 - 550) - i(200 - 350) \text{ MeV}$$
,

in the listing was fixed including only those analyses consistent with these data, Refs. [29,32,41,43,44,53,56,72], [81–85] and [88–103] as well as the advanced dispersion analyses [8–11]. The pole positions from those references are compared to the range of poles positions quoted above in Fig. 1. Note that this range is labeled as 'our estimate' — it is not an average over the quoted analyses but is chosen to include the bulk of the analyses consistent with the mentioned criteria. An averaging procedure is not justified, since the analyses use overlapping or identical data sets.

One might also take the more radical point of view and just average the most advanced dispersive analyses, Refs. [8–11],

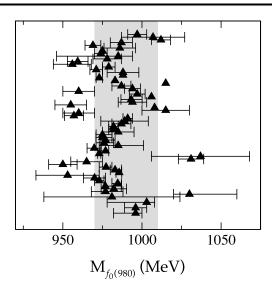

Figure 2: Values of the $f_0(980)$ masses as they appear in the listing compared to the currently quoted mass estimate. The newest references appear at the bottom, the oldest on the top. The corresponding references are given in the listing.

shown as solid dots in Fig. 1, for they provide a determination of the pole positions with minimal bias. This procedure leads to the much more restricted range of $f_0(500)$ parameters

$$\sqrt{s_{\text{Pole}}^{\sigma}} = (446 \pm 6) - i(276 \pm 5) \text{ MeV}$$
.

Due to the large strong width of the $f_0(500)$ an extraction of its two-photon width directly from data is not possible. Thus, the values for $\Gamma(\gamma\gamma)$ quoted in the literature as well as the listing are based on the expression in the narrow width approximation [104] $\Gamma(\gamma\gamma) \simeq \alpha^2 |g_{\gamma}|^2/(4\text{Re}(\sqrt{s_{\text{Pole}}^{\sigma}}))$ where g_{γ} is derived from the residue at the $f_0(500)$ pole to two photons and α denotes the electromagnetic fine structure constant. The explicit form of the expression may vary between different authors due to different definitions of the coupling constant, however, the expression given for $\Gamma(\gamma\gamma)$ is free of ambiguities. According to Refs. [105,106], the data for $f_0(500) \rightarrow \gamma \gamma$ are consistent with what is expected for a two-step process of $\gamma\gamma \to \pi^+\pi^-$ via pion exchange in the t- and u-channel, followed by a final state interaction $\pi^+\pi^- \to \pi^0\pi^0$. The same conclusion is drawn in Ref. 107 where the bulk part of the $f_0(500) \rightarrow \gamma \gamma$ decay width is dominated by re-scattering. Therefore, it might be difficult to learn anything new about the nature of the $f_0(500)$ from its $\gamma\gamma$ coupling. For the most recent work on $\gamma\gamma \to \pi\pi$, see Refs. [108,109]. There are theoretical indications (e.g., [110–113]) that the $f_0(500)$ pole behaves differently from a $q\bar{q}$ -state – see next section for details.

The $f_0(980)$ overlaps strongly with the background represented mainly by the $f_0(500)$ and the $f_0(1370)$. This can lead to a dip in the $\pi\pi$ spectrum at the $K\bar{K}$ threshold. It changes from a dip into a peak structure in the $\pi^0\pi^0$ invariant mass

spectrum of the reaction $\pi^-p \to \pi^0\pi^0n$ [114], with increasing four-momentum transfer to the $\pi^0\pi^0$ system, which means increasing the a_1 -exchange contribution in the amplitude, while the π -exchange decreases. The $f_0(500)$ and the $f_0(980)$ are also observed in data for radiative decays ($\phi \to f_0\gamma$) from SND [115,116], CMD2 [117], and KLOE [118,119]. Recently a dispersive analysis was used to simultaneously pin down the pole parameters of both the $f_0(500)$ and the $f_0(980)$ [10]; the uncertainty in the pole position quoted for the latter state is of the order of 10 MeV, only (see lowest point in Fig. 2). Compared to the 2010 issue of the Review of Particle Physics, in this issue we extended the allowed range of $f_0(980)$ masses to include the mass value derived in Ref. 10. We now quote for the mass

$$M_{f_0(980)} = 990 \pm 20 \text{ MeV}$$
.

As in case of the $f_0(500)$ (or σ), this range is not an average, but is labeled as 'our estimate'. A comparison of the mass values in the listing and the allocated range is shown in Fig. 2.

Analyses of $\gamma\gamma \to \pi\pi$ data [120–122] underline the importance of the $K\bar{K}$ coupling of $f_0(980)$, while the resulting two-photon width of the $f_0(980)$ cannot be determined precisely [123].

The f_0 's above 1 GeV. A meson resonance that is very well studied experimentally, is the $f_0(1500)$ seen by the Crystal Barrel experiment in five decay modes: $\pi\pi$, $K\bar{K}$, $\eta\eta$, $\eta\eta'(958)$, and 4π [14,72,73]. Due to its interference with the $f_0(1370)$ (and $f_0(1710)$), the peak attributed to $f_0(1500)$ can appear shifted in invariant mass spectra. Therefore, the application of simple Breit-Wigner forms arrive at slightly different resonance masses for $f_0(1500)$. Analyses of central-production data of the likewise five decay modes Refs. [124,125] agree on the description of the S-wave with the one above. The $p\bar{p}$, $p\bar{n}/n\bar{p}$ measurements [126–128,73] show a single enhancement at 1400 MeV in the invariant 4π mass spectra, which is resolved into $f_0(1370)$ and $f_0(1500)$ [129,130]. The data on 4π from central production [131] require both resonances, too, but disagree on the relative content of $\rho\rho$ and $f_0(500)f_0(500)$ in 4π . All investigations agree that the 4π decay mode represents about half of the $f_0(1500)$ decay width and is dominant for $f_0(1370)$.

The determination of the $\pi\pi$ coupling of $f_0(1370)$ is aggravated by the strong overlap with the broad $f_0(500)$ and $f_0(1500)$. Since it does not show up prominently in the 2π spectra, its mass and width are difficult to determine. Multichannel analyses of hadronically produced two- and three-body final states agree on a mass between 1300 MeV and 1400 MeV and a narrow $f_0(1500)$, but arrive at a somewhat smaller width for $f_0(1370)$.

Both Belle and BaBar have observed scalars in B and D meson decays. They observe broad or narrow structures between 1 and 1.6 GeV in K^+K^- and $\pi^+\pi^-$ decays [132–136] (see also [137]). It could be a result of interference of several resonances in this mass range, but lack of statistics prevents an

 $f_0(500)$

unambiguous identification of this effect. In $\gamma\gamma$ collisions the observation of scalars was reported in Refs. [121,138–196].

V. Interpretation of the scalars below 1 GeV: In the literature, many suggestions are discussed, such as conventional $q\bar{q}$ mesons, $q\bar{q}q\bar{q}$ or meson-meson bound states. In addition one expects a scalar glueball in this mass range. In reality, there can be superpositions of these components, and one often depends on models to determine the dominant one. Although we have seen progress in recent years, this question remains open. Here, we mention some of the present conclusions.

The $f_0(980)$ and $a_0(980)$ are often interpreted as multiquark states [140–144] or $K\bar{K}$ bound states [145]. The insight into their internal structure using two-photon widths [116,146–152] is not conclusive. The $f_0(980)$ appears as a peak structure in $J/\psi \to \phi \pi^+ \pi^-$ and in D_s decays without $f_0(500)$ background, while being nearly invisible in $J/\psi \to \omega \pi^+ \pi^-$. Based on that observation it is suggested that $f_0(980)$ has a large $s\bar{s}$ component, which according to Ref. 153 is surrounded by a virtual KKcloud (see also Ref. 154). Data on radiative decays ($\phi \to f_0 \gamma$ and $\phi \to a_0 \gamma$) from SND, CMD2, and KLOE (see above) are consistent with a prominent role of kaon loops. This observation is interpreted as evidence for a compact four-quark [155] or a molecular [160,156] nature of these states. Details of this controversy are given in the comments [157,158]; Ref. 159. It remains quite possible that the states $f_0(980)$ and $a_0(980)$, together with the $f_0(500)$ and the $K_0^*(800)$, form a new low-mass state nonet of predominantly four-quark states, where at larger distances the quarks recombine into a pair of pseudoscalar mesons creating a meson cloud (see e.g., Ref. 161). Different QCD sum rule studies [162–166] do not agree on a tetraquark configuration for the same particle group.

Models that start directly from chiral Lagrangians, either in non-linear [44,28,83,160] or in linear [167–172] realization, predict the existence of the $f_0(500)$ meson near 500 MeV. Here the $f_0(500)$, $a_0(980)$, $f_0(980)$, and $K_0^*(800)$ (in some models the $K_0^*(1430)$) would form a nonet (not necessarily $q\bar{q}$). In the linear sigma models the lightest pseudoscalars appear as their chiral partners. In these models the light $f_0(500)$ is often referred to as the "Higgs boson of strong interactions", since here the $f_0(500)$ plays a role similar to the Higgs particle in electro-weak symmetry breaking: within the linear sigma models it is important for the mechanism of chiral symmetry breaking, which generates most of the proton mass, and what is referred to as the constituent quark mass.

In the non–linear approaches of Ref. 28 [83], the above resonances together with the low lying vector states are generated starting from chiral perturbation theory predictions near the first open channel, and then by extending the predictions to the resonance regions using unitarity and analyticity.

Ref. 167 uses a framework with explicit resonances that are unitarized and coupled to the light pseudo-scalars in a chirally invariant way. Evidence for a non- $\bar{q}q$ nature of the lightest scalar resonances is derived from their mixing scheme. To

identify the nature of the resonances generated from scattering equations, in Ref. 175 the large N_c behavior of the poles was studied, with the conclusion that, while the light vector states behave consistent with what is predicted for $\bar{q}q$ states, the light scalars behave very differently. This finding provides strong support for a non- $\bar{q}q$ nature of the light scalar resonances. Note, the more refined study of Ref. 110 found, in case of the $f_0(500)$, in addition to a dominant non- $\bar{q}q$ nature, indications for a subdominant $\bar{q}q$ component located around 1 GeV. A model-independent method to identify hadronic molecules goes back to a proposal by Weinberg [176], shown to be equivalent to the pole counting arguments of Ref. 177 [178] in Ref. 179. The formalism allows one to extract the amount of molecular component in the wave function from the effective coupling constant of a physical state to a nearby continuum channel. It can be applied to near threshold states only and provided strong evidence that the $f_0(980)$ is a $\bar{K}K$ molecule, while the situation turned out to be less clear for the $a_0(980)$ (see also Refs. [152,150]). Further insights into $a_0(980)$ and $f_0(980)$ are expected from their mixing [180]. The corresponding signal predicted in Refs. [181,182] was recently observed at BES III [183].

In the unitarized quark model with coupled $q\bar{q}$ and meson-meson channels, the light scalars can be understood as additional manifestations of bare $q\bar{q}$ confinement states, strongly mass shifted from the 1.3 - 1.5 GeV region and very distorted due to the strong 3P_0 coupling to S-wave two-meson decay channels [173–184]. Thus, in these models the light scalar nonet comprising the $f_0(500)$, $f_0(980)$, $K_0^*(800)$, and $a_0(980)$, as well as the nonet consisting of the $f_0(1370)$, $f_0(1500)$ (or $f_0(1710)$), $K_0^*(1430)$, and $a_0(1450)$, respectively, are two manifestations of the same bare input states (see also Ref. 185).

Other models with different groupings of the observed resonances exist and may, e.g., be found in earlier versions of this review.

VI. Interpretation of the f_0 's above 1 GeV: The $f_0(1370)$ and $f_0(1500)$ decay mostly into pions $(2\pi$ and $4\pi)$ while the $f_0(1710)$ decays mainly into $K\bar{K}$ final states. The $K\bar{K}$ decay branching ratio of the $f_0(1500)$ is small [124,186].

If one uses the naive quark model, it is natural to assume that the $f_0(1370)$, $a_0(1450)$, and the $K_0^*(1430)$ are in the same SU(3) flavor nonet, being the $(u\bar{u}+d\bar{d})$, $u\bar{d}$ and $u\bar{s}$ states, probably mixing with the light scalars [187], while the $f_0(1710)$ is the $s\bar{s}$ state. Indeed, the production of $f_0(1710)$ (and $f_2'(1525)$) is observed in $p\bar{p}$ annihilation [188] but the rate is suppressed compared to $f_0(1500)$ (respectively, $f_2(1270)$), as would be expected from the OZI rule for $s\bar{s}$ states. The $f_0(1500)$ would also qualify as $(u\bar{u}+d\bar{d})$ state, although it is very narrow compared to the other states and too light to be the first radial excitation.

However, in $\gamma\gamma$ collisions leading to $K_S^0K_S^0$ [189] a spin 0 signal is observed at the $f_0(1710)$ mass (together with a dominant spin 2 component), while the $f_0(1500)$ is not observed

Meson Particle Listings $f_0(500)$

in $\gamma\gamma \to K\bar{K}$ nor $\pi^+\pi^-$ [190]. In $\gamma\gamma$ collisions leading to $\pi^0\pi^0$ Ref. 138 reports the observation of a scalar around 1470 MeV albeit with large uncertainties on the mass and $\gamma\gamma$ couplings. This state could be the $f_0(1370)$ or the $f_0(1500)$. The upper limit from $\pi^+\pi^-$ [190] excludes a large $n\bar{n}$ (here n stands for the two lightest quarks) content for the $f_0(1500)$ and hence points to a mainly $s\bar{s}$ state [191]. This appears to contradict the small $K\bar{K}$ decay branching ratio of the $f_0(1500)$ and makes a $q\bar{q}$ assignment difficult for this state. Hence the $f_0(1500)$ could be mainly glue due the absence of a 2γ -coupling, while the $f_0(1710)$ coupling to 2γ would be compatible with an $s\bar{s}$ state. However, the 2γ -couplings are sensitive to glue mixing with $q\bar{q}$ [192].

Note that an isovector scalar, possibly the $a_0(1450)$ (albeit at a lower mass of 1317 MeV) is observed in $\gamma\gamma$ collisions leading to $\eta \pi^0$ [193]. The state interferes destructively with the non-resonant background, but its $\gamma\gamma$ coupling is comparable to that of the $a_2(1320)$, in accord with simple predictions (see, e.g., Ref. 191).

The small width of $f_0(1500)$, and its enhanced production at low transverse momentum transfer in central collisions [197–199] also favor $f_0(1500)$ to be non- $q\bar{q}$. In the mixing scheme of Ref. 192, which uses central production data from WA102 and the recent hadronic J/ψ decay data from BES [200,201], glue is shared between $f_0(1370)$, $f_0(1500)$ and $f_0(1710)$. The $f_0(1370)$ is mainly $n\bar{n}$, the $f_0(1500)$ mainly glue and the $f_0(1710)$ dominantly $s\bar{s}$. This agrees with previous analyses [202,203].

However, alternative schemes have been proposed (e.g., inRef. 204 [205]; for a review see, e.g., Ref. 1). In particular, for a scalar glueball, the two-gluon coupling to $n\bar{n}$ appears to be suppressed by chiral symmetry [206] and therefore the $K\bar{K}$ decay could be enhanced. This mechanism would imply that the $f_0(1710)$ can possibly be interpreted as an unmixed glueball [207]. In Ref. 208, a large K^+K^- scalar signal reported by Belle in B decays into $KK\bar{K}$ [209], compatible with the $f_0(1500)$, is explained as due to constructive interference with a broad glueball background. However, the Belle data are inconsistent with the BaBar measurements which show instead a broad scalar at this mass for B decays into both $K^{\pm}K^{\pm}K^{\mp}$ [135] and $K^{+}K^{-}\pi^{0}$ [210].

Whether the $f_0(1500)$ is observed in 'gluon rich' radiative J/ψ decays is debatable [211] because of the limited amount of data - more data for this and the $\gamma\gamma$ mode are needed.

In Ref. 212 $f_0(1370)$ and $f_0(1710)$ (together with $f_2(1270)$ and $f_2'(1525)$) were interpreted as bound systems of two vector mesons. This picture could be tested in radiative J/ψ decays [213] as well as radiative decays of the states themselves [214].

| Illege the K data of | BATLEY 10c and the $\pi N \rightarrow \pi \pi N$ data of HVAMS 73 |

- Uses the $K_{\rm e4}$ data of BATLEY 10c and the $\pi N \to \pi\pi N$ data of HYAMS 73, GRAYER 74, and PROTOPOPESCU 73.
- $^2\,\mbox{\sc Analytic}$ continuation using Roy equations.
- ³Analytic continuation using GKPY equations.
- ⁴ Using Roy equations.
- S Average of three variants of the analytic K-matrix model. Uses the κ_{e4} data of BAT-
- LEY 08A and the $\pi N \to \pi \pi N$ data of HYAMS 73 and GRAYER 74. ⁶ Average of the analyses of three data sets in the K-matrix model. Uses the data of
- BATLEY 08A, HYAMS 73, and GRAYER 74, partially of COHEN 80 or ETKIN 82B 7 From the K_{e4} data of BATLEY 08A and $\pi\,N\,\to\,\pi\pi\,N$ data of HYAMS 73.
- 8 From the $K_{\rm e4}$ data of BATLEY 08A and $\pi\,N\to\pi\pi\,N$ data of PROTOPOPESCU 73, GRAYER 74, and ESTABROOKS 74.
- From a mean of three different $f_0(500)$ parametrizations. Uses 40k events.
- $^{10}\,\mathrm{From}$ an isobar model using 2.6k events.
- 11 Reanalysis of ABLIKIM 04A, PISLAK 01, and HYAMS 73 data.
- 12 Using the N/D method.
- 13 From the solution of the Roy equation (ROY 71) for the isoscalar S-wave and using a phase-shift analysis of HYAMS 73 and PROTOPOPESCU 73 data.

 14 Reanalysis of the data from PROTOPOPESCU 73, ESTABROOKS 74, GRAYER 74, ROSSELET 77, PISLAK 03, and AKHMETSHIN 04.
- 15 From a mean of six different analyses and $\emph{f}_{0}(500)$ parameterizations.
- 16 Using data on $\psi(2S) \to J/\psi \pi \pi$ from BAI 00E and on $\Upsilon(nS) \to \Upsilon(mS)\pi \pi$ from BUTLER 94B and ALEXANDER 98.

 17 Reanalysis of data from PROTOPOPESCU 73, ESTABROOKS 74, GRAYER 74, and COHEN 80 in the unitarized ChPT model.

 19 A similar analysis (KOMADA 01) finds $(580 + \frac{7}{30}) i(190 + \frac{107}{49})$ MeV.

- ²⁰ Coupled channel reanalysis of BATON 70, BENSINGER 71, BAILLON 72, HYAMS 73, HYAMS 75, ROSSELET 77, COHEN 80, and ETKIN 82B using the uniformizing variable.
- 21 Using the inverse amplitude method and data of ESTABROOKS 73, GRAYER 74, and PROTOPOPESCU 73.
- 22 Reanalysis of data from HYAMS 73, GRAYER 74, SRINIVASAN 75, and ROSSELET 77
- vising the interfering amplitude method.

 23 Average and spread of 4 variants ("up" and "down") of KAMINSKI 978 3-channel model.

 24 Uses data from BEIER 728, OCHS 73, HYAMS 73, GRAYER 74, ROSSELET 77, CASON 83, ASTON 88, and ARMSTRONG 918. Coupled channel analysis with flavor
- symmetry and all light two-pseudoscalars systems. 25 Demonstrates explicitly that $f_0(500)$ and $f_0(1370)$ are two different poles.
- ²⁶ Analysis of data from FALVARD 88.
- 27 Analysis of data from OCHS 73, ESTABROOKS 75, ROSSELET 77, and MUKHIN 80.
- 29 Coupled-channel analysis using data from PROTOPOPESCU 73, HYAMS 73, HYAMS 75, GRAYER 74, ESTABROOKS 74, ESTABROOKS 75, FROGGATT 77, CORDEN 79, BISWAS 81.
- ³⁰ Analysis of data from APEL 73, GRAYER 74, CASON 76, PAWLICKI 77. Includes spread and errors of 4 solutions
- 31 Analysis of data from BATON 70, BENSINGER 71, COLTON 71, BAILLON 72,PRO-TOPOPESCU 73, and WALKER 67.

 $\rho(770)$

 $I^G(J^{PC}) \ = \ 1^+(1^{\, - \, -})$

THE $\rho(770)$

Updated May 2012 by S. Eidelman (Novosibirsk) and G. Venanzoni (Frascati).

The determination of the parameters of the $\rho(770)$ is beset with many difficulties because of its large width. In physical region fits, the line shape does not correspond to a relativistic Breit-Wigner function with a P-wave width, but requires some additional shape parameter. This dependence on parameterization was demonstrated long ago [1]. Bose-Einstein correlations are another source of shifts in the $\rho(770)$ line shape, particularly in multiparticle final state systems [2].

The same model-dependence afflicts any other source of resonance parameters, such as the energy-dependence of the phase shift δ_1^1 , or the pole position. It is, therefore, not surprising that a study of $\rho(770)$ dominance in the decays of the η and η' reveals the need for specific dynamical effects, in addition to the $\rho(770)$ pole [3,4].

The cleanest determination of the $\rho(770)$ mass and width comes from e^+e^- annihilation and τ -lepton decays. Analysis of ALEPH [5] showed that the charged $\rho(770)$ parameters measured from τ -lepton decays are consistent with those of the neutral one determined from e^+e^- data [6]. This conclusion is qualitatively supported by the later studies of CLEO [7] and Belle [8]. However, model-independent comparison of the

$\rho(770)$

two-pion mass spectrum in τ decays, and the $e^+e^- \to \pi^+\pi^-$ cross section, gave indications of discrepancies between the overall normalization: τ data are about 3% higher than e^+e^- data [7,9]. A detailed analysis using such two-pion mass spectra from τ decays measured by OPAL [10], CLEO [7], and ALEPH [11,12], as well as recent pion form factor measurements in e^+e^- annihilation by CMD-2 [13,14], showed that the discrepancy can be as high as 10% above the ρ meson [15,16]. This discrepancy remains after recent measurements of the two-pion cross section in e^+e^- annihilation at KLOE [17,18] and SND [19,20]. This effect is not accounted for by isospin breaking [21–24], but the accuracy of its calculation may be overestimated [25,26].

This problem seems to be solved after a recent analysis in [27] which showed that after correcting the τ data for the missing ρ - γ mixing contribution, besides the other known isospin symmetry violating corrections, the $\pi\pi$ I=1 part of the hadronic vacuum polarization contribution to the muon g - 2 is fully compatible between τ based and e^+e^- based evaluations including more recent BaBar [28] and KLOE [29] data. Further proof of the consistency of the data on τ decays to two pions and e^+e^- annihilation is given by the global fit of the whole set of the ρ , ω , and ϕ decays, taking into account mixing effects in the hidden local symmetry model [30].

RVUE

(Confidence Level = 0.023)

0.0 22 1

760 ho(770) 0 mass (MeV)

¹ A combined fit of AKHMETSHIN 07, AULCHENKO 06, and AULCHENKO 05.

780

750

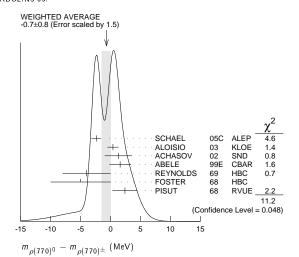

- 3 A fit of the SND data from 400 to 1000 MeV using parameters of the $\rho(1450)$ and $\rho(1700)$ from a fit of the data of BARKOV 85, BISELLO 89 and ANDERSON 00A. 4 Using the GOUNARIS 68 parametrization with the complex phase of the $\rho\text{-}\omega$ interference.
- ⁵ Update of A KH MET SHIN 02.
- 6 Assuming $m_{\rho^+}=m_{\rho^-}$, $\Gamma_{\rho^+}=\Gamma_{\rho^-}$. 7 From the GOUNARIS 68 parametrization of the pion form factor.
- ⁸ Assuming $m_{\rho^+}=m_{\rho^-}=m_{\rho^0}$, $\Gamma_{\rho^+}=\Gamma_{\rho^-}=\Gamma_{\rho^0}$.
- Without limitations on masses and widths.
- 10 Assuming $m_{\rho^0}=m_{\rho^\pm}$, $g_{\rho^0\,\pi\,\pi}=g_{\rho^\pm\,\pi\,\pi}$
- 11 Using the data of BARKOV 85 in the hidden local symmetry model. 12 From the fit to $e^+e^- \rightarrow \pi^+\pi^-$ data from the compilations of HEYN 81 and BARKOV 85, including the GOUNARIS 68 parametrization of the pion form factor. 13 A fit of BARKOV 85 data assuming the direct $\omega \pi \pi$ coupling.
- 14 Applying the S-matrix formalism to the BARKOV 85 data.
- 15 Includes BARKOV 85 data. Model-dependent width definition.
- $^{16}|F_{\pi}(0)|^2$ fixed to 1.
- $17 \frac{1}{\text{From the GOUNARIS}}$ 68 parametrization of the pion form factor.
- $^{18}\, ext{The}$ error combines statistical and systematic uncertainties. Supersedes BARATE 97M.
- $^{19}
 ho(1700)$ mass and width fixed at 1700 MeV and 235 MeV respectively.
- 20 From the GOUNARIS 68 parametrization of the pion form factor. The second error is a model error taking into account different parametrizations of the pion form factor.
- 21 Using the data of <code>BARATE</code> 97M and the effective chiral Lagrangian.
- $^{22}\mathrm{From}$ a fit of the model-independent parameterization of the pion form factor to the data of BARATE 97M.

- 23 Assuming the equality of ρ^+ and ρ^- masses and widths. 24 Mass errors enlarged by us to $\Gamma/\sqrt{N};$ see the note with the $K^*(892)$ mass.
- 25 Phase shift analysis. Systematic errors added corresponding to spread of different fits.
- 26 From fit of 3-parameter relativistic P-wave Breit-Wigner to total mass distribution. Includes BATON 68, MILLER 67B, ALFF-STEINBERGER 66, HAGOPIAN 66, HAGOPIAN 66B, JACOBS 66B, JAMES 66, WEST 66, BLIEDEN 65 and CARMONY 64.
- 27 From the parametrization according to SOEDING 66.
- $^{\mbox{\footnotesize 28}}\,\mbox{From the parametrization according to ROSS 66}.$
- $^{29}\,\mathrm{HEYN}$ 81 includes all spacelike and timelike F_π values until 1978.
- $^{30}\,\mathrm{From}$ pole extrapolation.
- 32 From poise extrapolation.
 32 From phase shift analysis of GRAYER 74 data.
 32 Includes MALAMUD 69, ARMENISE 68, BACON 67, HUWE 67, MILLER 67B, ALFF-STEINBERGER 66, HAGOPIAN 66, HAGOPIAN 66B, JACOBS 66B, JAMES 66, WEST 66, GOLDHABER 64, ABOLINS 63.
- 33 Breit-Wigner mass from a phase-shift analysis of HYAMS 73 and PROTOPOPESCU 73
- data. 34 Using relativistic Breit-Wigner and taking into account $\rho ext{-}\omega$ interference.
- 35 Systematic errors not evaluated.
- 36 Systematic effects not studied.
- 37 Systematic enects not study during.
 37 From fit of 3-parameter relativistic Breit-Wigner to helicity-zero part of P-wave intensity.
 CHABAUD 83 includes data of GRAYER 74.

$m_{\rho(770)^0} - m_{\rho(770)^{\pm}}$

ρ (770) RANGE PARAMETER

The range parameter R enters an energy-dependent correction to the width, of the form $(1+q_r^2\ R^2)\ /\ (1+q^2\ R^2)$, where q is the momentum of one of the pions in the $\pi\pi$ rest system. At resonance, q

 $^{^{77}}$ From the combined fit of the τ^- data from ANDERSON 00A and SCHAEL 05c and e^+e^- data from the compilation of BARKOV 85, AKH METSHIN 04, and ALOISIO 05. Supersedes BARATE 97M.

⁴⁴ Supersedes ACHASOV 05A.

⁴⁵ A fit of the SND data from 400 to 1000 MeV using parameters of the $\rho(1450)$ and $\rho(1700)$ from a fit of the data of BARKOV 85, BISELLO 89 and ANDERSON 00A.

 $^{^{46}}$ Using the GOUNARIS 68 parametrization with the complex phase of the ho- ω interference.

⁴⁷ From a fit in the energy range 0.61 to 0.96 GeV. Update of AKHMETSHIN 02.

⁴⁸ Assuming $m_{\rho^+}=m_{\rho^-}$, $\Gamma_{\rho^+}=\Gamma_{\rho^-}$.

⁴⁹ From the GOUNARIS 68 parametrization of the pion form factor.

⁵¹ Without limitations on masses and widths.

⁵² Assuming $m_{\rho^0}=m_{\rho^\pm}$, $g_{\rho^0\,\pi\pi}=g_{\rho^\pm\pi\pi}$

 $^{^{53}}$ Using the data of BARKOV 85 in the hidden local symmetry model. 54 From the fit to $e^+e^- \rightarrow \pi^+\pi^-$ data from the compilations of HEYN 81 and BARKOV 85, including the GOUNARIS 68 parametrization of the pion form factor.

 $^{^{55}}$ A fit of BARKOV 85 data assuming the direct $\omega\pi\pi$ coupling.

 $^{^{56}\,\}mathrm{Applying}$ the S-matrix formalism to the BARKOV 85 data.

⁵⁷ Includes BARKOV 85 data. Model-dependent width definition. $^{58}|F_\pi(0)|^2 \text{ fixed to } 1.$

⁵⁹ From the GOUNARIS 68 parametrization of the pion form factor.

 $^{^{60}}$ The error combines statistical and systematic uncertainties. Supersedes BARATE 97M.

 $^{^{61}\,}ho(1700)$ mass and width fixed at 1700 MeV and 235 MeV respectively.

⁶² From the GOUNARIS 68 parametrization of the pion form factor. The second error is a model error taking into account different parametrizations of the pion form factor.

 $^{^{63}\,\}text{Using}$ the data of BARATE 97M and the effective chiral Lagrangian.

⁶⁴ Assuming the equality of ρ^+ and ρ^- masses and widths.

⁶⁵ Width errors enlarged by us to $4\Gamma/\sqrt{N}$; see the note with the $K^*(892)$ mass.

⁶⁶ Phase shift analysis. Systematic errors added corresponding to spread of different fits.

⁶⁷ From fit of 3-parameter relativistic P-wave Breit-Wigner to total mass distribution. Includes BATON 68, MILLER 67B, ALFF-STEINBERGER 66, HAGOPIAN 66, HAGOPIAN 66B, JACOBS 66B, JAMES 66, WEST 66, BLIEDEN 65 and CARMONY 64.

⁶⁸ From the parametrization according to SOEDING 66.

⁶⁹ From the parametrization according to ROSS 66.

⁷⁰ From pole extrapolation.

⁷¹ From phase shift analysis of GRAYER 74 data. 72 Using relativistic Breit-Wigner and taking into account ρ - ω interference.

⁷³ Systematic errors not evaluated.

⁷⁴ From fit of 3-parameter relativistic Breit-Wigner to helicity-zero part of P-wave intensity.

CHABAUD 83 includes data of GRAYER 74. 75 HEYN 81 includes all spacelike and timelike F_π values until 1978.

⁷⁶ Includes MALAMUD 69, ARMENISE 68, BACON 67, HUWE 67, MILLER 67B, ALFF-STEINBERGER 66, HAGOPIAN 66, HAGOPIAN 66B, JACOBS 66B, JAMES 66, WEST 66, GOLDHABER 64, ABOLINS 63.

 $^{^{78} \}operatorname{Assuming} \ m_{\rho^+} = m_{\rho^-}, \ \Gamma_{\rho^+} = \Gamma_{\rho^-}.$

⁷⁹ Without limitations on masses and widths.

| Γ_{17} | $\eta e^+ e^-$ | | | |

[a] The $\omega \rho$ interference is then due to $\omega \rho$ mixing only, and is expected to be small. If $e\mu$ universality holds, $\Gamma(\rho^0 \to \mu^+ \mu^-) = \Gamma(\rho^0 \to e^+ e^-)$

CONSTRAINED FIT INFORMATION

An overall fit to the total width and a partial width uses 10 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 10.7$ for 8 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\left<\delta p_i \delta p_j \right>/(\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$$x_3 = \begin{bmatrix} -100 \\ \Gamma & 15 & -15 \\ \hline x_2 & x_3 \end{bmatrix}$$

CONSTRAINED FIT INFORMATION

An overall fit to 15 branching ratios uses 51 measurements and one constraint to determine 10 parameters. The overall fit has a $\chi^2 = 51.8$ for 42 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv$ $\Gamma_i/\Gamma_{\rm total}$. The fit constrains the x_i whose labels appear in this array to sum to

 $^{^1}$ Using all η' decays. 2 Systematic uncertainty not estimated. 3 Using η' decays into neutrals. Not independent of the other listed BASILE 71 η' mass measurement.

CONSTRAINED FIT INFORMATION

An overall fit to the total width, a partial width, 2 combinations of partial widths obtained from integrated cross section, and $13\,$ branching ratios uses 40 measurements and one constraint to determine 9 parameters. The overall fit has a $\chi^2=31.5$ for 32 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$\eta'(958) \rightarrow \eta \pi \pi$ DECAY PARAMETERS

$|MATRIX ELEMENT|^2 = |1 + \alpha Y|^2 + CX + DX^2$

X and Y are Dalitz variables; α is complex and C, and D are real-valued. Parameters C and D are not necessarily equal to c and d, respectively, in the generalized parameterization following this one. May be different for $\eta'(958) \to \eta \pi^+ \pi^-$ and $\eta'(958) \to \eta \pi^0 \pi^0$ decays. Because of different initial assumptions and strong correlations of the parameters we do not average the parameters in the section below.

 $\eta'(958)$

$\eta'(958) \rightarrow \eta \pi \pi$ DECAY PARAMETERS

$|MATRIX ELEMENT|^2 \propto 1 + a Y + b Y^2 + c X + d X^2$

X and Y are Dalitz variables and a, b, c, and d are real-valued parameters. May be different for $\eta'(958) \to \eta \pi^+ \pi^-$ and $\eta'(958) \to \eta \pi^0 \pi^0$ decays. We do not average measurements in the section below because parameter values from each experiment are strongly correlated.

¹ Quoted number refers to real part of pole position.

¹ Quoted number refers to real part of pole position.

² Analytic continuation using Roy equations. Uses the K_{e4} data of BATLEY 10c and the $\pi N \rightarrow \pi\pi N$ data of HYAMS 73, GRAYER 74, and PROTOPOPESCU 73.

³ Analytic continuation using GKPY equations. Uses the K_{e4} data of BATLEY 10c and the $\pi N \rightarrow \pi\pi N$ data of HYAMS 73, GRAYER 74, and PROTOPOPESCU 73.

⁴ Pole position. Used Roy equations.

⁵ Average of the analyses of three data sets in the K-matrix model. Uses the data of BATLEY 08A, HYAMS 73, and GRAYER 74, partially of COHEN 80 or ETKIN 82B.

⁶ On sheet H in a 2 pole solution. The other pole is found on sheet H in 4 (850–100) MeV

 6 On sheet II in a 2-pole solution. The other pole is found on sheet III at (850-100i) MeV $^7\,{\rm Using}$ a relativistic Breit-Wigner function and taking into account the finite D_S mass.

 8 Breit-Wigner mass. Using finite width corrections according to FLATTE 76 and ACHASOV 05, and the ratio $g_{f_0\ K\ K}^2/g_{f_0\ \pi\pi}^2=0.$

⁹In the kaon-loop fit.

To the kaon-loop in: 10 in the no-structure fit. 11 Systematic errors not estimated. 12 FLATTE 76 parameterization. $gf_0\pi\pi=329\pm96~{\rm MeV/c^2}$ assuming $gf_0KK/gf_0\pi\pi=2$.

 13 Breit-Wigner mass. Using finite width corrections according to FLATTE 76 and ACHASOV 05, and the ratio $g_{f_0\ K\ K}^2/g_{f_0\ \pi\pi}^2=4.21\pm0.25\pm0.21$ from ABLIKIM 05.

 $^{14}\ln$ the kaon-loop fit following formalism of ACHASOV 89.

 16 FLATTE 76 parameterization. Supersedes GARMASH 05. 17 FLATTE 76 parameterization, $g_{f_0}^2$ K $\overline{K}/g_{f_0}^2$ π π = 4.21 \pm 0.25 \pm 0.21.

$f_0(980)$

| ¹⁸ K-matrix pole from combined analysis of $\pi^- p \rightarrow \pi^0 \pi^0 n$, $\pi^- p \rightarrow K \overline{K}$ | ζn, |
|----------------------------------------------------------------------------------------------------------------------------------|-----|
| $ \begin{array}{cccccccccccccccccccccccccccccccccccc$ | π0, |
| $K^+ K^0_S \pi^-$ at rest, $\overline{p} n \to \pi^- \pi^- \pi^+$, $K^0_S K^- \pi^0$, $K^0_S K^0_S \pi^-$ at rest. | |

- ¹⁹ From the negative interference with the $f_0(500)$ meson of AITALA 01B using the ACHASOV 89 parameterization for the $f_0(980)$, a Breit-Wigner for the $f_0(500)$, and ACHASOV 01F for the $ho\pi$ contribution.
- 20 Coupled-channel Breit-Wigner, couplings $g_\pi=0.09\pm0.01\pm0.01, g_{\mbox{\it K}}=0.02\pm0.04\pm0.03.$
- $^{21}\,\mathrm{Supersedes}$ ACHASOV 981. Using the model of ACHASOV 89.
- ²² Supersedes ACHASOV 981.
- 23 In the "narrow resonance" approximation.
- 24 Assuming $\Gamma(f_0) = 40$ MeV.
- 25 From a narrow pole fit taking into account $\mathit{f}_{0}(980)$ and $\mathit{f}_{0}(1200)$ intermediate mecha-
- ²⁶ From the combined fit of the photon spectra in the reactions $e^+e^-
 ightarrow \pi^+\pi^-\gamma$,
- ²⁷ Supersedes BARBERIS 99 and BARBERIS 99B
- 28 T-matrix pole.
- ²⁹ From invariant mass fit.
- 30 On sheet II in a 2 pole solution. The other pole is found on sheet III at (1039–93*i*) MeV.
- 31 On sheet II in a 2 pole solution. The other pole is found on sheet III at (963-29i) MeV.
- 32 Reanalysis of data from HYAMS 73, GRAYER 74, SRINIVASAN 75, and ROSSELET 77 using the interfering amplitude method.
- ³³ At high |t|.
- 34 At low |t|.
- 35 On sheet II in a 4-pole solution, the other poles are found on sheet III at (953–55*i*) MeV and on sheet IV at (938–35*i*) MeV.
- ³⁶ Combined fit of ALDE 95B, ANISOVICH 94, AMSLER 94D.
- 37 On sheet II in a 2 pole solution. The other pole is found on sheet III at (996–103*i*) MeV.
- ³⁸ From sheet II pole position. 39 On sheet II in a 2 pole solution. The other pole is found on sheet III at (797–185*i*) MeV and can be interpreted as a shadow pole.
- 40 On sheet II in a 2 pole solution. The other pole is found on sheet III at (978-28i) MeV.
- $^{41}\,\mathrm{From}$ coupled channel analysis.
- 42 Coupled channel analysis with finite width corrections.
- 43 Included in AGUILAR-BENITEZ 78 fit.

f₀(980) WIDTH

Width determination very model dependent. Peak width in $\pi\pi$ is about 50 MeV, but decay width can be much larger.

- 44 Analytic continuation using Roy equations. Uses the $K_{\rm e4}$ data of BATLEY 10c and the $\pi\,N\,\to\,\pi\pi\,N$ data of HYAMS 73, GRAYER 74, and PROTOPOPESCU 73.
- 46 Quoted number refers to twice imaginary part of pole position. When 46 Analytic continuation using GKPY equations. Uses the $K_{\rm e4}$ data of BATLEY 10c and the $\pi N \to \pi\pi N$ data of HYAMS 73, GRAYER 74, and PROTOPOPESCU 73. 47 Pole position. Used Roy equations.
- 48 Average of the analyses of three data sets in the K-matrix model. Uses the data of BATLEY 08A, HYAMS 73, and GRAYER 74, partially of COHEN 80 or ETKIN 82B.
- 49 On sheet II in a 2-pole solution. The other pole is found on sheet III at (850-100i) MeV
- 50 Using a relativistic Breit-Wigner function and taking into account the finite D_s mass.
- 51 Breit-Wigner $\pi\pi$ width. Using finite width corrections according to FLATTE 76 and ACHASOV 05, and the ratio $g_{f_0 KK}^2/g_{f_0 \pi\pi}^2=0$.
- 52 Systematic errors not estimated.
- 53 Breit-Wigner $\pi\pi$ width. Using finite width corrections according to FLATTE 76 and ACHASOV 05, and the ratio $g_{f_0\ K\ K}^2/g_{f_0\ \pi\ \pi}^2=4.21\pm0.25\pm0.21$ from ABLIKIM 05.
- ⁵⁴ Breit-Wigner, solution 1, PWA ambiguous.
- 55 K-matrix pole from combined analysis of $\pi^-p \to \pi^0\pi^0$ n, $\pi^-p \to K\overline{K}$ n, $\pi^+\pi^- \to \pi^+\pi^-$, $\overline{p}p \to \pi^0\pi^0\pi^0$, $\pi^0\eta\eta$, $\pi^0\pi^0\eta$, $\pi^+\pi^-\pi^0$, $K^+K^-\pi^0$, K^0_S K^0_S π^0 , ${\cal K}^+ \; {\cal K}^0_S \; \pi^- \; \text{at rest, } \overline{\rho} \, n \to \; \pi^- \pi^- \pi^+ \text{, } \; {\cal K}^0_S \; {\cal K}^- \pi^0 \text{, } \; {\cal K}^0_S \; {\cal K}^0_S \; \pi^- \; \text{at rest.}$
- ⁵⁶ Using the data of AKHMETSHIN 99c, ACHASOV 00H, and ALOISIO 02D.
- 57 Breit-Wigner width.
 58 Supersedes ACHASOV 98I. Using the model of ACHASOV 89.
- ⁵⁹ Supersedes ACHASOV 981.
- 60 In the "narrow resonance" approximation.
- 61 From the combined fit of the photon spectra in the reactions $e^+\,e^- \to \pi^+\pi^-\gamma$,
- 62 Supersedes BARBERIS 99 and BARBERIS 99B
- 63 T-matrix pole.
- 64 On sheet II in a 2 pole solution. The other pole is found on sheet III at (1039-93i) MeV.
- 65 From invariant mass fit.
 66 On sheet II in a 2 pole solution. The other pole is found on sheet III at (963-29i) MeV. 67 Reanalysis of data from HYAMS 73, GRAYER 74, SRINIVASAN 75, and ROSSELET 77
- using the interfering amplitude method. 68 At high |t|
- ⁶⁹ At low |t|.
- 70 On sheet II in a 4-pole solution, the other poles are found on sheet III at (953-55i) MeV 71 Combined fit of ALDE 95B, ANISOVICH 94,
- 72 On sheet II in a 2 pole solution. The other pole is found on sheet III at (996-103i) MeV.
- ⁷³ From sheet II pole position.
- 74 On sheet II in a 2 pole solution. The other pole is found on sheet III at (797–185i) MeV and can be interpreted as a shadow pole.
- 75 On sheet II in a 2 pole solution. The other pole is found on sheet III at (978–28i) MeV.
- $^{76}\,\mathrm{From}$ coupled channel analysis.
- 77 Coupled channel analysis with finite width corrections.
- 78 From coupled channel fit to the HYAMS 73 and PROTOPOPESCU 73 data. With a simultaneous fit to the $\pi\pi$ phase-shifts, inelasticity and to the K^0_S K^0_S invariant mass.
- ⁷⁹Included in AGUILAR-BENITEZ 78 fit.

CONSTRAINED FIT INFORMATION

An overall fit to 30 branching ratios uses 79 measurements and one constraint to determine 14 parameters. The overall fit has a $\chi^2 =$ 57.4 for 66 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\left<\delta x_i \delta x_j\right>/(\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv$ $\Gamma_i/\Gamma_{ ext{total}}$. The fit constrains the x_i whose labels appear in this array to sum to

Weighted average of Γ_{ee} and $\sqrt{\Gamma_{e\,e}\Gamma_{\mu\mu}}$ from AMBROSINO 05 assuming lepton universality.

The combined fit assuming that the total $\phi(1020)$ production cross section is saturated by those of K^+K^- , K_SK_L , $\pi^+\pi^-\pi^0$, and $\eta\gamma$ decays modes and using ACHASOV 008 for the $\eta\gamma$ decay mode.

¹² Width errors enlarged by us to $4T/\sqrt{N}$; see the note with the $K^*(892)$ mass. 13 Strongly correlated with AKHMETSHIN 04.

versally. 16 Combined analysis of the CMD-2 data on $\phi \to K^+K^-$, $K^0_S K^0_L$, $\pi^+\pi^-\pi^0$, $\eta\gamma$ assuming that the sum of their branching fractions is 0.99741 ± 0.00007 .

- ¹ The $\rho^{\pm}\pi^{\mp}$ state can be also due to the $\pi(1300)$.
- ²Using the Breit-Wigner parameterization; strong correlation between mass and width.
- ³Using the data of BARATE 98R.
- 4 From a fit to the 3π mass spectrum including the $K\overline{K}^*(892)$ threshold.

- 5 Uses the model of ISGUR 89.
 7 Includes the effect of a possible a_1' state.
- 8 Uses the model of FEINDT 90. 9 Supersedes AKERS 95P.
- 10 Average and spread of values using 2 variants of the model of BOWLER 75.
- 11 Reanalysis of RUCKSTUHL 86.
- 12 Reanalysis of SCHMIDKE 86.
- 13 Reanalysis of ALBRECHT 86B.

 14 From a combined reanalysis of ALBRECHT 86B, SCHMIDKE 86, and RUCKSTUHL 86.
- 15 From a combined reanalysis of ALBRECHT 86B and DAUM 81B.
- 16 Uses the model of BOWLER 75. 17 Produced in K^- backward scattering.

- 19 Using the Breit-Wigner parameterization; strong correlation between mass and width.
- 20 Using the data of BARATE 98R.
- $^{21}\,\mathrm{From}$ a fit of the $\,\mathrm{K}^-\,\mathrm{K}^{*0}$ distribution assuming $m_{a_1}^{} = 1230$ MeV and purely resonant production of the K^-K^{*0} system. 22 From a fit to the 3π mass spectrum including the $K\overline{K}^*(892)$ threshold.
- $^{23}\,\mathrm{Using}$ the $a_1(1260)$ mass of 1230 MeV.
- 24 From AKHMETSHIN 99E and ASNER 00 data using the $a_1(1260)$ mass of 1230 MeV.
- $^{25}_{\rm 26}$ Uses the model of KUHN 90. $^{26}_{\rm Uses}$ the model of ISGUR 89.

$a_1(1260)$

- ¹ T-matrix pole.
- ² Mass errors enlarged by us to Γ/\sqrt{N} ; see the note with the $K^*(892)$ mass.
- ** Mass errors enlarged by us to 1/V M, see the note with the π (022) mass.

 ** From a partial-wave analysis of data using a K-matrix formalism with 5 poles.

 ** From an energy-independent partial-wave analysis.

 ** From an amplitude analysis of the reaction $\pi^+\pi^- \to 2\pi^0$.

 ** From an amplitude analysis of $\pi^+\pi^- \to \pi^+\pi^-$ scattering data.

- 7 4-poles, 5-channel K matrix fit.
 8 From analysis of L3 data at 91 and 183–209 GeV.
 9 Systematic uncertainties not estimated.
- 10 JOHNSON 68 includes BONDAR 63, LEE 64, DERADO 65, EISNER 67.

CONSTRAINED FIT INFORMATION

An overall fit to the total width, 4 partial widths, a combination of partial widths obtained from integrated cross sections, and 6 branching ratios uses 44 measurements and one constraint to determine 8 parameters. The overall fit has a $\chi^2 =$ 81.8 for 37 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\left\langle \delta \rho_i \delta \rho_j \right\rangle / (\delta \rho_i \cdot \delta \rho_j)$, in percent, from the fit to parameters ρ_i , including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

CONSTRAINED FIT INFORMATION

An overall fit to 7 branching ratios uses 16 measurements and one constraint to determine 5 parameters. The overall fit has a χ^2 = 24.7 for 12 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv$ $\Gamma_i/\Gamma_{
m total}$. The fit constrains the x_i whose labels appear in this array to sum to

 1.0 ± 0.4

$f_1(1285) \Gamma(i)\Gamma(\gamma\gamma)/\Gamma(total)$

CONSTRAINED FIT INFORMATION

An overall fit to 5 branching ratios uses 18 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 =$ $9.3 \ \text{for} \ 15 \ \text{degrees} \ \text{of} \ \text{freedom} \, .$

The following off-diagonal array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv$ $\Gamma_i/\Gamma_{\rm total}$. The fit constrains the x_i whose labels appear in this array to sum to

$$\begin{array}{c|ccccc} x_5 & & 10 & & \\ x_6 & & -89 & -46 & & \\ x_7 & & & -1 & -2 & -24 \\ \hline & x_1 & x_5 & x_6 & & \end{array}$$

```

- $^1\,\mathrm{Another}$ pole is found at (1510 \pm 130) $i~(800^{+}_{-150})$ MeV.
- ² Coupled channel analysis of $\pi^+\pi^-\pi^0$, $K^+K^-\pi^0$, and $K^{\pm}K^0_S\pi^{\mp}$.
- $^3\,\mathrm{Average}$ between $\pi^+\,\pi^-\,2\pi^0$ and $2(\pi^+\,\pi^-)$
- ⁴T-matrix pole on sheet — —
- ⁵ Supersedes ANISOVICH 94.
- Supersetes Amosovicity $\overline{\sigma}_{PP} \to 3\pi^0, \pi^0\eta\eta$, and $\pi^0\pi^0\eta$ on sheet IV. Demonstrates explicitly that $f_0(500)$ and $f_0(1370)$ are two different poles.
- ⁷ Analysis of data from FALVARD 88.
- ⁸The pole is on Sheet III. Demonstrates explicitly that $f_0(500)$ and $f_0(1370)$ are two
- ⁹ Uses data from BEIER 72B, OCHS 73, HYAMS 73, GRAYER 74, ROSSELET 77, CASON 83, ASTON 88, and ARMSTRONG 91B. Coupled channel analysis with flavor symmetry and all light two-pseudoscalars systems.
- 10 Reanalysis of ANISOVICH 94 data.
- 11 T-matrix pole on sheet III.
- 12 Analysis of data from OCHS 73, GRAYER 74, BECKER 79, and CASON 83.

 $f_0(1370)$

 $^{^{13}\,\}mathrm{Breit\text{--}Wigner}$ mass. $^{14}\,\mathrm{Breit\text{--}Wigner}$ mass. May also be the $\mathit{f}_{0}(1500).$

¹⁵ Reanalysis of ABELE 96c data.

¹⁶ Also observed by GARMASH 07 in $B^0 \to K_S^0 \, \pi^+ \, \pi^-$ decays. Supersedes GARMASH 05. 17 Uses data from BEIER 72B, OCHS 73, HYAMS 73, GRAYER 74, ROSSELET 77, CASON 83, ASTON 88, and ARMSTRONG 91B. Coupled channel analysis with flavor symmetry and all light two-pseudoscalars systems. 18 Also observed by ASNER 00 in $\tau^- \to \pi^- \pi^0 \pi^0 \nu_\tau$ decays

²² The systematic errors are not reported.
23 Breit-Wigner width. May also be the $f_0(1500)$.
24 Also observed by GARMASH 07 in $B^0 \to K_S^0 \pi^+ \pi^-$ decays. Supersedes GARMASH 05.
25 Uses data from BEIER 72B, OCHS 73, HYAMS 73, GRAYER 74, ROSSELET 77, CASON 83, ASTON 88, and ARMSTRONG 91B. Coupled channel analysis with flavor symmetry and all light two-pseudoscalars systems.
26 Also observed by ASNER 00 in $\tau^- \to \pi^- \pi^0 \pi^0 \nu_\tau$ decays

²⁷ Width defined as distance between 45 and 135° phase shift.

$$\eta(1405)$$

$$I^{G}(J^{PC}) = 0^{+}(0^{-}+)$$

THE $\eta(1405)$, $\eta(1475)$, $f_1(1420)$, AND $f_1(1510)$

Revised February 2012 by C. Amsler (Zürich) and A. Masoni (INFN Cagliari).

The first observation of the $\eta(1440)$ was made in $p\overline{p}$ annihilation at rest into $\eta(1440)\pi^+\pi^-$, $\eta(1440)\to K\overline{K}\pi$ [1]. This state was reported to decay through $a_0(980)\pi$ and $K^*(892)\overline{K}$ with roughly equal contributions. The $\eta(1440)$ was also observed in radiative $J/\psi(1S)$ decay into $K\overline{K}\pi$ [2–4] and $\gamma\rho$ [5]. There is evidence for the existence of two pseudoscalars in this mass region, the $\eta(1405)$ and $\eta(1475)$. The former decays mainly through $a_0(980)\pi$ (or direct $K\overline{K}\pi$) and the latter mainly to $K^*(892)\overline{K}$.

The simultaneous observation of two pseudoscalars is reported in three production mechanisms: π^-p [6,7]; radiative $J/\psi(1S)$ decay [8,9]; and $\overline{p}p$ annihilation at rest [10–13]. All of them give values for the masses, widths, and decay modes in reasonable agreement. However, Ref. [9] favors a state decaying into $K^*(892)\overline{K}$ at a lower mass than the state decaying into $a_0(980)\pi$. In $J/\psi(1S)$ radiative decay, the $\eta(1405)$ decays into $K\overline{K}\pi$ through $a_0(980)\pi$, and hence a signal is also expected in the $\eta\pi\pi$ mass spectrum. This was indeed observed by MARK III in $\eta\pi^+\pi^-$ [14], which reports a mass of 1400 MeV, in line with the existence of the $\eta(1405)$ decaying into $a_0(980)\pi$.

BES [15] reports an enhancement in $K^+K^-\pi^0$ around 1.44 GeV in $J/\psi(1S)$ decay, recoiling against an ω (but not a ϕ) without resolving the presence of two states nor performing a spin-parity analysis, due to low statistics. This state could also be the $f_1(1420)$ (see below). On the other hand, BES observes $\eta(1405) \to \eta \pi \pi$ in $J/\psi(1S)$ decay, recoiling against an ω [16].

The $\eta(1405)$ is also observed in $\overline{p}p$ annihilation at rest into $\eta \pi^+ \pi^- \pi^0 \pi^0$, where it decays into $\eta \pi \pi$ [17]. The intermediate $a_0(980)\pi$ accounts for roughly half of the $\eta \pi \pi$ signal, in agreement with MARK III [14] and DM2 [4].

However, the issue remains controversial as to whether two pseudoscalar mesons really exist. According to Ref. [18] the splitting of a single state could be due to nodes in the decay amplitudes which differ in $\eta\pi\pi$ and $K^*(892)\overline{K}$. Based on the isospin violating decay $J/\psi(1S) \to \gamma 3\pi$ observed by BES [19] the splitting could also be due to a triangular singularity mixing $\eta\pi\pi$ and $K^*(892)\overline{K}$ [20].

The $\eta(1295)$ has been observed by four π^-p experiments [7,21–23], and evidence is reported in $\overline{p}p$ annihilation [24–26].

In $J/\psi(1S)$ radiative decay, an $\eta(1295)$ signal is evident in the 0^{-+} $\eta\pi\pi$ wave of the DM2 data [9]. Also BaBar [27] reports evidence for a signal around 1295 MeV in B decays into $\eta\pi\pi K$. However, the existence of the $\eta(1295)$ is questioned in Refs. [18] and [28]. The authors claim a single pseudoscalar meson in the 1400 MeV region. This conclusion is based on properties of the wave functions in the 3P_0 model (and on an unpublished analysis of the annihilation $\bar{p}p \to 4\pi\eta$). The pseudoscalar signal around 1400 MeV is then attributed to the first radial excitation of the η .

Assuming establishment of the $\eta(1295)$, the $\eta(1475)$ could be the first radial excitation of the η' , with the $\eta(1295)$ being the first radial excitation of the η . Ideal mixing, suggested by the $\eta(1295)$ and $\pi(1300)$ mass degeneracy, would then imply that the second isoscalar in the nonet is mainly $s\bar{s}$, and hence couples to $K^*\bar{K}$, in agreement with properties of the $\eta(1475)$. Also, its width matches the expected width for the radially excited $s\bar{s}$ state [29,30]. A study of radial excitations of pseudoscalar mesons [31] favors the $s\bar{s}$ interpretation of the $\eta(1475)$. However, due to the strong kinematical suppression the data are not sufficient to exclude a sizeable $s\bar{s}$ admixture also in the $\eta(1405)$.

The $K\overline{K}\pi$ and $\eta\pi\pi$ channels were studied in $\gamma\gamma$ collisions by L3 [32]. The analysis led to a clear $\eta(1475)$ signal in $K\overline{K}\pi$, decaying into $K^*\overline{K}$, very well identified in the untagged data sample, where contamination from spin 1 resonances is not allowed. At the same time, L3 [32] did not observe the $\eta(1405)$, neither in $K\overline{K}\pi$ nor in $\eta\pi\pi$. The observation of the $\eta(1475)$, combined with the absence of an $\eta(1405)$ signal, strengthens the two-resonances hypothesis. Since gluonium production is presumably suppressed in $\gamma\gamma$ collisions, the L3 results [32] suggest that $\eta(1405)$ has a large gluonic content (see also Refs. [33] and [34]).

The L3 result is somewhat in disagreement with that of CLEO-II, which did not observe any pseudoscalar signal in $\gamma\gamma \to \eta(1475) \to K_S^0 K^{\pm}\pi^{\mp}$ [35]. However, more data are required. Moreover, after the CLEO-II result, L3 performed a further analysis with full statistics [36], confirming their previous evidence for the $\eta(1475)$. The CLEO upper limit [35] for $\Gamma_{\gamma\gamma}(\eta(1475))$, and the L3 results [36], are consistent with the world average for the $\eta(1475)$ width.

BaBar [27] also reports the $\eta(1475)$ in B decays into $K\bar{K}^*$ recoiling against a K, but upper limits only are given for the $\eta(1405)$. As mentioned above, in B decays into $\eta\pi\pi K$ the $\eta(1295) \to \eta\pi\pi$ is observed while only upper limits are given for the $\eta(1405)$. The $f_1(1420)$ (and the $f_1(1285)$) are not seen.

The gluonium interpretation for the $\eta(1405)$ is not favored by lattice gauge theories which predict the 0^{-+} state above 2 GeV [37,38] (see also the article on the "Quark model" in this issue of the Review). However, the $\eta(1405)$ is an excellent candidate for the 0^{-+} glueball in the fluxtube model [39]. In this model, the 0^{++} $f_0(1500)$ glueball is also naturally related to a 0^{-+} glueball with mass degeneracy broken in QCD. Also, Ref. 40 shows that the pseudoscalar glueball could lie at a lower

$\eta(1405)$

mass than predicted from lattice calculation. In this model the $\eta(1405)$ appears as the natural glueball candidate (see also Refs. [41] and [42]). A detailed review of the experimental situation is available in Ref. 43.

Let us now deal with 1⁺⁺ isoscalars. The $f_1(1420)$, decaying into $K^*\overline{K}$, was first reported in π^-p reactions at 4 GeV/c [44]. However, later analyses found that the 1400–1500 MeV region was far more complex [45–47]. A reanalysis of the MARK III data in radiative $J/\psi(1S)$ decay into $K\overline{K}\pi$ [8] shows the $f_1(1420)$ decaying into $K^*\overline{K}$. Also, a C=+1 state is observed in tagged $\gamma\gamma$ collisions (e.g., Ref. 48).

In $\pi^- p \to \eta \pi \pi n$ charge-exchange reactions at 8–9 GeV/c the $\eta \pi \pi$ mass spectrum is dominated by the $\eta(1440)$ and $\eta(1295)$ [21,49], and at 100 GeV/c Ref. 22 reports the $\eta(1295)$ and $\eta(1440)$ decaying into $\eta \pi^0 \pi^0$ with a weak $f_1(1285)$ signal, and no evidence for the $f_1(1420)$.

Axial (1⁺⁺) mesons are not observed in $\overline{p}p$ annihilation at rest in liquid hydrogen, which proceeds dominantly through S-wave annihilation. However, in gaseous hydrogen, P-wave annihilation is enhanced and, indeed, Ref. 11 reports $f_1(1420)$ decaying into $K^*\overline{K}$. The $f_1(1420)$, decaying into $K\overline{K}\pi$, is also seen in pp central production, together with the $f_1(1285)$. The latter decays via $a_0(980)\pi$, and the former only via $K^*\overline{K}$, while the $\eta(1440)$ is absent [50,51]. The $K_SK_S\pi^0$ decay mode of the $f_1(1420)$ establishes unambiguously C=+1. On the other hand, there is no evidence for any state decaying into $\eta\pi\pi$ around 1400 MeV, and hence the $\eta\pi\pi$ mode of the $f_1(1420)$ must be suppressed [52].

We now turn to the experimental evidence for the $f_1(1510)$. Two states, the $f_1(1420)$ and $f_1(1510)$, decaying into $K^*\overline{K}$, compete for the $s\overline{s}$ assignment in the 1^{++} nonet. The $f_1(1510)$ was seen in $K^-p\to \Lambda K\overline{K}\pi$ at 4 GeV/c [53], and at 11 GeV/c [54]. Evidence is also reported in π^-p at 8 GeV/c, based on the phase motion of the 1^{++} $K^*\overline{K}$ wave [47]. A somewhat broader 1^{++} signal is also observed in $J/\psi(1S)\to \gamma\eta\pi^+\pi^-$ [55] as well as a small signal in $J/\psi(1S)\to \gamma\eta'\pi^+\pi^-$, attributed to the $f_1(1510)$ [56].

The absence of $f_1(1420)$ in K^-p [54] argues against the $f_1(1420)$ being the $s\overline{s}$ member of the 1^{++} nonet. However, the $f_1(1420)$ was reported in K^-p but not in π^-p [57], while two experiments do not observe the $f_1(1510)$ in K^-p [57,58]. The latter is also not seen in central collisions [51], or $\gamma\gamma$ collisions [59], although, surprisingly for an $s\overline{s}$ state, a signal is reported in 4π decays [60]. These facts lead to the conclusion that $f_1(1510)$ is not well established [61].

Assigning the $f_1(1420)$ to the 1⁺⁺ nonet, one finds a nonet mixing angle of $\sim 50^{\circ}$ [61]. However, arguments favoring the $f_1(1420)$ being a hybrid $q\overline{q}g$ meson, or a four-quark state, were put forward in Refs. [62] and [63], respectively, while Ref. 64 argued for a molecular state formed by the π orbiting in a P-wave around an S-wave $K\overline{K}$ state.

Summarizing, there is convincing evidence for the $f_1(1420)$ decaying into $K^*\overline{K}$, and for two pseudoscalars (possibly one dynamically split into two) in the $\eta(1440)$ region, the $\eta(1405)$

and $\eta(1475)$, decaying into $a_0(980)\pi$ and $K^*\overline{K}$, respectively. The $f_1(1510)$ is not well established.

- ¹ The selected process is $J/\psi \rightarrow \omega a_0(980) \pi$.
- ² From fit to the $a_0(980) \pi 0^{-}$ + partial wave.
- ³Best fit with a single Breit Wigner.
- 4 Decaying dominantly directly to $K^+K^-\pi^0$. 5 Decaying into $(K\overline{K})_S\pi$, $(K\pi)_S\overline{K}$, and $a_0(980)\pi$. 6 From fit to the $a_0(980)\pi^0$ + partial wave. Cannot rule out a $a_0(980)\pi^1$ + + partial wave.
- $7\,\mbox{wave}.$ $7\,\mbox{Excluded}$ from averaging because averaging would be meaningless.
- ⁸Best fit with a single Breit Wigner.
- 9 This peak in the $\gamma \rho$ channel may not be related to the $\eta(1405)$. $^{
 m 10}\,{\rm Estimated}$ by us from various fits.
- 11 These experiments identify only one pseudoscalar in the 1400–1500 range. Data could

also refer to $\eta(1475)$.

 $\eta(1405)$

| Γ_4 | $\eta(\pi\pi)_{S-wave}$ | seen | |
| | $f_0(980)\eta$ | seen | |
| Γ ₆ | 4π | seen | |
| Γ_7 | ho ho | <58 % | 99.85% |
| Γ ₈ | $\gamma \gamma$ | | |
| Г ₈ Г ₉ | $ ho^0 \gamma$ | seen | |
| Γ ₁₀ | $\phi \gamma$ | | |
| Γ_{11} | K*(892) K | seen | |

 $^{^{14}}$ The selected process is $J/\psi\to \,\omega\,a_0(980)\,\pi.$ 15 From fit to the $a_0(980)\,\pi$ 0 $^-$ + partial wave.

 $^{^{16}\}mathrm{From}~\eta\pi^+\pi^-$ mass distribution - mainly $a_0(980)\pi$ - no spin-parity determination available. 17 Decaying dominantly directly to $K^+K^-\pi^0$.

¹⁸ Decaying into $(K^n)_S\pi$, $(K\pi)_SK$, and $a_0(980)\pi$. 19 From fit to the $a_0(980)\pi$ 0 $^{-+}$ partial wave , but $a_0(980)\pi$ 1 $^{++}$ cannot be excluded.

This peak in the $\gamma\rho$ channel may not be related to the $\eta(1405)$. 21 Estimated by us from various fits.

These experiments identify only one pseudoscalar in the 1400–1500 range. Data could also refer to $\eta(1475)$.

²⁹ Systematic uncertainty not evaluated. 24 From best fit to 0 $^{-}$ $^{+}$ partial wave , 50% $\it K^*(892)~K$, 50% $\it a_0(980)~\pi$.

 3 Using the data of AKHMETSHIN 03B and BISELLO 91B assuming the $\omega\pi^0$ and $\pi^+\pi^-$ mass dependence of the total width. $\rho(1700)$ mass and width fixed at 1700 MeV and and 340 MeV are selected as 1700 MeV and 17000 MeV and 17000 MeV and 240 MeV, respectively.

 4 Using Breit-Wigner parameterization of the $\rho(1450)$ and assuming the $\omega\pi^-$ mass dependence for the total width.

 5 Mass-independent width parameterization. ho(1700) mass and width fixed at 1700 MeV and 235 MeV respectively.

 6 Using data from BISELLO 91B, DOLINSKY 86 and ALBRECHT 87L. 7 Not separated from $b_1(1235)$, not pure $J^P=1^-$ effect.

^{0.6895. 2} Using $\eta(1475)$ mass of 1481 MeV and width of 48 MeV. The upper limit increases to 0.140 keV if the world average value, 87 MeV, of the width is used.

⁴ T-matrix pole, supersedes ANISOVICH 94 and AMSLER 92.

⁵ Reanalysis of AlTALA 01A data. This state could also be $f_0(1370)$.

 $^{^6\,\}mathrm{Breit ext{-}Wigner}$ mass. May also be the $\it f_0(1370)$.

⁷ Breit-Wigner mass.

⁸ Statistical error only.

o Statistical error only. 9 Breit-Wigner, solution 1, PWA ambiguous. 10 K-matrix pole from combined analysis of $\pi^-p \to \pi^0\pi^0n$, $\pi^-p \to K\overline{K}n$, $\pi^+\pi^- \to \pi^+\pi^-, \overline{p}p \to \pi^0\pi^0\pi^0, \pi^0\eta\eta, \pi^0\pi^0\eta, \pi^+\pi^-\pi^0, K^++\pi^-\eta^0, K^0_S K^0_S \pi^0, K^++K^0_S \pi^-$ at rest, $\overline{p}n \to \pi^-\pi^-\pi^+, K^0_S K^-\pi^0, K^0_S K^0_S \pi^-$ at rest. 11 Computed BARBERIS QUANTIFICATION OF THE PROPERTY
¹¹ Supersedes BARBERIS 99 and BARBERIS 99B.

 $^{^{12}}$ T-matrix pole on sheet --+

- $^{13}\,\mathrm{T}\text{-matrix}$ pole. Coupled-channel analysis of AMSLER 95B, AMSLER 95C, and AM-The Hallix polynomial confidence analysis of Amelica 36, Amelia SLER 94D. $^{14} \text{ Supersedes ABATZIS 94, ARMSTRONG 89E. Breit-Wigner mass.}$ $^{15} \text{ From a simultaneous analysis of the annihilations } \overline{\rho} p \rightarrow 3\pi^0, \pi^0 \eta \eta.$

- 16 Reanalysis of ANISOVICH 94 data.

VALUE (MeV) EVTS

 $^{17}\mathrm{From}$ central value and spread of two solutions. Breit-Wigner mass.

f₀(1500) WIDTH

 $^{18}\,\text{T-matrix pole}.$

¹⁹ Average between $\pi^+\pi^-2\pi^0$ and $2(\pi^+\pi^-)$.

²⁰ T-matrix pole, supersedes ANISOVICH 94.

21 T-matrix pole, supersedes ANISOVICH 94 and AMSLER 92.

 22 Breit-Wigner width. May also be the $f_0(1370)$.

²³ Breit-Wigner width.

24 Statistical error only.

25 Breit-Wigner, solution 1, PWA ambiguous.

26 K-matrix pole from combined analysis of $\pi^-p \to \pi^0\pi^0$ n, $\pi^-p \to K\overline{K}n$, $\pi^+\pi^- \to \pi^+\pi^-$, $\overline{p}p \to \pi^0\pi^0$ π^0 , π^0 , π^0 , π^0 , $\pi^+\pi^-$, π^0 , K^0 ,

27 Supersedes BARBERIS 99 and BARBERIS 99B.

 28 T-matrix pole on sheet --+

T-matrix pole on sheet --+.

97-matrix pole. Coupled-channel analysis of AMSLER 95B, AMSLER 95C, and AMSLER 94D.

30 Supersedes ABATZIS 94, ARMSTRONG 89E. Breit-Wigner mass.

31 From a simultaneous analysis of the annihilations $\bar{p}p \to 3\pi^0, \pi^0\eta\eta$.

32 Reanalysis of ANISOVICH 94 data.

33 From central value and spread of two solutions. Breit-Wigner mass.

CONSTRAINED FIT INFORMATION

An overall fit to 6 branching ratios uses 10 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 =$ 11.4 for 6 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv$ $\Gamma_i/\Gamma_{
m total}$. The fit constrains the x_i whose labels appear in this array to sum to

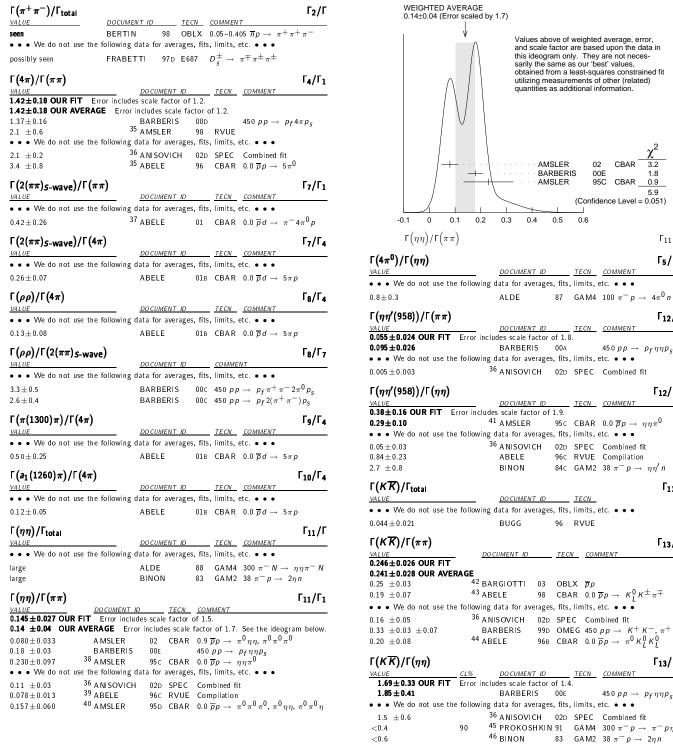

$f_0(1500) \Gamma(i)\Gamma(\gamma\gamma)/\Gamma(total)$

| $\Gamma(\pi\pi) \times \Gamma(\gamma)$ | γ)/Γ _{total} | 1 | | | Γ ₁ Γ ₁₄ /Γ | |

CONSTRAINED FIT INFORMATION

An overall fit to the total width, 2 partial widths, a combination of partial widths obtained from integrated cross sections, and ${\bf 3}$ branching ratios uses 16 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2=14.0$ for 12 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\sf total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

OMITTED FROM SUMMARY TABLE

Seen in the amplitude analysis of the $3\pi^0$ system produced in $\overline{p}\,\rho\to 4\pi^0$. Possibly seen in the study of the hadronic structure in decay $\tau\to 3\pi\nu_{\tau}$ (ABREU 98G and ASNER 00). Needs confirmation.

 1 From the combined fit of ANTONELLI 92, ACHASOV 01E, ACHASOV 02E, and ACHASOV 03D data on the $\pi^+\pi^-\pi^0$ and ANTONELLI 92 on the $\omega\pi^+\pi^-$ final states. Supersedes ACHASOV 99E and ACHASOV 02E.

Supersedes ACHASOV 992 and ACHASOV 922. 2 Using results of CORDIER 81 and preliminary data of DOLINSKY 91 and ANTONELLI 92. 3 Using the data of AKHMETSHIN 00D and ANTONELLI 92. The $\rho\pi$ dominance for the energy dependence of the ω (1420) and ω (150) width assumed.

⁴ Using data from BARKOV 87, DOLINSKY 91, and ANTONELLI 92.

Using the data from ANTONELLI 92.

6 Using the data from IVANOV 81 and BISELLO 88B.

7 Using the data from BISELLO 91c.
8 From a fit to two Breit-Wigner functions and using the data of DOLINSKY 91 and ANTONELLI 92. 9 From the combined fit of the $\rho\pi$ and $\omega\pi\pi$ final states.

 $^{^1}$ From $f_2(1270) \pi$ decay.

² From a fit to the invariant mass distribution. From a fit to $J^{PC}=2^{-}+f_2(1270)\pi$, $f_0(1370)\pi$ waves.

⁴ From a fit to $J^P=2^-S$ -wave $f_2(1270)\,\pi$ partial wave.

 5 Clear phase rotation seen in $2^{-}\tilde{S}$, $2^{-}P$, $2^{-}D$ waves. We quote central value and spread of single-resonance fits to three channels.

From a two-resonance fit to four 2^-0^+ waves. This should not be averaged with all the single resonance fits.

 9 From $f_2(1270) \pi$ decay.

10 From a fit to the invariant mass distribution. 11 From a fit to $JPC = 2^{-} + f_2(1270) \pi$, $f_0(1370) \pi$ waves.

From a fit to $J^P=2^{-\frac{1}{2}(1270)\pi}$ partial wave.

 13 Clear phase rotation seen in $^{2-}$ S, $^{2-}$ P, $^{2-}$ D waves. We quote central value and spread of single-resonance fits to three channels. 14 From $\rho\pi$ decay.

The form $\rho\pi$ decay. The form a flow of the following the form a flow-resonance fit to four 2^-0^+ waves. This should not be averaged with all the single resonance fits.

CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 6 measurements and one constraint to determine 4 parameters. The overall fit has a χ^2 = 1.9 for 3 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv$ $\Gamma_i/\Gamma_{\mathsf{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$$\begin{array}{c|ccccc} x_5 & -53 & & \\ x_7 & -29 & -59 & & \\ x_8 & -8 & -21 & -9 & \\ \hline & x_4 & x_5 & x_7 & & \end{array}$$

1 From a fit with two incoherent Breit-Wigners.
2 From the simultaneous fit to the $K\overline{K}^*(892)+$ c.c. and $\phi\eta$ data from AUBERT 08s using the results of AUBERT 07AK.
3 From the combined fit of AKHMETSHIN 03 and MANE 81 also including ρ , ω , and ϕ . Neither isospin nor flavor structure known.
4 Using data from IVANOV 81, BARKOV 87, BISELLO 88B, DOLINSKY 91, and ANTONELLI 92.
5 Using the data from BISELLO 91c.
6 Using BISELLO 88B and MANE 82 data.
7 From global fit including ρ , ω , ϕ and ρ (1700) assume mass 1570 MeV and width 510 MeV for ρ radial excitation.
8 From global fit of ρ , ω , ϕ and their radial excitations to channels $\omega\pi^+\pi^-$, K^+K^- , K^0_S , K^0_L ,

$\phi(1680) \Gamma(i)\Gamma(e^+e^-)/\Gamma^2(total)$

This combination of a branching ratio into channel (i) and branching ratio into e^+e^- is directly measured and obtained from the cross section at the peak. We list only data that have not been used to determine the branching ratio into (i) or e^+e^-

$\Gamma(K_L^0 K_S^0)/\Gamma_{ ext{total}} \times \Gamma(e^+ e^-)/\Gamma_{ ext{total}}$

CONSTRAINED FIT INFORMATION

An overall fit to 5 branching ratios uses 10 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2=$ 14.7 for 7 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv$ $\Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

 $\rho(1700)$

$$\rho$$
(1700)

$$I^{G}(J^{PC}) = 1^{+}(1^{-})$$

THE $\rho(1450)$ AND THE $\rho(1700)$

Updated May 2010 by S. Eidelman (Novosibirsk) and G. Venanzoni (Frascati).

In our 1988 edition, we replaced the $\rho(1600)$ entry with two new ones, the $\rho(1450)$ and the $\rho(1700)$, because there was emerging evidence that the 1600-MeV region actually contains two ρ -like resonances. Erkal [1] had pointed out this possibility with a theoretical analysis on the consistency of 2π and 4π electromagnetic form factors and the $\pi\pi$ scattering length. Donnachie [2], with a full analysis of data on the 2π and 4π final states in e^+e^- annihilation and photoproduction reactions, had also argued that in order to obtain a consistent picture, two resonances were necessary. The existence of $\rho(1450)$ was supported by the analysis of $\eta\rho^0$ mass spectra obtained in photoproduction and e^+e^- annihilation [3], as well as that of $e^+e^- \to \omega\pi$ [4].

The analysis of [2] was further extended by [5,6] to include new data on 4π -systems produced in e^+e^- annihilation, and in τ -decays (τ decays to 4π , and e^+e^- annihilation to 4π can be related by the Conserved Vector Current assumption). These systems were successfully analyzed using interfering contributions from two ρ -like states, and from the tail of the $\rho(770)$ decaying into two-body states. While specific conclusions on $\rho(1450) \to 4\pi$ were obtained, little could be said about the $\rho(1700)$.

Independent evidence for two 1⁻ states is provided by [7] in 4π electroproduction at $\langle Q^2 \rangle = 1$ (GeV/c)², and by [8] in a high-statistics sample of the $\eta\pi\pi$ system in π^-p charge exchange.

This scenario with two overlapping resonances is supported by other data. Bisello [9] measured the pion form factor in the interval 1.35–2.4 GeV, and observed a deep minimum around 1.6 GeV. The best fit was obtained with the hypothesis of ρ -like resonances at 1420 and 1770 MeV, with widths of about 250 MeV. Antonelli [10] found that the $e^+e^- \to \eta \pi^+ \pi^-$ cross section is better fitted with two fully interfering Breit-Wigners, with parameters in fair agreement with those of [2] and [9]. These results can be considered as a confirmation of the $\rho(1450)$.

Decisive evidence for the $\pi\pi$ decay mode of both $\rho(1450)$ and $\rho(1700)$ comes from $\overline{p}p$ annihilation at rest [11]. It has been shown that these resonances also possess a $K\overline{K}$ decay mode [12–14]. High-statistics studies of the decays $\tau \to \pi\pi\nu_{\tau}$ [15,16], and $\tau \to 4\pi\nu_{\tau}$ [17] also require the $\rho(1450)$, but are not sensitive to the $\rho(1700)$, because it is too close to the τ mass. A recent very-high-statistics study of the $\tau \to \pi\pi\nu_{\tau}$ decay performed at Belle [18] reports the first observation of both $\rho(1450)$ and $\rho(1700)$ in τ decays.

The structure of these ρ states is not yet completely clear. Barnes [19] and Close [20] claim that $\rho(1450)$ has a mass consistent with radial 2S, but its decays show characteristics of hybrids, and suggest that this state may be a 2S-hybrid mixture. Donnachie [21] argues that hybrid states could have a 4π decay mode dominated by the $a_1\pi$. Such behavior has been observed by [22] in $e^+e^- \to 4\pi$ in the energy range 1.05–1.38 GeV, and by [17] in $\tau \to 4\pi$ decays. Alexander [23] observes the $\rho(1450) \to \omega \pi$ decay mode in *B*-meson decays, however, does not find $\rho(1700) \to \omega \pi^0$. A similar conclusion is made by [24], who studied the process $e^+e^- \to \omega \pi^0$. Various decay modes of the $\rho(1450)$ and $\rho(1700)$ are observed in $\overline{p}n$ and $\overline{p}p$ annihilation [25,26], but no definite conclusions can be drawn. More data should be collected to clarify the nature of the ρ states, particularly in the energy range above 1.6 GeV.

We now list under a separate entry the $\rho(1570)$, the $\phi\pi$ state with $J^{PC}=1^{--}$ earlier observed by [27] (referred to as C(1480)) and recently confirmed by [28]. While [29] shows that it may be a threshold effect, [5] and [30] suggest two independent vector states with this decay mode. The C(1480) has not been seen in the $\overline{p}p$ [31] and e^+e^- [32,33] experiments. However, the sensitivity of the two latter is an order of magnitude lower than that of [28]. Note that [28] can not exclude that their observation is due to an OZI-suppressed decay mode of the $\rho(1700)$.

Several observations on the $\omega\pi$ system in the 1200-MeV region [34–40] may be interpreted in terms of either $J^P=1^ \rho(770) \to \omega\pi$ production [41], or $J^P=1^+$ $b_1(1235)$ production [39,40]. We argue that no special entry for a $\rho(1250)$ is needed. The LASS amplitude analysis [42] showing evidence for $\rho(1270)$ is preliminary and needs confirmation. For completeness, the relevant observations are listed under the $\rho(1450)$

Recently [43] reported a very broad 1^{--} resonance-like K^+K^- state in $J/\psi \to K^+K^-\pi^0$ decays. Its pole position corresponds to mass of 1576 MeV and width of 818 MeV. [44–46] suggest its exotic structure (molecular or multiquark), while [47] and [48] explain it by the interference between the $\rho(1450)$ and $\rho(1700)$. We quote [43] as X(1575) in the section "Further States."

Evidence for ρ -like mesons decaying into 6π states was first noted by [49] in the analysis of 6π mass spectra from e^+e^- annihilation [50,51] and diffractive photoproduction [52]. Clegg [49] argued that two states at about 2.1 and 1.8 GeV exist: while the former is a candidate for the $\rho(2150)$, the latter could be a manifestation of the $\rho(1700)$ distorted by threshold effects. BaBar reported observations of the new decay modes of the $\rho(2150)$ in the channels $\eta'(958)\pi^+\pi^-$ and $f_1(1285)\pi^+\pi^-$ [53]. The relativistic quark model [54] predicts the 2^3D_1 state with $J^{PC}=1^{--}$ at 2.15 GeV which can be identified with the $\rho(2150)$.

The E687 Collaboration at Fermilab reported an observation of a narrow-dip structure at 1.9 GeV in the $3\pi^+3\pi^-$ diffractive photoproduction [55]. A similar effect of the dip in the cross section of $e^+e^- \to 6\pi$ around 1.9 GeV has been earlier reported by DM2 [51], where 6π included both $3\pi^+3\pi^-$ and $2\pi^+2\pi^-2\pi^0$. Later the dip in the R value (the total cross section of $e^+e^- \to$ hadrons divided by the cross section of $e^+e^- \to \mu^+\mu^-$) was

[56], again around 1.9 GeV. This energy is close to the $N\overline{N}$ threshold, which hints at the possible relation between the dip and $N\overline{N}$, e.g., the frequently discussed narrow $N\overline{N}$ resonance or just a threshold effect. Such behaviour is also characteristic of exotic objects like vector $q\overline{q}$ hybrids. Note that [57] failed to find this state in the reaction $\overline{n}p \to 3\pi^+2\pi^-\pi^0$. A reanalysis of the E687 data by [58] shows that a dip may arise due to interference of a narrow object with a broad $\rho(1700)$ independently of the nature of the former. BaBar studied the processes $e^+e^- \to 3\pi^+3\pi^-$ and $e^+e^- \to 2\pi^+2\pi^-2\pi^0$ using the radiative return, and observed a structure around 1.9 GeV in both final states [59]. The data are not well described by a single Breit-Wigner state, and a good fit is achieved while taking into account the interference of such a structure with a Jacob-Slansky amplitude for continuum. The mass of this state obtained by BaBar is consistent with [56] and [55], but the width is substantially larger. Recently [28] observed a structure at 1.9 GeV in the radiative return to the $\phi\pi$ final state, with a much smaller width of 48 ± 17 MeV consistent with that of [56,58]. We list these observations under a separate particle $\rho(1900)$, which needs confirmation.

 COMMENT

 • • • We do not use the following data for averages, fits, limits, etc. • • •

⁴ T-matrix pole.

⁵ From phase shift analysis of HYAMS 73 data.

¹³ Simple relativistic Breit-Wigner fit with constant width.

¹⁴ One peak fit result.

¹⁵ Parameters roughly estimated, not from a fit.

From the GOUNARIS 68 parametrization of the pion form factor.

²¹ T-matrix pole

²² From phase shift analysis of HYAMS 73 data.

²³ Simple relativistic Breit-Wigner fit with constant width.

²⁴ An additional 40 MeV uncertainty in both the mass and width is present due to the choice of the background shape.

²⁵ Included in BECKER 79 analysis.

 $^{^{\}mbox{\footnotesize 28}}$ Simple relativistic Breit-Wigner fit with constant width.

²⁹ One peak fit result.

³⁰ Parameters roughly estimated, not from a fit.

³¹ Skew mass distribution compensated by Ross-Stodolsky factor.

 $^{^{32}}$ Width errors enlarged by us to $4\Gamma/\sqrt{N}$; see the note with the $K^*(892)$ mass.

³⁴ Taking into account the ρ (1700) contribution only. Using the data of ACHASOV 00i on $e^+e^-\to\omega\pi^0$ and of EDWARDS 00A on $\tau^-\to\omega\pi^-\nu_\tau$.

³⁵ From a fit with two resonances with the JACOB 72 continuum.

 $^{41}\, {\rm The} \,\, \pi \, \pi$ system is in S-wave.

| | | | | | | | |

In the SU(3) based model with a specific interference pattern of the $f_2(1270)$, $a_2^{
m U}(1320)$, and $f_2'(1525)$ mesons incoherently added to the $f_0(1710)$ and non-resonant background.

 2 This state may be different from $f_0(1710)$, see CLOSE 05.

 ${3 \atop 4} J^P = 0^+$ ${4 \atop T-matrix pole}$

⁵ Supersedes BARBERIS 99 and BARBERIS 99B.

Supersedes BARBERTS 99 and BARBERTS 99. 6 $JP = 0^+$, supersedes by ARMSTRONG 89D. 7 No JPC determination. 8 $JP = 2^+$. 9 Breit-Wigner mass.

9 Breit-Wigner mass. 10 Systematic errors not estimated. 11 K-matrix pole, assuming $J^P=0^+$, from combined analysis of $\pi^-p\to\pi^0\pi^0$ n, $\pi^-p\to K\overline{K}n$, $\pi^+\pi^-\to\pi^+\pi^-$, $\overline{p}p\to\pi^0\pi^0\pi^0$, $\pi^0\pi^0$, $\pi^0\eta\eta$, $\pi^0\pi^0\eta$, $\pi^+\pi^-\pi^0$, K^0_S ,

14 Not seen by AMSLER 02. 15 T-matrix pole, assuming $J^P=0+16$ No J^PC determination. 17 No J^PC determination, width not determined. 18 From a fit to the 0^+ partial wave. 19 ALDE 92D combines all the GAMS-2000 data. 20 $J^P=2^+$, superseded by FRENCH 99.

²¹ From an analysis ignoring interference with $f_2'(1525)$.

 22 From an analysis including interference with $\bar{t}_2'(1525)$.

 $^{23}\,\mbox{Superseded}$ by ALDE 92D.

24 Uses MRK3 data. From a partial-wave analysis of data using a K-matrix formalism with 5 poles, but assuming spin 2. Fit with constrained inelasticity.
 25 P = 2+ preferred.

 26 From fit neglecting nearby $f_2^\prime(1525)$. Replaced by BLOOM 83.

²⁷ Superseded by LONGACRE 86.

$f_0(1710)$

   ^{28} In the SU(3) based model with a specific interference pattern of the f_2(1270), a_2^0(1320),
        and f_2'(1525) mesons incoherently added to the f_0(1710) and non-resonant background.
   29 Breit-Wigner width.

30 J^P = 0^+.

31 T-matrix pole.
  33 J^P=0^+, supersedes by ARMSTRONG 89b. 34 No J^{PC} determination. 35 J^P=2^+.
   ^{
m 32}\,{\rm Supersedes} BARBERIS 99 and BARBERIS 99B.
   35 JP = 2^+
36 No JPC determination.
   37 Systematic errors not estimated.
   <sup>38</sup> This state may be different from f_0(1710), see CLOSE 05.
   <sup>39</sup> (Solution I)
   We will be a suming J^P=0^+, from combined analysis of \pi^-p\to\pi^0\pi^0 n, \pi^-p\to\kappa^0\pi^0 n, \pi^-p\to\kappa^0\pi^0 n, \pi^-p\to\pi^0\pi^0 n, \pi^+\pi^-\to\pi^+\pi^-, \pi^-p\to\pi^0\pi^0 n, \pi^0, \pi^0, \pi^0, \pi^0, \pi^0, \pi^0, \pi^0, \pi^+\pi^-\pi^0, \pi^0, 
   41 (Solution I)
   <sup>42</sup> Decaying to f_0(1370) \pi \pi.
   \begin{array}{l} 43 \ J^{P} = 0^{+} \\ 44 \ \text{Not seen by AMSLER 02.} \end{array}
   45 T-matrix pole, assuming J^P=0^+
46 No J^{PC} determination.
47 From a fit to the 0^+ partial wave.
   48 ALDE 92D combines all the GAMS-2000 data.
49 IP = 2+ (0+ \text{ excluded})
                 = 2^+, (0^+ \text{ excluded}).
   ^{50}\,\mathrm{From} an analysis ignoring interference with f_2'(1525)
   ^{51} From an analysis including interference with \bar{t}_2'(1525).
   ^{52} Uses MRK3 data. From a partial-wave analysis of data using a K-matrix formalism with 5 poles, but assuming spin 2. Fit with constrained inelasticity. ^{53}\,J^P=2^+ preferred.
   ^{54}\,\mathrm{From} fit neglecting nearby f_2'(1525). Replaced by BLOOM 83.
   ^{55} From an amplitude analysis of the \kappa_S^0 \kappa_S^0 system, superseded by LONGACRE 86.
                                                                   f<sub>0</sub>(1710) DECAY MODES

 $^{^{58}\,\}mathrm{From}$ a partial-wave analysis of data using a K-matrix formalism with 5 poles, but assuming spin 2.

59 Fit with constrained inelasticity.

60 Using data from ABLIKIM 04A.

$\eta(1760)$

$$I^{G}(J^{PC}) = 0^{+}(0^{-+})$$

OMITTED FROM SUMMARY TABLE

Seen by DM2 in the $\rho\rho$ system (BISELLO 89B). Structure in this region has been reported before in the same system (BAL-TRUSAITIS 86B) and in the $\omega\omega$ system (BALTRUSAITIS 85C, BISELLO 87).

OMITTED FROM SUMMARY TABLE

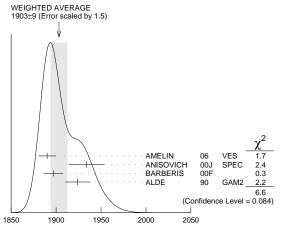

We list here three different peaks with close masses and widths seen in the mass distributions of $\omega\omega$, $\eta\eta'$, and K^+K^- final states. ALDE 91B argues that they are of different nature.

- 12 From the first PWA solution.
 13 From a partial-wave analysis of the data.
- 14 From an amplitude analysis of the reaction $\pi^+\pi^- \to 2\pi^0$.
- ¹⁵ K matrix pole.
- 16 Taking into account the $f_2(1950)$. Helicity-2 production favored.
- 17 Energy-dependent analysis.
- 18 Single energy analysis.
- ¹⁹ From solution A of amplitude analysis of data on $\overline{p}p \to \pi\pi$. See however KLOET 96 who fit $\pi^+\pi^-$ only and find waves only up to J=3 to be important but not significantly
- resonant. 20 From solution B of amplitude analysis of data on $\overline{p}p \to \pi\pi$. See however KLOET 96 who fit $\pi^+\pi^-$ only and find waves only up to J=3 to be important but not significantly
- 22 Width errors enlarged by us to $4\Gamma/\sqrt{N}$; see the note with the $K^*(892)$ mass.

 $^{^5}$ OAKDEN 94 makes an amplitude analysis of LEAR data on $\overline{\rho}\rho\to\pi\pi$ using a method based on Barrelet zeros. This is solution A. The amplitude analysis of HASAN 94 includes earlier data as well, and assume that the data can be parametrized in terms of towers of nearly degenerate resonances on the leading Regge trajectory. See also KLOET 96 and MARTIN 97 who make related analyses.

⁶ From solution B of amplitude analysis of data on $\overline{p}p \to \pi\pi$.

71(JP) = 0(2+) from simultaneous analysis of $p\overline{p} \to \pi^+$ and $\pi^0\pi^0$. 81 G (JP) = 0+(2+) from partial-wave amplitude analysis.

 K^{\pm}

STRANGE MESONS $(S = \pm 1, C = B = 0)$

$$K^+ = u\overline{s}$$
, $K^0 = d\overline{s}$, $\overline{K}^0 = \overline{d}s$, $K^- = \overline{u}s$, similarly for K^* 's

$$I(J^P) = \frac{1}{2}(0^-)$$

THE CHARGED KAON MASS

Revised 1994 by T.G. Trippe (LBNL).

The average of the six charged kaon mass measurements which we use in the Particle Listings is

$$m_{K^{\pm}} = 493.677 \pm 0.013 \text{ MeV (S} = 2.4),$$
 (1)

where the error has been increased by the scale factor S. The large scale factor indicates a serious disagreement between different input data. The average before scaling the error is

$$m_{K^{\pm}} = 493.677 \pm 0.005 \text{ MeV}$$
 ,
 $\chi^2 = 22.9 \text{ for 5 D.F., Prob.} = 0.04\%$, (2)

where the high χ^2 and correspondingly low χ^2 probability further quantify the disagreement.

The main disagreement is between the two most recent and precise results,

$$m_{K^{\pm}} = 493.696 \pm 0.007 \ \mbox{MeV} \ \ \ \ \mbox{DENISOV 91}$$

$$m_{K^{\pm}} = 493.636 \pm 0.011 \ \mbox{MeV (S} = 1.5) \ \mbox{GALL 88}$$

Average $=493.679 \pm 0.006 \text{ MeV}$

$$\chi^2 = 21.2 \text{ for } 1 \text{ D.F.}, \text{ Prob.} = 0.0004\%, (3)$$

both of which are measurements of x-ray energies from kaonic atoms. Comparing the average in Eq. (3) with the overall average in Eq. (2), it is clear that DENISOV 91 and GALL 88 dominate the overall average, and that their disagreement is responsible for most of the high χ^2 .

The GALL 88 measurement was made using four different kaonic atom transitions, K^- Pb (9 \to 8), K^- Pb (11 \to 10), K^- W (9 \to 8), and K^- W (11 \to 10). The m_{K^\pm} values they obtain from each of these transitions is shown in the Particle Listings and in Fig. 1. Their K^- Pb (9 \to 8) m_{K^\pm} is below and somewhat inconsistent with their other three transitions. The average of their four measurements is

$$m_{K^{\pm}} = 493.636 \pm 0.007$$
 ,
$$\gamma^2 = 7.0 \ \text{for 3 D.F., Prob.} = 7.2\% \ . \tag{4}$$

This is a low but acceptable χ^2 probability so, to be conservative, GALL 88 scaled up the error on their average by S=1.5 to obtain their published error ± 0.011 shown in Eq. (3) above and used in the Particle Listings average.

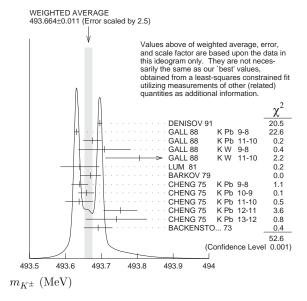

Figure 1: Ideogram of $m_{K^{\pm}}$ mass measurements. GALL 88 and CHENG 75 measurements are shown separately for each transition they measured.

The ideogram in Fig. 1 shows that the DENISOV 91 measurement and the GALL 88 K^- Pb (9 \rightarrow 8) measurement yield two well-separated peaks. One might suspect the GALL 88 K^- Pb (9 \rightarrow 8) measurement since it is responsible both for the internal inconsistency in the GALL 88 measurements and the disagreement with DENISOV 91.

To see if the disagreement could result from a systematic problem with the K^- Pb $(9 \to 8)$ transition, we have separated the CHENG 75 data, which also used K^- Pb, into its separate transitions. Figure 1 shows that the CHENG 75 and GALL 88 K^- Pb (9 \rightarrow 8) values are consistent, suggesting the possibility of a common effect such as contaminant nuclear γ rays near the K^- Pb (9 \rightarrow 8) transition energy, although the CHENG 75 errors are too large to make a strong conclusion. The average of all 13 measurements has a χ^2 of 52.6 as shown in Fig. 1 and the first line of Table 1, yielding an unacceptable χ^2 probability of 0.00005%. The second line of Table 1 excludes both the GALL 88 and CHENG 75 measurements of the K^- Pb (9 \rightarrow 8) transition and yields a χ^2 probability of 43%. The third [fourth] line of Table 1 excludes only the GALL 88 K^- Pb (9 \rightarrow 8) [DENISOV 91] measurement and yields a χ^2 probability of 20% [8.6%]. Table 1 shows that removing both measurements of the K^- Pb (9 \rightarrow 8) transition produces the most consistent set of data, but that excluding only the GALL 88 K^- Pb (9 \rightarrow 8) transition or DENISOV 91 also produces acceptable probabilities.

Table 1: $m_{K^{\pm}}$ averages for some combinations of Fig. 1 data.

| $m_{K^{\pm}} \; (\mathrm{MeV})$ | χ^2 | D.F. | Prob. (% | Measurements used | |
|---------------------------------|----------|------|-----------|---------------------------------------------|----|
| 493.664 ± 0.004 | 52.6 | 12 | 0.00005 a | all 13 measurements | |
| 493.690 ± 0.006 | 10.1 | 10 | | no $K^- \operatorname{Pb}(9 \rightarrow 8)$ | |
| 493.687 ± 0.006 | 14.6 | 11 | 20 | no GALL 88 K^- Pb(9 \rightarrow 8 | 8) |
| 493.642 ± 0.006 | 17.8 | 11 | 8.6 | no DENISOV 91 | |

Yu.M. Ivanov, representing DENISOV 91, has estimated corrections needed for the older experiments because of improved $^{192}\mathrm{Ir}$ and $^{198}\mathrm{Au}$ calibration $\gamma\text{-ray}$ energies. He estimates that CHENG 75 and BACKENSTOSS 73 m_{K^\pm} values could be raised by about 15 keV and 22 keV, respectively. With these estimated corrections, Table 1 becomes Table 2. The last line of Table 2 shows that if such corrections are assumed, then GALL 88 K^- Pb (9 \rightarrow 8) is inconsistent with the rest of the data even when DENISOV 91 is excluded. Yu.M. Ivanov warns that these are rough estimates. Accordingly, we do not use Table 2 to reject the GALL 88 K^- Pb (9 \rightarrow 8) transition, but we note that a future reanalysis of the CHENG 75 data could be useful because it might provide supporting evidence for such a rejection.

Table 2: $m_{K^{\pm}}$ averages for some combinations of Fig. 1 data after raising CHENG 75 and BACKENSTOSS 73 values by 0.015 and 0.022 MeV respectively.

| $m_{K^{\pm}} \; (\text{MeV})$ | χ^2 | D.F. | Prob. (% |) Measurements used |
|-------------------------------|----------|------|-----------|---------------------------------------------|
| 493.666 ± 0.004 | 53.9 | 12 | 0.00003 a | all 13 measurements |
| 493.693 ± 0.006 | 9.0 | 10 | 53 | no $K^- \operatorname{Pb}(9 \rightarrow 8)$ |
| 493.690 ± 0.006 | 11.5 | 11 | 40 ı | no GALL 88 K^- Pb(9 \rightarrow 8) |
| 493.645 ± 0.006 | 23.0 | 11 | 1.8 | no DENISOV 91 |

The GALL 88 measurement uses a Ge semiconductor spectrometer which has a resolution of about 1 keV, so they run the risk of some contaminant nuclear γ rays. Studies of γ rays following stopped π^- and Σ^- absorption in nuclei (unpublished) do not show any evidence for contaminants according to GALL 88 spokesperson, B.L. Roberts. The DENISOV 91 measurement uses a crystal diffraction spectrometer with a resolution of 6.3 eV for radiation at 22.1 keV to measure the 4f-3d transition in $K^{--12}C$. The high resolution and the light nucleus reduce the probability for overlap by contaminant γ rays, compared with the measurement of GALL 88. The DENISOV 91 measurement is supported by their high-precision measurement of the 4d-2p transition energy in $\pi^{--12}C$, which is good agreement with the calculated energy.

While we suspect that the GALL 88 K^- Pb (9 \rightarrow 8) measurements could be the problem, we are unable to find clear grounds for rejecting it. Therefore, we retain their measurement in the average and accept the large scale factor until further information can be obtained from new measurements and/or from reanalysis of GALL 88 and CHENG 75 data.

We thank B.L. Roberts (Boston Univ.) and Yu.M. Ivanov (Petersburg Nuclear Physics Inst.) for their extensive help in understanding this problem.

RARE KAON DECAYS

Revised November 2011 by L. Littenberg (BNL) and G. Valencia (Iowa State University).

- A. Introduction: There are several useful reviews on rare kaon decays and related topics [1–15]. Activity in rare kaon decays can be divided roughly into four categories:
- 1. Searches for explicit violations of the Standard Model
- 2. Measurements of Standard Model parameters
- 3. Searches for ${\cal CP}$ violation
- 4. Studies of strong interactions at low energy.

The paradigm of Category 1 is the lepton flavor violating decay $K_L \to \mu e$. Category 2 includes processes such as $K^+ \to \pi^+ \nu \overline{\nu}$, which is sensitive to $|V_{td}|$. Much of the interest in Category 3 is focused on the decays $K_L \to \pi^0 \ell \overline{\ell}$, where $\ell \equiv e, \mu, \nu$. Category 4 includes reactions like $K^+ \to \pi^+ \ell^+ \ell^-$ which constitute a testing ground for the ideas of chiral perturbation theory. Category 4 also includes $K_L \to \pi^0 \gamma \gamma$ and $K_L \to \ell^+ \ell^- \gamma$. The former is important in understanding a CP-conserving contribution to $K_L \to \pi^0 \ell^+ \ell^-$, whereas the latter could shed light on long distance contributions to $K_L \to \mu^+ \mu^-$.

The interplay between Categories 2-4 can be illustrated in Fig. 1. The modes $K \to \pi \nu \overline{\nu}$ are the cleanest ones theoretically. They can provide accurate determinations of certain CKM parameters (shown in the figure). In combination with alternate determinations of these parameters, they also constrain new interactions. The modes $K_L \to \pi^0 e^+ e^-$, $K_L \to \pi^0 \mu^+ \mu^-$ and $K_L \to \mu^+ \mu^-$ are also sensitive to CKM parameters. However, they suffer from a series of hadronic uncertainties that can be addressed, at least in part, through a systematic study of the additional modes indicated in the figure.

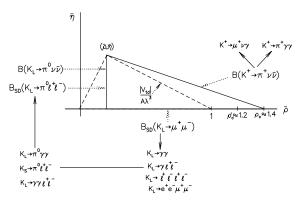

Figure 1: Role of rare kaon decays in determining the unitarity triangle. The solid arrows point to auxiliary modes needed to interpret the main results, or potential backgrounds to them.

B. Explicit violations of the Standard Model: Much activity has focussed on searches for lepton flavor violation (LFV). This is motivated by the fact that many extensions of the minimal Standard Model violate lepton flavor and by the potential to access very high energy scales. For example, the tree-level exchange of a LFV vector boson of mass M_X that couples to lefthanded fermions with electroweak strength and without mixing angles yields $B(K_L \to \mu e) = 4.7 \times 10^{-12} (148 \text{ TeV}/M_X)^4$ [4]. This simple dimensional analysis may be used to read from Table 1 that the reaction $K_L \to \mu e$ is already probing scales of over 100 TeV. Table 1 summarizes the present experimental situation vis a vis LFV. The decays $K_L \to \mu^{\pm} e^{\mp}$ and $K^+ \to \pi^+ e^{\mp} \mu^{\pm}$ (or $K_L \to \pi^0 e^{\mp} \mu^{\pm}$) provide complementary information on potential family number violating interactions, since the former is sensitive to parity-odd couplings and the latter is sensitive to parity-even couplings. Limits on certain lepton-number violating kaon decays also exist, some recent ones being those of Refs. [16–18]. Related searches in μ and au processes are discussed in our section "Tests of Conservation Laws."

Table 1: Searches for lepton flavor violation in K decay

| Mode | 90% CL upper limit | Exp't | Yr./Ref. |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|-----------------------------------------------|------------------------------------------------------------------------------|
| $\begin{array}{l} \overline{K^+ \to \pi^+ e^- \mu^+} \\ K^+ \to \pi^+ e^+ \mu^- \\ K_L \to \mu e \\ K_L \to \pi^0 e \mu \\ K_L \to \pi^0 \pi^0 e \mu \end{array}$ | $1.2 \times 10^{-11} \\ 5.2 \times 10^{-10} \\ 4.7 \times 10^{-12} \\ 7.6 \times 10^{-11} \\ 1.7 \times 10^{-10}$ | BNL-865 BNL-865 BNL-871 KTeV KTeV | 2005/Ref. 19 2000/Ref. 16 1998/Ref. 20 2008/Ref. 21 2008/Ref. 21 |

Physics beyond the SM is also pursued through the search for $K^+ \to \pi^+ X^0$, where X^0 is a new light particle. The searches cover both long-lived particles (e.g., hyperphoton, axion, familon, etc.), and short lived ones that decay to muon, electron or photon pairs. The 90% CL upper limit on $K^+ \to \pi^+ X^0$ is 7.3×10^{-11} [22]. Recent new bounds for a short lived

⁵ Result obtained by averaging the decay length and decay time analyses taking correlations

pseudoscalar X^0 decaying to muons or photons are $B(K_L \to \pi^0 \pi^0 \mu^+ \mu^-) < 1 \times 10^{-10}$ [23] and $B(K_L \to \pi^0 \pi^0 \gamma \gamma) < 2.4 \times 10^{-7}$ [24].

C. Measurements of Standard Model parameters:

In the SM, the decay $K^+ \to \pi^+ \nu \overline{\nu}$ is dominated by one-loop diagrams with top-quark intermediate states and long-distance contributions are known to be quite small [2,25]. This permits a precise calculation of this rate in terms of SM parameters. Studies of this process are thus motivated by the possibility of detecting non-SM physics when comparing with the results of global fits [28,29].

BNL-787 observed two candidate events [30,31] in the clean high π^+ momentum and one event [32] in the low-momentum region. The successor experiment BNL-949 observed one more in the high-momentum region [22] and three more in the low-momentum region [33] yielding a branching ratio of $(1.73^{+1.15}_{-1.05}) \times 10^{-10}$ [34]. A new experiment, NA62, with a sensitivity goal of $\sim 10^{-12}/\text{event}$ was proposed [35] at CERN in 2005. It has been approved and is scheduled to run with a partial detector in autumn 2012. In the future, this mode may provide grounds for precision tests of flavor dynamics [36]. The branching ratio can be written in a compact form that exhibits the different ingredients that go into the calculation [37],

$$B(K^{+} \to \pi^{+} \nu \overline{\nu}(\gamma)) = \kappa_{+} (1 + \Delta_{EM}) \left[\left(\frac{\operatorname{Im}(V_{ts}^{\star} V_{td})}{\lambda^{5}} X_{t} \right)^{2} + \left(\frac{\operatorname{Re}(V_{cs}^{\star} V_{cd})}{\lambda} (P_{c} + \delta P_{c,u}) + \frac{\operatorname{Re}(V_{ts}^{\star} V_{td})}{\lambda^{5}} X_{t} \right)^{2} \right]. \quad (1)$$

The parameters in Eq. (1) incorporate the a priori unknown hadronic matrix element in terms of the very well-measured K_{e3} rate [2] in κ_+ ; long distance QED corrections in $\Delta_{\rm EM}$ [27]; the Inami-Lim function for the short distance top-quark contribution [38] including NLO QCD corrections [39] and the two-loop electroweak correction [37], all in X_t ; and the charm-quark contributions due to short distance effects including NNLO QCD corrections [40] and NLO electroweak corrections via P_c [41], as well as certain long distance effects via $\delta P_{c,u}$ [26]. An interesting approximate way to cast this result in terms of the CKM parameters λ , V_{cb} , $\overline{\rho}$ and $\overline{\eta}$ (see our Section on "The Cabibbo-Kobayashi-Maskawa mixing matrix") [11] is:

$$B(K^+ \to \pi^+ \nu \overline{\nu}) \approx 1.6 \times 10^{-5} |V_{cb}|^4 [\sigma \overline{\eta}^2 + (\rho_c - \overline{\rho})^2],$$
 (2)

where $\rho_c \approx 1.45$ and $\sigma \equiv 1/(1-\frac{1}{2}\lambda^2)^2$. Thus, $\mathrm{B}(K^+ \to \pi^+ \nu \overline{\nu})$ determines an ellipse in the $\overline{\rho}$, $\overline{\eta}$ plane with center $(\rho_c,0)$ and semiaxes $\approx \frac{1}{|V_{cb}|^2} \sqrt{\frac{\mathrm{B}(K^+ \to \pi^+ \nu \overline{\nu})}{1.6 \times 10^{-5}}}$ and $\frac{1}{\sigma |V_{cb}|^2} \sqrt{\frac{\mathrm{B}(K^+ \to \pi^+ \nu \overline{\nu})}{1.6 \times 10^{-5}}}$. The latest numerical study leads to a predicted branching ratio $(7.81^{+0.80}_{-0.71} \pm 0.29) \times 10^{-11}$ [37], near the lower end of the measurement of BNL-787 and 949.

Modes with an extra pion, $K \to \pi\pi\nu\bar{\nu}$, could also be used in the extraction of CKM parameters as they are also dominated by short distance contributions [42]. However, they occur at much lower rates with branching rations of order 10^{-13} , and the current best bound from E391a is $B(K_L \to \pi^0\pi^0\nu\bar{\nu}) <$

 8.1×10^{-7} at 90% c.l. [43]. There is also an older bound of $B(K^+\to \pi^+\pi^0\nu\bar{\nu})<4.3\times 10^{-5}$ at 90% c.l. [44] from BNL E787.

The decay $K_L \to \mu^+ \mu^-$ also has a short distance contribution sensitive to the CKM parameter $\overline{\rho}$, given by [11]:

$$B_{SD}(K_L \to \mu^+ \mu^-) \approx 2.7 \times 10^{-4} |V_{cb}|^4 (\rho_c' - \overline{\rho})^2$$
 (3)

where ρ'_c depends on the charm quark mass and is approximately 1.2. This decay, however, is dominated by a long-distance contribution from a two-photon intermediate state. The absorptive (imaginary) part of the long-distance component is determined by the measured rate for $K_L \to \gamma \gamma$ to be $B_{abs}(K_L \to \mu^+ \mu^-) =$ $(6.64 \pm 0.07) \times 10^{-9}$; and it almost completely saturates the observed rate B($K_L \to \mu^+ \mu^-$) = $(6.84 \pm 0.11) \times 10^{-9}$ [45]. The difference between the observed rate and the absorptive component can be attributed to the (coherent) sum of the short-distance amplitude and the real part of the longdistance amplitude. The latter cannot be derived directly from experiment [46], but can be estimated with certain assumptions [47,48]. The decay $K_L \to e^+e^-$ is completely dominated by long distance physics and is easier to estimate. The result, $B(K_L \to e^+e^-) \sim 9 \times 10^{-12}$ [46,49], is in good agreement with the BNL-871 measurement, $(8.7^{+5.7}_{-4.1}) \times 10^{-12}$ [50].

D. Searches for direct CP violation: The mode $K_L \to \pi^0 \nu \overline{\nu}$ is dominantly CP-violating and free of hadronic uncertainties [2,51,52]. In the Standard Model, this mode is dominated by an intermediate top-quark state and does not suffer from the small uncertainty associated with the charm-quark intermediate state that affects the mode $K^+ \to \pi^+ \nu \overline{\nu}$. The branching ratio is given by Ref. 11:

$$B(K_L \to \pi^0 \nu \overline{\nu}) = \kappa_L \left(\frac{\text{Im}(V_{ts}^{\star} V_{td})}{\lambda^5} X_t \right)^2$$

$$\approx 7.6 \times 10^{-5} |V_{cb}|^4 \overline{\eta}^2 . \tag{4}$$

The hadronic matrix element can be related to that measured in $K_{\ell 3}$ decay and is parameterized in κ_L . The latest numerical evaluation leads to a predicted branching ratio $(2.43^{+0.40}_{-0.37}\pm0.06)\times10^{-11}$ [37]. The 90% CL bound on $K^+\to\pi^+\nu\overline{\nu}$ provides a nearly model-independent bound $B(K_L\to\pi^0\nu\overline{\nu})<1.46\times10^{-9}$ [53]. KEK-391a, which took data in 2004 and 2005, has published a 90% CL upper bound of $B(K_L\to\pi^0\nu\overline{\nu})\leq2.6\times10^{-8}$ [54] The KOTO experiment, whose initial goal is to reach the $10^{-11}/\text{event}$ level, is in the final stages of construction at J-PARC [55].

There has been much theoretical work on possible contributions to rare K decays beyond the SM. A comprehensive discussion of these can be found in Refs. [14] and [56].

The decay $K_L \to \pi^0 e^+ e^-$ also has sensitivity to the CKM parameter η through its CP-violating component. There are both direct and indirect CP-violating amplitudes which can interfere. The direct CP-violating amplitude is short distance dominated and has been calculated in detail within the SM [8]. The indirect CP-violating amplitude can be inferred from a

 K^{\pm}

measurement of $K_S \to \pi^0 e^+ e^-$. The complete CP-violating contribution to the rate can be written as [57,58]:

$$B_{\text{CPV}} \approx 10^{-12} \left[15.7 |a_S|^2 \pm 1.4 \left(\frac{|V_{cb}|^2 \overline{\eta}}{10^{-4}} \right) |a_S| + 0.12 \left(\frac{|V_{cb}|^2 \overline{\eta}}{10^{-4}} \right)^2 \right]$$
 (5)

where the three terms correspond to the indirect CP violation, the interference, and the direct CP violation respectively. The parameter a_S has been extracted by NA48 from a measurement of the decay $K_S \to \pi^0 e^+ e^-$ with the result $|a_S| = 1.06^{+0.26}_{-0.21} \pm 0.07$ [59], as well as from a measurement of the decay $K_S \to \pi^0 \mu^+ \mu^-$ with the result $|a_S| = 1.54^{+0.40}_{-0.32} \pm 0.06$ [60]. With current constraints on the CKM parameters, and assuming a positive sign for the interference term [58,61], this implies that $B_{\rm CPV}(K_L \to \pi^0 e^+ e^-) \approx (3.1 \pm 0.9) \times 10^{-11}$, and that the indirect CP violation is larger than the direct CP violation. The complete CP violating amplitude for the related mode $K_L \to \pi^0 \mu^+ \mu^-$ is predicted to be $B_{\rm CPV}(K_L \to \pi^0 \mu^+ \mu^-) \approx (1.4 \pm 0.5) \times 10^{-11}$ [62,15].

 $K_L \to \pi^0 \gamma \gamma$ also has a CP-conserving component dominated by a two-photon intermediate state. This component can be decomposed into an absorptive and a dispersive part. The absorptive part can be extracted from the measurement of the low $m_{\gamma\gamma}$ region of the $K_L \to \pi^0 \gamma \gamma$ spectrum. The rate and the shape of the distribution $d\Gamma/dm_{\gamma\gamma}$ in $K_L \to \pi^0 \gamma \gamma$ are well described in chiral perturbation theory in terms of three (a priori) unknown parameters [63,64].

Both KTeV and NA48 have studied the mode $K_L \to \pi^0 \gamma \gamma$, reporting similar results. KTeV finds $B(K_L \to \pi^0 \gamma \gamma) = (1.29 \pm 0.03_{\rm stat} \pm 0.05_{\rm sys}) \times 10^{-6}$ [65], while NA48 finds $B(K_L \to \pi^0 \gamma \gamma) = (1.36 \pm 0.03_{\rm stat} \pm 0.03_{\rm sys} \pm 0.03_{\rm norm}) \times 10^{-6}$ [66]. Both experiments are consistent with a negligible rate in the low $m_{\gamma\gamma}$ region, suggesting a very small CP-conserving component $B_{\rm CP}(K_L \to \pi^0 e^+ e^-) \sim \mathcal{O}(10^{-13})$ [58,64,66]. There remains some model dependence in the estimate of the dispersive part of the CP-conserving $K_L \to \pi^0 e^+ e^-$ [58].

The related process, $K_L \to \pi^0 \gamma e^+ e^-$, is potentially an additional background in some region of phase space [67]. This process has been observed with a branching ratio of $(1.62 \pm 0.14_{\rm stat} \pm 0.09_{\rm sys}) \times 10^{-8}$ [68].

The decay $K_L \to \gamma \gamma e^+ e^-$ constitutes the dominant background to $K_L \to \pi^0 e^+ e^-$. It was first observed by BNL-845 [69], and subsequently confirmed with a much larger sample by FNAL-799 [70]. It has been estimated that this background will enter at about the 10^{-10} level [71,72], comparable to or larger than the signal level. Because of this, the observation of $K_L \to \pi^0 e^+ e^-$ at the SM level will depend on background subtraction with good statistics. Possible alternative strategies are discussed in Ref. 58 and references cited therein.

The 90% CL upper bound for the process $K_L \to \pi^0 e^+ e^-$ is 2.8×10^{-10} [72]. For the closely related muonic process, the published upper bound is $B(K_L \to \pi^0 \mu^+ \mu^-) \leq 3.8 \times 10^{-10}$ [73], compared with the SM prediction of $(1.5 \pm 0.3) \times 10^{-11}$ [62]

(assuming positive interference between the direct- and indirect-CP violating components).

A study of $K_L \to \pi^0 \mu^+ \mu^-$ has indicated that it might be possible to extract the direct CP-violating contribution by a joint study of the Dalitz plot variables and the components of the μ^+ polarization [74]. The latter tends to be quite substantial so that large statistics may not be necessary.

Combined information from the two $K_L \to \pi^0 \ell^+ \ell^-$ modes complements the $K \to \pi \nu \overline{\nu}$ measurements in constraining physics beyond the SM [75].

E. Other long distance dominated modes:

The decays $K^+ \to \pi^+ \ell^+ \ell^-$ ($\ell = e$ or μ) have received considerable attention. The rate and spectrum have been measured for both the electron and muon modes [76,77,18]. Ref. 57 has proposed a parametrization inspired by chiral perturbation theory, which provides a successful description of data but indicates the presence of large corrections beyond leading order. More work is needed to fully understand the origin of these large corrections.

Much information has been recorded by KTeV and NA48 on the rates and spectrum for the Dalitz pair conversion modes $K_L \to \ell^+\ell^-\gamma$ [78,79], and $K_L \to \ell^+\ell^-\ell'^+\ell'^-$ for $\ell,\ell'=e$ or μ [17,80–82]. All these results are used to test hadronic models and could further our understanding of the long distance component in $K_L \to \mu^+\mu^-$.

- [a] See the Particle Listings below for the energy limits used in this mea-
- $\mbox{\it [b]}$ Most of this radiative mode, the low-momentum γ part, is also included in the parent mode listed without γ 's.
- [c] Structure-dependent part.

- [d] See the "Note on $\pi^\pm \to \ \ell^\pm \nu \gamma$ and $K^\pm \to \ \ell^\pm \nu \gamma$ Form Factors" in the π^{\pm} Particle Listings for definitions and details.
- [e] Direct-emission branching fraction.
- [f] Derived from an analysis of neutrino-oscillation experiments.
- [g] Violates angular-momentum conservation.

CONSTRAINED FIT INFORMATION

An overall fit to the mean life, a decay rate, and 13 branching ratios uses 32 measurements and one constraint to determine 8 parameters. The overall fit has a $\chi^2=$ 51.8 for 25 degrees of

The following off-diagonal array elements are the correlation coefficients $\left<\delta
ho_i \delta
ho_j \right> / (\delta
ho_i \cdot \delta
ho_j)$, in percent, from the fit to parameters ho_i , including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the x_i whose labels appear in this array to sum to one.
