REVIEW OF PARTICLE PHYSICS*

Particle Data Group

Abstract

This biennial Review summarizes much of particle physics. Using data from previous editions, plus 2658 new measurements from 644 papers, we list, evaluate, and average measured properties of gauge bosons, leptons, quarks, mesons, and baryons. We summarize searches for hypothetical particles such as Higgs bosons, heavy neutrinos, and supersymmetric particles. All the particle properties and search limits are listed in Summary Tables. We also give numerous tables, figures, formulae, and reviews of topics such as the Standard Model, particle detectors, probability, and statistics. Among the 112 reviews are many that are new or heavily revised including those on Heavy-Quark and Soft-Collinear Effective Theory, Neutrino Cross Section Measurements, Monte Carlo Event Generators, Lattice QCD, Heavy Quarkonium Spectroscopy, Top Quark, Dark Matter, V_{cb} & V_{ub} , Quantum Chromodynamics, High-Energy Collider Parameters, Astrophysical Constants, Cosmological Parameters, and Dark Matter.

A booklet is available containing the Summary Tables and abbreviated versions of some of the other sections of this full *Review*. All tables, listings, and reviews (and errata) are also available on the Particle Data Group website: http://pdg.lbl.gov.

DOI: 10.1103/PhysRevD.86.010001

The 2012 edition of $Review \ of \ Particle \ Physics$ is published for the Particle Data Group as article 010001 in volume 86 of $Physical \ Review \ D$.

This edition should be cited as: J. Beringer et al. (Particle Data Group), Phys. Rev. D 86, 010001 (2012).

HIGHLIGHTS OF THE 2012 EDITION OF THE REVIEW OF PARTICLE PHYSICS

644 new papers with 2658 new measurements

- Over 100 papers from **LHC** experiments (AT-LAS, CMS, and LHCb).
- Major exclusions in **SUSY** results from the LHC.
- Latest from **B-meson** physics: 120 papers with 555 measurements, including first LHCb results. Stringent limits on $B_s \to \mu^+\mu^-$ from LHCb and CMS approaching the SM expectation.
- Updated and new results in **neutrino mixing**, including observation of mixing angle θ_{13} from reactor experiments.
- 63 new **top** results since 2010, many from LHC experiments.
- New CDF/D0 value of *W*-mass with very small error, impact on prediction of Higgs mass.
- New $\eta_c(1S)$ branching ratio fit removing circular dependencies.
- First observations of $h_b(1P)$, $h_b(2P)$, and the $\chi_b(3P)$ triplet, as well as two exotic charged states with bottomonium content (unconfirmed).

112 reviews (most are revised or new)

- New reviews on:
 - Heavy-Quark and Soft-Collinear Effective Theory
 - Neutrino Cross Section Measurements
 - Neutrino Beam Lines at High-Energy Proton Synchrotrons
 - Monte Carlo Event Generators
 - Lattice QCD
 - Scalar Meson and $\sigma(500)$ Parameters
 - Heavy Quarkonium Spectroscopy
- Significant update/revision to reviews on:
 - Higgs Boson (with addendum on new July 2012 results)
 - Astrophysical Constants (extended to include more cosmological parameters from the 7-year WMAP analysis)
 - Dark Matter
 - **Top Quark** with detailed coverage of LHC results
 - V_{cb} and V_{ub} CKM elements
 - Quantum Chromodynamics
 - **High-Energy Collider Parameters** (includes CLIC and latest LHC parameters)
 - Particle Detectors for Non-Accel. Physics (addition of Coherent Radio Cherenkov Detectors)

See **pdgLive.lbl.gov** for online access to PDG database.

INTRODUCTION

1. Overview

The Review of Particle Physics and the abbreviated version, the Particle Physics Booklet, are reviews of the field of Particle Physics. This complete Review includes a compilation/evaluation of data on particle properties, called the "Particle Listings." These Listings include 2,658 new measurements from 644 papers, in addition to the 29,495 measurements from 8,300 papers that first appeared in previous editions [1].

Both books include Summary Tables with our best values and limits for particle properties such as masses, widths or lifetimes, and branching fractions, as well as an extensive summary of searches for hypothetical particles. In addition, we give a long section of "Reviews, Tables, and Plots" on a wide variety of theoretical and experimental topics, a quick reference for the practicing particle physicist.

The *Review* and the *Booklet* are published in evennumbered years. This edition is an updating through January 2012 (and, in some areas, well into 2012). As described in the section "Online Particle Physics Information" following this introduction, the content of this *Review* is available on the World-Wide Web, and is updated between printed editions (http://pdg.lbl.gov/).

The Summary Tables give our best values of the properties of the particles we consider to be well established, a summary of search limits for hypothetical particles, and a summary of experimental tests of conservation laws.

The Particle Listings contain all the data used to get the values given in the Summary Tables. Other measurements considered recent enough or important enough to mention, but which for one reason or another are not used to get the best values, appear separately just beneath the data we do use for the Summary Tables. The Particle Listings also give information on unconfirmed particles and on particle searches, as well as short "reviews" on subjects of particular interest or controversy.

The Particle Listings were once an archive of all published data on particle properties. This is no longer possible because of the large quantity of data. We refer interested readers to earlier editions for data now considered to be obsolete.

We organize the particles into six categories:

Gauge and Higgs bosons

Leptons

Quarks

Mesons

Baryons

Searches for monopoles, supersymmetry,

compositeness, extra dimensions, etc.

The last category only includes searches for particles that do not belong to the previous groups; searches for heavy charged leptons and massive neutrinos, by contrast, are with the leptons.

In Sec. 2 of this Introduction, we list the main areas of responsibility of the authors, and also list our large number of consultants, without whom we would not have been able to produce this *Review*. In Sec. 4, we mention briefly the naming scheme for hadrons. In Sec. 5, we discuss our procedures for choosing among measurements of particle properties and for obtaining best values of the properties

from the measurements.

The accuracy and usefulness of this *Review* depend in large part on interaction between its users and the authors. We appreciate comments, criticisms, and suggestions for improvements of any kind. Please send them to the appropriate author, according to the list of responsibilities in Sec. 2 below, or to the LBNL addresses below.

To order a copy of the *Review* or the *Particle Physics Booklet* from North and South America, Australia, and the Far East, send email to PDG@LBL.GOV

3. Consultants

The Particle Data Group benefits greatly from the assistance of some 700 physicists who are asked to verify every piece of data entered into this *Review*. Of special value is the advice of the PDG Advisory Committee which meets biennially and thoroughly reviews all aspects of our operation. The members of the 2012 committee are:

- D. Harris (FNAL)
- P. Janot (CERN)
- J. Olson (Princeton)
- G. Perez (Weizmann)
- J. Tanaka (Tokyo)

We have especially relied on the expertise of the following people for advice on particular topics:

- M. Achasov (BINP, Novosibirsk)
- K.S. Agashe (Maryland)
- H. Aihara (Tokyo)
- S.I. Alekhin (COMPAS Group, IHEP, Protvino)
- F. Anulli (INFN, Rome)
- M. Artuso (Syracuse University)
- H. Bachacou (CEA Saclay)
- S. Banerjee (Victoria U, BC)
- R. Barlow (Manchester U.)
- V. B. Bezerra (UFPb)
- M. Beneke (Aachen, Germany)
- A.M. Bernstein (MIT)
- M. Billing (Cornell University)
- P. B. Mackenzie (FNAL)
- C. Bozzi(INFN, Ferrara)
- T. Brooks (SLAC)
- T. Browder (University of Hawaii)
- O. Bruening (CERN)
- A. Buras (Munich Tech. U.)
- V.D. Burkert (Thomas Jefferson Lab)
- J. Butterworth (UCL)
- A. Chao (SLAC)
- C. Davies (U of Glasgow)
- F. Deliot (CEA, Sacley)
- L. Demortier (Rockefeller University)
- D. Denisov (FNAL)
- J. Dingfelder (Bonn, Germany)
- R. Dixon (FNAL)
- A. Donnachie (University of Manchester)
- A.T. Doyle (Glasgow Univ.)
- W. Fischer (BNL)
- M. Furman (LBNL)

- H. Gallagher (Tufts U.)
- P. Gambino (Univ. degli Studi di Torino)
- R. Garisto(PRL)
- A. Gasparian (NC A&T)
- T. Gershon (U. of Warwick, UK)
- E.W.N. Glover (Durham U)
- B. Golob (U. Ljubljana, Slovenia)
- O. Gonzalez Lopez (CIEMAT, Spain)
- M. Grazzini (U of Zurich)
- E. Gschwendtner (U. of Geneva)
- F. Harris (University of Hawaii)
- R. Harr (Wayne State University)
- R. Hawkings (CERN) verifier with useful comments
- Y. Hayato (ICRR, U. of Tokyo)
- J. Heinrich (University of Pennsylvania)
- C. Hill (Ohio State)
- G. Isidori (INFN, Frascati)
- R. Itoh (KEK)
- J. Jowett (CERN)

4. Naming scheme for hadrons

We introduced in the 1986 edition [2] a new naming scheme for the hadrons. Changes from older terminology affected mainly the heavier mesons made of u, d, and s quarks. Otherwise, the only important change to known hadrons was that the F^{\pm} became the D_s^{\pm} . None of the lightest pseudoscalar or vector mesons changed names, nor did the $c\bar{c}$ or $b\bar{b}$ mesons (we do, however, now use χ_c for the $c\bar{c}$ χ states), nor did any of the established baryons. The Summary Tables give both the new and old names whenever a change has occurred.

The scheme is described in "Naming Scheme for Hadrons" (p. 118) of this *Review*.

We give here our conventions on type-setting style. Particle symbols are italic (or slanted) characters: e^- , p, Λ , π^0 , K_L , D_s^+ , b. Charge is indicated by a superscript: B^- , Δ^{++} . Charge is not normally indicated for p, n, or the quarks, and is optional for neutral isosinglets: η or η^0 . Antiparticles and particles are distinguished by charge for charged leptons and mesons: τ^+ , K^- . Otherwise, distinct antiparticles are indicated by a bar (overline): $\overline{\nu}_\mu$, \overline{t} , \overline{p} , \overline{K}^0 , and $\overline{\Sigma}^+$ (the antiparticle of the Σ^-).

5. Procedures

5.1. Selection and treatment of data: The Particle Listings contain all relevant data known to us that are published in journals. With very few exceptions, we do not include results from preprints or conference reports. Nor do we include data that are of historical importance only (the Listings are not an archival record). We search every volume of 20 journals through our cutoff date for relevant data. We also include later published papers that are sent to us by the authors (or others).

In the Particle Listings, we clearly separate measurements that are used to calculate or estimate values given in the Summary Tables from measurements that are not used. We give explanatory comments in many such cases. Among the reasons a measurement might be excluded are the following:

- It is superseded by or included in later results.
- No error is given.
- It involves assumptions we question.
- It has a poor signal-to-noise ratio, low statistical significance, or is otherwise of poorer quality than other data available.
- It is clearly inconsistent with other results that appear to be more reliable. Usually we then state the criterion, which sometimes is quite subjective, for selecting "more reliable" data for averaging. See Sec. 5.4.
- It is not independent of other results.
- It is not the best limit (see below).
- It is quoted from a preprint or a conference report.

In some cases, *none* of the measurements is entirely reliable and no average is calculated. For example, the masses of many of the baryon resonances, obtained from partial-wave analyses, are quoted as estimated ranges thought to probably include the true values, rather than as averages with errors. This is discussed in the Baryon Particle Listings.

For upper limits, we normally quote in the Summary Tables the strongest limit. We do not average or combine upper limits except in a very few cases where they may be re-expressed as measured numbers with Gaussian errors.

As is customary, we assume that particle and antiparticle share the same spin, mass, and mean life. The Tests of Conservation Laws table, following the Summary Tables, lists tests of CPT as well as other conservation laws.

We use the following indicators in the Particle Listings to tell how we get values from the tabulated measurements:

- OUR AVERAGE—From a weighted average of selected data.
- OUR FIT—From a constrained or overdetermined multiparameter fit of selected data.
- OUR EVALUATION—Not from a direct measurement, but evaluated from measurements of related quantities.
- OUR ESTIMATE—Based on the observed range of the data. Not from a formal statistical procedure.
- OUR LIMIT—For special cases where the limit is evaluated by us from measured ratios or other data. Not from a direct measurement.

An experimentalist who sees indications of a particle will of course want to know what has been seen in that region in the past. Hence we include in the Particle Listings all reported states that, in our opinion, have sufficient statistical merit and that have not been disproved by more reliable data. However, we promote to the Summary Tables only those states that we feel are well established. This judgment is, of course, somewhat subjective and no precise criteria can be given. For more detailed discussions, see the minireviews in the Particle Listings.

- **5.2.** Averages and fits: We divide this discussion on obtaining averages and errors into three sections:
- (1) treatment of errors; (2) unconstrained averaging;
- (3) constrained fits.

5.2.1. Treatment of errors: In what follows, the "error" δx means that the range $x \pm \delta x$ is intended to be a 68.3% confidence interval about the central value x. We treat this error as if it were Gaussian. Thus when the error is Gaussian, δx is the usual one standard deviation (1σ) . Many experimenters now give statistical and systematic errors separately, in which case we usually quote both errors, with the statistical error first. For averages and fits, we then add the the two errors in quadrature and use this combined error for δx .

When experimenters quote asymmetric errors $(\delta x)^+$ and $(\delta x)^-$ for a measurement x, the error that we use for that measurement in making an average or a fit with other measurements is a continuous function of these three quantities. When the resultant average or fit \overline{x} is less than $x-(\delta x)^-$, we use $(\delta x)^-$; when it is greater than $x+(\delta x)^+$, we use $(\delta x)^+$. In between, the error we use is a linear function of x. Since the errors we use are functions of the result, we iterate to get the final result. Asymmetric output errors are determined from the input errors assuming a linear relation between the input and output quantities.

In fitting or averaging, we usually do not include correlations between different measurements, but we try to select data in such a way as to reduce correlations. Correlated errors are, however, treated explicitly when there are a number of results of the form $A_i \pm \sigma_i \pm \Delta$ that have identical systematic errors Δ . In this case, one can first average the $A_i \pm \sigma_i$ and then combine the resulting statistical error with Δ . One obtains, however, the same result by averaging $A_i \pm (\sigma_i^2 + \Delta_i^2)^{1/2}$, where $\Delta_i = \sigma_i \Delta [\sum (1/\sigma_j^2)]^{1/2}$. This procedure has the advantage that, with the modified systematic errors Δ_i , each measurement may be treated as independent and averaged in the usual way with other data. Therefore, when appropriate, we adopt this procedure. We tabulate Δ and invoke an automated procedure that computes Δ_i before averaging and we include a note saying that there are common systematic errors.

Another common case of correlated errors occurs when experimenters measure two quantities and then quote the two and their difference, e.g., m_1 , m_2 , and $\Delta = m_2 - m_1$. We cannot enter all of m_1 , m_2 and Δ into a constrained fit because they are not independent. In some cases, it is a good approximation to ignore the quantity with the largest error and put the other two into the fit. However, in some cases correlations are such that the errors on m_1 , m_2 and Δ are comparable and none of the three values can be ignored. In this case, we put all three values into the fit and invoke an automated procedure to increase the errors prior to fitting such that the three quantities can be treated as independent measurements in the constrained fit. We include a note saying that this has been done.

5.2.2. Unconstrained averaging: To average data, we use a standard weighted least-squares procedure and in some cases, discussed below, increase the errors with a "scale factor." We begin by assuming that measurements of a given quantity are uncorrelated, and calculate a weighted average and error as

$$\overline{x} \pm \delta \overline{x} = \frac{\sum_{i} w_i x_i}{\sum_{i} w_i} \pm \left(\sum_{i} w_i\right)^{-1/2} , \qquad (1)$$

where

$$w_i = 1/(\delta x_i)^2$$
.

Here x_i and δx_i are the value and error reported by the *i*th experiment, and the sums run over the N experiments. We then calculate $\chi^2 = \sum w_i(\overline{x} - x_i)^2$ and compare it with N-1, which is the expectation value of χ^2 if the measurements are from a Gaussian distribution.

If $\chi^2/(N-1)$ is less than or equal to 1, and there are no known problems with the data, we accept the results.

If $\chi^2/(N-1)$ is very large, we may choose not to use the average at all. Alternatively, we may quote the calculated average, but then make an educated guess of the error, a conservative estimate designed to take into account known problems with the data.

Finally, if $\chi^2/(N-1)$ is greater than 1, but not greatly so, we still average the data, but then also do the following:

(a) We increase our quoted error, $\delta \overline{x}$ in Eq. (1), by a scale factor S defined as

$$S = \left[\chi^2 / (N - 1) \right]^{1/2} . \tag{2}$$

Our reasoning is as follows. The large value of the χ^2 is likely to be due to underestimation of errors in at least one of the experiments. Not knowing which of the errors are underestimated, we assume they are all underestimated by the same factor S. If we scale up all the input errors by this factor, the χ^2 becomes N-1, and of course the output error $\delta \overline{x}$ scales up by the same factor. See Ref. 3.

When combining data with widely varying errors, we modify this procedure slightly. We evaluate S using only the experiments with smaller errors. Our cutoff or ceiling on δx_i is arbitrarily chosen to be

$$\delta_0 = 3N^{1/2} \, \delta \overline{x} \, ,$$

where $\delta \overline{x}$ is the unscaled error of the mean of all the experiments. Our reasoning is that although the low-precision experiments have little influence on the values \overline{x} and $\delta \overline{x}$, they can make significant contributions to the χ^2 , and the contribution of the high-precision experiments thus tends to be obscured. Note that if each experiment has the same error δx_i , then $\delta \overline{x}$ is $\delta x_i/N^{1/2}$, so each δx_i is well below the cutoff. (More often, however, we simply exclude measurements with relatively large errors from averages and fits: new, precise data chase out old, imprecise data.)

Our scaling procedure has the property that if there are two values with comparable errors separated by much more than their stated errors (with or without a number of other values of lower accuracy), the scaled-up error $\delta \overline{x}$ is approximately half the interval between the two discrepant values

We emphasize that our scaling procedure for errors in no way affects central values. And if you wish to recover the unscaled error $\delta \overline{x}$, simply divide the quoted error by S.

(b) If the number M of experiments with an error smaller than δ_0 is at least three, and if $\chi^2/(M-1)$ is greater than 1.25, we show in the Particle Listings an ideogram of the data. Figure 1 is an example. Sometimes one or two data points lie apart from the main body; other times the data split into two or more groups. We extract no numbers from these ideograms; they are simply visual aids, which the reader may use as he or she sees fit.

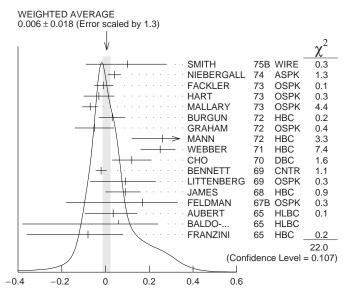

Figure 1: A typical ideogram. The arrow at the top shows the position of the weighted average, while the width of the shaded pattern shows the error in the average after scaling by the factor S. The column on the right gives the χ^2 contribution of each of the experiments. Note that the next-to-last experiment, denoted by the incomplete error flag (\bot) , is not used in the calculation of S (see the text).

Each measurement in an ideogram is represented by a Gaussian with a central value x_i , error δx_i , and area proportional to $1/\delta x_i$. The choice of $1/\delta x_i$ for the area is somewhat arbitrary. With this choice, the center of gravity of the ideogram corresponds to an average that uses weights $1/\delta x_i$ rather than the $(1/\delta x_i)^2$ actually used in the averages. This may be appropriate when some of the experiments have seriously underestimated systematic errors. However, since for this choice of area the height of the Gaussian for each measurement is proportional to $(1/\delta x_i)^2$, the peak position of the ideogram will often favor the high-precision measurements at least as much as does the least-squares average. See our 1986 edition [2] for a detailed discussion of the use of ideograms.

5.2.3. Constrained fits: In some cases, such as branching ratios or masses and mass differences, a constrained fit may be needed to obtain the best values of a set of parameters. For example, most branching ratios and rate measurements are analyzed by making a simultaneous least-squares fit to all the data and extracting the partial decay fractions P_i , the partial widths Γ_i , the full width Γ (or mean life), and the associated error matrix.

Assume, for example, that a state has m partial decay fractions P_i , where $\sum P_i = 1$. These have been measured in N_r different ratios R_r , where, e.g., $R_1 = P_1/P_2$, R_2

 $= P_1/P_3$, etc. [We can handle any ratio R of the form $\sum \alpha_i P_i/\sum \beta_i P_i$, where α_i and β_i are constants, usually 1 or 0. The forms $R = P_i P_j$ and $R = (P_i P_j)^{1/2}$ are also allowed.] Further assume that each ratio R has been measured by N_k experiments (we designate each experiment with a subscript k, e.g., R_{1k}). We then find the best values of the fractions P_i by minimizing the χ^2 as a function of the m-1 independent parameters:

$$\chi^2 = \sum_{r=1}^{N_r} \sum_{k=1}^{N_k} \left(\frac{R_{rk} - R_r}{\delta R_{rk}} \right)^2 , \qquad (3)$$

where the R_{rk} are the measured values and R_r are the fitted values of the branching ratios.

In addition to the fitted values \overline{P}_i , we calculate an error matrix $\langle \delta \overline{P}_i \ \delta \overline{P}_j \rangle$. We tabulate the diagonal elements of $\delta \overline{P}_i = \langle \delta \overline{P}_i \ \delta \overline{P}_i \rangle^{1/2}$ (except that some errors are scaled as discussed below). In the Particle Listings, we give the complete correlation matrix; we also calculate the fitted value of each ratio, for comparison with the input data, and list it above the relevant input, along with a simple unconstrained average of the same input.

Three comments on the example above:

- (1) There was no connection assumed between measurements of the full width and the branching ratios. But often we also have information on partial widths Γ_i as well as the total width Γ . In this case we must introduce Γ as a parameter in the fit, along with the P_i , and we give correlation matrices for the widths in the Particle Listings.
- (2) We try to pick those ratios and widths that are as independent and as close to the original data as possible. When one experiment measures all the branching fractions and constrains their sum to be one, we leave one of them (usually the least well-determined one) out of the fit to make the set of input data more nearly independent. We now do allow for correlations between input data.
- (3) We calculate scale factors for both the R_r and P_i when the measurements for any R give a larger-than-expected contribution to the χ^2 . According to Eq. (3), the double sum for χ^2 is first summed over experiments k=1 to N_k , leaving a single sum over ratios $\chi^2 = \sum \chi_r^2$. One is tempted to define a scale factor for the ratio r as $S_r^2 = \chi_r^2/\langle \chi_r^2 \rangle$. However, since $\langle \chi_r^2 \rangle$ is not a fixed quantity (it is somewhere between N_k and N_{k-1}), we do not know how to evaluate this expression. Instead we define

$$S_r^2 = \frac{1}{N_k} \sum_{k=1}^{N_k} \frac{\left(R_{rk} - \overline{R}_r\right)^2}{\left((R_{rk} - \overline{R}_r)^2\right)}.$$
 (4)

With this definition the expected value of S_r^2 is one. We can show that

$$\langle (R_{rk} - \overline{R}_r)^2 \rangle = \langle (\delta R_{rk})^2 \rangle - (\delta \overline{R}_r)^2 ,$$
 (5)

where $\delta \overline{R}_r$ is the fitted error for ratio r.

The fit is redone using errors for the branching ratios that are scaled by the larger of S_r and unity, from which new and often larger errors $\delta \overline{P}_i'$ are obtained. The scale factors we finally list in such cases are defined by $S_i = \delta \overline{P}_i'/\delta \overline{P}_i$. However, in line with our policy of not letting S affect the central values, we give the values of \overline{P}_i obtained from the original (unscaled) fit.

There is one special case in which the errors that are obtained by the preceding procedure may be changed. When a fitted branching ratio (or rate) \overline{P}_i turns out to be less than three standard deviations $(\delta \overline{P}'_i)$ from zero, a new smaller error $(\delta \overline{P}''_i)^-$ is calculated on the low side by requiring the area under the Gaussian between $\overline{P}_i - (\delta \overline{P}''_i)^-$ and \overline{P}_i to be 68.3% of the area between zero and \overline{P}_i . A similar correction is made for branching fractions that are within three standard deviations of one. This keeps the quoted errors from overlapping the boundary of the physical region.

5.3. Rounding: While the results shown in the Particle Listings are usually exactly those published by the experiments, the numbers that appear in the Summary Tables (means, averages and limits) are subject to a set of rounding rules.

The basic rule states that if the three highest order digits of the error lie between 100 and 354, we round to two significant digits. If they lie between 355 and 949, we round to one significant digit. Finally, if they lie between 950 and 999, we round up to 1000 and keep two significant digits. In all cases, the central value is given with a precision that matches that of the error. So, for example, the result (coming from an average) 0.827 ± 0.119 would appear as 0.83 ± 0.12 , while 0.827 ± 0.367 would turn into 0.8 ± 0.4 .

Rounding is not performed if a result in a Summary Table comes from a single measurement, without any averaging. In that case, the number of digits published in the original paper is kept, unless we feel it inappropriate. Note that, even for a single measurement, when we combine statistical and systematic errors in quadrature, rounding rules apply to the result of the combination. It should be noted also that most of the limits in the Summary Tables come from a single source (the best limit) and, therefore, are not subject to rounding.

Finally, we should point out that in several instances, when a group of results come from a single fit to a set of data, we have chosen to keep two significant digits for all the results. This happens, for instance, for several properties of the W and Z bosons and the τ lepton.

5.4. *Discussion*: The problem of averaging data containing discrepant values is nicely discussed by Taylor in Ref. 4. He considers a number of algorithms that attempt to incorporate inconsistent data into a meaningful average. However, it is difficult to develop a procedure that handles simultaneously in a reasonable way two basic types of situations: (a) data that lie apart from the main body of the data are incorrect (contain unreported errors); and (b) the opposite—it is the main body of data that is incorrect. Unfortunately, as Taylor shows, case (b) is not infrequent. He concludes that the choice of procedure is less significant than the initial choice of data to include or exclude.

We place much emphasis on this choice of data. Often we solicit the help of outside experts (consultants). Sometimes, however, it is simply impossible to determine which of a set of discrepant measurements are correct. Our scale-factor technique is an attempt to address this ignorance by increasing the error. In effect, we are saying that present experiments do not allow a precise determination of this quantity because of unresolvable discrepancies, and one must await further measurements. The reader is warned of this situation by the size of the scale factor, and if he or she desires can go back to the literature (via the Particle

Listings) and redo the average with a different choice of data.

Our situation is less severe than most of the cases Taylor considers, such as estimates of the fundamental constants like \hbar , etc. Most of the errors in his case are dominated by systematic effects. For our data, statistical errors are often at least as large as systematic errors, and statistical errors are usually easier to estimate. A notable exception occurs in partial-wave analyses, where different techniques applied to the same data yield different results. In this case, as stated earlier, we often do not make an average but just quote a range of values.

A brief history of early Particle Data Group averages is given in Ref. 3. Figure 2 shows some histories of our values of a few particle properties. Sometimes large changes occur. These usually reflect the introduction of significant new data or the discarding of older data. Older data are discarded in favor of newer data when it is felt that the newer data have smaller systematic errors, or have more checks on systematic errors, or have made corrections unknown at the time of the older experiments, or simply have much smaller errors. Sometimes, the scale factor becomes large near the time at which a large jump takes place, reflecting the uncertainty introduced by the new and inconsistent data. By and large, however, a full scan of our history plots shows a dull progression toward greater precision at central values quite consistent with the first data points shown.

We conclude that the reliability of the combination of experimental data and our averaging procedures is usually good, but it is important to be aware that fluctuations outside of the quoted errors can and do occur.

ACKNOWLEDGMENTS

The publication of the Review of Particle Physics is supported by the Director, Office of Science, Office of High Energy and Nuclear Physics, the Division of High Energy Physics of the U.S. Department of Energy under Contract No. DE-AC02-05CH11231; by the U.S. National Science Foundation under Agreement No. PHY-0652989; by the European Laboratory for Particle Physics (CERN); by an implementing arrangement between the governments of Japan (Monbusho) and the United States (DOE) on cooperative research and development.

We thank all those who have assisted in the many phases of preparing this *Review*. We particularly thank the many who have responded to our requests for verification of data entered in the Listings, and those who have made suggestions or pointed out errors.

1. Introduction

The collection of online information resources in particle physics and related areas presented in this chapter is of necessity incomplete. An expanded and regularly updated online version can be found at

http://library.web.cern.ch/library/rpp.

Suggestions for additions and updates are very welcome. $\,$

2. Particle Data Group (PDG) resources

• REVIEW OF PARTICLE PHYSICS (RPP): A comprehensive report on the fields of particle physics and cosmology, including both review articles and a compilation/evaluation of data on particle properties. The review section includes articles, tables and plots on a wide variety of theoretical and experimental topics of interest to particle physicists and astrophysicists. The particle properties section provides tables of published measurements as well as the Particle Data Group's best values and limits for particle properties such as masses, widths, lifetimes, and branching fractions, and an extensive summary of searches for hypothetical particles. RPP is published as a 1400-page book every two years, with partial updates made available once each year on the web. All the contents of the 1400-page book version of RPP are available online at:

http://pdg.lbl.gov

 PARTICLE PHYSICS BOOKLET: An abridged version of the Review of Particle Physics available as a pocket-sized 300-page booklet. Although produced in print and available online only as a PDF file, the booklet is included in this guide because it is one of the most useful summaries of physics data. The booklet contains an abbreviated set of reviews and the summary tables from the most recent edition of the Review of Particle Physics.

The PDF file of the booklet can be downloaded:

http://pdg.lbl.gov/current/booklet.pdf.

The printed booklet can be ordered:

http://pdg.lbl.gov/current/html/receive_our_products.html.

PDGLive: A web application for browsing the contents of the PDG database that contains the information published in the Review of Particle Physics. It allows one to navigate to a particle of interest, see a summary of the information available, and then proceed to the detailed information published in the Review of Particle Physics. Data entries are directly linked to the corresponding bibliographic information in INSPIRE. pdgLive can be accessed at:

http://pdglive.lbl.gov

 COMPUTER-READABLE FILES: Data files that can be downloaded from PDG include tables of particle masses and widths, PDG Monte Carlo particle numbers, and cross-section data. The files are updated with each new edition of the Review of Particle Physics and are available at:

http://pdg.lbl.gov/current/html/computer_read.html

Of historical interest is the complete RPP collection which, apart from the very first version from the year 1957, can be found online at

http://tiny.cc/RPP_historical

3. Particle Physics Information Platforms

- SPIRES: This indispensable information tool for high energy physicists worldwide was replaced by INSPIRE in November 2011. SPIRES started as a bibliographic database SPIRES-HEP in 1974 hosted at SLAC in collaboration with DESY and became remotely accessible in the mid 80's. Several databases CONF, EXP, INST, HEPNames and JOBS followed and FermiLab joined the team. In December 1991 SPIRES became the first web server outside Europe, from the start closely related to the arXiv repository. For High Energy Physics SPIRES-HEP was the reference for publications, covering not only journal articles and preprints but also conference proceedings, technical reports, theses and other 'gray' literature, the value of the information enhanced by thorough proof-reading, keywords and links to the sister SPIRES databases and other information services. Content and service are now taken over by INSPIRE.
- INSPIRE: The time-honored SPIRES database suite has now been replaced by INSPIRE which combines the most successful aspects of SPIRES like comprehensive content and high-quality metadata with the modern technology of Invenio, the CERN open-source digital-library software, offering major improvements like increased speed and Google-like free-text search syntax. INSPIRE serves as one-stop information platform for the particle physics community, comprising 6 interlinked databases on literature, conferences, institutions, researchers, experiments, jobs. INSPIRE is jointly developed and maintained by the three laboratories that have been running SPIRES (DESY, Fermilab and SLAC) and CERN. Close interaction with the user community and with arXiv, ADS, HepData, PDG and publishers is the backbone of INSPIRE's evolution.

http://inspirehep.net/ More information on this project at

http://www.projecthepinspire.net/

4. Literature Databases

• ADS: The SAO/NASA Astrophysics Data System is a Digital Library portal for researchers in Astronomy and Physics, operated by the Smithsonian Astrophysical Observatory (SAO) under a NASA grant. The ADS maintains three bibliographic databases containing more than 9.3 million records: Astronomy and Astrophysics, Physics, and arXiv e-prints. The main body of data in the ADS consists of bibliographic records, which are searchable through highly customizable query forms, and full-text scans of much of the astronomical literature which can be browsed or searched via a full-text search interface. Integrated in its databases, the ADS provides access and pointers to a wealth of external resources, including electronic articles, data catalogues and archives. In addition, ADS provides the myADS Update Service, a free custom

[†]Please send comments and corrections to Annette.Holtkamp@cern.ch or tullio.basaglia@cern.ch.

notification service promoting current awareness of the recent literature in astronomy and physics based on each individual subscriber's queries.

http://adswww.harvard.edu/

arXiv.org: A repository of full text papers in physics, mathematics, computer science, statistics, nonlinear sciences, quantitative finance and quantitative biology interlinked with ADS and INSPIRE.
 Papers are usually sent by their authors to arXiv in advance of submission to a journal for publication. Primarily covers 1991 to the present but authors are encouraged to post older papers retroactively. Permits searching by author, title, and words in abstract and experimentally also in the fulltext. Allows limiting by subfield archive or by date.

http://arXiv.org

 CDS: The CERN Document Server contains records of more than 1,000,000 CERN and non-CERN articles, preprints, theses. It includes records for internal and technical notes, official CERN committee documents, and multimedia objects. CDS is going to focus on its role as institutional repository covering all CERN material from the early 50s and reflecting the holdings of the CERN library. Non-CERN particle and accelerator physics content is in the process of being exported to INSPIRE.

http://cdsweb.cern.ch

• INSPIRE HEP: The HEP database serves almost 1 Mio bibliographic records covering particle physics and related topics with a growing number of fulltexts attached and metadata including author affiliations, abstracts, references, keywords as well as links to arXiv, PDG, HepData and publisher platforms. It provides fast metadata and fulltext searches, plots extracted from fulltext, author disambiguation, author profile pages and citation analysis and is expanding its content to e.g. experimental notes.

http://inspirehep.net

• JACoW: The Joint Accelerator Conference Website publishes the proceedings of APAC, EPAC, PAC, ABDW, BIW, COOL, CYCLOTRONS, DIPAC, ECR, FEL, ICALEPCS, ICAP, LINAC, North American PAC, PCaPAC, RuPAC, SRF. A custom interface allows searching on keywords, titles, authors, and in the fulltext.

http://www.JACoW.org/

• KISS (KEK INFORMATION SERVICE SYSTEM) FOR PREPRINTS: The KEK Library preprint and technical report database contains bibliographic records of preprints and technical reports held in the KEK library with links to the full text images of more than 100,000 papers scanned from their worldwide collection of preprints. Particularly useful for older scanned preprints:

http://www-lib.kek.jp/KISS/kiss_prepri.html

• OSTI: The Office of Scientific and Technical Information databases search collections of research results, including those produced throughout the DOE National Laboratory complex and by Departmental grantees. You can find current and legacy research results, search ongoing research and development project descriptions, browse scientific subject portals of interest, access and search scientific e-prints, sign up for alerts, search science conference papers and proceedings. Among the key resources are the Energy Citations Database, providing free access to over 2,450,000 science research citations and 292,000 electronic documents, primarily from 1943 forward, and Information Bridge, covering DOE R&D reports with searchable full-text and bibliographic citations.

http://www.osti.gov/

5. Particle Physics Journals and Conference Proceedings Series

A list of journals and conference series publishing particle physics content can be found at:

http://library.web.cern.ch/library/journals.html For each journal or conference series, information is given on Open Access and copyright policies and terms of use.

6. Conference Databases

• INSPIRE CONFERENCES: The database of more than 18,400 past, present and future conferences, schools, and meetings of interest to high-energy physics and related fields is searchable by title, acronym, series, date, location. Included are information about published proceedings, links to conference contributions in the INSPIRE HEP database, and links to the conference Web site when available. New conferences can be submitted from the entry page.

http://inspirehep.net/Conferences

7. Research Institutions

• INSPIRE INSTITUTIONS: The database of over 9,800 institutes, laboratories, and university departments in which research on particle physics and astrophysics is performed covers six continents and over a hundred countries. Included are address, e-mail address, and Web links where available as well as links to the papers from each institution in the HEP database. Searches can be performed by name, acronym, location, etc. The site offers an alphabetical list by country as well as a list of the top 500 HEP and astrophysics institutions sorted by country.

http://inspirehep.net/Institutions

8. People

• INSPIRE HEPNames: Searchable worldwide database of over 97,000 people associated with particle physics and related fields. The affiliation history of these researchers, their e-mail addresses, web pages, experiments they participated in, PhD advisor, information on their graduate students and links to their papers in the INSPIRE HEP, arXiv and ADS databases are provided as well as a user interface to update these information.

http://inspirehep.net/HepNames

9. Experiments

• SPIRES/INSPIRE EXPERIMENTS: Contains more than 2,400 past, present, and future experiments in particle physics. Lists both accelerator and non-accelerator experiments. Includes official experiment name and number, location, and collaboration lists. Simple searches by participant, title, experiment number, institution, date approved, accelerator, or detector, return a description of the experiment, including a complete list of authors, title, overview of the experiment's goals and methods, and a link to the experiment's Web page if available. Publication lists distinguish articles in refereed journals, theses, technical or instrumentation papers and those which rank among Topcite at 50 or more citations.

http://www.slac.stanford.edu/spires/experiments/soon to be replaced by

http://inspirehep.net/Experiments

• COSMIC RAY/GAMMA RAY/NEUTRINO AND SIMILAR EXPERIMENTS: This extensive collection of experimental Web sites is organized by focus of study and also by location. Additional sections link to educational materials, organizations, related Web sites, etc. The site is maintained at the Max Planck Institute for Nuclear Physics, Heidelberg:

 $\verb|http://www.mpi-hd.mpg.de/hfm/CosmicRay/CosmicRaySites.html|\\$

10. Jobs

 APS Careers: gateway for physicists, students, and physics enthusiasts to information about physics jobs and careers. Physics job listings, career advice, upcoming workshops and meetings, and career and job related resources provided by the American Physical Society:

http://www.aps.org/jobs/

BRIGHTRECRUITS.COM: A recruitment service run by IOP
 Publishing that connects employers from different industry sectors
 with jobseekers who have a background in physics and engineering

http://brightrecruits.com/

 IOP CAREERS: careers information and resources primarily aimed at university students provided by the UK Institute of Physics:

http://www.iop.org/careers/

 INSPIRE HEPJobs: lists academic and research jobs in high energy physics, nuclear physics, accelerator physics and astrophysics with the option to post a job or to receive email notices of new job listings. About 1300 jobs are currently listed.

http://inspirehep.net/Jobs

 PHYSICSTODAY JOBS: online recruitment advertising website forPhysics Todaymagazine, published by the American Institute of Physics. Physics TodayJobs is the managing partner of the AIP Career Network, an online job board network for the physical science, engineering, and computing disciplines. Over 8,500 resumes are currently available, and almost 3,000 jobs were posted in 2011.

http://www.physicstoday.org/jobs

11. Software Repositories

Particle Physics

 BSM Generators: a repository of codes relevant to Beyond-the-Standard-Model (BSM) physics

http://www.ippp.dur.ac.uk/montecarlo/BSM

 CERNLIB: The CERN PROGRAM LIBRARY contains a large collection of general purpose libraries and modules offered in both source code and object code forms. It provides programs applicable to a wide range of physics research problems such as general mathematics, data analysis, detectors simulation, data-handling, etc. It also includes links to commercial, free, and other software. Development of this site has been discontinued.

http://wwwasd.web.cern.ch/wwwasd/index.html

 FERMITOOLS: Fermilab's software tools program provides a repository of Fermilab-developed software packages of value to the HEP community. Permits searching for packages by title or subject category:

http://www.fnal.gov/fermitools/

FREEHEP: A collection of software and information about software
useful in high-energy physics and adjacent disciplines, focusing on
open-source software for data analysis and visualization. Searching
can be done by title, subject, date acquired, date updated, or by
browsing an alphabetical list of all packages. The site does not seem
to be updated any longer but still provides useful information.

http://www.freehep.org/

 GEANT4: Toolkit for the simulation of the passage of particles through matter, maintained by a world-wide collaboration of scientists and software engineers. Its areas of application include high energy, nuclear and accelerator physics, as well as studies in medical and space science.

http://geant4.cern.ch/

 GENSER: The Generator Services project collaborates with Monte Carlo (MC) generators authors and with LHC experiments in order to prepare validated LCG compliant code for both the theoretical and experimental communities at the LHC, sharing the user support duties, providing assistance for the development of the new object-oriented generators and guaranteeing the maintenance of the older packages on the LCG supported platforms. The project consists of the generators repository, validation, HepMC record and MCDB event databases.

http://sftweb.cern.ch/generators/

 HEPFORGE: A development environment for high-energy physics software development projects, in particular housing many eventgenerator related projects, that offers a ready-made, easy-to-use set of Web based tools, including shell account with up to date development tools, web page hosting, subversion and CVS code management systems, mailing lists, bug tracker and wiki system.

http://www.hepforge.org/

 PYTHIA: A program for the generation of high-energy physics events, i.e. for the description of collisions at high energies between elementary particles such as e+, e-, p and p-bar in various combinations. It contains theory and models for a number of physics aspects, including hard and soft interactions, parton distributions, initial- and final-state parton showers, multiple interactions, fragmentation and decay.

http://home.thep.lu.se/torbjorn/Pythia.html

 QUDA: library for performing calculations in lattice QCD on GPUs using NVIDIA's "C for CUDA" API. The current release includes optimized solvers for Wilson, Clover-improved Wilson. Twisted mass, Improved staggered (asqtad or HISQ) and Domain wall fermion actions

http://lattice.github.com/quda/

 ROOT: This framework for data processing in high-energy physics, born at CERN, offers applications to store, access, process, analyze and represent data or perform simulations.

http://root.cern.ch/drupal

 tmLQCD: This freely available software suite provides a set of tools to be used in lattice QCD simulations, mainly a (P)HMC implementation for Wilson and Wilson twisted mass fermions and inverter for different versions of the Dirac operator.

https://github.com/etmc/tmLQCD

• USQCD: The software suite enables lattice QCD computations to be performed with high performance across a variety of architectures. The page contains links to the project web pages of the individual software modules, as well as to complete lattice QCD application packages which use them.

http://usqcd.jlab.org/usqcd-software/

A list of Monte Carlo generators may be found at

http://cmsdoc.cern.ch/cms/PRS/gentools/www/geners/collection/

collection.html

The homepage of the SUSY Les Houches Accord contains links to codes relevant for supersymmetry calculations and phenomenology

http://home.fnal.gov/skands/slha/

A variety of codes and algorithmic tools for analysing supersymmetric phenomenology is described in ${\tt arXiv:0805.2088}$

http://arxiv.org/abs/0805.2088

Astrophysics

• IRAF: The Image Reduction and Analysis Facility is a general purpose software system for the reduction and analysis of astronomical data. IRAF is written and supported by the IRAF programming group at the National Optical Astronomy Observatories (NOAO) in Tucson, Arizona.

http://iraf.noao.edu/

• STARLINK: Starlink was a UK Project supporting astronomical data processing. It was shut down in 2005 but its open-source software continues to be developed at the Joint Astronomy Centre. The software products are a collection of applications and libraries, usually focused on a specific aspect of data reduction or analysis.

http://starlink.jach.hawaii.edu/starlink

Links to a large number of astronomy software archives are listed at http://heasarc.nasa.gov/docs/heasarc/astro-update/

12. Data repositories

Particle Physics

• HEPDATA: The HepData Project, funded by the STFC(UK) and based at the IPPP at Durham University, has for more than 30 years compiled a Reaction Data database, comprising total and differential cross sections, structure functions, fragmentation functions, distributions of jet measures, polarisations, etc from a wide range of particle physics scattering experiments worldwide. It is regularly updated to cover the latest data including those from the LHC. In addition, it provides a series of on-line data reviews on a wide variety of topics with links to the data in the Reaction Database. It also hosts a Parton Distribution Function server with an on-line PDF calculator and plotter.

http://durpdg.dur.ac.uk/

• ILDG: The International Lattice Data Grid is an international organization which provides standards, services, methods and tools that facilitates the sharing and interchange of lattice QCD gauge configurations among scientific collaborations, by uniting their regional data grids. It offers semantic access with local tools to worldwide distributed data. See e.g.

http://www.usqcd.org/ildg/

 MCPLOTS: mcplots is a repository of Monte Carlo plots comparing High Energy Physics event generators to a wide variety of available experimental data. The site is supported by the LHC Physics Centre at CERN.

http://mcplots.cern.ch/

Astrophysics

 SIMBAD: archives data in the form of object catalogues from many heterogeneous sources

http://simbad.u-strasbg.fr/simbad/

• NED: NASA/IPAC extragalactic database, operated by the Jet Propulsion Laboratory, California Institute of Technology

http://ned.ipac.caltech.edu/

 The NASA archives provide access to raw and processed datasets from numerous NASA missions.

Hubble telescope, other missions (UV, optical):

http://archive.stsci.edu/

Spitzer telescope, other missions (Infrared):

http://irsa.ipac.caltech.edu/

Chandra, Fermi telescopes, other missions:

http://heasarc.gsfc.nasa.gov/

 The Virtual Observatory provides a suite of resources to query for original data from a large number of archives. Two main tools are provided. One runs queries across multiple databases (such as the SDSS database) and combines the results. The other queries hundreds of archives for all datasets that fall on a particular piece of sky.

http://www.us-vo.org/

General Physics

NIST PHYSICAL MEASUREMENT LABORATORY: The National Institute of Standards and Technology provides access to physical reference data (physical constants, atomic spectroscopy data, x-ray and gamma-ray data, radiation dosimetry data, nuclear physics data and more) and measurements and calibrations data (dimensional measurements, electromagnetic measurements). The site points to a general interest page, linking to exhibits of the Physical Measurement Laboratory in the NIST Virtual Museum.

http://physics.nist.gov/

• SPRINGER MATERIALS - THE LANDOLT-BÖRNSTEIN DATABASE: Landolt-Börnstein is a high-quality data collection in all areas of physical sciences and engineering, among others particle physics, electronic structure and transport, magnetism, superconductivity. International experts scan the primary literature in more than 8,000 peer-reviewed journals and evaluate and select the most valid information to be included in the database. It includes more than 100,000 online documents, 1,2 million references, and covers 250,000 chemical substances. The search functionality is freely accessible and the search results are displayed in their context, whereas the full text is secured to subscribers:

http://www.springermaterials.com/

13. Data preservation

Particle Physics

• DPHEP: The efforts to define and coordinate Data Preservation and Long Term Analysis in HEP are coordinated by a study group formed to investigate the issues associated with these activities. The group, DPHEP, was initiated during 2008-2009 and includes all HEP major experiments and laboratories. It is endorsed by the International Committee for Future Accelerators (ICFA). Details of the organizational structure, the objectives, workshops and publications can be found at

http://dphep.org

The experiments at colliders: BaBar, Belle, BES-III, Cleo, CDF, D0, H1 and ZEUS and the associated computing centres at SLAC (USA), KEK (Japan), IHEP (China), Jlab (USA), BNL (USA), Fermilab (USA), DESY (Germany), and CERN are all represented in the group. The LHC collaborations have also joined the initiative in 2011. The participating experiments are in various stages of studying, preparing, or operating long-term data preservation and analysis systems. Technological methods, such as virtualization, and information management tools such as INSPIRE are also helpful in this area of research. Data access policies and outreach in HEP using real data are among the investigative areas of the DPHEP Study Group.

Astrophysics

More formal and advanced data preservation activity is ongoing in the field of Experimental Astrophysics, including

• SDSS

http://sdss.org

• Fermi

http://fermi.gsfc.nasa.gov/ssc/data

• IVOA

http://www.ivoa.net/

14. Particle Physics Education and Outreach Sites

Science Educators' Networks:

• IPPOG: The International Particle Physics Outreach Group is a network of particle physicists, researchers, informal science educators and science explainers aiming to raise awareness, understanding and standards of global outreach efforts in particle physics and general science by providing discussion forums and regular information exchange for science institutions, proposing and implementing strategies to share lessons learned and best practices and promoting current outreach efforts of network members:

http://ippog.web.cern.ch/ippog/

• Interactions.org: designed to serve as a central resource for communicators of particle physics. The daily updated site provides links to current particle physics news from the world's press, high-resolution photos and graphics from the particle physics laboratories of the world; links to education and outreach programs; information about science policy and funding; links to universities; a glossary; a conference calendar; and links to many educational sites

http://www.interactions.org

Physics Courses

 MIT OPENCOURSEWARE - PHYSICS: These MIT course materials reflect almost all the undergraduate and graduate subjects taught at MIT. In addition to physics courses, supplementary educational resources are also available.

http://ocw.mit.edu/courses/physics/

Master Classes

• INTERNATIONAL MASTERCLASSES: Each year about 6000 high school students in 28 countries come to one of about 130 nearby universities or research centres for one day in order to unravel the mysteries of particle physics. Lectures from active scientists give insight in topics and methods of basic research at the fundaments of matter and forces, enabling the students to perform measurements on real data from particle physics experiments themselves. At the end of each day, like in an international research collaboration, the participants join in a video conference for discussion and combination of their results.

http://physicsmasterclasses.org/

General Sites

• CONTEMPORARY PHYSICS EDUCATION PROJECT (CPEP): Provides charts, brochures, Web links, and classroom activities. Online interactive courses include: Fundamental Particles and Interactions; Plasma Physics and Fusion; History and Fate of the Universe; and Nuclear Science.

http://www.cpepweb.org/

 PHYSICSCENTRAL: This site maintained by the American Physical Society provides information about current research and people in physics, experiments that can be performed at home or at school and the possibility to get physics questions answered by physicists.

http://www.physicscentral.com

General Physics Lessons & Activities

 HYPERPHYSICS: An exploration environment for concepts in physics employing concept maps and other linking strategies and providing opportunities for numerical exploration.

http://hyperphysics.phy-astr.gsu.edu/hbase/hph.html

PHYSICS2000: An interactive journey through modern physics.
 Have fun learning visually and conceptually about 20th century science and high-tech devices. Supported by the Colorado Commission on Higher Education and the National Science Foundation

http://www.colorado.edu/physics/2000

Particle Physics Lessons & Activities

 Angels and Demons: With the aim of looking at the myth versus the reality of science at CERN this site offers teacher resources, slide shows and videos of talks given to teachers visiting CERN

http://angelsanddemons.web.cern.ch/

 ANTIMATTER: MIRROR OF THE UNIVERSE: Find out what antimatter is, where it is made, the history behind its discovery, and how it is a part of our lives. Features colorful photos, illustrations, webcasts, a Kids Corner, and CERN physicists answering your questions on antimatter:

http://livefromcern.web.cern.ch/livefromcern/antimatter/

 BIG BANG: An exhibition of the UK Science Museum with an interactive game about the hunt for the Higgs

http://www.sciencemuseum.org.uk/antenna/bigbang/

• BIG BANG SCIENCE: EXPLORING THE ORIGINS OF MATTER: This Web site, produced by the Particle Physics and Astronomy Research Council of the UK (PPARC), explains what physicists are looking for with their giant instruments. Big Bang Science focuses on CERN particle detectors and on United Kingdom scientists' contribution to the search for the fundamental building blocks of matter.

http://hepwww.rl.ac.uk/pub/bigbang/part1.html

 CERNland: With a range of games, multimedia applications and films CERNland is the virtual theme park developed to bring the excitement of CERN's research to a young audience aged between 7 and 12. CERNland is designed to show children what is being done at CERN and inspire them with some physics at the same time.

http://www.cernland.net/

 Colliding particles: a series of films following a team of physicists involved in research at the LHC

http://www.collidingparticles.com/

 Lancaster Particle Physics: This site, suitable for 16+ students, offers a number of simulations and explanations of particle physics, including a section on the LHC.

http://www.lppp.lancs.ac.uk/

 PARTICLE ADVENTURE: One of the most popular Web sites for learning the fundamentals of matter and force. An award-winning interactive tour of quarks, neutrinos, antimatter, extra dimensions, dark matter, accelerators and particle detectors from the Particle Data Group of Lawrence Berkeley National Laboratory. Simple elegant graphics and translations into 15 languages:

http://ParticleAdventure.org

 PARTICLE DETECTIVES: This website, maintained by the Science and Technology Facilities Council (STFC), is for inquisitive 14-19 year olds, their teachers and for researchers who want to find out and talk about the world's biggest scientific adventure, the Large Hadron Collider, featuring e.g. An LHC experiment simulator.

http://www.lhc.ac.uk/The+Particle+Detectives/15273.aspx

 Quarked! - Adventures in the Subatomic Universe: This project, targeted to kids aged 7-12 (and their families), brings subatomic physics to life through a multimedia project including an interactive website, a facilitated program for museums and schools, and an educational outreach program

http://www.quarked.org/

• QUARKNET: QuarkNet brings the excitement of particle physics research to high school teachers and their students. Teachers join research groups at about 50 universities and labs across the country. These research groups are part of particle physics experiments at CERN or Fermilab. About 100,000 students from 500+ US high schools learn fundamental physics as they participate in inquiry-oriented investigations and analyze real data online. QuarkNet is supported in part by the National Science Foundation and the U.S. Department of Energy:

http://QuarkNet.fnal.gov

 Rewarding Learning videos about CERN: The three videos based on interviews with scientists and engineers at CERN introduce pupils to CERN and the type of research and work undertaken there and are accompanied by teachers' notes.

http://www.rewardinglearning.org.uk/STEM/cern/

Lab Education Offices

Brookhaven National Laboratory (BNL) Educational Programs:
 The Office of Educational Programs mission is to design, develop, implement, and facilitate workforce development and education initiatives that support the scientific mission at Brookhaven National Laboratory and the Department of Energy.

http://www.bnl.gov/education/

• CERN: The CERN education website offers information about teacher programmes and educational resources for schools

http://education.web.cern.ch/education/

 DESY: offers courses for pupils and teachers as well as information for the general public, mostly in German.

http://www.desy.de/information_services/education/

• FERMILAB EDUCATION OFFICE: provides education resources and information about activities for educators, physicists, students

and visitors to the Lab. In addition to information on 25 programs, the site provides online data-based investigations for high school students, online versions of exhibits in the Lederman Science Center, links to particle physics discovery resources, web-based instructional resources, what works for education and outreach, and links to the Lederman Science Center and the Teacher Resource Center.

http://ed.fnal.gov/

 LBL: Berkeley Lab's Center for Science & Engineering Education (CSEE) carries out the Department of Energy's education mission to train the next generation of scientists, as well as helping them to gain an understanding of the relationships among frontier science, technology, and society.

http://www.lbl.gov/Education/

 EXPLORING SLAC SCIENCE: This Stanford Linear Accelerator Center Web site explains physics concepts related to experiments conducted at SLAC.

http://www6.slac.stanford.edu/ExploringSLACScience.aspx

 Symmetry: This magazine about particle physics and its connections to other aspects of life and science, from interdisciplinary collaborations to policy to culture is published 6 times per year by Fermilab and SLAC.

http://www.symmetrymagazine.org

Educational Programs of Experiments

 ATLAS DISCOVERY QUEST: One of several access points to ATLAS education and outreach pages. This page gives access to explanations of physical concepts, blogs, ATLAS facts, news, and information for students and teachers.

http://www.atlas.ch/physics.html

 ATLAS eTours: give a description of the Large Hadron Collider, explain how the ATLAS detector at the LHC works and give an overview over the experiments and their physics goals.

http://www.atlas.ch/etours.html

CMS EDUCATION: Provides access to educational resources (Story
of the Universe, The Size of Things, What is a Particle), and to
multimedia material, such as interviews, movies and photos.

http://cms.web.cern.ch/content/cms-education

• EDUCATION AND OUTREACH @ ICECUBE: Educational pages of the IceCube (South Pole Neutrino Detector)

http://icecube.wisc.edu/outreach

• LIGO SCIENCE EDUCATION CENTER: The LIGO (Laser Interferometer Gravitational-wave Observatory) Science Education Center has over 40 interactive, hands-on exhibits that relate to the science of LIGO. The site hosts field trips for students, teacher training programs, and tours for the general public. Visitors can explore science concepts such as light, gravity, waves, and interference; learn about LIGO's search for gravitational waves; and interact with scientists and engineers.

 $\verb|http://www.ligo-la.caltech.edu/SEC.html||$

PIERRE AUGER OBSERVATORY'S EDUCATIONAL PAGES:
 The site offers information about cosmic rays and their detection,
 and provides material for students and teachers.

http://www.auger.org/cosmic_rays/

Art in Physics

 Arts@CERN: a 3-year artist's residency programme in Digital Arts and Dance/Performance

http://arts.web.cern.ch/collide/

 Art of Physics Competition: The Canadian Association of Physicists organizes this competition, the first was launched in 1992, with the aim of stimulating interest, especially among non-scientists, in some of the captivating imagery associated with physics. The challenge is to capture photographically a beautiful or unusual physics phenomenon and explain it in less than 200 words in terms that everyone can understand.

http://www.cap.ca/aop/art.html

 Photowalk: More than 200 amateur photographers from around the world had the opportunity to experience state-of-the-art accelerators and detectors. Five of the world's leading particle physics laboratories in Asia, Europe and North America offered special behind-the-scenes access to their scientific facilities. The winning photos can be viewed.

http://www.interactions.org/cms/?pid=1029664

Blogs

This is a very incomplete collection of particle physics related blogs:

• ATLAS blog

http://www.atlas.ch/blog

 U.S. LHC blog: The blog give a vivid account of the daily activity of US LHC researchers.

http://www.quantumdiaries.org/lab-81/

 Physics arXiv blog: Technology Review blog on new ideas at arXiv.org

http://www.technologyreview.com/blog/arxiv/

• CERN Love:

http://www.cernlove.org/blog/

 Not Even Wrong: Peter Woit's blog on topics in physics and mathematics

http://www.math.columbia.edu/woit/wordpress/

 Quantum diaries: Thoughts on work and life from particle physicists from around the world.

http://www.quantumdiaries.org/

 Science blogs: Launched in January 2006, ScienceBlogs features bloggers from a wide array of scientific disciplines, including physics:

http://scienceblogs.com/channel/physical-science/

 Life and Physics: Jon Butterworth's blog in the Guardian http://www.guardian.co.uk/science/life-and-physics

Higgs Bosons — H^0 and H^{\pm} , Searches for

The July 2012 news about Higgs searches is described in the addendum to the Higgs review in the data listings, but is not reflected here.

The limits for H_1^0 and A^0 refer to the m_h^{\max} benchmark scenario for the supersymmetric parameters.

 \emph{H}^{0} Mass m>115.5 and none 127–600 GeV, CL =95%

H_1^0 in Supersymmetric Models $(m_{H_1^0} < m_{H_2^0})$

Mass m > 92.8 GeV, CL = 95%

A⁰ Pseudoscalar Higgs Boson in Supersymmetric Models [/]

Mass m > 93.4 GeV, CL = 95% $tan \beta > 0.4$

 H^{\pm} Mass m > 79.3 GeV. CL = 95%

See the Particle Listings for a Note giving details of Higgs Bosons.

Heavy Bosons Other Than Higgs Bosons, Searches for

Additional W Bosons

W' with standard couplings Mass $m > 2.150 \times 10^3$ GeV, CL = 95%

Additional Z Bosons

```
Z'_{SM} with standard couplings
  Mass m > 1.830 \times 10^3 \text{ GeV}, CL = 95%
                                                        (p\overline{p} \text{ direct search})
  Mass m > 1.500 \times 10^3 \text{ GeV}, CL = 95%
Z_{LR} of SU(2)_L \times SU(2)_R \times U(1) (with g_L = g_R)
  Mass m > 630 GeV, CL = 95\% (p\overline{p} \text{ direct search})
  Mass m > 1162 GeV, CL = 95\% (electroweak fit)
Z_{\chi} of SO(10) \rightarrow SU(5)\timesU(1)_{\chi} (with g_{\chi} = e/\cos\theta_W)
  Mass m > 1.640 \times 10^3 \text{ GeV}, CL = 95%
                                                        (p\overline{p} \text{ direct search})
  Mass m > 1.141 \times 10^3 \text{ GeV}, CL = 95%
                                                        (electroweak fit)
Z_{\psi} of E_6 \rightarrow SO(10) \times U(1)_{\psi} (with g_{\psi} = e/\cos\theta_W)
  Mass m > 1.490 \times 10^3 GeV, CL = 95\% (p\overline{p} direct search)
  Mass m > 476 GeV, CL = 95\% (electroweak fit)
Z_n of E_6 \rightarrow SU(3) \times SU(2) \times U(1) \times U(1)_n (with g_n = e/\cos\theta_W)
  Mass m > 1.540 \times 10^3 GeV, CL = 95\% (p\overline{p} direct search)
  Mass m > 619 GeV, CL = 95\% (electroweak fit)
```

Scalar Leptoquarks

```
Mass m>660 GeV, CL = 95% (1st generation, pair prod.)
Mass m>298 GeV, CL = 95% (1st gener., single prod.)
Mass m>422 GeV, CL = 95% (2nd gener., pair prod.)
Mass m>73 GeV, CL = 95% (2nd gener., single prod.)
Mass m>247 GeV, CL = 95% (3rd gener., pair prod.)
(See the Particle Listings for assumptions on leptoquark quantum numbers and branching fractions.)
```

Axions (A⁰) and Other Very Light Bosons, Searches for

The standard Peccei-Quinn axion is ruled out. Variants with reduced couplings or much smaller masses are constrained by various data. The Particle Listings in the full *Review* contain a Note discussing axion searches.

The best limit for the half-life of neutrinoless double beta decay with Majoron emission is $>7.2\times10^{24}$ years (CL = 90%).

Gauge & Higgs Boson Summary Table

NOTES

In this Summary Table:

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor" S, defined as S = $\sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when S > 1, which often indicates that the measurements are inconsistent. When S > 1.25, we also show in the Particle Listings an ideogram of the measurements. For more about S, see the Introduction.

A decay momentum p is given for each decay mode. For a 2-body decay, p is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay, p is the largest momentum any of the products can have in this frame.

- [a] Theoretical value. A mass as large as a few MeV may not be precluded.
- [b] ℓ indicates each type of lepton $(e, \mu, \text{ and } \tau)$, not sum over them.
- [c] This represents the width for the decay of the W boson into a charged particle with momentum below detectability, p< 200 MeV.

- [d] The Z-boson mass listed here corresponds to a Breit-Wigner resonance parameter. It lies approximately 34 MeV above the real part of the position of the pole (in the energy-squared plane) in the Z-boson propagator.
- [e] This partial width takes into account Z decays into $\nu\overline{\nu}$ and any other possible undetected modes.
- [f] This ratio has not been corrected for the au mass.
- [g] Here $A \equiv 2g_V g_A / (g_V^2 + g_A^2)$.
- [h] The value is for the sum of the charge states or particle/antiparticle states indicated.
- [i] This value is updated using the product of (i) the $Z \to b\overline{b}$ fraction from this listing and (ii) the b-hadron fraction in an unbiased sample of weakly decaying b-hadrons produced in Z-decays provided by the Heavy Flavor Averaging Group (HFAG, http://www.slac.stanford.edu/xorg/hfag/osc/PDG_2009/#FRACZ).
- [j] See the Z Particle Listings for the γ energy range used in this measurement.
- [k] For $m_{\gamma\gamma}=$ (60 \pm 5) GeV.
- [/] The limits assume no invisible decays.

Heavy Charged Lepton Searches

L± - charged lepton

Mass m > 100.8 GeV, CL = 95% [h] Decay to νW .

L^{\pm} – stable charged heavy lepton

Mass m > 102.6 GeV, CL = 95%

Neutrino Properties

See the note on "Neutrino properties listings" in the Particle Listings.

Mass m < 2 eV (tritium decay)

Mean life/mass, $\tau/m > 300 \text{ s/eV}$, CL = 90% (reactor)

Mean life/mass, $\tau/m > 7 \times 10^9$ s/eV (solar)

Mean life/mass, $\tau/m > 15.4 \text{ s/eV}$, CL = 90% (accelerator)

Magnetic moment $\mu < 0.32 \times 10^{-10} \mu_B$, CL = 90% (solar)

Number of Neutrino Types

Number $N=2.984\pm0.008$ (Standard Model fits to LEP data) Number $N=2.92\pm0.05$ (S = 1.2) (Direct measurement of invisible Z width)

Neutrino Mixing

The following values are obtained through data analyses based on the 3-neutrino mixing scheme described in the review "Neutrino Mass, Mixing, and Oscillations" by K. Nakamura and S.T. Petcov in this *Review*.

```
\begin{array}{l} \sin^2(2\theta_{12}) = 0.857 \pm 0.024 \\ \Delta m^2_{21} = (7.50 \pm 0.20) \times 10^{-5} \text{ eV}^2 \\ \sin^2(2\theta_{23}) > 0.95 \text{ i}^1 \\ \Delta m^2_{32} = (2.32 ^{+0.12}_{-0.08}) \times 10^{-3} \text{ eV}^2 \text{ i}^1 \\ \sin^2(2\theta_{13}) = 0.098 \pm 0.013 \end{array}
```

Heavy Neutral Leptons, Searches for

For excited leptons, see Compositeness Limits below.

Stable Neutral Heavy Lepton Mass Limits

```
Mass m > 45.0 GeV, CL = 95\% (Dirac)
Mass m > 39.5 GeV, CL = 95\% (Majorana)
```

Neutral Heavy Lepton Mass Limits

```
Mass m>90.3 GeV, CL = 95% (Dirac \nu_L coupling to e, \mu, \tau; conservative case(\tau)) Mass m>80.5 GeV, CL = 95% (Majorana \nu_L coupling to e, \mu, \tau; conservative case(\tau))
```

NOTES

In this Summary Table:

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor" S, defined as S = $\sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when S > 1, which often indicates that the measurements are inconsistent. When S > 1.25, we also show in the Particle Listings an ideogram of the measurements. For more about S, see the Introduction.

A decay momentum p is given for each decay mode. For a 2-body decay, p is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay, p is the largest momentum any of the products can have in this frame.

- [a] This is the best limit for the mode $e^- \to \nu \gamma$. The best limit for "electron disappearance" is 6.4×10^{24} yr.
- [b] See the "Note on Muon Decay Parameters" in the μ Particle Listings for definitions and details.
- [c] P_μ is the longitudinal polarization of the muon from pion decay. In standard V-A theory, $P_\mu=1$ and $\rho=\delta=3/4$.
- [d] This only includes events with the γ energy > 10 MeV. Since the $e^-\overline{\nu}_e\,\nu_\mu$ and $e^-\overline{\nu}_e\,\nu_\mu\gamma$ modes cannot be clearly separated, we regard the latter mode as a subset of the former.
- [e] See the relevant Particle Listings for the energy limits used in this measurement.
- [f] A test of additive vs. multiplicative lepton family number conservation.
- [g] Basis mode for the τ .
- [h] L^{\pm} mass limit depends on decay assumptions; see the Full Listings.
- [i] The limit quoted corresponds to the projection onto the $\sin^2(2\theta_{23})$ axis of the 90% CL contour in the $\sin^2(2\theta_{23}) \Delta m_{32}^2$ plane.
- [j] The sign of Δm_{32}^2 is not known at this time. The range quoted is for the absolute value.

QUARKS

The u--, d--, and s--quark masses are estimates of so-called "current-quark masses," in a mass-independent subtraction scheme such as $\overline{\text{MS}}$ at a scale $\mu\approx 2$ GeV. The c-- and b--quark masses are the "running" masses in the $\overline{\text{MS}}$ scheme. For the b---quark we also quote the 1S mass. These can be different from the heavy quark masses obtained in potential models.

NOTES

- [a] A discussion of the definition of the top quark mass in these measurements can be found in the review "The Top Quark."
- [b] Based on published top mass measurements using data from Tevatron Run-I and Run-II and LHC at $\sqrt{s}=7$ TeV. Including the most recent unpublished results from Tevatron Run-II, the Tevatron Electroweak Working Group reports a top mass of 173.2 \pm 0.9 GeV. See the note "The Top Quark' in the Quark Particle Listings of this $\it Review$.
- [c] ℓ means e or μ decay mode, not the sum over them.
- [d] Assumes lepton universality and W-decay acceptance.
- [e] This limit is for $\Gamma(t \to \gamma q)/\Gamma(t \to W b)$.
- [f] This limit is for $\Gamma(t \to Zq)/\Gamma(t \to Wb)$.

Meson Summary Table

LIGHT UNFLAVORED MESONS (S = C = B = 0)

For I=1 (π,b,ρ,∂) : $u\overline{d}$, $(u\overline{u}-d\overline{d})/\sqrt{2}$, $d\overline{u}$; for I=0 $(\eta,\eta',h,h',\omega,\phi,f,f')$: $c_1(u\overline{u}+d\overline{d})+c_2(s\overline{s})$

$$I^{G}(J^{P}) = 1^{-}(0^{-})$$

Mass $m=139.57018\pm0.00035$ MeV ${\rm (S=1.2)}$ Mean life $\tau=(2.6033\pm0.0005)\times10^{-8}$ s ${\rm (S=1.2)}$ $c_{\tau}=7.8045$ m

$\pi^{\pm} \rightarrow \ell^{\pm} \nu \gamma$ form factors [a]

 $F_V = 0.0254 \pm 0.0017 \\ F_A = 0.0119 \pm 0.0001 \\ F_V \ \text{slope parameter} \ a = 0.10 \pm 0.06 \\ R = 0.059^{+0.009}_{-0.008}$

 π^- modes are charge conjugates of the modes below.

For decay limits to particles which are not established, see the section on Searches for Axions and Other Very Light Bosons.

Most decay modes (other than the semileptonic modes) that involve a neutral K meson are now given as K_S^0 modes, not as \overline{K}^0 modes. Nearly always it is a K_S^0 that is measured, and interference between Cabibbo-allowed and doubly Cabibbo-suppressed modes can invalidate the assumption that $2\Gamma(K_S^0) = \Gamma(\overline{K}^0)$.

Most decay modes (other than the semileptonic modes) that involve a neutral K meson are now given as K_S^0 modes, not as \overline{K}^0 modes. Nearly always it is a K_S^0 that is measured, and interference between Cabibbo-allowed and doubly Cabibbo-suppressed modes can invalidate the assumption that $2 \Gamma(K_S^0) = \Gamma(\overline{K}^0)$.

BOTTOM MESONS $(B=\pm 1)$

 $B^+ = u \overline{b}$, $B^0 = d \overline{b}$, $\overline{B}{}^0 = \overline{d}b$, $B^- = \overline{u}b$, similarly for B^* 's

B-particle organization

Many measurements of B decays involve admixtures of Bhadrons. Previously we arbitrarily included such admixtures in the B^{\pm} section, but because of their importance we have created two new sections: " B^{\pm}/B^0 Admixture" for $\Upsilon(4S)$ results and " $B^{\pm}/B^0/B_s^0/b$ -baryon Admixture" for results at higher energies. Most inclusive decay branching fractions and $\chi_{\it b}$ at high energy are found in the Admixture sections. $B^0 - \overline{B}{}^0$ mixing data are found in the B^0 section, while B^0_s - \overline{B}_s^0 mixing data and B- \overline{B} mixing data for a B^0/B_s^0 admixture are found in the B_s^0 section. \overrightarrow{CP} -violation data are found in the B^{\pm} , B^{0} , and \tilde{B}^{\pm} B^{0} Admixture sections. b-baryons are found near the end of the Baryon section.

The organization of the B sections is now as follows, where bullets indicate particle sections and brackets indicate reviews

- B[±]
 - mass, mean life, CP violation, branching fractions
- B⁰
 - mass, mean life, $B^0 \overline{B}{}^0$ mixing, CP violation, branching fractions
- B[±] B⁰ Admixtures
 - CP violation, branching fractions
- $B^{\pm}/B^0/B_s^0/b$ -baryon Admixtures
 - mean life, production fractions, branching fractions
- B*
- mass
- $B_1(5721)^0$
- mass
- $B_2^*(5747)^0$
- mass B_s⁰

mass, mean life, $B_c^0 - \overline{B}_c^0$ mixing, CP violation, branching fractions

B[∗]_c

 B^- modes are charge conjugates of the modes below. Modes which do not identify the charge state of the B are listed in the B^\pm/B^0 ADMIXTURE section

The branching fractions listed below assume 50% $B^0\overline{B}^0$ and 50% B^+B^- production at the $\Upsilon(4S)$. We have attempted to bring older measurements up to date by rescaling their assumed $\Upsilon(4S)$ production ratio to 50:50 and their assumed D, D_S , D^* , and ψ branching ratios to current values whenever this would affect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

For inclusive branching fractions, e.g., $B\to D^\pm$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

The branching fraction measurements are for an admixture of B mesons at the $\Upsilon(4S)$. The values quoted assume that B($\Upsilon(4S) \to B\overline{B}$) = 100%. For inclusive branching fractions, e.g., $B o D^{\pm}$ anything, the treatment of multiple D's in the final state must be defined. One possibility would be to count the number of events with one-or-more D's and divide by the total number of B's. Another possibility would be to count the total number of D's and divide by the total number of B's, which is the definition of average multiplicity. The two definitions are identical if only one D is allowed in the final state. Even though the "one-or-more" definition seems sensible, for practical reasons inclusive branching fractions are almost always measured using the multiplicity definition. For heavy final state particles, authors call their results inclusive branching fractions while for light particles some authors call their results multiplicities. In the B sections, we list all results as inclusive branching fractions, adopting a multiplicity definition. This means that inclusive branching fractions can exceed 100% and that inclusive partial widths can exceed total widths, just as inclusive cross sections can exceed total cross section. $\overline{\emph{B}}$ modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing. Scale factor/ B DECAY MODES Fraction (Γ_i/Γ) Confidence level (MeV/c) Semileptonic and leptonic modes $e^+\,

< 5.1

```
Mean life 	au = (1.568 \pm 0.009) 	imes 10^{-12} 	ext{ s}
Mean life \tau = (1.72 \pm 0.10) \times 10^{-12} s Charged b-hadron
    admixture
```

Mean life $au=(1.58\pm0.14) imes10^{-12}$ s Neutral b-hadron admixture

$$\begin{array}{l} \tau_{\rm charged\ b-hadron}/\tau_{\rm neutral\ b-hadron} = 1.09 \pm 0.13 \\ |\Delta\tau_b|/\tau_{b,\overline{b}} = -0.001 \pm 0.014 \\ {\rm Re}(\epsilon_b)\ /\ (1+|\epsilon_b|^2) = (-2.0 \pm 0.5) \times 10^{-3} \end{array}$$

The branching fraction measurements are for an admixture of B mesons and baryons at energies above the $\Upsilon(4S).$ Only the highest energy results (LHC, LEP, Tevatron, $Sp\overline{p}S$) are used in the branching fraction averages. In the following, we assume that the production fractions are the same at the LHC, LEP, and at the Tevatron.

For inclusive branching fractions, e.g., $B o D^\pm$ anything, the values usually are multiplicities, not branching fractions. They can be greater

The modes below are listed for a \overline{b} initial state. b modes are their charge conjugates. Reactions indicate the weak decay vertex and do not include mixing.

PRODUCTION FRACTIONS

The production fractions for weakly decaying b-hadrons at high energy have been calculated from the best values of mean lives, mixing parameters, and branching fractions in this edition by the Heavy Flavor Averaging Group (HFAG) as described in the note " B^0 – \overline{B}^0 Mixing" in the B^0 Particle Listings. The production fractions in b-hadronic Z decay or $p\overline{p}$ collisions at the Tevatron are also listed at the end of the section. Values assume

$$\begin{array}{ll} B(\overline{b} \to B^+) = B(\overline{b} \to B^0) \\ B(\overline{b} \to B^+) + B(\overline{b} \to B^0) + B(\overline{b} \to B^0_S) + B(b \to b\text{-baryon}) = 100 \ \%. \end{array}$$

The correlation coefficients between production fractions are also reported:

 $cor(B_c^0, b\text{-baryon}) = -0.277$ $cor(B_c^{\bar{0}}, B^{\pm}=B^0) = -0.119$ cor(b-baryon, $B^{\pm}=B^{0}) = -0.921$.

The notation for production fractions varies in the literature $(f_d, d_{R^0},$ $f(b \to \overline{B}{}^0)$, ${\rm Br}(b \to \overline{B}{}^0))$. We use our own branching fraction notation here, $B(\overline{b} \rightarrow B^0)$.

Note these production fractions are b-hadronization fractions, not the conventional branching fractions of b-quark to a B-hadron, which may have considerable dependence on the initial and final state kinematic and pro-

BOTTOM, STRANGE MESONS $(B = \pm 1, S = \mp 1)$

 $B_s^0 = s\overline{b}, \overline{B}_s^0 = \overline{s}b,$ similarly for B_s^* 's

$$I(J^P) = 0(0^-)$$

 ${\it I}$, ${\it J}$, ${\it P}$ need confirmation. Quantum numbers shown are quark-model predictions.

Mass
$$m_{B_s^0} = 5366.77 \pm 0.24$$
 MeV $m_{B_s^0} - m_B = 87.35 \pm 0.23$ MeV Mean life $\tau = (1.497 \pm 0.015) \times 10^{-12}$ s $c\tau = 449~\mu\text{m}$ $\Delta\Gamma_{B_s^0} = \Gamma_{B_s^0} - \Gamma_{B_{sH}^0} = (0.100 \pm 0.013) \times 10^{12} \,\text{s}^{-1}$

$B_s^0 - \overline{B}_s^0$ mixing parameters

$$\begin{split} \Delta m_{B_s^0} &= m_{B_{sH}^0} - m_{B_{sL}^0} = (17.69 \pm 0.08) \times 10^{12} \; \hbar \; \text{s}^{-1} \\ &= (116.4 \pm 0.5) \times 10^{-10} \; \text{MeV} \\ x_s &= \Delta m_{B_s^0} / \Gamma_{B_s^0} = 26.49 \pm 0.29 \\ \chi_s &= 0.499292 \pm 0.000016 \end{split}$$

CP violation parameters in B_s^0

$$\begin{array}{l} {\rm Re}(\epsilon_{B_s^0}) \ / \ (1 + |\epsilon_{B_s^0}|^2) = (-2.6 \pm 1.6) \times 10^{-3} \\ CP \ {\rm Violation \ phase} \ \beta_s = 0.08^{+0.05}_{-0.07} \\ A_{CP}(B_s \to \ \pi^+ K^-) = 0.39 \pm 0.17 \end{array}$$

These branching fractions all scale with $B(\overline{b} \rightarrow B_s^0)$.

The branching fraction ${\sf B}(B_s^0\to D_s^-\ell^+\nu_\ell$ anything) is not a pure measurement since the measured product branching fraction ${\sf B}(\overline{b}\to B_s^0)\times {\sf B}(B_s^0\to D_s^-\ell^+\nu_\ell$ anything) was used to determine ${\sf B}(\overline{b}\to B_s^0)$, as described in the note on " $B^0-\overline{B}^0$ Mixing"

For inclusive branching fractions, e.g., $B\to D^\pm$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one

$\psi(3770)$

$$I^{G}(J^{PC}) = 0^{-}(1^{-})$$

Mass $m = 3773.15 \pm 0.33 \text{ MeV}$ Full width Γ = 27.2 \pm 1.0 MeV $\Gamma_{ee} = 0.262 \pm 0.018 \; \text{keV} \quad (S = 1.4) \label{eq:ee}$

In addition to the dominant decay mode to $D\overline{D}$, $\psi(3770)$ was found to decay into the final states containing the J/ψ (BAI 05, ADAM 06). ADAMS 06 and HUANG 06A searched for various decay modes with light hadrons and found a statistically significant signal for the decay to $\phi\eta$ only (ADAMS 06).

Due to the complexity of the $c\overline{c}$ threshold region, in this listing, "seen" ("not seen") means that a cross section for the mode in question has been measured at effective \sqrt{s} near this particle's central mass value, more (less) than 2σ above zero, without regard to any peaking behavior in \sqrt{s} or absence thereof. See mode listing(s) for details and references.

NOTES

In this Summary Table:

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor" S, defined as S = $\sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when S > 1, which often indicates that the measurements are inconsistent. When S > 1.25, we also show in the Particle Listings an ideogram of the measurements. For more about S, see the Introduction.

A decay momentum p is given for each decay mode. For a 2-body decay, p is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay, p is the largest momentum any of the products can have in this frame.

- [a] See the "Note on $\pi^\pm\to\ell^\pm\nu\gamma$ and $K^\pm\to\ell^\pm\nu\gamma$ Form Factors" in the π^\pm Particle Listings for definitions and details.
- [b] Measurements of $\Gamma(e^+\nu_e)/\Gamma(\mu^+\nu_\mu)$ always include decays with γ 's, and measurements of $\Gamma(e^+\nu_e\gamma)$ and $\Gamma(\mu^+\nu_\mu\gamma)$ never include low-energy γ 's. Therefore, since no clean separation is possible, we consider the modes with γ 's to be subreactions of the modes without them, and let $[\Gamma(e^+\nu_e) + \Gamma(\mu^+\nu_\mu)]/\Gamma_{\rm total} = 100\%$.
- [c] See the π^\pm Particle Listings for the energy limits used in this measurement; low-energy γ 's are not included.
- [d] Derived from an analysis of neutrino-oscillation experiments.
- [e] Astrophysical and cosmological arguments give limits of order 10 $^{-13}$; see the π^0 Particle Listings.
- [f] C parity forbids this to occur as a single-photon process.
- [g] See the "Note on scalar mesons" in the $f_0(500)$ Particle Listings . The interpretation of this entry as a particle is controversial.
- [h] See the "Note on ho(770)" in the ho(770) Particle Listings .
- [i] The $\omega \rho$ interference is then due to $\omega \rho$ mixing only, and is expected to be small. If $e \mu$ universality holds, $\Gamma(\rho^0 \to \mu^+ \mu^-) = \Gamma(\rho^0 \to e^+ e^-) \times 0.99785$.
- [j] See the "Note on scalar mesons" in the $f_0(500)$ Particle Listings .
- [k] See the "Note on $a_1(1260)$ " in the $a_1(1260)$ Particle Listings in PDG 06, Journal of Physics, G **33** 1 (2006).
- [/] This is only an educated guess; the error given is larger than the error on the average of the published values. See the Particle Listings for details.
- [m] See the "Note on non- $q\overline{q}$ mesons" in the Particle Listings in PDG 06, Journal of Physics, G **33** 1 (2006).
- [n] See the "Note on the $\eta(1405)$ " in the $\eta(1405)$ Particle Listings.
- [o] See the "Note on the f_1 (1420)" in the $\eta(1405)$ Particle Listings.
- [p] See also the $\omega(1650)$ Particle Listings.
- [q] See the "Note on the $\rho(1450)$ and the $\rho(1700)$ " in the $\rho(1700)$ Particle Listings.
- [r] See also the $\omega(1420)$ Particle Listings.
- [s] See the "Note on $f_0(1710)$ " in the $f_0(1710)$ Particle Listings in 2004 edition of *Review of Particle Physics*.
- [t] See the note in the K^{\pm} Particle Listings.
- [u] The definition of the slope parameter g of the $K \to 3\pi$ Dalitz plot is as follows (see also "Note on Dalitz Plot Parameters for $K \to 3\pi$ Decays" in the K^{\pm} Particle Listings):

$$|M|^2 = 1 + g(s_3 - s_0)/m_{\pi^+}^2 + \cdots$$

- [v] For more details and definitions of parameters see the Particle Listings.
- [w] See the K[±] Particle Listings for the energy limits used in this measurement.
- [x] Most of this radiative mode, the low-momentum γ part, is also included in the parent mode listed without γ 's.
- [y] Structure-dependent part.
- [z] Direct-emission branching fraction.
- [aa] Violates angular-momentum conservation.
- [bb] Derived from measured values of ϕ_{+-} , ϕ_{00} , $|\eta|$, $|m_{K^0_L} m_{K^0_S}|$, and $\tau_{K^0_S}$, as described in the introduction to "Tests of Conservation Laws."
- [cc] The CP-violation parameters are defined as follows (see also "Note on CP Violation in $K_5 \to 3\pi$ " and "Note on CP Violation in K_L^0 Decay" in the Particle Listings):

$$\eta_{+-} = |\eta_{+-}| e^{i\phi_{+-}} = \frac{A(K_L^0 \to \pi^+ \pi^-)}{A(K_S^0 \to \pi^+ \pi^-)} = \epsilon + \epsilon'$$

$$\eta_{00} = |\eta_{00}| e^{i\phi_{00}} = \frac{A(K_L^0 \to \pi^0 \pi^0)}{A(K_S^0 \to \pi^0 \pi^0)} = \epsilon - 2\epsilon'$$

$$\delta = \frac{\Gamma(K_L^0 \to \ \pi^-\ell^+\nu) - \Gamma(K_L^0 \to \ \pi^+\ell^-\nu)}{\Gamma(K_L^0 \to \ \pi^-\ell^+\nu) + \Gamma(K_L^0 \to \ \pi^+\ell^-\nu)} \ ,$$

$$\label{eq:mass_energy} {\rm Im}(\eta_{+-0})^2 = \frac{\Gamma(K_S^0 \to \ \pi^+ \, \pi^- \pi^0)^{CP \ viol.}}{\Gamma(K_L^0 \to \ \pi^+ \pi^- \pi^0)} \; .$$

$${\rm Im}(\eta_{000})^2 = rac{\Gamma(K_S^0 o \pi^0 \pi^0 \pi^0)}{\Gamma(K_I^0 o \pi^0 \pi^0 \pi^0)} \, .$$

where for the last two relations *CPT* is assumed valid, *i.e.*, ${\rm Re}(\eta_{+-0})\simeq$ 0 and ${\rm Re}(\eta_{000})\simeq~$ 0.

- [dd] See the K^0_S Particle Listings for the energy limits used in this measurement.
- [ee] The value is for the sum of the charge states or particle/antiparticle states indicated.
- [ff] $\text{Re}(\epsilon'/\epsilon) = \epsilon'/\epsilon$ to a very good approximation provided the phases satisfy *CPT* invariance.
- [gg] This mode includes gammas from inner bremsstrahlung but not the direct emission mode $K_1^0 \to \pi^+\pi^-\gamma({\sf DE})$.
- [hh] See the K_L^0 Particle Listings for the energy limits used in this measurement.
- [ii] Allowed by higher-order electroweak interactions.
- [jj] Violates CP in leading order. Test of direct CP violation since the indirect CP-violating and CP-conserving contributions are expected to be suppressed.
- [kk] See the "Note on $f_0(1370)$ " in the $f_0(1370)$ Particle Listings and in the 1994 edition.
- [II] See the note in the L(1770) Particle Listings in Reviews of Modern Physics **56** S1 (1984), p. S200. See also the "Note on $K_2(1770)$ and the $K_2(1820)$ " in the $K_2(1770)$ Particle Listings .
- [mm] See the "Note on $K_2(1770)$ and the $K_2(1820)$ " in the $K_2(1770)$ Particle Listings .
- [nn] This result applies to $Z^0 \to c\,\overline{c}$ decays only. Here ℓ^+ is an average (not a sum) of e^+ and μ^+ decays.
- [00] See the Particle Listings for the (complicated) definition of this quantity.
- [pp] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers in the Particle Listings.
- [qq] These subfractions of the $K^-2\pi^+$ mode are uncertain: see the Particle Listings.
- [rr] Submodes of the $D^+ \to K^- 2\pi^+ \pi^0$ and $K_S^0 2\pi^+ \pi^-$ modes were studied by ANJOS 92C and COFFMAN 92B, but with at most 142 events for the first mode and 229 for the second not enough for precise results. With nothing new for 18 years, we refer to our 2008 edition, Physics Letters **B667** 1 (2008), for those results.
- [ss] The unseen decay modes of the resonances are included.
- [tt] This is not a test for the Δ C=1 weak neutral current, but leads to the $\pi^+\ell^+\ell^-$ final state.
- [uu] This mode is not a useful test for a $\Delta C=1$ weak neutral current because both quarks must change flavor in this decay.
- $[\nu\nu]$ In the 2010 Review, the values for these quantities were given using a measure of the asymmetry that was inconsistent with the usual definition.
- $[\mathit{ww}]$ This value is obtained by subtracting the branching fractions for 2-, 4- and 6-prongs from unity.
- [xx] This is the sum of our $K^-2\pi^+\pi^-$, $K^-2\pi^+\pi^-\pi^0$, $K^-2\pi^+\pi^-\pi^0$, $K^+2\pi^+\pi^-\pi^0$, $K^+2\pi^+\pi^-\pi^0$, branching fractions.
- [yy] This is the sum of our $K^-3\pi^+2\pi^-$ and $3\pi^+3\pi^-$ branching fractions.
- [zz] The branching fractions for the $K^-e^+\nu_e$, $K^*(892)^-e^+\nu_e$, $\pi^-e^+\nu_e$, and $\rho^-e^+\nu_e$ modes add up to 6.19 \pm 0.17 %.
- [aaa] This is a doubly Cabibbo-suppressed mode.
- [bbb] The two experiments measuring this fraction are in serious disagreement. See the Particle Listings.
- [ccc] Submodes of the $D^0 \to K_S^0 \pi^+ \pi^- \pi^0$ mode with a K^* and/or ρ were studied by COFFMAN 92B, but with only 140 events. With nothing new for 18 years, we refer to our 2008 edition, Physics Letters **B667** 1 (2008), for those results.

- [ddd] This branching fraction includes all the decay modes of the resonance in the final state.
- [eee] The experiments on the division of this charge mode amongst its submodes disagree, and the submode branching fractions here add up to considerably more than the charged-mode fraction.
- [fff] However, these upper limits are in serious disagreement with values obtained in another experiment.
- [ggg] This limit is for either D^0 or $\overline{D}{}^0$ to pe^- .
- [hhh] This limit is for either D^0 or $\overline{D}{}^0$ to $\overline{p}e^+$.
- [iii] This is the purely e^+ semileptonic branching fraction: the e^+ fraction from τ^+ decays has been subtracted off. The sum of our (non- τ) e^+ exclusive fractions an $e^+\nu_e$ with an $\eta,\,\eta',\,\phi,\,K^0,\,K^{*0}$, or $f_0(980)$ is $7.0\pm0.4~\%$
- [jjj] This fraction includes η from η' decays.
- [kkk] Two times (to include μ decays) the $\eta'\,e^+\,\nu_e$ branching fraction, plus the $\eta'\,\pi^+$, $\eta'\,\rho^+$, and $\eta'\,K^+$ fractions, is $(18.6\pm2.3)\%$, which considerably exceeds the inclusive η' fraction of $(11.7\pm1.8)\%$. Our best guess is that the $\eta'\,\rho^+$ fraction, $(12.5\pm2.2)\%$, is too large.
- [///] This branching fraction includes all the decay modes of the final-state resonance.
- [mmm] A test for $u\overline{u}$ or $d\overline{d}$ content in the D_s^+ . Neither Cabibbo-favored nor Cabibbo-suppressed decays can contribute, and $\omega-\phi$ mixing is an unlikely explanation for any fraction above about 2×10^{-4} .
- [nnn] We decouple the $D_s^+ \to \phi \pi^+$ branching fraction obtained from mass projections (and used to get some of the other branching fractions) from the $D_s^+ \to \phi \pi^+$, $\phi \to K^+ K^-$ branching fraction obtained from the Dalitz-plot analysis of $D_s^+ \to K^+ K^- \pi^+$. That is, the ratio of these two branching fractions is not exactly the $\phi \to K^+ K^-$ branching fraction 0.491.
- [ooo] This is the average of a model-independent and a K-matrix parametrization of the $\pi^+\pi^-$ S-wave and is a sum over several f_0 mesons.
- [ppp] An ℓ indicates an e or a μ mode, not a sum over these modes.
- [qqq] An $\mathit{CP}(\pm 1)$ indicates the $\mathit{CP}{=}+1$ and $\mathit{CP}{=}-1$ eigenstates of the $\mathit{D^0}\text{-}\overline{\mathit{D}^0}$ system.
- [rrr] D denotes D^0 or \overline{D}^0 .
- [sss] D^{*0}_{CP+} decays into $D^0\pi^0$ with the D^0 reconstructed in CP-even eigenstates K^+K^- and $\pi^+\pi^-$.
- [ttt] \overline{D}^{**} represents an excited state with mass 2.2 < M < 2.8 GeV/c².
- $[uuu] X (3872)^+$ is a hypothetical charged partner of the X(3872).
- $[vvv]\,\Theta(1710)^{++}$ is a possible narrow pentaquark state and G(2220) is a possible glueball resonance.
- [www] $(\overline{\Lambda}_c^- p)_s$ denotes a low-mass enhancement near 3.35 GeV/c².
- [xxx] Stands for the possible candidates of $K^*(1410),\ K_0^*(1430)$ and $K_2^*(1430).$
- [yyy] B^0 and B^0_s contributions not separated. Limit is on weighted average of the two decay rates.
- [zzz] This decay refers to the coherent sum of resonant and nonresonant J^P = 0^+ $K\pi$ components with 1.60 < $m_{K\pi}$ < 2.15 GeV/ c^2 .
- [aaaa] X(214) is a hypothetical particle of mass 214 MeV/c² reported by the HyperCP experiment, Physical Review Letters **94** 021801 (2005)
- [bbbb] $\Theta(1540)^+$ denotes a possible narrow pentaquark state.
- [cccc] These values are model dependent.
- [dddd] Here "anything" means at least one particle observed.
- [eeee] D^{**} stands for the sum of the $D(1\,^1\!P_1)$, $D(1\,^3\!P_0)$, $D(1\,^3\!P_1)$, $D(1\,^3\!P_2)$, $D(2\,^1\!S_0)$, and $D(2\,^1\!S_1)$ resonances.
- [ffff] $D^{(*)}\overline{D}^{(*)}$ stands for the sum of $D^*\overline{D}^*$, $D^*\overline{D}$, $D\overline{D}^*$, and $D\overline{D}$.
- [gggg] X(3915) denotes a near-threshold enhancement in the $\omega J/\psi$ mass spectrum.
- [hhhh] Inclusive branching fractions have a multiplicity definition and can be greater than 100%.
- [iiii] D_j represents an unresolved mixture of pseudoscalar and tensor D^{**} (P-wave) states.
- [jjjj] Not a pure measurement. See note at head of B_s^0 Decay Modes.
- [kkkk] For $E_{\gamma} > 100$ MeV.
- [///] Includes $p \overline{p} \pi^+ \pi^- \gamma$ and excludes $p \overline{p} \eta$, $p \overline{p} \omega$, $p \overline{p} \eta'$.
- [mmmm] For a narrow state A with mass less than 960 MeV.
- [nnnn] For a narrow resonance in the range 2.2 < M(X) < 2.8 GeV.

[pppp] J^{PC} known by production in e^+e^- via single photon annihilation. I^G is not known; interpretation of this state as a single resonance is unclear because of the expectation of substantial threshold effects in this energy region.

[qqqq] $2m_{ au} < M(au^+ au^-) < 7500$ MeV [rrrr] $2 < m_{K^+ K^-} < 3$ GeV [ssss] X = scalar with <math>m < 8.0 GeV

[tttt] $X \overline{X} = \text{vectors with } m < 3.1 \text{ GeV}$

[uuuu] X and $\overline{X}={\sf zero}\,{\sf spin}\,\,{\sf with}\,\,m<$ 4.5 GeV

[vvvv] 1.5 GeV $< m_X <$ 5.0 GeV

 $[wwww]\,201 < {
m M}(\mu^+\mu^-) < 3565 \;{
m MeV}$

 $[{\ensuremath{\mathsf{xxxx}}}] Spectroscopic labeling for these states is theoretical, pending experimental information.$

[yyyy] 1.5 GeV $< m_X <$ 5.0 GeV

[zzzz] 1.5 GeV $< m_X <$ 5.0 GeV

[aaaaa] For $m_{\tau^+\tau^-}$ in the ranges 4.03–9.52 and 9.61–10.10 GeV.

See also the table of suggested $q\overline{q}$ quark-model assignments in the Quark Model section.

• Indicates particles that appear in the preceding Meson Summary Table. We do not regard the other entries as being established.

This short table gives the name, the quantum numbers (where known), and the status of baryons in the Review. Only the baryons with 3- or 4-star status are included in the Baryon Summary Table. Due to insufficient data or uncertain interpretation, the other entries in the table are not established baryons. The names with masses are of baryons that decay strongly. The spin-parity J^P (when known) is given with each particle. For the strongly decaying particles, the J^P values are considered to be part of the names.

| | | | | | | | | | | | | | | |

^{****} Existence is certain, and properties are at least fairly well explored.

^{***} Existence ranges from very likely to certain, but further confirmation is desirable and/or quantum numbers, branching fractions, etc. are not well determined.

^{**} Evidence of existence is only fair.

^{*} Evidence of existence is poor.

See the "Note on Nucleon Decay" in our 1994 edition (Phys. Rev. ${\bf D50}, 1173)$ for a short review.

The "partial mean life" limits tabulated here are the limits on τ/B_i , where τ is the total mean life and B_i is the branching fraction for the mode in question. For N decays, p and n indicate proton and neutron partial lifetimes

```

Nearly all branching fractions of the $\Lambda_{\mathcal{C}}^+$ are measured relative to the $p\ K^-\pi^+$ mode, but there are no model-independent measurements of this branching fraction. We explain how we arrive at our value of $B(\Lambda_c^+ \to 0)$ $ho \, K^- \, \pi^+)$ in a Note at the beginning of the branching-ratio measurements in the Listings. When this branching fraction is eventually well determined, all the other branching fractions will slide up or down proportionally as the true value differs from the value we use here.

$\Lambda_c(2595)^+$

 $pK^+\pi^-$

$$I(J^P) = 0(\frac{1}{2})$$

The spin-parity follows from the fact that $\Sigma_c(2455)\pi$ decays, with little available phase space, are dominant. This assumes that ${\it J}^{\it P}=$ $1/2^{+}$ for the $\Sigma_{c}(2455)$.

Mass
$$m=2592.25\pm0.28$$
 MeV $m-m_{\Lambda_c^+}=305.79\pm0.24$ MeV Full width $\Gamma=2.6\pm0.6$ MeV

 $\Lambda_{C}^{+}\pi\pi$ and its submode $\Sigma_{C}(2455)\pi$ — the latter just barely — are the only strong decays allowed to an excited Λ_{C}^{+} having this mass; and the submode seems to dominate.

| 1 _c (2595)+ DECAY MODES | Fraction (Γ _i /Γ) | p (MeV/c) |

$$A_{CP}(\Lambda_b\to p\pi^-)=0.03\pm0.18$$

$$A_{CP}(\Lambda_b\to pK^-)=0.37\pm0.17$$

The branching fractions B(b-baryon $\to \Lambda \ell^- \overline{\nu}_\ell$ anything) and B($\Lambda^0_b \to \Lambda^+_c \ell^- \overline{\nu}_\ell$ anything) are not pure measurements because the underlying measured products of these with B($b \to b$ -baryon) were used to determine B($b \to b$ -baryon), as described in the note "Production and Decay of b-Flavored Hadrons."

For inclusive branching fractions, e.g., $\Lambda_b \to \overline{\Lambda}_C$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

b-baryon ADMIXTURE $(\Lambda_b, \Xi_b, \Sigma_b, \Omega_b)$

Mean life
$$au = (1.382 \pm 0.029) \times 10^{-12} \text{ s}$$

These branching fractions are actually an average over weakly decaying b-baryons weighted by their production rates at the LHC, LEP, and Tevatron, branching ratios, and detection efficiencies. They scale with the b-baryon production fraction B($b \rightarrow b$ -baryon).

The branching fractions B(b-baryon $\to \Lambda \ell^- \overline{\nu}_\ell$ anything) and B($\Lambda^0_b \to \Lambda^+_c \ell^- \overline{\nu}_\ell$ anything) are not pure measurements because the underlying measured products of these with B($b \to b$ -baryon) were used to determine B($b \to b$ -baryon), as described in the note "Production and Decay of b-Flavored Hadrons."

For inclusive branching fractions, e.g., $B \to D^\pm$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

NOTES

This Summary Table only includes established baryons. The Particle Listings include evidence for other baryons. The masses, widths, and branching fractions for the resonances in this Table are Breit-Wigner parameters, but pole positions are also given for most of the N and Δ resonances.

For most of the resonances, the parameters come from various partial-wave analyses of more or less the same sets of data, and it is not appropriate to treat the results of the analyses as independent or to average them together. Furthermore, the systematic errors on the results are not well understood. Thus, we usually only give ranges for the parameters. We then also give a best guess for the mass (as part of the name of the resonance) and for the width. The Note on N and Δ Resonances and the Note on N and Σ Resonances in the Particle Listings review the partial-wave analyses.

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor" S, defined as $S=\sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when S > 1, which often indicates that the measurements are inconsistent. When S > 1.25, we also show in the Particle Listings an ideogram of the measurements. For more about S, see the Introduction.

A decay momentum p is given for each decay mode. For a 2-body decay, p is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay, p is the largest momentum any of the products can have in this frame. For any resonance, the nominal mass is used in calculating p. A dagger ("†") in this column indicates that the mode is forbidden when the nominal masses of resonances are used, but is in fact allowed due to the nonzero widths of the resonances.

- [a] The masses of the p and n are most precisely known in u (unified atomic mass units). The conversion factor to MeV, 1 u=931.494028(23) MeV, is less well known than are the masses in u.
- [b] The $|m_p-m_{\overline{\rho}}|/m_p$ and $|q_p+q_{\overline{\rho}}|/e$ are not independent, and both use the more precise measurement of $|q_{\overline{\rho}}/m_{\overline{\rho}}|/(q_p/m_p)$.
- [c] The limit is from neutrality-of-matter experiments; it assumes $q_n=q_p+q_e$. See also the charge of the neutron.

- [d] The first limit is for $p \to anything$ or "disappearance" modes of a bound proton. The second entry, a rough range of limits, assumes the dominant decay modes are among those investigated. For antiprotons the best limit, inferred from the observation of cosmic ray \overline{p} 's is $\tau_{\overline{p}} > 10^7$ yr, the cosmic-ray storage time, but this limit depends on a number of assumptions. The best direct observation of stored antiprotons gives $\tau_{\overline{p}}/B(\overline{p} \to e^-\gamma) > 7 \times 10^5$ yr.
- [e] There is some controversy about whether nuclear physics and model dependence complicate the analysis for bound neutrons (from which the best limit comes). The first limit here is from reactor experiments with free neutrons.
- [f] Lee and Yang in 1956 proposed the existence of a mirror world in an attempt to restore global parity symmetry—thus a search for oscillations between the two worlds. Oscillations between the worlds would be maximal when the magnetic fields B and B' were equal. The limit for any B' in the range 0 to 12.5 μT is >12 s (95% CL).
- [g] The parameters g_A , g_V , and g_{WM} for semileptonic modes are defined by $\overline{B}_f[\gamma_\lambda(g_V+g_A\gamma_5)+i(g_{WM}/m_{B_i})\;\sigma_{\lambda\nu}\;q^\nu]B_i$, and ϕ_{AV} is defined by $g_A/g_V=|g_A/g_V|e^{i\phi_{AV}}$. See the "Note on Baryon Decay Parameters" in the neutron Particle Listings.
- [h] Time-reversal invariance requires this to be 0° or 180° .
- [i] This coefficient is zero if time invariance is not violated.
- [j] This limit is for γ energies between 15 and 340 keV.
- [k] The decay parameters γ and Δ are calculated from lpha and ϕ using

$$\gamma = \sqrt{1-\alpha^2} \cos \phi$$
, $\tan \Delta = -\frac{1}{\alpha} \sqrt{1-\alpha^2} \sin \phi$.

See the "Note on Baryon Decay Parameters" in the neutron Particle Listings.

- [/] See the Listings for the pion momentum range used in this measurement.
- [m] The error given here is only an educated guess. It is larger than the error on the weighted average of the published values.
- [n] A theoretical value using QED.
- [o] See the note on " Λ_c^+ Branching Fractions" in the Λ_c^+ Particle Listings.
- [p] This branching fraction includes all the decay modes of the final-state resonance
- [q] An ℓ indicates an e or a μ mode, not a sum over these modes.
- [r] The value is for the sum of the charge states or particle/antiparticle states indicated.
- [s] Assuming isospin conservation, so that the other third is $\Lambda_c^+ \pi^0 \pi^0$.
- [t] A test that the isospin is indeed 0, so that the particle is indeed a Λ_c^+ .
- [u] No absolute branching fractions have been measured. The value here is the branching ratio relative to $\Xi^-2\pi^+$.
- [v] Not a pure measurement. See note at head of Λ_h^0 Decay Modes.
- [w] Here h^- means π^- or K^- .

SEARCHES FOR MONOPOLES, SUPERSYMMETRY, TECHNICOLOR, COMPOSITENESS, EXTRA DIMENSIONS, etc.

Magnetic Monopole Searches

Isolated supermassive monopole candidate events have not been confirmed. The most sensitive experiments obtain negative results.

Best cosmic-ray supermassive monopole flux limit:

$$< 1.0 \times 10^{-15} \text{ cm}^{-2} \text{sr}^{-1} \text{s}^{-1}$$
 for $1.1 \times 10^{-4} < \beta < 0.1$

Supersymmetric Particle Searches

Limits are based on the Minimal Supersymmetric Standard Model. Assumptions include: 1) $\widetilde{\chi}_1^0$ (or $\widetilde{\gamma}$) is lightest supersymmetric particle; 2) R-parity is conserved; 3) With the exception of \widetilde{t} and \widetilde{b} , all scalar quarks are assumed to be degenerate in mass and $m_{\widetilde{q}_R} = m_{\widetilde{q}_L}$. 4) Limits for sleptons refer to the $\widetilde{\ell}_R$ states. 5) Gaugino mass unification at the GUT scale.

See the Particle Listings for a Note giving details of supersymmetry.

$$\begin{array}{l} \widetilde{\chi}_{i}^{0} - \text{neutralinos (mixtures of } \widetilde{\gamma}, \widetilde{Z}^{0}, \text{ and } \widetilde{H}_{i}^{0}) \\ \text{Mass } m_{\widetilde{\chi}_{1}^{0}} > 46 \text{ GeV, CL} = 95\% \\ \text{[all } \tan\beta, \text{ all } m_{0}, \text{ all } m_{\widetilde{\chi}_{2}^{0}} - m_{\widetilde{\chi}_{1}^{0}}] \\ \text{Mass } m_{\widetilde{\chi}_{2}^{0}} > 62.4 \text{ GeV, CL} = 95\% \\ \text{[1<\tan}\beta < 40, \text{ all } m_{0}, \text{ all } m_{\widetilde{\chi}_{2}^{0}} - m_{\widetilde{\chi}_{1}^{0}}] \\ \text{Mass } m_{\widetilde{\chi}_{3}^{0}} > 99.9 \text{ GeV, CL} = 95\% \\ \text{[1<\tan}\beta < 40, \text{ all } m_{0}, \text{ all } m_{\widetilde{\chi}_{2}^{0}} - m_{\widetilde{\chi}_{1}^{0}}] \\ \text{Mass } m_{\widetilde{\chi}_{4}^{0}} > 116 \text{ GeV, CL} = 95\% \\ \text{[1<\tan}\beta < 40, \text{ all } m_{0}, \text{ all } m_{\widetilde{\chi}_{2}^{0}} - m_{\widetilde{\chi}_{1}^{0}}] \\ \end{array}$$

$$\widetilde{\chi}_i^\pm$$
 — charginos (mixtures of \widetilde{W}^\pm and \widetilde{H}_i^\pm)
Mass $m_{\widetilde{\chi}_1^\pm} >$ 94 GeV, CL = 95%
 $[\tan \! eta < 40, \ m_{\widetilde{\chi}_1^\pm} - m_{\widetilde{\chi}_1^0} >$ 3 GeV, all $m_0]$

 \tilde{e} — scalar electron (selectron)

Mass
$$m>~$$
 107 GeV, CL $=~$ 95% $[$ all $m_{\widetilde{e}_R}-m_{\widetilde{\chi}_1^0}]$

 $\widetilde{\mu}$ — scalar muon (smuon)

Mass
$$m>$$
 94 GeV, CL $=$ 95%
$$[1 \leq \tan\beta \leq$$
 40, $m_{\widetilde{\mu}_R} - m_{\widetilde{\chi}_+^0} >$ 10 GeV]

 $\widetilde{ au}$ — scalar tau (stau)

Mass
$$m>81.9$$
 GeV, CL = 95% $[m_{\widetilde{\tau}_R}-m_{\widetilde{\chi}_1^0}>$ >15 GeV, all $\theta_{\tau}]$

 \tilde{q} — scalar quark (squark)

These limits include the effects of cascade decays, evaluated assuming a fixed value of the parameters μ and $\tan\beta$. The limits are weakly sensitive to these parameters over much of parameter space. Limits assume GUT relations between gaugino masses and the gauge coupling.

Mass $m > 1.100 \times 10^3$ GeV, CL = 95% [tan β =10, μ >0, A_0 =0]

 \widetilde{b} — scalar bottom (sbottom)

Mass
$$m>$$
 89 GeV, CL = 95% $[m_{\widetilde{b}_1}-m_{\widetilde{\chi}_1^0}>$ 8 GeV, all θ_b]

 \tilde{t} — scalar top (stop)

$$\widetilde{g}$$
 — gluino

The limits summarised here refer to the high-mass region $(m_{\widetilde{g}} \gtrsim 5~{\rm GeV})$, and include the effects of cascade decays, evaluated assuming a fixed value of the parameters μ and $\tan\beta$. The limits are weakly sensitive to these parameters over much of parameter space. Limits assume GUT relations between gaugino masses and the gauge coupling,

Mass
$$m > 500$$
 GeV, $CL = 95\%$ [any $m_{\widetilde{a}}$]

Technicolor

Searches for a color-octet techni- ρ constrain its mass to be greater than 260 to 480 GeV, depending on allowed decay channels. Similar bounds exist on the color-octet techni- ω .

Quark and Lepton Compositeness, Searches for

Scale Limits A for Contact Interactions (the lowest dimensional interactions with four fermions)

If the Lagrangian has the form

$$\pm \frac{g^2}{2\Lambda^2} \, \overline{\psi}_{\mathsf{L}} \, \gamma_{\mu} \psi_{\mathsf{L}} \, \overline{\psi}_{\mathsf{L}} \, \gamma^{\mu} \psi_{\mathsf{L}}$$

(with $g^2/4\pi$ set equal to 1), then we define $\Lambda \equiv \Lambda_{LL}^{\pm}$. For the full definitions and for other forms, see the Note in the Listings on Searches for Quark and Lepton Compositeness in the full *Review* and the original literature.

TESTS OF CONSERVATION LAWS

Updated May 2012 by L. Wolfenstein (Carnegie-Mellon University) and C.-J. Lin (LBNL) .

In keeping with the current interest in tests of conservation laws, we collect together a Table of experimental limits on all weak and electromagnetic decays, mass differences, and moments, and on a few reactions, whose observation would violate conservation laws. The Table is given only in the full Review of Particle Physics, not in the Particle Physics Booklet. For the benefit of Booklet readers, we include the best limits from the Table in the following text. Limits in this text are for CL=90% unless otherwise specified. The Table is in two parts: "Discrete Space-Time Symmetries," i.e., C, P, T, CP, and CPT; and "Number Conservation Laws," i.e., lepton, baryon, hadronic flavor, and charge conservation. The references for these data can be found in the the Particle Listings in the Review. A discussion of these tests follows.

CPT INVARIANCE

General principles of relativistic field theory require invariance under the combined transformation CPT. The simplest tests of CPT invariance are the equality of the masses and lifetimes of a particle and its antiparticle. The best test comes from the limit on the mass difference between K^0 and \overline{K}^0 . Any such difference contributes to the CP-violating parameter ϵ . Assuming CPT invariance, ϕ_{ϵ} , the phase of ϵ should be very close to 44°. (See the review "CP Violation in K_L decay" in this edition.) In contrast, if the entire source of CP violation in K^0 decays were a $K^0 - \overline{K}^0$ mass difference, ϕ_{ϵ} would be $44^{\circ} + 90^{\circ}$.

Assuming that there is no other source of CPT violation than this mass difference, it is possible to deduce that [1]

$$m_{\overline{K}^0} - m_{K^0} \approx \frac{2(m_{K_L^0} - m_{K_S^0}) \, |\eta| \, (\frac{2}{3}\phi_{+-} + \frac{1}{3}\phi_{00} - \phi_{\rm SW})}{\sin\phi_{\rm SW}} \; ,$$

where $\phi_{\rm SW}=(43.51\pm0.05)^\circ$, the superweak angle. Using our best values of the CP-violation parameters, we get $|(m_{\overline{K}^0}-m_{K^0})/m_{K^0}| \leq 0.6 \times 10^{-18}$ at CL=90%. Limits can also be placed on specific CPT-violating decay amplitudes. Given the small value of $(1-|\eta_{00}/\eta_{+-}|)$, the value of $\phi_{00}-\phi_{+-}$ provides a measure of CPT violation in $K_L^0 \to 2\pi$ decay. Results from CERN [1] and Fermilab [2] indicate no CPT-violating effect.

CP AND T INVARIANCE

Given CPT invariance, CP violation and T violation are equivalent. The original evidence for CP violation came from the measurement of $|\eta_{+-}| = |A(K_L^0 \to \pi^+\pi^-)/A(K_S^0 \to \pi^+\pi^-)| = (2.232 \pm 0.011) \times 10^{-3}$. This could be explained in terms of $K^0 - \overline{K}^0$ mixing, which also leads to the asymmetry $[\Gamma(K_L^0 \to \pi^- e^+ \nu) - \Gamma(K_L^0 \to \pi^+ e^- \overline{\nu})]/[\text{sum}] = (0.334 \pm 0.007)\%$. Evidence for CP violation in the kaon decay amplitude comes from the measurement of $(1 - |\eta_{00}/\eta_{+-}|)/3 = Re(\epsilon'/\epsilon) = (1.66 \pm 0.23) \times 10^{-3}$. In the Standard Model much larger CP-violating effects are expected. The first of these, which is associated with $B - \overline{B}$ mixing, is the parameter $sin(2\beta)$ now measured

quite accurately to be 0.679 ± 0.020 . A number of other CP-violating observables are being measured in B decays; direct evidence for CP violation in the B decay amplitude comes from the asymmetry $[\Gamma(\overline{B}^0\to K^-\pi^+)-\Gamma(B^0\to K^+\pi^-)]/[\text{sum}]=-0.097\pm0.012$. Direct tests of T violation are much more difficult; a measurement by CPLEAR of the difference between the oscillation probabilities of K^0 to $\overline{K^0}$ and $\overline{K^0}$ to K^0 is related to T violation [3]. Other searches for CP or T violation involve effects that are expected to be unobservable in the Standard Model. The most sensitive are probably the searches for an electric dipole moment of the neutron, measured to be $<2.9\times10^{-26}~e$ cm, and the electron $(10.5\pm0.07)\times10^{-28}~e$ cm. A nonzero value requires both P and T violation.

CONSERVATION OF LEPTON NUMBERS

Present experimental evidence and the standard electroweak theory are consistent with the absolute conservation of three separate lepton numbers: electron number L_e , muon number L_{μ} , and tau number L_{τ} , except for the effect of neutrino mixing associated with neutrino masses. Searches for violations are of the following types:

- a) $\Delta L=2$ for one type of charged lepton. The best limit comes from the search for neutrinoless double beta decay $(Z,A) \to (Z+2,A) + e^- + e^-$. The best laboratory limit is $t_{1/2} > 1.9 \times 10^{25}$ yr (CL=90%) for ⁷⁶Ge.
- b) Conversion of one charged-lepton type to another. For purely leptonic processes, the best limits are on $\mu \to e \gamma$ and $\mu \to 3e$, measured as $\Gamma(\mu \to e \gamma)/\Gamma(\mu \to \text{all}) < 2.4 \times 10^{-12}$ and $\Gamma(\mu \to 3e)/\Gamma(\mu \to \text{all}) < 1.0 \times 10^{-12}$. For semileptonic processes, the best limit comes from the coherent conversion process in a muonic atom, $\mu^- + (Z,A) \to e^- + (Z,A)$, measured as $\Gamma(\mu^-\text{Ti} \to e^-\text{Ti})/\Gamma(\mu^-\text{Ti} \to \text{all}) < 4.3 \times 10^{-12}$. Of special interest is the case in which the hadronic flavor also changes, as in $K_L \to e \mu$ and $K^+ \to \pi^+ e^- \mu^+$, measured as $\Gamma(K_L \to e \mu)/\Gamma(K_L \to \text{all}) < 4.7 \times 10^{-12}$ and $\Gamma(K^+ \to \pi^+ e^- \mu^+)/\Gamma(K^+ \to \text{all}) < 1.3 \times 10^{-11}$. Limits on the conversion of τ into e or μ are found in τ decay and are much less stringent than those for $\mu \to e$ conversion, e.g., $\Gamma(\tau \to \mu \gamma)/\Gamma(\tau \to \text{all}) < 4.4 \times 10^{-8}$ and $\Gamma(\tau \to e \gamma)/\Gamma(\tau \to \text{all}) < 3.3 \times 10^{-8}$.
- c) Conversion of one type of charged lepton into another type of charged antilepton. The case most studied is $\mu^- + (Z,A) \rightarrow e^+ + (Z-2,A)$, the strongest limit being $\Gamma(\mu^-\text{Ti} \rightarrow e^+\text{Ca})/\Gamma(\mu^-\text{Ti} \rightarrow \text{all}) < 3.6 \times 10^{-11}$.
- d) Neutrino oscillations. It is expected even in the standard electroweak theory that the lepton numbers are not separately conserved, as a consequence of lepton mixing analogous to Cabibbo-Kobayashi-Maskawa quark mixing. However, if the only source of lepton-number violation is the mixing of low-mass neutrinos then processes such as $\mu \to e \gamma$ are expected to have extremely small unobservable probabilities. For small neutrino masses, the lepton-number violation would be observed first in neutrino oscillations, which have been the subject of extensive experimental studies. Compelling evidence for neutrino mixing has come from atmospheric, solar, accelerator, and

reactor neutrinos. Recently, the reactor neutrino experiments have measured the last neutrino mixing angle θ_{13} and found it to be relatively large. For a comprehensive review on neutrino mixing, including the latest results on θ_{13} , see the review "Neutrino Mass, Mixing, and Oscillations" by K. Nakamura and S.T. Petcov in this edition of RPP.

CONSERVATION OF HADRONIC FLAVORS

In strong and electromagnetic interactions, hadronic flavor is conserved, i.e. the conversion of a quark of one flavor (d, u, s, c, b, t) into a quark of another flavor is forbidden. In the Standard Model, the weak interactions violate these conservation laws in a manner described by the Cabibbo-Kobayashi-Maskawa mixing (see the section "Cabibbo-Kobayashi-Maskawa Mixing Matrix"). The way in which these conservation laws are violated is tested as follows:

- (a) $\Delta S = \Delta Q$ rule. In the strangeness-changing semileptonic decay of strange particles, the strangeness change equals the change in charge of the hadrons. Tests come from limits on decay rates such as $\Gamma(\Sigma^+ \to n e^+ \nu)/\Gamma(\Sigma^+ \to \text{all}) < 5 \times 10^{-6}$, and from a detailed analysis of $K_L \to \pi e \nu$, which yields the parameter x, measured to be $(\text{Re } x, \text{Im } x) = (-0.002 \pm 0.006, 0.0012 \pm 0.0021)$. Corresponding rules are $\Delta C = \Delta Q$ and $\Delta B = \Delta Q$.
- (b) Change of flavor by two units. In the Standard Model this occurs only in second-order weak interactions. The classic example is $\Delta S=2$ via $K^0-\overline{K}^0$ mixing, which is directly measured by $m(K_L)-m(K_S)=(0.5293\pm0.0009)\times10^{10}~\hbar s^{-1}.$ The $\Delta B=2$ transitions in the B^0 and B_s^0 systems via mixing are also well established. The measured mass differences between the eigenstates are $(m_{B_{\rm H}^0}-m_{B_{\rm L}^0})=(0.507\pm0.004)\times10^{12}~\hbar s^{-1}$ and $(m_{B_{\rm sH}^0}-m_{B_{\rm sL}^0})=(17.69\pm0.08)\times10^{12}~\hbar s^{-1}.$ There is now strong evidence of $\Delta C=2$ transition in the charm sector with the mass difference $m_{D_H^0}-m_{D_L^0}=(1.44^{+0.48}_{-0.50})\times10^{10}~\hbar s^{-1}.$ All results are consistent with the second-order calculations in the Standard Model.
- (c) Flavor-changing neutral currents. In the Standard Model the neutral-current interactions do not change flavor. The low rate $\Gamma(K_L \to \mu^+\mu^-)/\Gamma(K_L \to \text{all}) = (6.84 \pm 0.11) \times 10^{-9}$ puts limits on such interactions; the nonzero value for this rate is attributed to a combination of the weak and electromagnetic interactions. The best test should come from $K^+ \to \pi^+\nu\overline{\nu}$, which occurs in the Standard Model only as a second-order weak process with a branching fraction of $(0.4 \text{ to } 1.2) \times 10^{-10}$. Combining results from BNL-E787 and BNL-E949 experiments yield $\Gamma(K^+ \to \pi^+\nu\overline{\nu})/\Gamma(K^+ \to \text{all}) = (1.7 \pm 1.1) \times 10^{-10} [4]$. Limits for charm-changing or bottom-changing neutral currents are less stringent: $\Gamma(D^0 \to \mu^+\mu^-)/\Gamma(D^0 \to \text{all}) < 1.4 \times 10^{-7}$ and $\Gamma(B^0 \to \mu^+\mu^-)/\Gamma(B^0 \to \text{all}) < 1.4 \times 10^{-9}$. One cannot isolate flavor-changing neutral current (FCNC) effects in non leptonic

decays. For example, the FCNC transition $s \to d + (\overline{u} + u)$ is equivalent to the charged-current transition $s \to u + (\overline{u} + d)$. Tests for FCNC are therefore limited to hadron decays into lepton pairs. Such decays are expected only in second-order in the electroweak coupling in the Standard Model.

Allowed by higher-order electroweak interactions.

$$\Gamma(t \rightarrow Z q(q=u,c))/\Gamma_{\text{total}}$$
 [z] $<3.2 \times 10^{-2}$, CL = 95%

NOTES

In this Summary Table:

When a quantity has "(S = ...)" to its right, the error on the quantity has been enlarged by the "scale factor" S, defined as S = $\sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when S > 1, which often indicates that the measurements are inconsistent. When S > 1.25, we also show in the Particle Listings an ideogram of the measurements. For more about S, see the Introduction.

- $[a]\ C$ parity forbids this to occur as a single-photon process.
- [b] See the Particle Listings for the (complicated) definition of this quantity.
- [c] Time-reversal invariance requires this to be 0° or 180° .
- [d] This coefficient is zero if time invariance is not violated.
- [e] Allowed by higher-order electroweak interactions.
- [f] Violates CP in leading order. Test of direct CP violation since the indirect CP-violating and CP-conserving contributions are expected to be suppressed.
- [g] In the 2010 Review, the values for these quantities were given using a measure of the asymmetry that was inconsistent with the usual definition.
- $[\hbar]$ Re $(\epsilon'/\epsilon)=\epsilon'/\epsilon$ to a very good approximation provided the phases satisfy *CPT* invariance.
- [i] This mode includes gammas from inner bremsstrahlung but not the direct emission mode $K_I^0 \to \pi^+\pi^-\gamma({\sf DE})$.
- [j] Neglecting photon channels. See, e.g., A. Pais and S.B. Treiman, Phys. Rev. **D12**, 2744 (1975).
- [k] Derived from measured values of ϕ_{+-} , ϕ_{00} , $|\eta|$, $|m_{K^0_L}-m_{K^0_S}|$, and $\tau_{K^0_S}$, as described in the introduction to "Tests of Conservation Laws."
- [I] The $|m_P-m_{\overline{P}}|/m_P$ and $|q_P+q_{\overline{P}}|/e$ are not independent, and both use the more precise measurement of $|q_{\overline{P}}/m_{\overline{P}}|/(q_P/m_P)$.
- [m] The value is for the sum of the charge states or particle/antiparticle states indicated.
- [n] A test of additive vs. multiplicative lepton family number conservation.
- [o] The limit quoted corresponds to the projection onto the $\sin^2(2\theta_{23})$ axis of the 90% CL contour in the $\sin^2(2\theta_{23}) \Delta m_{32}^2$ plane.
- [p] The sign of Δm^2_{32} is not known at this time. The range quoted is for the absolute value.
- [q] Derived from an analysis of neutrino-oscillation experiments.
- [r] This limit is for either D^0 or $\overline{D}{}^0$ to $p\,e^-$.
- [s] This limit is for either D^0 or $\overline{D}{}^0$ to $\overline{p}\,e^+$.
- [t] The first limit is for $p\to$ anything or "disappearance" modes of a bound proton. The second entry, a rough range of limits, assumes the dominant decay modes are among those investigated. For antiprotons the best limit, inferred from the observation of cosmic ray \overline{p} 's is $\tau_{\overline{p}} > 10^7$ yr, the cosmic-ray storage time, but this limit depends on a number of assumptions. The best direct observation of stored antiprotons gives $\tau_{\overline{p}}/B(\overline{p}\to e^-\gamma) > 7\times 10^5$ yr.
- [u] There is some controversy about whether nuclear physics and model dependence complicate the analysis for bound neutrons (from which the best limit comes). The first limit here is from reactor experiments with free neutrons.
- [ν] This is the best limit for the mode e $^- \to \nu \gamma$. The best limit for "electron disappearance" is 6.4 \times 10²⁴ yr.
- [w] See the K_S^0 Particle Listings for the energy limits used in this measurement
- [x] See the \mathcal{K}^0_L Particle Listings for the energy limits used in this measurement.
- [y] An ℓ indicates an e or a μ mode, not a sum over these modes.
- [z] This limit is for $\Gamma(t \to Zq)/\Gamma(t \to Wb)$.

1. PHYSICAL CONSTANTS

Table 1.1. Reviewed 2011 by P.J. Mohr (NIST). Mainly from the "CODATA Recommended Values of the Fundamental Physical Constants: 2010" by P.J. Mohr, B.N. Taylor, and D.B. Newell in arXiv:1203.5425 and Rev. Mod. Phys. (to be published). The last group of constants (beginning with the Fermi coupling constant) comes from the Particle Data Group. The figures in parentheses after the values give the 1-standard-deviation uncertainties in the last digits; the corresponding fractional uncertainties in parts per 109 (ppb) are given in the last column. This set of constants (aside from the last group) is recommended for international use by CODATA (the Committee on Data for Science and Technology). The full 2010 CODATA set of constants may be found at http://physics.nist.gov/constants. See also P.J. Mohr and D.B. Newell, "Resource Letter FC-1: The Physics of Fundamental Constants," Am. J. Phys, 78 (2010) 338.

^{*} The meter is the length of the path traveled by light in vacuum during a time interval of 1/299 792 458 of a second. † At $Q^2 \approx m_W^2$ the value is $\sim 1/128$.

 $^{^\}ddagger$ Absolute lab measurements of G_N have been made only on scales of about 1 cm to 1 m.

^{**} See the discussion in Sec. 10, "Electroweak model and constraints on new physics."

^{††} The corresponding $\sin^2\theta$ for the effective angle is 0.23146(12).

2. ASTROPHYSICAL CONSTANTS AND PARAMETERS

Table 2.1. Revised February 2012 by E. Bergren and D.E. Groom (LBNL). The figures in parentheses after some values give the 1- σ uncertainties in the last digit(s). Physical constants are from Ref. 1. While every effort has been made to obtain the most accurate current values of the listed quantities, the table does not represent a critical review or adjustment of the constants, and is not intended as a primary reference. The values and uncertainties for the cosmological parameters depend on the exact data sets, priors, and basis parameters used in the fit.

The values and uncertainties for the cosmological parameters depend on the exact data sets, priors, and basis parameters used in the fit. Many of the derived parameters reported in this table have non-Gaussian likelihoods. Parameters may be highly correlated, so care must be taken in propagating errors. Unless otherwise specified, cosmological parameters are from six-parameter fits to a flat Λ CDM cosmology using 7-year WMAP data alone [2]. For more information see Ref. 3 and the original papers.

- While A is approximately equal to the semi-major axis of the Earth's orbit, it is not exactly so. Nor is it exactly the mean Earth-Sun distance. There are a number of reasons: a) the Earth's orbit is not exactly Keplerian due to relativity and to perturbations from other planets; b) the adopted value for the Gaussian gravitational constant k is not exactly equal to the Earth's mean motion; and c) the mean distance in a Keplerian orbit is not equal to the semi-major axis a: $\langle r \rangle = a(1 + e^2/2)$, where e is the eccentricity. (Discussion courtesy of Myles Standish, JPL).
- The distance at which 1 A subtends 1 arc sec: 1 A divided by $\pi/648\,000$.
- Product of $2/c^2$ and the heliocentric gravitational constant $G_N M_{\odot} = A^3 k^2 / 86400^2$, where k is the Gaussian gravitational constant, 0.01720209895 (exact) [5]. The value and error for A given in this table are used.
- Obtained from the $G_N M_{\odot}$ product [5] and G_N [1]. .
- T. M. Brown & J. Christensen-Dalsgaard, Astrophys. J. 500, L195 (1998) Many values for the Solar radius have been published, most of which are consistent with this result.
- $4\pi A^2 \times (1361 \text{ W m}^{-2})$ [31]. Assumes isotropic irradiance. 11.
- Schwarzschild radius of the Sun (above) scaled by the Earth/Sun mass ratio given in Ref. 5.
- Obtained from the $G_N M_{\oplus}$ product [5] and G_N [1].
- E.W. Kolb & M.S. Turner, The Early Universe, Addison-Wesley (1990): The IAU (Commission 36) has recommended 3.055×10^{28} W for
 - the zero point. Based on newer Solar measurements, the value and significance given in the table seems more appropriate.

- 26. Conversion using length of sidereal year.
- Average of WMAP7 [2] and independent Cephid-based measurement by A.G. Reiss et al., Astrophys. J. 730, 119 (2011). Other high-quality measurements could have been included.
- R. Amanullah et al., Astrophys. J. 716, 712 (2010). Fit with curvature unconstrained. For a flat Universe, $w = -1.00 \pm 0.08$.
- $\Omega_{\nu}h^2 = \sum m_{\nu_i}/93\,\text{eV}$, where the sum is over all neutrino mass eigenstates. The lower limit follows from neutrino mixing results reported in this *Review* combined with the assumptions that there are three light neutrinos $(m_{\nu} < 45 \ {\rm GeV}/c^2)$ and that the lightest neutrino is substantially less massive than the others: $\Delta m_{32}^2 =$ $(2.43\pm0.13)\times10^{-3}~{\rm eV^2},~{\rm so}~\sum m_{\nu_j}\geq m_{\nu_3}\approx\sqrt{\Delta m_{32}^2}=0.05~{\rm eV}.$ (This becomes 0.10 eV if the mass hierarchy is inverted, with $m_{\nu_1} \approx m_{\nu_2} \gg m_{\nu_3}$.) Astrophysical determinations of $\sum m_{\nu_j}$, reported in the Full Listings of this Review under "Sum of the neutrino masses," range from $< 0.17\,\mathrm{eV}$ to $< 2.3\,\mathrm{eV}$ in papers published since 2003. Alternatively, if the limit obtained from tritium decay experiments $(m_{\nu} < 2 \,\mathrm{eV})$ is used for the upper limit, then $\Omega_{\nu} < 0.04$.
- If the Universe were reionized instantaneously at z_{reion} .
- 31. G. Kopp & J.L. Lean, Geophys. Res. Lett. 38, L01706 (2011). Kopp & Lean give $1360.8 \pm 0.6 \text{W m}^{-2}$, but given the scatter in the data we use the rounded value without quoting an error.

[†] Derived parameter in six-parameter ΛCDM fit [2].

[‡] Extended model parameter [2].

Table 4.1. Revised 2011 by D.E. Groom (LBNL), and E. Bergren. Atomic weights of stable elements are adapted from the Commission on Isotopic Abundances and Atomic Weights, "Atomic Weights of the Elements 2007," http://www.chem.qmul.ac.uk/iupac/AtWt/. The atomic number (top left) is the number of protons in the nucleus. The atomic mass (bottom) of a stable elements is weighted by isotopic abundances in the Earth's surface. If the element has no stable isotope, the atomic mass (in parentheses) of the most stable isotope currently known is given. In this case the mass is from http://www.nndc.bnl.gov/amdc/masstables/Ame2003/mass.mas03 and the longest-lived isotope is from www.nndc.bnl.gov/ensdf/za_form.jsp. The exceptions are Th, Pa, and U, which do have characteristic terrestrial compositions. Atomic masses are relative to the mass of ¹²C, defined to be exactly 12 unified atomic mass units (u) (approx. g/mole). Relative isotopic abundances often vary considerably, both in natural and commercial samples; this is reflected in the number of significant figures given for the atomic mass. IUPAC does not accept the claims for elements 113, 115, 117, and 118 as conclusive at this time.

5. ELECTRONIC STRUCTURE OF THE ELEMENTS

Table 5.1. Reviewed 2011 by J.E. Sansonetti (NIST). The electronic configurations and the ionization energies are from the NIST database, "Ground Levels and Ionization Energies for the Neutral Atoms," W.C. Martin, A. Musgrove, S. Kotochigova, and J.E. Sansonetti, http://www.nist.gov/pml/data/ion_energy.cfm. The electron configuration for, say, iron indicates an argon electronic core (see argon) plus six 3d electrons and two 4s electrons.

| | Elen | aant | Electron configuration $(3d^5 = \text{five } 3d \text{ electron})$ | | | Ground state ${}^{2S+1}L_J$ | Ionization energy |
|----------|---------------------|----------------------|--------------------------------------------------------------------|--------------|--------------|-------------------------------|----------------------|
| | | | ` | s, etc.) | | | (eV) |
| 1 | Н | Hydrogen | $\frac{1s}{1s^2}$ | | | ${}^{2}S_{1/2}$ | 13.5984 |
| 2 | Не | Helium | | | | $^{1}S_{0}$ | 24.5874 |

^{*} The usual LS coupling scheme does not apply for these three elements. See the introductory note to the NIST table from which this table is taken.

6. ATOMIC AND NUCLEAR PROPERTIES OF MATERIALS

Table 6.1 Abridged from pdg.lbl.gov/AtomicNuclearProperties by D. E. Groom (2007). See web pages for more detail about entries in this table including chemical formulae, and for several hundred other entries. Quantities in parentheses are for NTP (20° C and 1 atm), and square brackets indicate quantities evaluated at STP. Boiling points are at 1 atm. Refractive indices n are evaluated at the sodium D line blend (589.2 nm); values $\gg 1$ in brackets are for $(n-1) \times 10^6$ (gases).

| $\begin{array}{c ccccccccccccccccccccccccccccccccccc$ | Material | Z | A | $\langle Z/A \rangle$ | length λ_T | Nucl.inter. length λ_I | X_0 | $\{ MeV $ | $\{ {\rm g \ cm^{-3}} \}$ | Melting point (K) | Boiling point (K) | Refract. index (@ Na D) |

7.1. Impedances (SI units)

 $\rho = \text{resistivity at room temperature in } 10^{-8} \,\Omega \text{ m}$:

For alternating currents, instantaneous current I, voltage V, angular frequency ω :

$$V = V_0 e^{j\omega t} = ZI . (7.1)$$

Impedance of self-inductance L: $Z = j\omega L$.

Impedance of capacitance $C\colon\thinspace Z=1/j\omega C$.

Impedance of free space: $Z = \sqrt{\mu_0/\epsilon_0} = 376.7 \ \Omega$.

High-frequency surface impedance of a good conductor:

$$Z = \frac{(1+j) \rho}{\delta} , \quad \text{where } \delta = \text{skin depth} ;$$
 (7.2)

$$\delta = \sqrt{\frac{\rho}{\pi \nu \mu}} \approx \frac{6.6 \text{ cm}}{\sqrt{\nu \text{ (Hz)}}} \text{ for Cu}.$$
 (7.3)

7.2. Capacitors, inductors, and transmission Lines

The capacitance between two parallel plates of area A spaced by the distance d and enclosing a medium with the dielectric constant ε is

$$C = K\varepsilon A/d, \tag{7.4}$$

where the correction factor K depends on the extent of the fringing field. If the dielectric fills the capacitor volume without extending beyond the electrodes. the correction factor $K\approx 0.8$ for capacitors of typical geometry.

The inductance at high frequencies of a straight wire whose length ℓ is much greater than the wire diameter d is

$$L \approx 2.0 \left[\frac{\mathrm{nH}}{\mathrm{cm}} \right] \cdot \ell \left(\ln \left(\frac{4\ell}{d} \right) - 1 \right)$$
 (7.5)

For very short wires, representative of vias in a printed circuit board, the inductance is

$$L(\text{in nH}) \approx \ell/d$$
. (7.6)

A transmission line is a pair of conductors with inductance L and capacitance C. The characteristic impedance $Z=\sqrt{L/C}$ and the phase velocity $v_p=1/\sqrt{LC}=1/\sqrt{\mu\varepsilon}$, which decreases with the inverse square root of the dielectric constant of the medium. Typical coaxial and ribbon cables have a propagation delay of about $5\,\mathrm{ns/cm}$. The impedance of a coaxial cable with outer diameter D and inner diameter d is

$$Z = 60 \Omega \cdot \frac{1}{\sqrt{\varepsilon_r}} \ln \frac{D}{d}, \qquad (7.7)$$

where the relative dielectric constant $\varepsilon_r = \varepsilon/\varepsilon_0$. A pair of parallel wires of diameter d and spacing $a>2.5\,d$ has the impedance

$$Z = 120 \,\Omega \cdot \frac{1}{\sqrt{\varepsilon_r}} \ln \frac{2a}{d} \,. \tag{7.8}$$

This yields the impedance of a wire at a spacing h above a ground plane,

$$Z = 60 \Omega \cdot \frac{1}{\sqrt{\varepsilon_r}} \ln \frac{4h}{d}. \tag{7.9}$$

A common configuration utilizes a thin rectangular conductor above a ground plane with an intermediate dielectric (microstrip). Detailed calculations for this and other transmission line configurations are given by Gunston.*

7.3. Synchrotron radiation (CGS units)

For a particle of charge e, velocity $v = \beta c$, and energy $E = \gamma mc^2$, traveling in a circular orbit of radius R, the classical energy loss per revolution δE is

$$\delta E = \frac{4\pi}{3} \, \frac{e^2}{R} \, \beta^3 \, \gamma^4 \, . \tag{7.10}$$

For high-energy electrons or positrons ($\beta \approx 1$), this becomes

$$\delta E \text{ (in MeV)} \approx 0.0885 \ [E(\text{in GeV})]^4 / R(\text{in m}) \ .$$
 (7.11)

For $\gamma \gg 1$, the energy radiated per revolution into the photon energy interval $d(\hbar\omega)$ is

$$dI = \frac{8\pi}{9} \alpha \gamma F(\omega/\omega_c) d(\hbar\omega) , \qquad (7.12)$$

where $\alpha = e^2/\hbar c$ is the fine-structure constant and

$$\omega_c = \frac{3\gamma^3 c}{2R} \tag{7.13}$$

is the critical frequency. The normalized function F(y) is

$$F(y) = \frac{9}{8\pi} \sqrt{3} y \int_{y}^{\infty} K_{5/3}(x) dx$$
, (7.14)

where $K_{5/3}\left(x\right)$ is a modified Bessel function of the third kind. For electrons or positrons,

$$\hbar\omega_c \,(\text{in keV}) \approx 2.22 \,\left[E(\text{in GeV})\right]^3 / R(\text{in m}) \,.$$
 (7.15)

Fig. 7.1 shows F(y) over the important range of y.

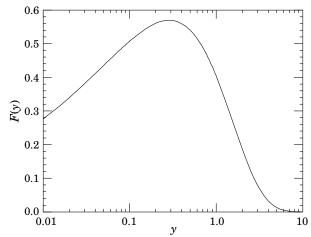

Figure 7.1: The normalized synchrotron radiation spectrum F(y).

For $\gamma \gg 1$ and $\omega \ll \omega_c$,

$$\frac{dI}{d(\hbar\omega)} \approx 3.3\alpha \left(\omega R/c\right)^{1/3} ,$$
 (7.16)

whereas for

$$\gamma \gg 1$$
 and $\omega \gtrsim 3\omega_c$.

$$\frac{dI}{d(\hbar\omega)} \approx \sqrt{\frac{3\pi}{2}} \, \alpha \, \gamma \left(\frac{\omega}{\omega_c}\right)^{1/2} e^{-\omega/\omega_c} \left[1 + \frac{55}{72} \frac{\omega_c}{\omega} + \ldots\right] \quad . \tag{7.17}$$

The radiation is confined to angles $\lesssim 1/\gamma$ relative to the instantaneous direction of motion. For $\gamma \gg 1$, where Eq. (7.12) applies, the mean number of photons emitted per revolution is

$$N_{\gamma} = \frac{5\pi}{\sqrt{3}} \alpha \gamma , \qquad (7.18)$$

and the mean energy per photon is

$$\langle \hbar \omega \rangle = \frac{8}{15\sqrt{3}} \hbar \omega_c \ . \tag{7.19}$$

When $\langle \hbar \omega \rangle \gtrsim O(E)$, quantum corrections are important.

See J.D. Jackson, Classical Electrodynamics, $3^{\rm rd}$ edition (John Wiley & Sons, New York, 1998) for more formulae and details. (Note that earlier editions had ω_c twice as large as Eq. (7.13).

8. NAMING SCHEME FOR HADRONS

Revised 2008 by M. Roos (University of Finland) and C.G. Wohl (LBNL).

8.1. Introduction

We introduced in the 1986 edition [1] a new naming scheme for the hadrons. Changes from older terminology affected mainly the heavier mesons made of the light (u, d, and s) quarks. Old and new names were listed alongside until 1994. Names also change from edition to edition because some characteristic like mass or spin changes. The Summary Tables give both the new and old names whenever a change occurred.

8.2. "Neutral-flavor" mesons (S=C=B=T=0)

Table 8.1 shows the names for mesons having the strangeness and all heavy-flavor quantum numbers equal to zero. The scheme is designed for all ordinary non-exotic mesons, but it will work for many exotic types too, if needed.

Table 8.1: Symbols for mesons with the strangeness and all heavy-flavor quantum numbers equal to zero.

| | $J^{PC} =$ | $\begin{cases} 0^{-+} \\ 2^{-+} \\ \vdots \end{cases}$ | 1 ⁺⁻ 3 ⁺⁻ : | 1 2 : | 0 ⁺⁺ 1 ⁺⁺ : |
|-----------------------------------------------------------|----------------|--------------------------------------------------------|-----------------------------------------|-----------------------|-----------------------------------------|
| $q\overline{q}$ content | $^{2S+1}L_J =$ | $^{1}(L \operatorname{even})_{J}$ | $^1(L \operatorname{odd})_J$ | $^3(L {\rm even})_J$ | $^3(L \text{ odd})_J$ |
| $u\overline{d}, u\overline{u} - d\overline{d},$ | | π | b | ρ | a |
| $d\overline{d} + u\overline{u}$ and/or $s\overline{s}$ | $ \} (I=0)$ | η,η' | h, h' | ω,ϕ | f, f' |
| $c\overline{c}$ | | η_c | h_c | ψ^\dagger | χ_c |
| $b\overline{b}$ | | η_b | h_b | Υ | χ_b |
| $t\overline{t}$ | | η_t | h_t | θ | χ_t |

[†]The J/ψ remains the J/ψ .

First, we assign names to those states with quantum numbers compatible with being $q\overline{q}$ states. The rows of the Table give the possible $q\overline{q}$ content. The columns give the possible parity/charge-conjugation states.

$$PC = -+, +-, --, \text{ and } ++;$$

these combinations correspond one-to-one with the angular-momentum state $^{2S+1}L_J$ of the $q\overline{q}$ system being

$$^{1}(L \text{ even})_{J}$$
, $^{1}(L \text{ odd})_{J}$, $^{3}(L \text{ even})_{J}$, or $^{3}(L \text{ odd})_{J}$.

Here S, L, and J are the spin, orbital, and total angular momenta of the $q\overline{q}$ system. The quantum numbers are related by $P=(-1)^{L+1}$, $C=(-1)^{L+S}$, and G parity $=(-1)^{L+S+I}$,

where of course the C quantum number is only relevant to neutral mesons.

The entries in the Table give the meson names. The spin J is added as a subscript except for pseudoscalar and vector mesons, and the mass is added in parentheses for mesons that decay strongly. However, for the lightest meson resonances, we omit the mass.

Measurements of the mass, quark content (where relevant), and quantum numbers $I,\ J,\ P,$ and C (or G) of a meson thus fix its symbol. Conversely, these properties may be inferred unambiguously from the symbol.

If the main symbol cannot be assigned because the quantum numbers are unknown, X is used. Sometimes it is not known whether a meson is mainly the isospin-0 mix of $u\overline{u}$ and $d\overline{d}$ or is mainly $s\overline{s}$. A prime (or pair ω , ϕ) may be used to distinguish two such mixing states.

We follow custom and use spectroscopic names such as $\Upsilon(1S)$ as the primary name for most of those ψ , Υ , and χ states whose spectroscopic identity is known. We use the form $\Upsilon(9460)$ as an alternative, and as the primary name when the spectroscopic identity is not known.

Names are assigned for $t\bar{t}$ mesons, although the top quark is evidently so heavy that it is expected to decay too rapidly for bound states to form.

Gluonium states or other mesons that are not $q\overline{q}$ states are, if the quantum numbers are *not* exotic, to be named just as are the $q\overline{q}$ mesons. Such states will probably be difficult to distinguish from $q\overline{q}$ states and will likely mix with them, and we make no attempt to distinguish those "mostly gluonium" from those "mostly $q\overline{q}$."

An "exotic" meson with J^{PC} quantum numbers that a $q\overline{q}$ system cannot have, namely $J^{PC}=0^{--},0^{+-},1^{-+},2^{+-},3^{-+},\cdots$, would use the same symbol as does an ordinary meson with all the same quantum numbers as the exotic meson except for the C parity. But then the J subscript may still distinguish it; for example, an isospin-0 1^{-+} meson could be denoted ω_1 .

8.3. Mesons with nonzero S, C, B, and/or T

Since the strangeness or a heavy flavor of these mesons is nonzero, none of them are eigenstates of charge conjugation, and in each of them one of the quarks is heavier than the other. The rules are:

 The main symbol is an upper-case italic letter indicating the heavier quark as follows:

$$s \to \overline{K}$$
 $c \to D$ $b \to \overline{B}$ $t \to T$.

We use the convention that the flavor and the charge of a quark have the same sign. Thus the strangeness of the s quark is negative, the charm of the c quark is positive, and the bottom of the b quark is negative. In addition, I_3 of the u and d quarks are positive and negative, respectively. The effect of this convention is as follows: Any flavor carried by a charged meson has the same sign as its charge. Thus the K^+ , D^+ , and B^+ have positive strangeness, charm, and bottom, respectively, and all have positive I_3 . The D_s^+ has positive charm and strangeness. Furthermore, the $\Delta(\text{flavor}) = \Delta Q$ rule, best known for the kaons, applies to every flavor.

- 2. If the lighter quark is not a u or a d quark, its identity is given by a subscript. The D_s^+ is an example.
- 3. If the spin-parity is in the "normal" series, $J^P = 0^+, 1^-, 2^+, \cdots$, a superscript "*" is added.
- The spin is added as a subscript except for pseudoscalar or vector mesons.

8.4. Ordinary (3-quark) baryons

The symbols N, Δ , Λ , Σ , Ξ , and Ω used for more than 30 years for the baryons made of light quarks (u, d, and s quarks) tell the isospin and quark content, and the same information is conveyed by the symbols used for the baryons containing one or more heavy quarks (c and b quarks). The rules are:

- Baryons with three u and/or d quarks are N's (isospin 1/2) or \(\Delta's \) (isospin 3/2).
- 2. Baryons with $two\ u$ and/or d quarks are Λ 's (isospin 0) or Σ 's (isospin 1). If the third quark is a c, b, or t quark, its identity is given by a subscript.
- Baryons with one u or d quark are Ξ's (isospin 1/2). One or two subscripts are used if one or both of the remaining quarks are heavy: thus Ξ_c, Ξ_{cc}, Ξ_b, etc.*
- 4. Baryons with no~u or d quarks are Ω 's (isospin 0), and subscripts indicate any heavy-quark content.
- 5. A baryon that decays strongly has its mass as part of its name. Thus $p, \Sigma^-, \Omega^-, \Lambda_c^+, etc.$, but $\Delta(1232)^0, \Sigma(1385)^-, \Xi_c(2645)^+, etc.$

In short, the number of u plus d quarks together with the isospin determine the main symbol, and subscripts indicate any content of heavy quarks. A Σ always has isospin 1, an Ω always has isospin 0, etc.

8.5. Exotic baryons

In 2003, several experiments reported finding a strangeness S=+1, charge Q=+1 baryon, and one experiment reported finding an $S=-2,\,Q=-2$ baryon. Baryons with such quantum numbers cannot be made from three quarks, and thus they are exotic. The S=+1 baryon, which once would have been called a Z, was quickly dubbed the $\Theta(1540)^+$, and we proposed to name the S=-2 baryon the $\Phi(1860)$. However, these "discoveries" were then completely ruled out by many experiments with far larger statistics: See our 2008 Review [2].

9. QUANTUM CHROMODYNAMICS

Revised April 2012 by S. Bethke (MPP, Munich), G. Dissertori (ETH, Zurich) and G.P. Salam (CERN, Princeton University and LPTHE, Paris).

9.1. Basics

Quantum Chromodynamics (QCD), the gauge field theory that describes the strong interactions of colored quarks and gluons, is the SU(3) component of the SU(3)×SU(2)×U(1) Standard Model of Particle Physics.

The Lagrangian of QCD is given by

$$\mathcal{L} = \sum_{q} \bar{\psi}_{q,a} (i \gamma^{\mu} \partial_{\mu} \delta_{ab} - g_s \gamma^{\mu} t^{C}_{ab} \mathcal{A}^{C}_{\mu} - m_{q} \delta_{ab}) \psi_{q,b} - \frac{1}{4} F^{A}_{\mu\nu} F^{A \mu\nu} , \ (9.1)$$

where repeated indices are summed over. The γ^{μ} are the Dirac γ -matrices. The $\psi_{q,a}$ are quark-field spinors for a quark of flavor q and mass m_q , with a color-index a that runs from a=1 to $N_c=3$, i.e. quarks come in three "colors." Quarks are said to be in the fundamental representation of the SU(3) color group.

The \mathcal{A}^C_μ correspond to the gluon fields, with C running from 1 to $N_c^2-1=8$, i.e. there are eight kinds of gluon. Gluons are said to be in the adjoint representation of the SU(3) color group. The t^C_{ab} correspond to eight 3×3 matrices and are the generators of the SU(3) group (cf. the section on "SU(3) isoscalar factors and representation matrices" in this Review with $t^C_{ab}\equiv \lambda^C_{ab}/2$). They encode the fact that a gluon's interaction with a quark rotates the quark's color in SU(3) space. The quantity g_s is the QCD coupling constant. Finally, the field tensor $F^A_{\mu\nu}$ is given by

$$F_{\mu\nu}^{A} = \partial_{\mu} A_{\nu}^{A} - \partial_{\nu} A_{\mu}^{A} - g_{s} f_{ABC} A_{\mu}^{B} A_{\nu}^{C} \qquad [t^{A}, t^{B}] = i f_{ABC} t^{C} , \tag{9.2}$$

where the f_{ABC} are the structure constants of the SU(3) group.

Neither quarks nor gluons are observed as free particles. Hadrons are color-singlet (i.e. color-neutral) combinations of quarks, antiquarks, and gluons.

Ab-initio predictive methods for QCD include lattice gauge theory and perturbative expansions in the coupling. The Feynman rules of QCD involve a quark-antiquark-gluon $(q\bar{q}g)$ vertex, a 3-gluon vertex (both proportional to g_s), and a 4-gluon vertex (proportional to g_s^2). A full set of Feynman rules is to be found for example in Ref. 3.

Useful color-algebra relations include: $t_a^A t_b^A = C_F \delta_{ac}$, where $C_F \equiv (N_c^2-1)/(2N_c) = 4/3$ is the color-factor ("Casimir") associated with gluon emission from a quark; $f^{ACD} f^{BCD} = C_A \delta_{AB}$ where $C_A \equiv N_c = 3$ is the color-factor associated with gluon emission from a gluon; $t_{ab}^A t_{ab}^B = T_R \delta_{AB}$, where $T_R = 1/2$ is the color-factor for a gluon to split to a $q\bar{q}$ pair.

The fundamental parameters of QCD are the coupling g_s (or $\alpha_s=\frac{g_s^2}{4\pi}$) and the quark masses m_q .

There is freedom for an additional CP-violating term to be present in the QCD Lagrangian, $\theta \frac{\alpha_s}{8\pi} F_{\mu\nu}^A \tilde{F}^{A\mu\nu}$, where $F_{\mu\nu}^A \tilde{F}^{A\mu\nu}$ is the dual of the gluon field tensor, $\frac{1}{2} \epsilon_{\mu\nu\sigma\rho} F^{A\sigma\rho}$. Experimental limits on the neutron electric dipole moment [1] constrain the coefficient of this contribution to satisfy $|theta| \lesssim 10^{-10}$. Further discussion is to be found in Ref. 2 and Axions section in the Listings of this Review.

This section will concentrate mainly on perturbative aspects of QCD as they relate to collider physics. Related textbooks and reviews include Refs. 3–6. Aspects specific to Monte Carlo event generators are reviewed in a dedicated section Chap. 38. Lattice QCD is also reviewed in a section of its own Chap. 17, with additional discussion of non-perturbative aspects to be found in the sections on "Quark Masses", "The CKM quark-mixing matrix", "Structure Functions" and event generators in this *Review*. For an overview of some of the QCD issues and recent results in heavy-ion physics, see for example Refs. 7, 8.

9.1.1. Running coupling:

In the framework of perturbative QCD (pQCD), predictions for observables are expressed in terms of the renormalized coupling $\alpha_s(\mu_R^2)$, a function of an (unphysical) renormalization scale μ_R . When one takes μ_R close to the scale of the momentum transfer Q in a given process, then $\alpha_s(\mu_R^2 \simeq Q^2)$ is indicative of the effective strength of the strong interaction in that process.

The coupling satisfies the following renormalization group equation (RGE):

$$\mu_R^2 \frac{d\alpha_s}{d\mu_D^2} = \beta(\alpha_s) = -(b_0 \alpha_s^2 + b_1 \alpha_s^3 + b_2 \alpha_s^4 + \cdots)$$
 (9.3)

where $b_0=(11C_A-4n_fT_R)/(12\pi)=(33-2n_f)/(12\pi)$ is referred to as the 1-loop beta-function coefficient, the 2-loop coefficient is $b_1=(17C_A^2-n_fT_R(10C_A+6C_F))/(24\pi^2)=(153-19n_f)/(24\pi^2),$ and the 3-loop coefficient is $b_2=(2857-\frac{5033}{9}n_f+\frac{325}{27}n_f^2)/(128\pi^3).$ The 4-loop coefficient, b_3 , is to be found in Refs. 9, 10^{\dagger} . The minus sign in Eq. (9.3) is the origin of Asymptotic Freedom, i.e. the fact that the strong coupling becomes weak for processes involving large momentum transfers ("hard processes"), $\alpha_s\sim 0.1$ for momentum transfers in the 100 GeV – TeV range.

The β -function coefficients, the b_i , are given for the coupling of an effective theory in which n_f of the quark flavors are considered light $(m_q \ll \mu_R)$, and in which the remaining heavier quark flavors decouple from the theory. One may relate the coupling for the theory with n_f+1 light flavors to that with n_f flavors through an equation of the form

$$\alpha_s^{(n_f+1)}(\mu_R^2) = \alpha_s^{(n_f)}(\mu_R^2) \left(1 + \sum_{n=1}^{\infty} \sum_{\ell=0}^{n} c_{n\ell} \left[\alpha_s^{(n_f)}(\mu_R^2) \right]^n \ln^{\ell} \frac{\mu_R^2}{m_h^2} \right), \tag{9.4}$$

where m_h is the mass of the $(n_f+1)^{\rm th}$ flavor, and the first few $c_{n\ell}$ coefficients are $c_{11}=\frac{1}{6\pi},\ c_{10}=0,\ c_{22}=c_{11}^2,\ c_{21}=\frac{19}{24\pi^2},$ and $c_{20}=-\frac{11}{72\pi^2}$ when m_h is the $\overline{\rm MS}$ mass at scale m_h $(c_{20}=\frac{7}{24\pi^2}$ when m_h is the pole mass — mass definitions are discussed below and in the review on "Quark Masses"). Terms up to $c_{4\ell}$ are to be found in Refs. 11, 12. Numerically, when one chooses $\mu_R=m_h$, the matching is a modest effect, owing to the zero value for the c_{10} coefficient. Relations between n_f and (n_f+2) flavors where the two heavy flavors are close in mass are given to three loops in Ref. 13.

Working in an energy range where the number of flavors is taken constant, a simple exact analytic solution exists for Eq. (9.3) only if one neglects all but the b_0 term, giving $\alpha_s(\mu_R^2) = (b_0 \ln(\mu_R^2/\Lambda^2))^{-1}$. Here Λ is a constant of integration, which corresponds to the scale where the perturbatively-defined coupling would diverge, *i.e.* it is the non-perturbative scale of QCD. A convenient approximate analytic solution to the RGE that includes also the b_1 , b_2 , and b_3 terms is given by (see for example Ref. 14),

$$\alpha_s(\mu_R^2) \simeq \frac{1}{b_0 t} \left(1 - \frac{b_1}{b_0^2} \frac{\ln t}{t} + \frac{b_1^2 (\ln^2 t - \ln t - 1) + b_0 b_2}{b_0^4 t^2} \right)$$

$$-\frac{b_1^3(\ln^3 t - \frac{5}{2}\ln^2 t - 2\ln t + \frac{1}{2}) + 3b_0b_1b_2\ln t - \frac{1}{2}b_0^2b_3}{b_0^6t^3}\right), \quad t \equiv \ln\frac{\mu_R^2}{\Lambda^2},$$
(9.5)

again parametrized in terms of a constant Λ . Note that Eq. (9.5) is one of several possible approximate 4-loop solutions for $\alpha_s(\mu_R^2)$, and that a value for Λ only defines $\alpha_s(\mu_R^2)$ once one knows which particular approximation is being used. An alternative to the use of formulas such as Eq. (9.5) is to solve the RGE exactly, numerically (including the discontinuities, Eq. (9.4), at flavor thresholds). In such cases the quantity Λ is not defined at all. For these reasons, in determinations

 $^{^\}dagger$ One should be aware that the b_2 and b_3 coefficients are renormalization-scheme-dependent, and given here in the $\overline{\rm MS}$ scheme, as discussed below.

of the coupling, it has become standard practice to quote the value of α_s at a given scale (typically M_Z) rather than to quote a value for Λ .

The value of the coupling, as well as the exact forms of the b_2 , c_{10} (and higher order) coefficients, depend on the renormalization scheme in which the coupling is defined, *i.e.* the convention used to subtract infinities in the context of renormalization. The coefficients given above hold for a coupling defined in the modified minimal subtraction $(\overline{\text{MS}})$ scheme [15], by far the most widely used scheme.

A discussion of determinations of the coupling and a graph illustrating its scale dependence ("running") are to be found in Section 9.3.4.

9.1.2. Quark masses:

Free quarks are never observed, i.e. a quark never exists on its own for a time longer than $\sim 1/\Lambda$: up, down, strange, charm, and bottom quarks all hadronize, i.e. become part of a meson or baryon, on a timescale $\sim 1/\Lambda$; the top quark instead decays before it has time to hadronize. This means that the question of what one means by the quark mass is a complex one, which requires that one adopts a specific prescription. A perturbatively defined prescription is the pole mass, m_q , which corresponds to the position of the divergence of the propagator. This is close to one's physical picture of mass. However, when relating it to observable quantities, it suffers from substantial non-perturbative ambiguities (see e.g. Ref. 16). An alternative is the $\overline{\rm MS}$ mass, $\overline{m}_q(\mu_R^2)$, which depends on the renormalization scale μ_R .

Results for the masses of heavier quarks are often quoted either as the pole mass or as the $\overline{\rm MS}$ mass evaluated at a scale equal to the mass, $\overline{m}_q(\overline{m}_q^2)$; light quark masses are generally quoted in the $\overline{\rm MS}$ scheme at a scale $\mu_R\sim 2~{\rm GeV}$. The pole and $\overline{\rm MS}$ masses are related by a slowly converging series that starts $m_q=\overline{m}_q(\overline{m}_q^2)(1+\frac{4\alpha_s(\overline{m}_q^2)}{3\pi}+\mathcal{O}(\alpha_s^2)),$ while the scale-dependence of $\overline{\rm MS}$ masses is given by

$$\mu_R^2 \frac{d\overline{m}_q(\mu_R^2)}{d\mu_R^2} = \left[-\frac{\alpha_s(\mu_R^2)}{\pi} + \mathcal{O}(\alpha_s^2) \right] \overline{m}_q(\mu_R^2). \tag{9.6}$$

More detailed discussion is to be found in a dedicated section of the Review, "Quark Masses."

9.2. Structure of QCD predictions

9.2.1. Fully inclusive cross sections:

The simplest observables in QCD are those that do not involve initial-state hadrons and that are fully inclusive with respect to details of the final state. One example is the total cross section for $e^+e^- \to \text{hadrons}$ at center-of-mass energy Q, for which one can write

$$\frac{\sigma(e^+e^- \to \text{hadrons}, Q)}{\sigma(e^+e^- \to \mu^+\mu^-, Q)} \equiv R(Q) = R_{\text{EW}}(Q)(1 + \delta_{\text{QCD}}(Q)), \quad (9.7)$$

where $R_{\text{EW}}(Q)$ is the purely electroweak prediction for the ratio and $\delta_{\text{QCD}}(Q)$ is the correction due to QCD effects. To keep the discussion simple, we can restrict our attention to energies $Q \ll M_Z$, where the process is dominated by photon exchange $(R_{\text{EW}} = 3 \sum_q e_q^2)$, neglecting finite-quark-mass corrections),

$$\delta_{\text{QCD}}(Q) = \sum_{n=1}^{\infty} c_n \cdot \left(\frac{\alpha_s(Q^2)}{\pi}\right)^n + \mathcal{O}\left(\frac{\Lambda^4}{Q^4}\right) .$$
 (9.8)

The first four terms in the α_s series expansion are then to be found in Refs. 17, 18

$$c_1 = 1$$
, $c_2 = 1.9857 - 0.1152n_f$, (9.9a)

$$c_3 = -6.63694 - 1.20013n_f - 0.00518n_f^2 - 1.240\eta \tag{9.9b}$$

$$c_4 = -156.61 + 18.77n_f - 0.7974n_f^2 + 0.0215n_f^3 + C\eta$$
, (9.9c)

with $\eta = (\sum e_q)^2/(3\sum e_q^2)$ and where the coefficient C of the η -dependent piece in the α_s^4 term has yet to be determined. For

corresponding expressions including also Z exchange and finite-quark-mass effects, see Refs. 19, 20.

A related series holds also for the QCD corrections to the hadronic decay width of the τ lepton, which essentially involves an integral of R(Q) over the allowed range of invariant masses of the hadronic part of the τ decay (see e.g. Ref. 17). The series expansions for QCD corrections to Higgs-boson (partial) decay widths are summarized in Refs. 21, 22.

One characteristic feature of Eqs. (9.8) and (9.9) is that the coefficients of α_s^n increase rapidly order by order: calculations in perturbative QCD tend to converge more slowly than would be expected based just on the size of $\alpha_s^{\dagger\dagger}$. Another feature is the existence of an extra "power-correction" term $\mathcal{O}(\Lambda^4/Q^4)$ in Eq. (9.8), which accounts for contributions that are fundamentally non-perturbative. All high-energy QCD predictions involve such corrections, though the exact power of Λ/Q depends on the observable.

Scale dependence. In Eq. (9.8) the renormalization scale for α_s has been chosen equal to Q. The result can also be expressed in terms of the coupling at an arbitrary renormalization scale μ_R ,

$$\delta_{\rm QCD}(Q) = \sum_{n=1}^{\infty} \overline{c}_n \left(\frac{\mu_R^2}{Q^2} \right) \cdot \left(\frac{\alpha_s(\mu_R^2)}{\pi} \right)^n + \mathcal{O}\left(\frac{\Lambda^4}{Q^4} \right) \,, \tag{9.10}$$

where $\overline{c}_1(\mu_R^2/Q^2) \equiv c_1$, $\overline{c}_2(\mu_R^2/Q^2) = c_2 + \pi b_0 c_1 \ln(\mu_R^2/Q^2)$, $\overline{c}_3(\mu_R^2/Q^2) = c_3 + (2b_0 c_2 \pi + b_1 c_1 \pi^2) \ln(\mu_R^2/Q^2) + b_0^2 c_1 \pi^2 \ln^2(\mu_R^2/Q^2)$, etc. Given an infinite number of terms in the α_s expansion, the μ_R dependence of the $\overline{c}_n(\mu_R^2/Q^2)$ coefficients will exactly cancel that of $\alpha_s(\mu_R^2)$, and the final result will be independent of the choice of μ_R : physical observables do not depend on unphysical scales.

With just terms up to n=N, a residual μ_R dependence will remain, which implies an uncertainty on the prediction of R(Q) due to the arbitrariness of the scale choice. This uncertainty will be $\mathcal{O}(\alpha_s^{N+1})$, i.e. of the same order as the neglected terms. For this reason it is standard to use QCD predictions' scale dependence as an estimate of the uncertainties due to neglected terms. One usually takes a central value for $\mu_R \sim Q$, in order to avoid the poor convergence of the perturbative series that results from the large $\ln^{n-1}(\mu_R^2/Q^2)$ terms in the \overline{c}_n coefficients when $\mu_R \ll Q$ or $\mu_R \gg Q$.

9.2.1.1. Processes with initial-state hadrons:

Deep Inelastic Scattering. To illustrate the key features of QCD cross sections in processes with initial-state hadrons, let us consider deep-inelastic scattering (DIS), $ep \rightarrow e + X$, where an electron e with four-momentum k emits a highly off-shell photon (momentum q) that interacts with the proton (momentum p). For photon virtualities $Q^2 \equiv -q^2$ far above the squared proton mass (but far below the Z mass), the differential cross section in terms of the kinematic variables Q^2 , $x = Q^2/(2p \cdot q)$ and $y = (q \cdot p)/(k \cdot p)$ is

$$\frac{d^2\sigma}{dxdQ^2} = \frac{4\pi\alpha}{2xQ^4} \left[(1 + (1-y)^2)F_2(x,Q^2) - y^2F_L(x,Q^2) \right], \quad (9.11)$$

where α is the electromagnetic coupling and $F_2(x,Q^2)$ and $F_L(x,Q^2)$ are proton structure functions, which encode the interaction between the photon (in given polarization states) and the proton. In the presence of parity-violating interactions (e.g. νp scattering) an additional F_3 structure function is present. For an extended review, including equations for the full electroweak and polarized cases, see Sec. 18 of this Review.

Structure functions are not calculable in perturbative QCD, nor is any other cross section that involves initial-state hadrons. To zeroth order in α_s , the structure functions are given directly in terms of non-perturbative parton (quark or gluon) distribution functions (PDFs),

$$F_2(x,Q^2) = x \sum_q e_q^2 f_{q/p}(x) \,, \qquad F_L(x,Q^2) = 0 \,, \eqno(9.12)$$

 $^{^{\}dagger\dagger}$ The situation is significantly worse near thresholds, e.g. the $t\bar{t}$ production threshold. An overview of some of the effective field theory techniques used in such cases is to be found for example in Ref. 23.

where $f_{q/p}(x)$ is the PDF for quarks of type q inside the proton, *i.e.* the number density of quarks of type q inside a fast-moving proton that carry a fraction x of its longitudinal momentum (the quark flavor index q, here, is not to be confused with the photon momentum q in the lines preceding Eq. (9.11)). Since PDFs are non-perturbative, and difficult to calculate in lattice QCD [24], they must be extracted from data.

The above result, with PDFs $f_{q/p}(x)$ that are independent of the scale Q, corresponds to the "quark-parton model" picture in which the photon interacts with point-like free quarks, or equivalently, one has incoherent elastic scattering between the electron and individual constituents of the proton. As a consequence, in this picture also F_2 and F_L are independent of Q. When including higher orders in pQCD, Eq. (9.12) becomes

$$F_{2}(x, Q^{2}) = x \sum_{n=0}^{\infty} \frac{\alpha_{s}^{n}(\mu_{R}^{2})}{(2\pi)^{n}} \sum_{i=q,g} \int_{x}^{1} \frac{dz}{z} C_{2,i}^{(n)}(z, Q^{2}, \mu_{R}^{2}, \mu_{F}^{2}) f_{i/p}(\frac{x}{z}, \mu_{F}^{2}) + \mathcal{O}\left(\frac{\Lambda^{2}}{Q^{2}}\right).$$

$$(9.13)$$

Just as in Eq. (9.10), we have a series in powers $\alpha_s(\mu_R^2)$, each term involving a coefficient $C_{2,i}^{(n)}$ that can be calculated using Feynman graphs. An important difference relative to Eq. (9.10) stems from the fact that the quark's momentum, when it interacts with the photon, can differ from its momentum when it was extracted from the proton, because it may have radiated gluons in between. As a result, the $C_{2,i}^{(n)}$ coefficients are functions that depend on the ratio, z, of these two momenta, and one must integrate over z. At zeroth order, $C_{2,q}^{(0)} = e_q^2 \delta(1-z)$ and $C_{2,g}^{(0)} = 0$.

The majority of the emissions that modify a parton's momentum are collinear (parallel) to that parton, and don't depend on the fact that the parton is destined to interact with a photon. It is natural to view these emissions as modifying the proton's structure rather than being part of the coefficient function for the parton's interaction with the photon. Technically, one uses a procedure known as collinear factorization to give a well-defined meaning to this distinction, most commonly through the MS factorization scheme, defined in the context of dimensional regularization. The $\overline{\rm MS}$ factorization scheme involves an arbitrary choice of factorization scale, μ_F , whose meaning can be understood roughly as follows: emissions with transverse momenta above μ_F are included in the $C_{2,q}^{(n)}(z,Q^2,\mu_R^2,\mu_F^2)$; emissions with transverse momenta below μ_F are accounted for within the PDFs, $f_{i/p}(x,\mu_F^2)$. While collinear factorization is generally believed to be valid for suitable (sufficiently inclusive) observables in processes with hard scales, Ref. 35, which reviews the factorization proofs in detail, is cautious in the statements it makes about their exhaustivity, notably for the hadron-collider processes that we shall discuss below. Further discussion is to be found in Refs. 36.37.

The PDFs' resulting dependence on μ_F is described by the Dokshitzer-Gribov-Lipatov-Altarelli-Parisi (DGLAP) equations [25], which to leading order (LO) read*

$$\mu^{2} \frac{\partial f_{i/p}(x, \mu_{F}^{2})}{\partial \mu_{F}^{2}} = \sum_{j} \frac{\alpha_{s}(\mu_{F}^{2})}{2\pi} \int_{x}^{1} \frac{dz}{z} P_{i \leftarrow j}^{(1)}(z) f_{j/p}\left(\frac{x}{z}, \mu_{F}^{2}\right), \quad (9.14)$$

with, for example, $P_{q \leftarrow g}^{(1)}(z) = T_R(z^2 + (1-z)^2)$. The other LO splitting functions are listed in Sec. 18 of this *Review*, while results up

to next-to-leading order (NLO), α_s^2 , and next-to-next-to-leading order (NNLO), α_s^3 , are given in Refs. 26 and 27 respectively. The coefficient functions are also μ_F dependent, for example $C_{2,i}^{(1)}(x,Q^2,\mu_R^2,\mu_F^2) = C_{2,i}^{(1)}(x,Q^2,\mu_R^2,Q^2) - \ln(\frac{\mu_F^2}{Q^2}) \sum_j \int_x^1 \frac{dz}{z} C_{2,j}^{(0)}(\frac{x}{z}) P_{j\leftarrow i}^{(1)}(z)$. For the electromagnetic component of DIS with light quarks and gluons they are known to $\mathcal{O}(\alpha_s^3)$ (N³LO) [28]. For weak currents they are known fully to α_s^2 (NNLO) [29] with substantial results known also at N³LO [30]. For heavy quark production they are known to $\mathcal{O}(\alpha_s^2)$ [31] (NLO insofar as the series starts at $\mathcal{O}(\alpha_s)$), with work ongoing towards NNLO [32,33].

As with the renormalization scale, the choice of factorization scale is arbitrary, but if one has an infinite number of terms in the perturbative series, the μ_F -dependences of the coefficient functions and PDFs will compensate each other fully. Given only N terms of the series, a residual $\mathcal{O}(\alpha_s^{N+1})$ uncertainty is associated with the ambiguity in the choice of μ_F . As with μ_R , varying μ_F provides an input in estimating uncertainties on predictions. In inclusive DIS predictions, the default choice for the scales is usually $\mu_R = \mu_F = Q$. Hadron-hadron collisions. The extension to processes with two initial-state hadrons is straightforward, and for example the total (inclusive) cross section for W boson production in collisions of

$$\begin{split} \sigma(h_1 h_2 \to W + X) &= \sum_{n=0}^{\infty} \alpha_s^n(\mu_R^2) \sum_{i,j} \int dx_1 dx_2 \, f_{i/h_1} \Big(x_1, \mu_F^2 \Big) f_{j/h_2} \Big(x_2, \mu_F^2 \Big) \\ &\times \hat{\sigma}_{ij \to W + X}^{(n)} \Big(x_1 x_2 s, \mu_R^2, \mu_F^2 \Big) \,, \end{split} \tag{9.15}$$

hadrons h_1 and h_2 can be written as

where s is the squared center-of-mass energy of the collision. At LO, n=0, the hard (partonic) cross section $\hat{\sigma}_{ij\to W+X}^{(0)}(x_1x_2s,\mu_R^2,\mu_F^2)$ is simply proportional to $\delta(x_1x_2s-M_W^2)$, in the narrow W-boson width approximation (see Sec. 44 of this Review for detailed expressions for this and other hard scattering cross sections). It is non-zero only for choices of i,j that can directly give a W, such as $i=u,\ j=\bar{d}$. At higher orders, $n\geq 1$, new partonic channels contribute, such as gq, and there is no restriction $x_1x_2s=M_W^2$.

Equation 9.15 involves a collinear factorization between hard cross section and PDFs, just like Eq. (9.13). As long as the same factorization scheme is used in DIS and pp or $p\bar{p}$ (usually the $\overline{\rm MS}$ scheme), then PDFs extracted in DIS can be directly used in pp and $p\bar{p}$ predictions [34,35] (with the anti-quark distributions in an anti-proton being the same as the quark distributions in a proton). Note that Eq. (9.15) only holds to within contributions that are suppressed by powers of m_p^2/m_W^2 .

Fully inclusive hard cross sections are known to NNLO, i.e. corrections up to relative order α_s^2 , for Drell-Yan (DY) lepton-pair and vector-boson production [38,39], Higgs-boson production via gluon fusion [39–41], Higgs-boson production in association with a vector boson [42] and Higgs-boson production via vector-boson fusion [43](in an approximation that factorizes the production of the two vector bosons). A review of fully inclusive Higgs-related results is to be found in Ref. 44.

Photoproduction. γp (and $\gamma \gamma$) collisions are similar to pp collisions, with the subtlety that the photon can behave in two ways: there is "direct" photoproduction, in which the photon behaves as a point-like particle and takes part directly in the hard collision, with hard subprocesses such as $\gamma g \to q\bar{q}$; there is also resolved photoproduction, in which the photon behaves like a hadron, with non-perturbative partonic substructure and a corresponding PDF for its quark and gluon content, $f_{i/\gamma}(x,Q^2)$.

While useful to understand the general structure of γp collisions, the distinction between direct and resolved photoproduction is not well defined beyond leading order, as discussed for example in Ref. 45.

The high-energy limit. In situations in which the total center-of-mass energy \sqrt{s} is much larger than other scales in the problem (e.g. Q in DIS, m_b for $b\bar{b}$ production in pp collisions, etc.), each power of α_s beyond LO can be accompanied by a power of $\ln(s/Q^2)$ (or $\ln(s/m_b^2)$, etc.). This is known as the high-energy or Balitsky-Fadin-Kuraev-Lipatov (BFKL) limit [46–48]. Currently it is possible to account

^{*} LO is generally taken to mean the lowest order at which a quantity is non-zero. This definition is nearly always unambiguous, the one major exception being for the case of the hadronic branching ratio of virtual photons, Z, τ , etc., for which two conventions exist: LO can either mean the lowest order that contributes to the hadronic branching fraction, *i.e.* the term "1" in Eq. (9.7); or it can mean the lowest order at which the hadronic branching ratio becomes sensitive to the coupling, n=1 in Eq. (9.8), as is relevant when extracting the value of the coupling from a measurement of the branching ratio. Because of this ambiguity, we avoided use of the term "LO" in that context.

for the dominant and first subdominant [49,50] power of $\ln s$ at each order of α_s , and also to estimate further subdominant contributions that are numerically large (see Refs. 51–53 and references therein).

Physically, the summation of all orders in α_s can be understood as leading to a growth with s of the gluon density in the proton. At sufficiently high energies this implies non-linear effects, whose treatment has been the subject of intense study (see for example Refs. 54, 55 and references thereto). Note that it is not straightforward to relate these results to the genuinely non-perturbative total, elastic and diffractive cross sections for hadron-hadron scattering (experimental results for which are summarized in section Chap. 46 of this Review).

9.2.2. Non fully inclusive cross-sections:

QCD final states always consist of hadrons, while perturbative QCD calculations deal with partons. Physically, an energetic parton fragments ("showers") into many further partons, which then, on later timescales, undergo a transition to hadrons ("hadronization"). Fixed-order perturbation theory captures only a small part of these dynamics.

This does not matter for the fully inclusive cross sections discussed above: the showering and hadronization stages are "unitary", i.e. they do not change the overall probability of hard scattering, because they occur long after it has taken place.

Less inclusive measurements, in contrast, may be affected by the extra dynamics. For those sensitive just to the main directions of energy flow (jet rates, event shapes, cf. Sec. 9.3.1) fixed order perturbation theory is often still adequate, because showering and hadronization don't substantially change the overall energy flow. This means that one can make a prediction using just a small number of partons, which should correspond well to a measurement of the same observable carried out on hadrons. For observables that instead depend on distributions of individual hadrons (which, e.g., are the inputs to detector simulations), it is mandatory to account for showering and hadronization. The range of predictive techniques available for QCD final states reflects this diversity of needs of different measurements.

While illustrating the different methods, we shall for simplicity mainly use expressions that hold for e^+e^- scattering. The extension to cases with initial-state partons will be mostly straightforward (space constraints unfortunately prevent us from addressing diffraction and exclusive hadron-production processes; extensive discussion is to be found in Refs. 56, 57).

9.2.2.1. Preliminaries: Soft and collinear limits:

Before examining specific predictive methods, it is useful to be aware of a general property of QCD matrix elements in the soft and collinear limits. Consider a squared tree-level matrix element $|M_n^2(p_1,\ldots,p_n)|$ for the process $e^+e^- \to n$ partons with momenta p_1,\ldots,p_n , and a corresponding phase-space integration measure $d\Phi_n$. If particle n is a gluon, and additionally it becomes collinear (parallel) to another particle i and its momentum tends to zero (it becomes "soft"), the matrix element simplifies as follows,

$$\begin{split} &\lim_{\theta_{in}\to 0, E_{n}\to 0} d\Phi_{n} |M_{n}^{2}(p_{1},\dots,p_{n})| \\ &= d\Phi_{n-1} |M_{n-1}^{2}(p_{1},\dots,p_{n-1})| \frac{\alpha_{s}C_{i}}{\pi} \frac{d\theta_{in}^{2}}{\theta_{in}^{2}} \frac{dE_{n}}{E_{n}} , \ (9.16) \end{split}$$

where $C_i=C_F$ (C_A) if i is a quark (gluon). This formula has non-integrable divergences both for the inter-parton angle $\theta_{in} \to 0$ and for the gluon energy $E_n \to 0$, which are mirrored also in the structure of divergences in loop diagrams. These divergences are important for at least two reasons: firstly, they govern the typical structure of events (inducing many emissions either with low energy or at small angle with respect to hard partons); secondly, they will determine which observables can be calculated within perturbative QCD.

9.2.2.2. Fixed-order predictions:

Let us consider an observable \mathcal{O} that is a function $\mathcal{O}_n(p_1,\ldots,p_n)$ of the four-momenta of the n particles in an event (whether partons or hadrons). In what follows, we shall consider the cross section for events weighted with the value of the observable, $\sigma_{\mathcal{O}}$. As examples, if $\mathcal{O}_n \equiv 1$ for all n, then $\sigma_{\mathcal{O}}$ is just the total cross section; if $\mathcal{O}_n \equiv \hat{\tau}(p_1,\ldots,p_n)$ where $\hat{\tau}$ is the value of the Thrust for that event (see Sec. 9.3.1.2), then the average value of the Thrust is $\langle \tau \rangle = \sigma_{\mathcal{O}}/\sigma_{\text{tot}}$; if $\mathcal{O}_n \equiv \delta(\tau - \hat{\tau}(p_1,\ldots,p_n))$ then one gets the differential cross section as a function of the Thrust, $\sigma_{\mathcal{O}} \equiv d\sigma/d\tau$.

In the expressions below, we shall omit to write the non-perturbative power correction term, which for most common observables is proportional to a single power of Λ/Q .

LO. If the observable $\mathcal O$ is non-zero only for events with at least n particles, then the LO QCD prediction for the weighted cross section in e^+e^- annihilation is

$$\sigma_{\mathcal{O},LO} = \alpha_s^{n-2}(\mu_R^2) \int d\Phi_n |M_n^2(p_1,\dots,p_n)| \mathcal{O}_n(p_1,\dots,p_n), \quad (9.17)$$

where the squared tree-level matrix element, $|M_n^2(p_1,\ldots,p_n)|$, includes relevant symmetry factors, has been summed over all subprocesses (e.g. $e^+e^-\to q\bar qq\bar q$, $e^+e^-\to q\bar qgg$) and has had all factors of α_s extracted in front. In processes other than e^+e^- collisions, the powers of the coupling are often brought inside the integrals, with the scale μ_R chosen event by event, as a function of the event kinematics.

Other than in the simplest cases (see the review on Cross Sections in this *Review*), the matrix elements in Eq. (9.17) are usually calculated automatically with programs such as CompHEP [58], MadGraph [59], Alpgen [60], Comix/Sherpa [61], and Helac/Phegas [62]. Some of these (CompHEP, MadGraph) use formulas obtained from direct evaluations of Feynman diagrams. Others (Alpgen, Helac/Phegas and Comix/Sherpa) use methods designed to be particularly efficient at high multiplicities, such as Berends-Giele recursion [63] (see also the reviews [64,65]), which builds up amplitudes for complex processes from simpler ones.

The phase-space integration is usually carried out by Monte Carlo sampling, in order to deal with the sometimes complicated cuts that are used in corresponding experimental measurements. Because of the divergences in the matrix element, Eq. (9.16), the integral converges only if the observable vanishes for kinematic configurations in which one of the n particles is arbitrarily soft or it is collinear to another particle. As an example, the cross section for producing any configuration of n partons will lead to an infinite integral, whereas a finite result will be obtained for the cross section for producing n deposits of energy (or jets, see Sec. 9.3.1.1), each above some energy threshold and well separated from each other in angle.

LO calculations can be carried out for $2 \to n$ processes with $n \lesssim 6-10$. The exact upper limit depends on the process, the method used to evaluate the matrix elements (recursive methods are more efficient), and the extent to which the phase-space integration can be optimized to work around the large variations in the values of the matrix elements.

NLO. Given an observable that is non-zero starting from n particles, its prediction at NLO involves supplementing the LO result with the (n+1)-particle tree-level matrix element $(|M_{n+1}^2|)$, and the interference of a n-particle tree-level and n-particle 1-loop amplitude $(2\text{Re}(M_nM_{n,1-\text{loop}}^*))$,

$$\begin{split} \sigma_{\mathcal{O}}^{NLO} &= \sigma_{\mathcal{O}}^{LO} + \alpha_s^{n-1}(\mu_R^2) \int \!\! d\Phi_{n+1} \\ &| M_{n+1}^2(p_1, \dots, p_{n+1})| \, \mathcal{O}_{n+1}(p_1, \dots, p_{n+1}) \\ &+ \alpha_s^{n-1}(\mu_R^2) \int \!\! d\Phi_n \, 2 \mathrm{Re}[M_n(p_1, \dots, p_n) \\ &M_{n,1-\mathrm{loop}}^*(p_1, \dots, p_n) \,] \, \mathcal{O}_n(p_1, \dots, p_n) \,. \end{split} \tag{9.18}$$

Relative to LO calculations, two important issues appear in the NLO calculations. Firstly, the extra complexity of loop-calculations relative to tree-level calculations means that their automation is at a comparatively early stage (see below). Secondly, loop amplitudes

are infinite in 4 dimensions, while tree-level amplitudes are finite, but their *integrals* are infinite, due to the divergences of Eq. (9.16). These two sources of infinities have the same soft and collinear origins and cancel after the integration only if the observable \mathcal{O} satisfies the property of infrared and collinear safety,

$$\mathcal{O}_{n+1}(p_1, \dots, p_s, \dots, p_n) \to \mathcal{O}_n(p_1, \dots, p_n) \quad \text{if } p_s \to 0
\mathcal{O}_{n+1}(p_1, \dots, p_a, p_b, \dots, p_n) \to \mathcal{O}_n(p_1, \dots, p_a + p_b, \dots, p_n)
\quad \text{if } p_a \mid\mid p_b. \tag{9.19}$$

Examples of infrared safe quantities include event-shape distributions and jet cross sections (with appropriate jet algorithms, see below). Unsafe quantities include the distribution of the momentum of the hardest QCD particle (which is not conserved under collinear splitting), observables that require the complete absence of radiation in some region of phase-space (e.g. rapidity gaps or 100% isolation cuts, which are affected by soft emissions), or the particle multiplicity (affected by both soft and collinear emissions). The non-cancellation of divergences at NLO due to infrared or collinear unsafety compromises the usefulness not only of the NLO calculation, but also that of a LO calculation, since LO is only an acceptable approximation if one can prove that higher order terms are smaller. Infrared and collinear unsafety usually also imply large non-perturbative effects.

As with LO calculations, the phase-space integrals in Eq. (9.18) are usually carried out by Monte Carlo integration, so as to facilitate the study of arbitrary observables. Various methods exist to obtain numerically efficient cancellation among the different infinities. These include notably dipole [66], FKS [67] and antenna [68] subtraction.

NLO calculations have existed for a while for a wide range of $2 \rightarrow n$ processes with $n \leq 3$, as reviewed in Ref. 69. Some of the corresponding codes are public, and those that provide access to multiple processes include NLOJet++ [70] for e^+e^- , DIS, and hadron-hadron processes involving just light partons in the final state, MCFM [71] for hadron-hadron processes with vector bosons and/or heavy quarks in the final state, VBFNLO for vector-boson fusion, di- and tri-boson processes [72], and the Phox family [73] for processes with photons in the final state. One forefront of NLO calculations is $2 \to 4$ and $2 \to 5$ processes in pp scattering (and for $1 \to 5$ in $e^+e^- \to \gamma/Z \to \text{hadrons}$ [74]), where recent results include $t\bar{t}b\bar{b}$ [80,81], $t\bar{t}+2\mathrm{jets}$ [82] and $b\bar{b}b\bar{b}$ [83], $pp \to W/Z+3\mathrm{jets}$ [75,76,77] and $pp \rightarrow W/Z + 4$ jets [78,79] as well as $W^+W^-b\bar{b}$ [84] and $W^+W^\pm + 2$ jets [85]. A related forefront is automation: a number of the above results have been obtained with partially automated approaches. A first example of full automation applied to a large number of processes has been presented recently in Ref. 86, and a public automated code is described in Ref. 87. A number of the above calculations have made use of unitarity-type techniques [88] and powerful integrand reduction methods (notably Ref. 89), which have seen significant development over the past few years, as reviewed in

NNLO. Conceptually, NNLO and NLO calculations are similar, except that one must add a further order in α_s , consisting of: the squared (n+2)-parton tree-level amplitude, the interference of the (n+1)-parton tree-level and 1-loop amplitudes, the interference of the n-parton tree-level and 2-loop amplitudes, and the squared n-parton 1-loop amplitude.

Each of these elements involves large numbers of soft and collinear divergences, satisfying relations analogous to Eq. (9.16) that now involve multiple collinear or soft particles and higher loop orders (see e.g. Refs. 88,91,92). Arranging for the cancellation of the divergences after numerical Monte Carlo integration is one of the significant challenges of NNLO calculations, as is the determination of the relevant 2-loop amplitudes. At the time of writing, the processes for which fully exclusive NNLO calculations exist include the 3-jet cross section in e^+e^- collisions [93,94] (for which NNLO means α_s^3), as well as vector-boson [95,96], Higgs-boson [97,98], WH [99] and di-photon [100] production in pp and $p\bar{p}$ collisions.

9.2.2.3. Resummation:

Many experimental measurements place tight constraints on emissions in the final state, for example, in e^+e^- events, that one minus the Thrust should be less than some value $\tau \ll 1$, or in $pp \to Z$ events that the Z-boson transverse momentum should be much smaller than its mass, $p_{t,Z} \ll M_Z$. A further example is the production of heavy particles or jets near threshold (so that little energy is left over for real emissions) in DIS and pp collisions.

In such cases, the constraint vetoes a significant part of the integral over the soft and collinear divergence of Eq. (9.16). As a result, there is only a partial cancellation between real emission terms (subject to the constraint) and loop (virtual) contributions (not subject to the constraint), causing each order of α_s to be accompanied by a large coefficient $\sim L^2$, where e.g. $L = \ln \tau$ or $L = \ln(M_Z/p_{t,Z})$. One ends up with a perturbative series whose terms go as $\sim (\alpha_s L^2)^n$. It is not uncommon that $\alpha_s L^2 \gg 1$, so that the perturbative series converges very poorly if at all.** In such cases one may carry out a "resummation," which accounts for the dominant logarithmically enhanced terms to all orders in α_s , by making use of known properties of matrix elements for multiple soft and collinear emissions, and of the all-orders properties of the divergent parts of virtual corrections, following original works such as Refs. 101-110 and also through soft-collinear effective theory [111,112] (cf. also the review in Ref. 113).

For cases with double logarithmic enhancements (two powers of logarithm per power of α_s), there are two classification schemes for resummation accuracy. Writing the cross section including the constraint as $\sigma(L)$ and the unconstrained (total) cross section as $\sigma_{\rm tot}$, the series expansion takes the form

$$\sigma(L) \simeq \sigma_{\text{tot}} \sum_{n=0}^{\infty} \sum_{k=0}^{2n} R_{nk} \alpha_s^n(\mu_R^2) L^k, \qquad L \gg 1$$
 (9.20)

and leading log (LL) resummation means that one accounts for all terms with k=2n, next-to-leading-log (NLL) includes additionally all terms with k=2n-1, etc. Often $\sigma(L)$ (or its Fourier or Mellin transform) exponentiates ‡ ,

$$\sigma(L) \simeq \sigma_{\text{tot}} \exp\left[\sum_{n=1}^{\infty} \sum_{k=0}^{n+1} G_{nk} \alpha_s^n(\mu_R^2) L^k\right], \qquad L \gg 1, \qquad (9.21)$$

where one notes the different upper limit on $k (\leq n+1)$ compared to Eq. (9.20). This is a more powerful form of resummation: the G_{12} term alone reproduces the full LL series in Eq. (9.20). With the form Eq. (9.21) one still uses the nomenclature LL, but this now means that all terms with k=n+1 are included, and NLL implies all terms with k=n, etc.

For a large number of observables, NLL resummations are available in the sense of Eq. (9.21) (see Refs. 117–119 and references therein). NNLL has been achieved for the DY and Higgs-boson p_t distributions [120,121,122,123] (in addition the NLL ResBos program [124] is still widely used), the back-to-back energy-energy correlation in e^+e^- [125], the production of top anti-top pairs near threshold [126–128] (and references therein), high- p_t W and Z production [129], and an event-shape type observable known as the beam Thrust [130]. Finally, the parts believed to be dominant in the N³LL resummation are available for the Thrust variable and

^{**} To be precise one should distinguish two causes of the divergence of perturbative series. That which interests us here is associated with the presence of a new large parameter (e.g. ratio of scales). Nearly all perturbative series also suffer from "renormalon" divergences $\alpha_s^n n!$ (reviewed in Ref. 16), which however have an impact only at very high perturbative orders and have a deep connection with non-perturbative uncertainties.

[‡] Whether or not this happens depends on the quantity being resummed. A classic example involves jet rates in e^+e^- collisions as a function of a jet-resolution parameter y_{cut} . The logarithms of $1/y_{\text{cut}}$ exponentiate for the k_t (Durham) jet algorithm [114], but not [115] for the JADE algorithm [116] (both are discussed below in Sec. 9.3.1.1).

heavy-jet mass in e^+e^- annihilations [131,132] (confirmed for Thrust at NNLL in Ref. 133), and for Higgs- and vector-boson production near threshold [134,135] in hadron collisions (NNLL in Refs. 136,137). The inputs and methods involved in these various calculations are somewhat too diverse to discuss in detail here, so we recommend that the interested reader consult the original references for further details.

9.2.2.4. Fragmentation functions:

Since the parton-hadron transition is non-perturbative, it is not possible to perturbatively calculate quantities such as the energy-spectra of specific hadrons in high-energy collisions. However, one can factorize perturbative and non-perturbative contributions via the concept of fragmentation functions. These are the final-state analogue of the parton distribution functions that are used for initial-state hadrons.

It should be added that if one ignores the non-perturbative difficulties and just calculates the energy and angular spectrum of partons in perturbative QCD with some low cutoff scale $\sim \Lambda$ (using resummation to sum large logarithms of \sqrt{s}/Λ), then this reproduces many features of the corresponding hadron spectra. This is often taken to suggest that hadronization is "local" in momentum space.

Sec. 19 of this *Review* provides further information (and references) on these topics, including also the question of heavy-quark fragmentation.

9.2.2.5. Parton-shower Monte Carlo generators:

Parton-shower Monte Carlo (MC) event generators like PYTHIA [138–140], HERWIG [141–143], SHERPA [144], and ARIADNE [145] provide fully exclusive simulations of QCD events. Because they provide access to "hadron-level" events they are a crucial tool for all applications that involve simulating the response of detectors to QCD events. Here we give only a brief outline of how they work and refer the reader to Chap. 38 and Ref. 146 for a full overview.

The MC generation of an event involves several stages. It starts with the random generation of the kinematics and partonic channels of whatever hard scattering process the user has requested at some high scale Q_0 . This is followed by a parton shower, usually based on the successive random generation of gluon emissions (or $g \to q\bar{q}$ splittings). Each is generated at a scale lower than the previous emission, following a (soft and collinear resummed) perturbative QCD distribution that depends on the momenta of all previous emissions. Common choices of scale for the ordering of emissions are virtuality, transverse momentum or angle. Parton showering stops at a scale of order 1 GeV, at which point a hadronization model is used to convert the resulting partons into hadrons. One widely-used model involves stretching a color "string" across quarks and gluons, and breaking it up into hadrons [147,148]. Another breaks each gluon into a $q\bar{q}$ pair and then groups quarks and anti-quarks into colorless "clusters"; which then give the hadrons [141]. For pp and γp processes, modeling is also needed to treat the collision between the two hadron remnants, which generates an underlying event (UE), usually implemented via additional $2 \rightarrow 2$ scatterings ("multiple parton interactions") at a scale of a few GeV, following Ref. 149.

A deficiency of the soft and collinear approximations that underlie parton showers is that they may fail to reproduce the full pattern of hard wide-angle emissions, important, for example, in many new physics searches. It is therefore common to use LO multi-parton matrix elements to generate hard high-multiplicity partonic configurations as additional starting points for the showering, supplemented with some prescription (CKKW [150], MLM [151]) for consistently merging samples with different initial multiplicities.

MCs, as described above, generate cross sections for the requested hard process that are correct at LO. For a number of processes there also exist MC implementations that are correct to NLO, using the MC@NLO [152] or POWHEG [153] prescriptions. Techniques also exist to combine NLO accuracy for a low order process, with LO accuracy for higher multiplicity processes [154,155].

9.2.3. Accuracy of predictions:

Estimating the accuracy of perturbative QCD predictions is not an exact science. It is often said that LO calculations are accurate to within a factor of two. This is based on experience with NLO corrections in the cases where these are available. In processes involving new partonic scattering channels at NLO and/or large ratios of scales (such as the production of high- p_t jets containing B-hadrons), the NLO to LO K-factors can be substantially larger than 2.

For calculations beyond LO, a conservative approach to estimate the perturbative uncertainty is to take it to be the last known perturbative order; a more widely used method is to estimate it from the change in the prediction when varying the renormalization and factorization scales around a central value Q that is taken close to the physical scale of the process. A conventional range of variation is $Q/2 < \mu_R, \mu_F < 2Q$, however this should not be assumed to give uncertainty estimates of guaranteed reliability. ††

There does not seem to be a broad consensus on whether μ_R and μ_F should be kept identical or varied independently. One option is to vary them independently with the restriction $\frac{1}{2}\mu_R < \mu_F < 2\mu_R$ [160]. This limits the risk of misleadingly small uncertainties due to fortuitous cancellations between the μ_F and μ_R dependence when both are varied together, while avoiding the appearance of large logarithms of μ_R^2/μ_F^2 when both are varied completely independently.

Calculations that involve resummations usually have an additional source of uncertainty associated with the choice of argument of the logarithms being resummed, e.g. $\ln(2\frac{p_{t,Z}}{M_Z})$ as opposed to $\ln(\frac{1}{2}\frac{p_{t,Z}}{M_Z})$. In addition to varying renormalization and factorization scales, it is therefore also advisable to vary the argument of the logarithm by a factor of two in either direction with respect to the "natural" argument.

The accuracy of QCD predictions is limited also by non-perturbative corrections, which typically scale as a power of Λ/Q . For measurements that are directly sensitive to the structure of the hadronic final state the corrections are usually linear in Λ/Q . The non-perturbative corrections are further enhanced in processes with a significant underlying event (i.e. in pp and $p\bar{p}$ collisions) and in cases where the perturbative cross sections fall steeply as a function of p_t or some other kinematic variable.

Non-perturbative corrections are commonly estimated from the difference between Monte Carlo events at the parton level and after hadronization. An issue to be aware of with this procedure is that "parton level" is not a uniquely defined concept. For example, in an event generator it depends on a (somewhat arbitrary and tunable) internal cutoff scale that separates the parton showering from the hadronization. In contrast no such cutoff scale exists in a NLO or NNLO partonic calculation. For this reason there are widespread reservations as to the appropriateness of deriving hadronization corrections from a Monte Carlo program and then applying them to NLO or NNLO prediction. There exist alternative methods for estimating hadronization corrections, which attempt to analytically deduce non-perturbative effects in one observable based on measurements of other observables (see the reviews [16,161]). While they directly address the problem of different possible definitions of parton level, it should also be said that they are far less flexible than Monte Carlo programs and not always able to provide equally good descriptions of the data.

9.3. Experimental QCD

Since we are not able to directly measure partons (quarks or gluons), but only hadrons and their decay products, a central issue for every experimental test of QCD is establishing a correspondence between observables obtained at the partonic and the hadronic level. The only theoretically sound correspondence is achieved by means of infrared and collinear safe quantities, which allow one to obtain finite predictions at any order of perturbative QCD.

^{‡‡} A number of prescriptions also exist for setting the scale automatically, e.g. Refs. 156–159, eliminating uncertainties from scale variation, though not from the truncation of the perturbative series itself.

As stated above, the simplest case of infrared and collinear safe observables are total cross sections. More generally, when measuring fully inclusive observables, the final state is not analyzed at all regarding its (topological, kinematical) structure or its composition. Basically the relevant information consists in the rate of a process ending up in a partonic or hadronic final state. In e^+e^- annihilation, widely used examples are the ratios of partial widths or branching ratios for the electroweak decay of particles into hadrons or leptons, such as Z or τ decays, (cf. Sec. 9.2.1). Such ratios are often favored over absolute cross sections or partial widths because of large cancellations of experimental and theoretical systematic uncertainties. The strong suppression of non-perturbative effects, $\mathcal{O}(\Lambda^4/Q^4)$, is one of the attractive features of such observables, however, at the same time the sensitivity to radiative QCD corrections is small, which for example affects the statistical uncertainty when using them for the determination of the strong coupling constant. In the case of τ decays not only the hadronic branching ratio is of interest, but also moments of the spectral functions of hadronic tau decays, which sample different parts of the decay spectrum and thus provide additional information. Other examples of fully inclusive observables are structure functions (and related sum rules) in DIS. These are extensively discussed in Sec. 18 of this Review.

On the other hand, often the structure or composition of the final state are analyzed and cross sections differential in one or more variables characterizing this structure are of interest. Examples are jet rates, jet substructure, event shapes or transverse momentum distributions of jets or vector bosons in hadron collisions. The case of fragmentation functions, *i.e.* the measurement of hadron production as a function of the hadron momentum relative to some hard scattering scale, is discussed in Sec. 19 of this *Review*.

It is worth mentioning that, besides the correspondence between the parton and hadron level, also a correspondence between the hadron level and the actually measured quantities in the detector has to be established. The simplest examples are corrections for finite experimental acceptance and efficiencies. Whereas acceptance corrections essentially are of theoretical nature, since they involve extrapolations from the measurable (partial) to the full phase space, other corrections such as for efficiency, resolution and response, are of experimental nature. For example, measurements of differential cross sections such as jet rates require corrections in order to relate, e.g. the energy deposits in a calorimeter to the jets at the hadron level. Typically detector simulations and/or data driven methods are used in order to obtain these corrections. Care should be taken here in order to have a clear separation between the parton-to-hadron level and hadron-to-detector level corrections. Finally, for the sake of an easy comparison to the results of other experiments and/or theoretical calculations, it is suggested to provide, whenever possible, measurements corrected for detector effects and/or all necessary information related to the detector response (e.g. the detector response matrix).

9.3.1. Hadronic final-state observables:

9.3.1.1. Jets:

In hard interactions, final-state partons and hadrons appear predominantly in collimated bunches. These bunches are generically called *jets*. To a first approximation, a jet can be thought of as a hard parton that has undergone soft and collinear showering and then hadronization. Jets are used both for testing our understanding and predictions of high-energy QCD processes, and also for identifying the hard partonic structure of decays of massive particles like top quarks.

In order to map observed hadrons onto a set of jets, one uses a jet definition. The mapping involves explicit choices: for example when a gluon is radiated from a quark, for what range of kinematics should the gluon be part of the quark jet, or instead form a separate jet? Good jet definitions are infrared and collinear safe, simple to use in theoretical and experimental contexts, applicable to any type of inputs (parton or hadron momenta, charged particle tracks, and/or energy deposits in the detectors) and lead to jets that are not too sensitive to non-perturbative effects. An extensive treatment of the topic of jet definitions is given in Ref. 162 (for e^+e^- collisions) and Refs. 163, 164 (for pp or $p\bar{p}$ collisions). Here we briefly review the two main

classes: cone algorithms, extensively used at older hadron colliders, and sequential recombination algorithms, more widespread in e^+e^- and ep colliders and at the LHC.

Very generically, most (iterative) cone algorithms start with some seed particle i, sum the momenta of all particles j within a cone of opening-angle R, typically defined in terms of (pseudo-)rapidity and azimuthal angle. They then take the direction of this sum as a new seed and repeat until the cone is stable, and call the contents of the resulting stable cone a jet if its transverse momentum is above some threshold $p_{t,\min}$. The parameters R and $p_{t,\min}$ should be chosen according to the needs of a given analysis.

There are many variants of cone algorithm, and they differ in the set of seeds they use and the manner in which they ensure a one-to-one mapping of particles to jets, given that two stable cones may share particles ("overlap"). The use of seed particles is a problem w.r.t. infrared and collinear safety, and seeded algorithms are generally not compatible with higher-order (or sometimes even leading-order) QCD calculations, especially in multi-jet contexts, as well as potentially subject to large non-perturbative corrections and instabilities. Seeded algorithms (JetCLU, MidPoint, and various other experiment-specific iterative cone algorithms) are therefore to be deprecated. A modern alternative is to use a seedless variant, SISCone [165].

Sequential recombination algorithms at hadron colliders (and in DIS) are characterized by a distance $d_{ij} = \min(k_{t,i}^{2p}, k_{t,j}^{2p}) \Delta_{ij}^2/R^2$ between all pairs of particles i, j, where Δ_{ij} is their distance in the rapidity-azimuthal plane, $k_{t,i}$ is the transverse momentum w.r.t. the incoming beams, and R is a free parameter. They also involve a "beam" distance $d_{iB}=k_{t,i}^{2p}$. One identifies the smallest of all the d_{ij} and d_{iB} , and if it is a d_{ij} , then i and j are merged into a new pseudo-particle (with some prescription, a recombination scheme, for the definition of the merged four-momentum). If the smallest distance is a d_{iB} , then i is removed from the list of particles and called a jet. As with cone algorithms, one usually considers only jets above some transverse-momentum threshold $p_{t,\min}$. The parameter p determines the kind of algorithm: p = 1 corresponds to the (inclusive-) k_t algorithm [114,166,167], p=0 defines the Cambridge-Aachen algorithm [168,169], while for p = -1 we have the anti- k_t algorithm [170]. All these variants are infrared and collinear safe to all orders of perturbation theory. Whereas the former two lead to irregularly shaped jet boundaries, the latter results in cone-like boundaries. The anti- k_t algorithm has become the de-facto standard for the LHC experiments.

In e^+e^- annihilations the k_t algorithm [114] uses $y_{ij}=2 \min(E_i^2,E_j^2)(1-\cos\theta_{ij})/Q^2$ as distance measure and repeatedly merges the pair with smallest y_{ij} , until all y_{ij} distances are above some threshold $y_{\rm cut}$, the jet resolution parameter. The (pseudo)-particles that remain at this point are called the jets. Here it is $y_{\rm cut}$ (rather than R and $p_{t,\rm min}$) that should be chosen according to the needs of the analysis. As mentioned above, the k_t algorithm has the property that logarithms $\ln(1/y_{\rm cut})$ exponentiate in resummation calculations. This is one reason why it is preferred over the earlier JADE algorithm [116], which uses the distance measure $y_{ij}=2\,E_i\,E_j\,(1-\cos\theta_{ij})/Q^2$.

Efficient implementations of the above algorithms are available through the FastJet package [171], which is also packaged within SpartyJet [172].

9.3.1.2. Event Shapes:

Event-shape variables are functions of the four momenta in the hadronic final state that characterize the topology of an event's energy flow. They are sensitive to QCD radiation (and correspondingly to the strong coupling) insofar as gluon emission changes the shape of the energy flow.

The classic example of an event shape is the $Thrust\ [173,174]$ in e^+e^- annihilations, defined as

$$\hat{\tau} = \max_{\vec{n}_{\tau}} \frac{\sum_{i} |\vec{p}_{i} \cdot \vec{n}_{\tau}|}{\sum_{i} |\vec{p}_{i}|}, \qquad (9.22)$$

where $\vec{p_i}$ are the momenta of the particles or the jets in the final-state and the maximum is obtained for the Thrust axis $\vec{n_\tau}$. In the Born

limit of the production of a perfect back-to-back $q\bar{q}$ pair the limit $\hat{\tau} \to 1$ is obtained, whereas a perfectly symmetric many-particle configuration leads to $\hat{\tau} \to 1/2$. Further event shapes of similar nature have been defined and extensively measured at LEP and at HERA, and for their definitions and reviews we refer to Refs. 3,4,161,175,176. Phenomenological discussions of event shapes at hadron colliders can be found in Refs. 177–179. Very recently, measurements of hadronic event-shape distributions have been published by CDF [180] and CMS [181].

Event shapes are used for many purposes. These include measuring the strong coupling, tuning the parameters of Monte Carlo programs, investigating analytical models of hadronization and distinguishing QCD events from events that might involve decays of new particles (giving event-shape values closer to the spherical limit).

9.3.1.3. Jet substructure, quark vs. gluon jets:

Jet substructure, which can be resolved by finding subjets or by measuring jet shapes, is sensitive to the details of QCD radiation in the shower development inside a jet and has been extensively used to study differences in the properties of quark and gluon induced jets, strongly related to their different color charges. In general there is clear experimental evidence that gluon jets are "broader" and have a softer particle spectrum than (light-) quark jets, whereas b-quark jets are similar to gluon jets. As an example of an observable, the jet shape $\Psi(r/R)$ is the fractional transverse momentum contained within a sub-cone of cone-size r for jets of cone-size R. It is sensitive to the relative fractions of quark and gluon jets in an inclusive jet sample and receives contributions from soft-gluon initial-state radiation and beam remnant-remnant interactions. Therefore, it has been widely employed for validation and tuning of Monte Carlo models. CDF has measured the jet shape $\Psi(r/R)$ for an inclusive jet sample [182] as well as for b-jets [183]. Similar measurements in photo-production and DIS at HERA have been reported in Refs. 184–186. First measurements at the LHC have been presented by ATLAS [187]. Further discussions, references and recent summaries can be found in Refs. 176, 188 and Sec. 4 of Ref. 189.

The use of jet substructure has also been suggested in order to distinguish QCD jets from jets that originate from hadronic decays of boosted massive particles (high- p_t electroweak bosons, top quarks and hypothesized new particles). For reviews and detailed references, see Ref. 189 and sec. 5.3 of Ref. 163.

9.3.2. State of the art QCD measurements at colliders:

There exists an enormous wealth of data on QCD-related measurements in e^+e^- , ep, pp, and $p\bar{p}$ collisions, to which a short overview like this would not be able to do any justice. Extensive reviews of the subject have been published in Refs. 175, 176 for e^+e^- colliders, whereas for hadron colliders comprehensive overviews are given in Refs. 164, 190, and recent summaries can be found in, e.g. Refs. 191–194. Below we concentrate our discussion on measurements that are most sensitive to hard QCD processes, in particular jet production.

9.3.2.1. e^+e^- colliders: Analyses of jet production in e^+e^- collisions are mostly based on JADE data at center-of-mass energies between 14 and 44 GeV, as well as on LEP data at the Z resonance and up to 209 GeV. They cover the measurements of (differential or exclusive) jet rates (with multiplicities typically up to 4, 5 or 6 jets), the study of 3-jet events and particle production between the jets as a tool for testing hadronization models, as well as 4-jet production and angular correlations in 4-jet events. The latter are useful for measurements of the strong coupling constant and putting constraints on the QCD color factors, thus probing the non-abelian nature of QCD. There have also been extensive measurements of event shapes. The tuning of parton shower MC models, typically matched to matrix elements for 3-jet production, has led to good descriptions of the available, highly precise data. Especially for the large LEP data sample at the Zpeak, the statistical errors are mostly negligible and the experimental systematic uncertainties are at the per-cent level or even below. These are usually dominated by the uncertainties related to the MC model dependence of the efficiency and acceptance corrections (often referred to as "detector corrections").

9.3.2.2. DIS and photoproduction: Multi-jet production in ep collisions at HERA, both in the DIS and photoproduction regime, allows for tests of QCD factorization (one initial-state proton and its associated PDF versus the hard scattering which leads to high- p_t jets) and NLO calculations which exist for 2- and 3-jet final states. Sensitivity is also obtained to the product of the coupling constant and the gluon PDF. By now experimental uncertainties of the order of 5-10% have been achieved, mostly dominated by jet energy scale uncertainties, whereas statistical errors are negligible to a large extent. For comparison to theoretical predictions, at large jet p_t the PDF uncertainty dominates the theoretical error (typically of order 5 - 10%, in some regions of phase-space up to 20%), therefore jet observables become useful inputs for PDF fits. In general, for Q^2 above $\sim 100 \, \mathrm{GeV^2}$ the data are well described by NLO matrix element calculations, combined with DGLAP evolution equations. Results at lower values ($Q^2 < 100 \,\mathrm{GeV^2}$) point to the necessity of including NNLO effects. Also, at low values of Q^2 and x, in particular for large jet pseudo-rapidities, there are indications for the need of BFKL-type evolution, though the predictions for such schemes are still limited. In the case of photoproduction, the data-theory comparisons are hampered by the uncertainties related to the photon PDF.

A few examples of recent measurements can be found in Refs. 195-200 for DIS and in Refs. 201-205 for photoproduction.

9.3.2.3. Hadron colliders: Jet measurements at the TEVATRON have been published for data samples up to $\sim 2\,{\rm fb}^{-1}$. Also, first results from the LHC have become available, for a center-of-mass energy of 7 TeV and sample sizes of up to $\sim 36\,\mathrm{pb}^{-1}$. Among the most important cross sections measured is the inclusive jet production as a function of the jet transverse energy (E_t) or the jet transverse momentum (p_t) , for several rapidity regions and for p_t up to 700 GeV at the TEVATRON and ~ 1 TeV at the LHC. The TEVATRON experiments have measurements based on the infrared- and collinear-safe k_t algorithm in addition to the more widely used Midpoint and JetCLU algorithms of the past, whereas the LHC experiments focus on the $anti-k_t$ algorithm. Results by the CDF and D0 collaborations can be found in Refs. 206-208, whereas first measurements of ATLAS and CMS have been published in Refs. 209 and 210, respectively. In general we observe a good description of the data by the NLO QCD predictions. The experimental systematic uncertainties are dominated by the jet energy scale error, by now quoted to be in the range of 1 to 3% and thus leading to uncertainties of 10 to 60% on the cross section, increasing with p_t . The PDF uncertainties dominate the theoretical error. In fact, inclusive jet data are important inputs to global PDF fits, in particular for constraining the high-x gluon PDF.

A rather comprehensive summary, comparing NLO QCD predictions to data for inclusive jet production in DIS, pp, and $p\bar{p}$ collisions, is given in Ref. 211 and reproduced here in Fig. 9.1.

Dijet events are analyzed in terms of their invariant mass and angular distributions, which allow one to put stringent limits on deviations from the Standard Model, such as quark compositeness (some recent examples can be found in Refs. 212–217). Furthermore, dijet azimuthal correlations between the two leading jets, normalized to the total dijet cross cross section, are an extremely valuable tool for studying the spectrum of gluon radiation in the event. For example, results from the TEVATRON [218] and the LHC [219,220] show that the LO (non-trivial) prediction for this observable, with at most three partons in the final state, is not able to describe the data for an azimuthal separation below $2\pi/3$, where NLO contributions (with 4 partons) restore the agreement with data. In addition, this observable can be employed to tune Monte Carlo predictions of soft gluon radiation. Beyond dijet final states, recently measurements of the production of three or more jets have been performed [221–223], as a means of testing perturbative QCD predictions, tuning MC models, constraining PDFs or determining the strong coupling constant.

Similarly important tests of QCD arise from measurements of vector boson (photon, W, Z) production together with jets. A recent analysis of photon+jet production by D0 [224] indicates that NLO calculations, combined with modern PDF sets, are unable to describe the shape of the photon p_t across the entire measured range, showing the need for an improved and consistent theoretical description of this

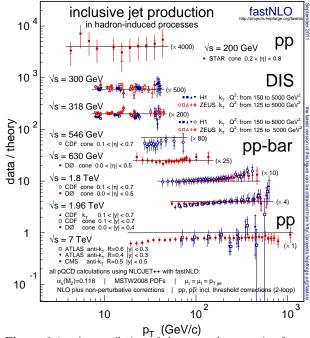

Figure 9.1: A compilation of data-over-theory ratios for inclusive jet cross sections as a function of jet transverse momentum (p_T) , measured in different hadron-induced processes at different center-of-mass energies; from Ref. 211. The various ratios are scaled by arbitrary numbers (indicated between parentheses) for better readability of the plot. The theoretical predictions have been obtained at NLO accuracy, for parameter choices (coupling constant, PDFs, renormalization, and factorization scales) as indicated at the bottom of the figure.

process.

In the case of Z+jets, the Z momentum can be precisely reconstructed using the leptons, allowing for a precise determination of the Z p_t distribution, which is sensitive to QCD radiation both at high and low scales and thus probes perturbative as well as non-perturbative effects. For example, a recent D0 result [225] quotes experimental statistical and systematic uncertainties of the order of 10%, increasing up to 20% in the lowest momentum range. The data are compared to predictions from NLO QCD and from different Monte Carlo models, where, for example, LO matrix elements for up to three partons are matched to a parton shower. Whereas the total cross section is underestimated, the shape is well reproduced over a large phase-space region. Similar conclusions are drawn from further results on Z (or W) plus jets production, both from the TEVATRON [226–231] and the LHC [232,233]. A very important recent development is the completion of NLO calculations for vector boson plus 3jet [75–77] and 4jet production [78,79], which is relevant also for background estimations in the searches for new physics. This type of process is an example where jets need to be found with an infrared and collinear safe jet algorithm in order to obtain finite NLO predictions. This would not be possible with algorithms such as Midpoint or JetCLU, used in analyses at the TEVATRON [228,231]. There the measurements are compared to the NLO QCD prediction obtained with SISCone as jet algorithm. Besides this inconsistency, the agreement appears to be reasonably good.

Finally, examples of recent TEVATRON measurements of heavy quark (b, c) jet production, inclusive or in association with vector bosons, can be found in Refs. 234–240. Also, first results for vector boson production in association with b-jets have been obtained at the LHC [241,242]. It is worth noting that for W+b production there is some tension between the measurements and the NLO predictions, in particular in the case of the CDF result [239].

9.3.3. Tests of the non-abelian nature of QCD:

QCD is a gauge theory with SU(3) as underlying gauge group. For a general gauge theory with a simple Lie group, the couplings of the fermion fields to the gauge fields and the self-interactions in the non-abelian case are determined by the coupling constant and Casimir operators of the gauge group, as introduced in Sec. 9.1. Measuring the eigenvalues of these operators, called color factors, probes the underlying structure of the theory in a gauge invariant way and provides evidence of the gluon self-interactions. Typically, cross sections can be expressed as functions of the color factors, for example $\sigma = f(\alpha_s C_F, C_A/C_F, n_f T_R/C_F)$. Sensitivity at leading order in perturbation theory can be achieved by measuring angular correlations in 4-jet events in e^+e^- annihilation or 3-jet events in DIS. Some sensitivity, although only at NLO, is also obtained from event-shape distributions. Scaling violations of fragmentation functions and the different subjet structure in quark and gluon induced jets also give access to these color factors. In order to extract absolute values, e.g. for C_F and C_A , certain assumptions have to be made for other parameters, such as T_R , n_f or α_s , since typically only combinations (ratios, products) of all the relevant parameters appear in the perturbative prediction. A recent compilation of results [176] quotes world average values of $C_A = 2.89 \pm 0.03 (\mathrm{stat}) \pm 0.21 (\mathrm{syst})$ and $C_F = 1.30 \pm 0.01 ({\rm stat}) \pm 0.09 ({\rm syst})$, with a correlation coefficient of 82%. These results are in perfect agreement with the expectations from SU(3) of $C_A = 3$ and $C_F = 4/3$. An overview of the history and the current status of tests of Asymptotic Freedom, closely related to the non-abelian nature of QCD, can be found in Ref. 243.

9.3.4. Measurements of the strong coupling constant:

If the quark masses are fixed, there is only one free parameter in the QCD Lagrangian, the strong coupling constant α_s . The coupling constant in itself is not a physical observable, but rather a quantity defined in the context of perturbation theory, which enters predictions for experimentally measurable observables, such as R in Eq. (9.7).

Many experimental observables are used to determine α_s . Considerations in such determinations include:

- The observable's sensitivity to α_s as compared to the experimental precision. For example, for the e^+e^- cross section to hadrons (cf. R in Sec. 9.2.1), QCD effects are only a small correction, since the perturbative series starts at order α_s^0 , 3-jet production or event shapes in e^+e^- annihilations are directly sensitive to α_s since they start at order α_s ; the hadronic decay width of heavy quarkonia, $\Gamma(\Upsilon \to \text{hadrons})$, is very sensitive to α_s since its leading order term is $\propto \alpha_s^3$.
- The accuracy of the perturbative prediction, or equivalently of the relation between α_s and the value of the observable. The minimal requirement is generally considered to be an NLO prediction. Some observables are predicted to NNLO (many inclusive observables, 3-jet rates and event shapes in e^+e^- collisions) or even N³LO (e^+e^- hadronic cross section and τ branching fraction to hadrons). In certain cases, fixed-order predictions are supplemented with resummation. The precise magnitude of theory uncertainties is usually estimated as discussed in Sec. 9.2.3.
- The size of uncontrolled non-perturbative effects (except for lattice-based determinations of α_s). Sufficiently inclusive quantities, like the e^+e^- cross section to hadrons, have small non-perturbative uncertainties $\sim \Lambda^4/Q^4$. Others, such as event-shape distributions, have uncertainties $\sim \Lambda/Q$.
- The scale at which the measurement is performed. An uncertainty δ on a measurement of $\alpha_s(Q^2)$, at a scale Q, translates to an uncertainty $\delta' = (\alpha_s^2(M_Z^2)/\alpha_s^2(Q^2)) \cdot \delta$ on $\alpha_s(M_Z^2)$. For example, this enhances the already important impact of precise low-Q measurements, such as from τ decays, in combinations performed at the M_Z scale.

In this review, we update the measurements of α_s summarized in the 2009 review, which was based on an analysis by Bethke [244], and we extract a new world average value of $\alpha_s(M_Z^2)$ from the most significant and complete results available today.

 $^{^{\}sharp}$ The time evolution of α_s combinations can be followed by consult-

While in general we follow the same selection strategy and summary procedure as applied in the 2009 review, here we restrict the selection of results from which to calculate the world average value of $\alpha_s(M_Z^2)$ to those which are

- published in a peer-reviewed journal
- based on the most complete perturbative QCD predictions, i.e. to those using NNLO or higher order expansions.

While this excludes e.g. results from jet production in DIS at HERA and at the Tevatron, as well as those from heavy quarkonia decays for which calculations are available in NLO only, these NLO results will nevertheless be listed and cited in this review as they are important ingredients for the experimental evidence of the energy dependence of α_s , i.e. for Asymptotic Freedom, one of the key features of QCD.

In addition, here we add an intermediate step of pre-averaging results within certain sub-fields like e^+e^- -annihilation, DIS and hadronic τ -decays, and calculate the overall world average from those pre-averages rather than from individual measurements. This is done because in a number of sub-fields one observes that different determinations of the strong coupling from substantially similar datasets lead to values of α_s that are only marginally compatible with each other, or with the final world average value, which presumably is a reflection of the challenges of evaluating systematic uncertainties. In such cases, a pre-average value will be determined, with a symmetric, overall error that encompasses the central values of all individual determinations.

$Hadronic \tau decays$

Several re-analyses of the hadronic τ decay width [17,246–250], based on the new N³LO predictions [17], have been performed, with different approaches towards the detailed treatment of the perturbative (fixed-order or contour-improved perturbative expansions) and nonperturbative contributions. We also include the result from τ decay and lifetime measurements, obtained in Sec. Electroweak Model and constraints on New Physics of this Review, which amounts, if converted to the τ -mass scale and for $n_f = 3$ quark flavours, to $\alpha_s(M_\tau)=0.327^{+0.019}_{-0.016}.$ This result and the one from Baikov et al. [17] include both fixed-order and contour-improved perturbation, while the others adhere to either one or the other of the two. All these results are summarized in Fig. 9.2(a). We note that there are more studies of α_s from τ -decays, [251–254], which are not yet available as peer-reviewed publications but which are compatible with the overall picture. Another recent study [255] argues that an improved treatment of non-perturbative effects results in values of α_s which are systematically lower than those discussed above. Results using the same analysis framework, but employing an updated version of the OPAL tau spectral function data are reported in Ref. 256, which at the time of writing was as yet unpublished.

We determine the pre-average result from τ -decays, to be used for calculating the final world average of $\alpha_s(M_Z^2)$, using the simple method defined above, as $\alpha_s(M_\tau^2) = 0.330 \pm 0.014$, which spans the range of central values obtained by the different groups. This value of $\alpha_s(M_\tau^2)$ corresponds, when evolved to the scale of the Z-boson, using the QCD 4-loop beta-function plus 3-loop matching at the charmand the bottom-quark masses (see Sec. Quark Masses in this Review), to $\alpha_s(M_Z^2) = 0.1197 \pm 0.0016$, unchanged from its value in the 2009 review.

Lattice QCD

There are several recent results on α_s from lattice QCD, see also Sec. Lattice QCD in this Review. The HPQCD collaboration [257] computes Wilson loops and similar short-distance quantities with lattice QCD and analyzes them with NNLO perturbative QCD. This yields a value for α_s , but the lattice scale must be related to a physical energy/momentum scale. This is achieved with the Υ' - Υ mass difference, however, many other quantities could be used as well [258]. HPQCD obtains $\alpha_s(M_Z^2) = 0.1184 \pm 0.0006$, where the uncertainty includes effects from truncating perturbation theory, finite lattice spacing and extrapolation of lattice data. An

independent perturbative analysis of a subset of the same lattice-QCD data yields $\alpha_s(M_Z^2) = 0.1192 \pm 0.0011$ [259]. Using another, independent methodology, the current-current correlator method, HPQCD obtains $\alpha_s(M_Z^2) = 0.1183 \pm 0.0007$ [257]. The analysis of Ref. 89, which avoids the staggered fermion treatment of Ref. 257, finds $\alpha_s(M_Z^2) = 0.1205 \pm 0.0008 \pm 0.0005 ^{+0.0000}_{-0.0017}$, where the first uncertainty is statistical and the others are from systematics. Since this approach uses a different discretization of lattice fermions and a different general methodology, it provides an independent cross check of other lattice extractions of α_s . Finally, the JLQCD collaboration - in an analysis of Adler functions - obtains $\alpha_s(M_Z^2) = 0.1181 \pm 0.0003 ^{+0.0014}_{-0.0012}$ [261]. A very recent but unpublished study of the ETM collaboration [262] used lattice data with u, d, s and c quarks in the sea, obtaining results which are compatible with those quoted above.

The published lattice results are summarized in Fig. 9.2(b). Since they are compatible with each other, we calculate a pre-average of lattice results using the same method as applied to determine the final world average value of the strong coupling, i.e. calculate a weighted average and a (correlated) error such that the overall χ^2 equals unity per degree of freedom - rather than using the simple method as applied in the case of τ decays. This gives $\alpha_s(M_Z^2) = 0.1185 \pm 0.0007$ which we take as result from the sub-field of lattice determinations.

Deep inelastic lepton-nucleon scattering (DIS)

Studies of DIS final states have led to a number of precise determinations of α_s : A combination [263] of precision measurements at HERA, based on NLO fits to inclusive jet cross sections in neutral current DIS at high Q^2 , quotes a combined result of $\alpha_s(M_Z^2) = 0.1198 \pm 0.0032$, which includes a theoretical uncertainty of ± 0.0026 . A combined analysis of non-singlet structure functions from DIS [264], based on QCD predictions up to N³LO in some of its parts, gave $\alpha_s(M_Z^2) = 0.1142 \pm 0.0023$, including a theoretical error of ± 0.0008 (BBG). Further studies of singlet and non-singlet structure functions, based on NNLO predictions, resulted in $\alpha_s(M_Z^2) = 0.1129 \pm 0.0014$ [265] (ABKM; updated in a recent unpublished note [266]) and in $\alpha_s(M_Z^2) = 0.1158 \pm 0.0035$ [267](JR). The MSTW group [268], also including data on jet production at the Tevatron, obtains, at NNLO $^{\sharp\sharp}$, $\alpha_s(M_Z^2) = 0.1171 \pm 0.0024$. Most recently, the NNPDF group [269] has presented a result, $\alpha_s(M_Z^2) = 0.1173 \pm 0.0011$. which is in line with the one from the MSTW group.

Summarizing these results from world data on structure functions, applying the same method as in the case of summarizing results from τ decays, leads to a pre-average value of $\alpha_s(M_Z^2) = 0.1151 \pm 0.0022$ (see Fig. 9.2(c)).

We note that criticism has been expressed on some of the above extractions. Among the issues raised, we mention the neglect of singlet contributions at $x \ge 0.3$ in pure non-singlet fits [270], the impact and detailed treatment of particular classes of data in the fits [270,271] and possible biases due to insufficiently flexible parametrizations of the PDFs [272].

Heavy quarkonia decays

The most recent extraction of the strong coupling constant from an analysis of radiative Υ decays [273] resulted in $\alpha_s(M_Z)=0.119^{+0.000}_{-0.005}$ This determination is based on QCD in NLO only, so it will not be considered for the final extraction of the world average value of α_s ; it is, however, an important ingredient for the demonstration of Asymptotic Freedom as given in Fig. 9.4.

Hadronic final states of e^+e^- annihilations

Re-analyses of event shapes in e^+e^- -annihilation, measured at the Z peak and LEP2 energies up to 209 GeV, using NNLO predictions matched to NLL resummation, resulted in $\alpha_s(M_Z^2)$ = 0.1224 ± 0.0039 [274], with a dominant theoretical uncertainty of 0.0035, and in $\alpha_s(M_Z^2)=0.1189\pm0.0043$ [275]. Similarly, an analysis of JADE data [276] at center-of-mass energies between 14 and 46 GeV gives $\alpha_s(M_Z^2) = 0.1172 \pm 0.0051$, with contributions from hadronization model (perturbative QCD) uncertainties of 0.0035 (0.0030). A precise determination of α_s from 3-jet production alone, in NNLO, resulted in

 $^{^{\}sharp\sharp}$ Note that for jet production at the hadron collider, only NLO predictions are available, while for the structure functions full NNLO was utilized.

 $\alpha_s(M_Z^2)=0.1175\pm0.0025$ [277]. Computation of the NLO corrections to 5-jet production and comparison to the measured 5-jet rates at LEP [74] gave $\alpha_s(M_Z^2)=0.1156^{+0.0041}_{-0.0034}$. More recently, a study using the world data of Thrust distributions and soft-collinear effective theory, including fixed order NNLO, gave $\alpha_s(M_Z^2)=0.1135\pm0.0010$ [278]. We note that there is criticism on both classes of α_s extractions just described: those based on corrections of non-perturbative hadronisation effects using QCD-inspired Monte Carlo generators (since the parton level of a Monte Carlo is not defined in a manner equivalent to that of a fixed-order calculation), as well as the studies based on effective field theory, as their systematics have not yet been verified e.g. by using observables other than Thrust.

A summary of the e^+e^- results based on NNLO predictions is shown in Fig. 9.2(d). They average, according to the simple procedure defined above, to $\alpha_s(M_Z^2)=0.1172\pm0.0037$.

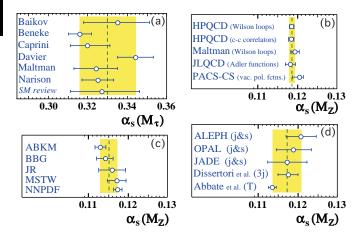

Figure 9.2: Summary of determinations of α_s from hadronic τ -decays (a), from lattice calculations (b), from DIS structure functions (c) and from event shapes and jet production in e^+e^- -annihilation (d). The shaded bands indicate the average values chosen to be included in the determination of the new world average of α_s .

Hadron collider jets

A determination of α_s from the p_T dependence of the inclusive jet cross section in $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV, in the transverse momentum range of $50 < p_T < 145$ GeV, based on NLO $(\mathcal{O}(\alpha_s^3))$ QCD, led to $\alpha_s(M_Z^2)=0.1161^{+0.0041}_{-0.0048}$ [279], which is the most precise α_s result obtained at a hadron collider. Experimental uncertainties from the jet energy calibration, the p_T resolution and the integrated luminosity dominate the overall error.

Electroweak precision fits

The N³LO calculation of the hadronic Z decay width was used in a revision of the global fit to electroweak precision data [280], resulting in $\alpha_s(M_Z^2)=0.1193\pm0.0028$, claiming a negligible theoretical uncertainty. For this Review the value obtained in Sec. Electroweak model and constraints on new physics from data at the Z-pole, $\alpha_s(M_Z^2)=0.1197\pm0.0028$ will be used instead, as it is based on a more constrained data set where QCD corrections directly enter through the hadronic decay width of the Z. We note that all these results from electroweak precision data, however, strongly depend on the strict validity of Standard Model predictions and the existence of the minimal Higgs mechanism to implement electroweak symmetry breaking. Any - even small - deviation of nature from this model could strongly influence this extraction of α_s .

Determination of the world average value of $\alpha_s(M_Z^2)$

A non-trivial exercise consists in the evaluation of a world-average value for $\alpha_s(M_Z^2)$. A certain arbitrariness and subjective component is inevitable because of the choice of measurements to be included in the average, the treatment of (non-Gaussian) systematic uncertainties of mostly theoretical nature, as well as the treatment of correlations among the various inputs, of theoretical as well as experimental origin.

In earlier reviews [243–245] an attempt was made to take account of such correlations, using methods as proposed, e.g., in Ref. 281, and - likewise - to treat cases of apparent incompatibilities or possibly underestimated systematic uncertainties in a meaningful and well defined manner:

The central value is determined as the weighted average of the different input values. An initial error of the central value is determined treating the uncertainties of all individual measurements as being uncorrelated and being of Gaussian nature, and the overall χ^2 to the central value is determined. If this initial χ^2 is larger than the number of degrees of freedom, i.e. larger than the number of individual inputs minus one, then all individual errors are enlarged by a common factor such that $\chi^2/\text{d.o.f.}$ equals unity. If the initial value of χ^2 is smaller than the number of degrees of freedom, an overall, a-priori unknown correlation coefficient is introduced and determined by requiring that the total $\chi^2/\text{d.o.f.}$ of the combination equals unity. In both cases, the resulting final overall uncertainty of the central value of α_s is larger than the initial estimate of a Gaussian error.

This procedure is only meaningful if the individual measurements are known not to be correlated to large degrees, i.e. if they are not - for instance - based on the same input data, and if the input values are largely compatible with each other and with the resulting central value, within their assigned uncertainties. The list of selected individual measurements discussed above, however, violates both these requirements: there are several measurements based on (partly or fully) identical data sets, and there are results which apparently do not agree with others and/or with the resulting central value, within their assigned individual uncertainty. Examples for the first case are results from the hadronic width of the τ lepton, from DIS processes and from jets and event shapes in e^+e^- final states. An example of the second case is the apparent disagreement between results from the τ width and those from DIS [264] or from Thrust distributions in e^+e^- annihilation [278].

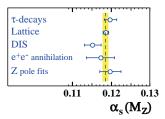

Figure 9.3: Summary of values of $\alpha_s(M_Z^2)$ obtained for various sub-classes of measurements (see Fig. 9.2 (a) to (d)). The new world average value of $\alpha_s(M_Z^2) = 0.1184 \pm 0.0007$ is indicated by the dashed line and the shaded band.

Due to these obstacles, we have chosen to determine pre-averages for each class of measurements, and then to combine those to the final world average value of $\alpha_s(M_Z)$, using the methods of error treatment as just described. The five pre-averages are summarized in Fig. 9.3; we recall that these are exclusively obtained from extractions which are based on (at least) full NNLO QCD predictions, and are published in peer-reviewed journals at the time of completing this Review. From these, we determine the new world average value of

$$\alpha_s(M_Z^2) = 0.1184 \pm 0.0007 ,$$
 (9.23)

with an uncertainty of well below 1 %.*** This world average value is - in spite of several new contributions to this determination - identical to and thus, in excellent agreement with the 2009 result [244]. For

^{***} The weighted average, treating all inputs as uncorrelated measurements with Gaussian errors, results in $\alpha_s(M_Z^2) = 0.11844 \pm 0.00059$ with $\chi^2/\text{d.o.f.} = 3.2/4$. Requiring $\chi^2/\text{d.o.f.}$ to reach unity leads to a common correlation factor of 0.19 which increases the overall error to 0.00072.

convenience, we also provide corresponding values for $\Lambda_{\overline{MS}}$ suitable for use with Eq. (9.5):

$$\Lambda_{\overline{MS}}^{(5)} = (213 \pm 8) \text{ MeV} , \qquad (9.24a)$$

$$\Lambda_{\overline{MS}}^{(4)} = (296 \pm 10) \text{ MeV} ,$$
 (9.24b)

$$\Lambda_{\overline{MS}}^{(3)} = (339 \pm 10) \text{ MeV} ,$$
 (9.24c)

for $n_f = 5$, 4 and 3 quark flavors, respectively.

In order to further test and verify the sensitivity of the new average value of $\alpha_s(M_Z^2)$ to the different pre-averages and classes of α_s determinations, we give each of the averages obtained when leaving out one of the five input values:

$$\alpha_s(M_Z^2) = 0.1182 \pm 0.0007 \text{ (w/o } \tau \text{ results)},$$
 (9.25a)

$$\alpha_s(M_Z^2) = 0.1183 \pm 0.0012 \text{ (w/o lattice results)},$$
 (9.25b)

$$\alpha_s(M_Z^2) = 0.1187 \pm 0.0009 \text{ (w/o DIS results)},$$
 (9.25c)

$$\alpha_s(M_Z^2) = 0.1185 \pm 0.0006 \text{ (w/o } e^+e^- \text{ results)}, \text{ and } (9.25d)$$

$$\alpha_s(M_Z^2) = 0.1184 \pm 0.0006$$
 (w/o res. from e.w. prec. fit)(9.25e)

They are well within the error of the overall world average quoted above. Most notably, the result from lattice calculations, which has the smallest assigned error, agrees well with the exclusive average of the other results. However, it largely determines the size of the (small) overall uncertainty.

There are apparent systematic differences between the various structure function results, and also between the new result from Thrust in e^+e^- annihilation and the other determinations. Expressing this in terms of a χ^2 between a given measurement and the world average as obtained when excluding that particular measurement, the largest values are $\chi^2 = 12.6$ and $\chi^2 = 16.1$, corresponding to 3.5 and 4.0 standard deviations, for the measurements of [265] and [278], respectively. We note that such and other differences between some of the measurements have been extensively discussed at a specific workshop on measurements of α_s , however none of the explanations proposed so far have obtained enough of a consensus to definitely resolve the tensions between different extractions [282].

Notwith standing these open issues, a rather stable and well defined world average value emerges from the compilation of current determinations of α_s :

$$\alpha_s(M_Z^2) = 0.1184 \pm 0.0007$$
.

The results also provide a clear signature and proof of the energy dependence of α_s , in full agreement with the QCD prediction of Asymptotic Freedom. This is demonstrated in Fig. 9.4, where results of $\alpha_s(Q^2)$ obtained at discrete energy scales Q, now also including those based just on NLO QCD, are summarized and plotted.

10. ELECTROWEAK MODEL AND CONSTRAINTS ON NEW PHYSICS

Revised December 2011 by J. Erler (U. Mexico and Institute for Advanced Study) and P. Langacker (Princeton University and Institute for Advanced Study).

- 10.1 Introduction
- 10.2 Renormalization and radiative corrections
- 10.3 Low energy electroweak observables
- 10.4 W and Z boson physics
- 10.5 Precision flavor physics
- 10.6 Experimental results
- 10.7 Constraints on new physics

10.1. Introduction

The standard model of the electroweak interactions (SM) [1] is based on the gauge group SU(2) × U(1), with gauge bosons W_{μ}^{i} , i=1,2,3, and B_{μ} for the SU(2) and U(1) factors, respectively, and the corresponding gauge coupling constants g and g'. The left-handed fermion fields of the i^{th} fermion family transform as doublets

$$\begin{split} \Psi_i &= \begin{pmatrix} \nu_i \\ \ell_i^- \end{pmatrix} \text{ and } \begin{pmatrix} u_i \\ d_i' \end{pmatrix} \text{ under SU(2), where } d_i' \equiv \sum_j V_{ij} \, d_j, \text{ and } V \text{ is} \\ \text{the Cabibbo-Kobayashi-Maskawa mixing matrix. (Constraints on } V \\ \text{and tests of universality are discussed in Ref. 2 and in the Section on "The CKM Quark-Mixing Matrix". The extension of the formalism to allow an analogous leptonic mixing matrix is discussed in the Section on "Neutrino Mass, Mixing, and Oscillations".) The right-handed fields are SU(2) singlets. In the minimal model there are three fermion families. \end{split}$$

A complex scalar Higgs doublet, $\phi \equiv \begin{pmatrix} \phi^+ \\ \phi^0 \end{pmatrix}$, is added to the model for mass generation through spontaneous symmetry breaking with potential* given by,

$$V(\phi) = \mu^2 \phi^{\dagger} \phi + \frac{\lambda^2}{2} (\phi^{\dagger} \phi)^2. \tag{10.1}$$

For μ^2 negative, ϕ develops a vacuum expectation value, $v/\sqrt{2}$, where $v\approx 246.22$ GeV, breaking part of the electroweak (EW) gauge symmetry, after which only one neutral Higgs scalar, H, remains in the physical particle spectrum. In non-minimal models there are additional charged and neutral scalar Higgs particles [3].

After the symmetry breaking the Lagrangian for the fermion fields, ψ_i , is

$$\mathcal{L}_{F} = \sum_{i} \overline{\psi}_{i} \left(i \partial - m_{i} - \frac{g m_{i} H}{2 M_{W}} \right) \psi_{i}$$

$$- \frac{g}{2 \sqrt{2}} \sum_{i} \overline{\Psi}_{i} \gamma^{\mu} (1 - \gamma^{5}) (T^{+} W_{\mu}^{+} + T^{-} W_{\mu}^{-}) \Psi_{i}$$

$$- e \sum_{i} q_{i} \overline{\psi}_{i} \gamma^{\mu} \psi_{i} A_{\mu}$$

$$- \frac{g}{2 \cos \theta_{W}} \sum_{i} \overline{\psi}_{i} \gamma^{\mu} (g_{V}^{i} - g_{A}^{i} \gamma^{5}) \psi_{i} Z_{\mu} . \tag{10.2}$$

 $\theta_W \equiv \tan^{-1}(g'/g)$ is the weak angle; $e = g \sin \theta_W$ is the positron electric charge; and $A \equiv B \cos \theta_W + W^3 \sin \theta_W$ is the photon field (γ) . $W^{\pm} \equiv (W^1 \mp i W^2)/\sqrt{2}$ and $Z \equiv -B \sin \theta_W + W^3 \cos \theta_W$ are the charged and neutral weak boson fields, respectively. The Yukawa coupling of H to ψ_i in the first term in \mathcal{L}_F , which is flavor diagonal in the minimal model, is $gm_i/2M_W$. The boson masses in the EW sector are given (at tree level, *i.e.*, to lowest order in perturbation theory) by,

$$M_H = \lambda v, \tag{10.3a}$$

$$M_W = \frac{1}{2}g\,v = \frac{e\,v}{2\sin\theta_W},\tag{10.3b}$$

$$M_Z = \frac{1}{2} \sqrt{g^2 + g'^2} v = \frac{e \, v}{2 \sin \theta_W \cos \theta_W} = \frac{M_W}{\cos \theta_W},$$
 (10.3c)

$$M_{\gamma} = 0. \tag{10.3d}$$

The second term in \mathscr{L}_F represents the charged-current weak interaction [4–7], where T^+ and T^- are the weak isospin raising and lowering operators. For example, the coupling of a W to an electron and a neutrino is

$$-\frac{e}{2\sqrt{2}\sin\theta_W} \left[W_{\mu}^{-} \overline{e} \gamma^{\mu} (1 - \gamma^5) \nu + W_{\mu}^{+} \overline{\nu} \gamma^{\mu} (1 - \gamma^5) e \right]. \quad (10.4)$$

For momenta small compared to M_W , this term gives rise to the effective four-fermion interaction with the Fermi constant given by $G_F/\sqrt{2}=1/2v^2=g^2/8M_W^2$. CP violation is incorporated into the EW model by a single observable phase in V_{ij} .

The third term in \mathcal{L}_F describes electromagnetic interactions (QED) [8–10], and the last is the weak neutral-current interaction [5–7]. The vector and axial-vector couplings are

$$g_V^i \equiv t_{3L}(i) - 2q_i \sin^2 \theta_W, \tag{10.5a}$$

$$g_A^i \equiv t_{3L}(i), \tag{10.5b}$$

where $t_{3L}(i)$ is the weak isospin of fermion i (+1/2 for u_i and ν_i ; -1/2 for d_i and e_i) and q_i is the charge of ψ_i in units of e.

The first term in Eq. (10.2) also gives rise to fermion masses, and in the presence of right-handed neutrinos to Dirac neutrino masses. The possibility of Majorana masses is discussed in the Section on "Neutrino Mass, Mixing, and Oscillations".

10.2. Renormalization and radiative corrections

In addition to the Higgs boson mass, M_H , the fermion masses and mixings, and the strong coupling constant, α_s , the SM has three parameters. A particularly useful set contains the Z mass**, the Fermi constant, and the fine structure constant, which will be discussed in turn:

The Z boson mass, $M_Z=91.1876\pm0.0021$ GeV, has been determined from the Z lineshape scan at LEP 1 [11].

The Fermi constant, $G_F=1.1663787(6)\times 10^{-5}~{\rm GeV^{-2}},$ is derived from the muon lifetime formula***,

$$\frac{\hbar}{\tau_{\mu}} = \frac{G_F^2 m_{\mu}^5}{192\pi^3} F(\rho) \left[1 + H_1(\rho) \frac{\widehat{\alpha}(m_{\mu})}{\pi} + H_2(\rho) \frac{\widehat{\alpha}^2(m_{\mu})}{\pi^2} \right], \quad (10.6)$$

where $\rho = m_e^2/m_\mu^2$, and where

$$F(\rho) = 1 - 8\rho + 8\rho^3 - \rho^4 - 12\rho^2 \ln \rho = 0.99981295,$$
 (10.7a)

$$H_1(\rho) = \frac{25}{8} - \frac{\pi^2}{2} - \left(9 + 4\pi^2 + 12\ln\rho\right)\rho$$
$$+ 16\pi^2\rho^{3/2} + \mathcal{O}(\rho^2) = -1.80793, \tag{10.7b}$$

$$\begin{split} H_2(\rho) &= \frac{156815}{5184} - \frac{518}{81}\pi^2 - \frac{895}{36}\zeta(3) + \frac{67}{720}\pi^4 + \frac{53}{6}\pi^2\ln 2 \\ &- (0.042 \pm 0.002)_{\rm had} - \frac{5}{4}\pi^2\sqrt{\rho} + \mathcal{O}(\rho) = 6.64, \end{split} \tag{10.7c}$$

$$\hat{\alpha}(m_{\mu})^{-1} = \alpha^{-1} + \frac{1}{3\pi} \ln \rho + \mathcal{O}(\alpha) = 135.901$$
 (10.7d)

The massless corrections to H_1 and H_2 have been obtained in Refs. 13 and 14, respectively, where the term in parentheses is from the hadronic vacuum polarization [14]. The mass corrections to H_1 have been known for some time [15], while those to H_2 are more recent [16]. Notice the term linear in m_e whose appearance was

^{*} There is no generally accepted convention to write the quartic term. Our numerical coefficient simplifies Eq. (10.3a) below and the squared coupling preserves the relation between the number of external legs and the power counting of couplings at a given loop order. This structure also naturally emerges from physics beyond the SM, such as supersymmetry.

^{**} We emphasize that in the fits described in Sec. 10.6 and Sec. 10.7 the values of the SM parameters are affected by all observables that depend on them. This is of no practical consequence for α and G_F , however, since they are very precisely known.

^{***} In the spirit of the Fermi theory, we incorporated the small propagator correction, $3/5~m_{\mu}^2/M_W^2$, into Δr (see below). This is also the convention adopted by the MuLan collaboration [12]. While this breaks with historical consistency, the numerical difference was negligible in the past.

unforeseen and can be traced to the use of the muon pole mass in the prefactor [16]. The remaining uncertainty in G_F is experimental and has recently been reduced by an order of magnitude by the MuLan collaboration [12] at the PSI.

The fine structure constant, $\alpha = 1/137.035999074(44)$, is currently dominated by the e^{\pm} anomalous magnetic moment [10]. In most EW renormalization schemes, it is convenient to define a running α dependent on the energy scale of the process, with $\alpha^{-1} \sim 137$ appropriate at very low energy, i.e. close to the Thomson limit. (The running has also been observed [17] directly.) For scales above a few hundred MeV this introduces an uncertainty due to the low energy hadronic contribution to vacuum polarization. In the modified minimal subtraction (MS) scheme [18] (used for this Review), and with $\alpha_s(M_Z) = 0.120$, we have $\hat{\alpha}(m_\tau)^{-1} = 133.471 \pm 0.014$ and $\widehat{\alpha}(M_Z)^{-1} = 127.944 \pm 0.014$. (In this Section we denote quantities defined in the modified minimal subtraction (MS) scheme by a caret; the exception is the strong coupling constant, α_s , which will always correspond to the $\overline{\rm MS}$ definition and where the caret will be dropped.) The latter corresponds to a quark sector contribution (without the top) to the conventional (on-shell) QED coupling, $\alpha(M_Z) = \frac{\alpha}{1 - \Delta \alpha(M_Z)}$

of $\Delta\alpha_{\rm had}^{(5)}(M_Z)\approx 0.02772\pm 0.00010$. These values are updated from Ref. 19 with $\Delta\alpha_{\rm had}^{(5)}(M_Z)$ moved downwards and its uncertainty halved (partly due to a more precise charm quark mass). Its correlation with the μ^\pm anomalous magnetic moment (see Sec. 10.5), as well as the non-linear α_s dependence of $\widehat{\alpha}(M_Z)$ and the resulting correlation with the input variable α_s , are fully taken into account in the fits. This is done by using as actual input (fit constraint) instead of $\Delta\alpha_{\rm had}^{(5)}(M_Z)$ the analogous low energy contribution by the three light quarks, $\Delta\alpha_{\rm had}^{(3)}(1.8~{\rm GeV}) = (55.50\pm 0.78)\times 10^{-4}~[20]$, and by calculating the perturbative and heavy quark contributions to $\widehat{\alpha}(M_Z)$ in each call of the fits according to Ref. 19. Part of the uncertainty ($\pm 0.49\times 10^{-4}$) is from e^+e^- annihilation data below 1.8 GeV and τ decay data (including uncertainties from isospin breaking effects), but uncalculated higher order perturbative ($\pm 0.41\times 10^{-4}$) and non-perturbative ($\pm 0.44\times 10^{-4}$) QCD corrections and the $\overline{\rm MS}$ quark mass values (see below) also contribute. Various recent evaluations of $\Delta\alpha_{\rm had}^{(5)}$ are summarized in Table 10.1, where the leading order relation between the $\overline{\rm MS}$ and on-shell definitions is given by,

$$\Delta\widehat{\alpha}(M_Z) - \Delta\alpha(M_Z) = \frac{\alpha}{\pi} \left(\frac{100}{27} - \frac{1}{6} - \frac{7}{4} \ln \frac{M_Z^2}{M_W^2} \right) \approx 0.0072, \quad (10.8)$$

and where the first term is from fermions and the other two are from W^{\pm} loops which are usually excluded from the on-shell definition. Most of the older results relied on $e^+e^- \rightarrow \text{hadrons cross-section}$ measurements up to energies of 40 GeV, which were somewhat higher than the QCD prediction, suggested stronger running, and were less precise. The most recent results typically assume the validity of perturbative QCD (PQCD) at scales of 1.8 GeV and above, and are in reasonable agreement with each other. There is, however, some discrepancy between analyses based on $e^+e^- \rightarrow$ hadrons cross-section data and those based on τ decay spectral functions [20]. The latter utilize data from OPAL [43], CLEO [44], ALEPH [45], and Belle [46] and imply lower central values for the extracted M_H of about 6%. This discrepancy is smaller than in the past and at least some of it appears to be experimental. The dominant $e^+e^- \to \pi^+\pi^-$ crosssection was measured with the CMD-2 [47] and SND [48] detectors at the VEPP-2M e^+e^- collider at Novosibirsk and the results are (after an initial discrepancy due to a flaw in the Monte Carlo event generator used by SND) in good agreement with each other. As an alternative to cross-section scans, one can use the high statistics radiative return events at e^+e^- accelerators operating at resonances such as the Φ or the $\Upsilon(4S)$. The method [49] is systematics limited but dominates

over the Novosibirsk data throughout. The BaBar collaboration [50]studied multi-hadron events radiatively returned from the $\Upsilon(4S)$, reconstructing the radiated photon and normalizing to $\mu^{\pm}\gamma$ final states. Their result is higher compared to VEPP-2M and in fact agrees quite well with the τ analysis including the energy dependence (shape). In contrast, the shape and smaller overall cross-section from the $\pi^+\pi^-$ radiative return results from the Φ obtained by the KLOE collaboration [51] differs significantly from what is observed by BaBar. The discrepancy originates from the kinematic region $\sqrt{s} \gtrsim 0.6$ GeV, and is most pronounced for $\sqrt{s} \gtrsim 0.85$ GeV. All measurements including older data [52] and multi-hadron final states (there are also discrepancies in the $e^+e^- \rightarrow 2\pi^+2\pi^-$ channel [20]) are accounted for and corrections have been applied for missing channels [20]. Further improvement of this dominant theoretical uncertainty in the interpretation of precision data will require better measurements of the cross-section for $e^+e^- \rightarrow$ hadrons below the charmonium resonances including multi-pion and other final states. To improve the precisions in $\widehat{m}_c(\widehat{m}_c)$ and $\widehat{m}_b(\widehat{m}_b)$ it would help to remeasure the threshold regions of the heavy quarks as well as the electronic decay widths of the narrow $c\bar{c}$ and $b\bar{b}$ resonances.

Further free parameters entering into Eq. (10.2) are the quark and lepton masses, where m_i is the mass of the i^{th} fermion ψ_i . For the quarks these are the current masses. For the light quarks, as described in the note on "Quark Masses" in the Quark Listings, $\hat{m}_u = 2.5^{+0.6}_{-0.6}~{\rm MeV},~\hat{m}_d = 5.0^{+0.7}_{-0.9}~{\rm MeV},$ and $\hat{m}_s = 100^{+30}_{-20}~{\rm MeV}.$ These are running $\overline{\rm Ms}$ masses evaluated at the scale $\mu=2~{\rm GeV}.$ For the heavier quarks we use QCD sum rule [53] constraints [54] and recalculate their masses in each call of our fits to account for their direct α_s dependence. We find $\P,~\hat{m}_c(\mu=\hat{m}_c)=1.267^{+0.032}_{-0.042}~{\rm GeV}$ and $\hat{m}_b(\mu=\hat{m}_b)=4.197\pm0.025~{\rm GeV},$ with a correlation of 24%.

The top quark "pole" mass (the quotation marks are a reminder that quarks do not form asymptotic states), $m_t = 173.4 \pm 0.9$ GeV, is an average of published and preliminary CDF and DØ results from run I and II [56] with first results by the CMS [57] and ATLAS [58] collaborations averaged in ignoring correlations. To gauge the possible impact of the neglect of correlations involving the LHC experiments, we also averaged the results conservatively assuming that the entire 0.75 GeV systematic of the Tevatron average is fully correlated with a 0.75 GeV component in both CMS and ATLAS. Incidentally, this yields correlations of similar size as those between the two Tevatron experiments and the two Runs and reduces the central value by 0.15 GeV. Within round-off we expect a more refined average to coincide with ours. Our average\$ differs slightly from the value, $m_t = 173.5 \pm 0.6 \pm 0.8$ GeV, which appears in the top quark Listings in this *Review* and which is based exclusively on published results. We are working, however, with $\overline{\text{MS}}$ masses in all expressions to minimize theoretical uncertainties. Such a short distance mass definition (unlike the pole mass) is free from non-perturbative and renormalon [59] uncertainties. We therefore convert to the top quark $\overline{\text{MS}}$ mass,

$$\hat{m}_t(\mu = \hat{m}_t) = m_t [1 - \frac{4}{3} \frac{\alpha_s}{\pi} + \mathcal{O}(\alpha_s^2)],$$
 (10.9)

using the three-loop formula [60]. This introduces an additional uncertainty which we estimate to 0.5 GeV (the size of the three-loop term) and add in quadrature to the experimental pole mass error. This is convenient because we use the pole mass as an external constraint while fitting to the $\overline{\rm MS}$ mass. We are assuming that the kinematic

 $^{^{\}dagger}$ Eq. (10.8) is for illustration only. Higher order contributions are directly evaluated in the $\overline{\rm MS}$ scheme using the FORTRAN package GAPP [21], including three-loop QED contributions of both leptons and quarks. The leptonic three-loop contribution in the on-shell scheme has been obtained in Ref. 22.

Other authors [55] advocate to evaluate and quote $\widehat{m}_c(\mu=3~{\rm GeV})$ instead. We use $\widehat{m}_c(\mu=\widehat{m}_c)$ because in the global analysis it is convenient to nullify any explicitly m_c dependent logarithms. Note also that our uncertainty for m_c (and to a lesser degree for m_b) is larger than the one in Ref. 55, for example. The reason is that we determine the continuum contribution for charm pair production using only resonance data and theoretical consistency across various sum rule moments, and then use any difference to the experimental continuum data as an additional uncertainty. We also include an uncertainty for the condensate terms which grows rapidly for higher moments in the sum rule analysis.

[§] At the time of writing this review, the efforts to establish a top quark averaging group involving both the Tevatron and the LHC were still in progress. Therefore we perform a simplified average ourselves.

mass extracted from the collider events corresponds within this uncertainty to the pole mass. Using the BLM optimized [61] version of the two-loop perturbative QCD formula [62] (as we did in previous editions of this Review) gives virtually identical results. In summary, we will use $m_t = 173.4 \pm 0.9 \; (\text{exp.}) \pm 0.5 \; (\text{QCD}) \; \text{GeV} = 173.4 \pm 1.0 \; \text{GeV}$ (together with $M_H = 117 \; \text{GeV}$) for the numerical values quoted in Sec. 10.2–Sec. 10.5.

 $\sin^2 \theta_W$ and M_W can be calculated from M_Z , $\widehat{\alpha}(M_Z)$, and G_F , when values for m_t and M_H are given; conversely (as is done at present), M_H can be constrained by $\sin^2 \theta_W$ and M_W . The value of $\sin^2 \theta_W$ is extracted from neutral-current processes (see Sec. 10.3) and Z pole observables (see Sec. 10.4) and depends on the renormalization prescription. There are a number of popular schemes [63–70] leading to values which differ by small factors depending on m_t and M_H . The notation for these schemes is shown in Table 10.1.

Table 10.1: Notations used to indicate the various schemes discussed in the text. Each definition of $\sin^2 \theta_W$ leads to values that differ by small factors depending on m_t and M_H . Approximate values are also given for illustration.

| Scheme | Notation | Value |
|---------------------------------------|------------------------|--------|
| On-shell | s_W^2 | 0.2231 |
| NOV | $s_{M_Z}^2$ | 0.2310 |
| $\overline{ m MS}$ | \widehat{s}_Z^2 | 0.2312 |
| $\overline{\mathrm{MS}}\ \mathrm{ND}$ | $\hat{s}_{	ext{ND}}^2$ | 0.2314 |
| Effective angle | \overline{s}_f^2 | 0.2315 |

(i) The on-shell scheme [63] promotes the tree-level formula $\sin^2\theta_W = 1 - M_W^2/M_Z^2$ to a definition of the renormalized $\sin^2\theta_W$ to all orders in perturbation theory, i.e., $\sin^2\theta_W \to s_W^2 \equiv 1 - M_W^2/M_Z^2$:

$$M_W = \frac{A_0}{s_W (1 - \Delta r)^{1/2}} , \qquad M_Z = \frac{M_W}{c_W} , \qquad (10.10)$$

where $c_W \equiv \cos\theta_W$, $A_0 = (\pi\alpha/\sqrt{2}G_F)^{1/2} = 37.28039(1)$ GeV, and Δr includes the radiative corrections relating α , $\alpha(M_Z)$, G_F , M_W , and M_Z . One finds $\Delta r \sim \Delta r_0 - \rho_t/\tan^2\theta_W$, where $\Delta r_0 = 1 - \alpha/\widehat{\alpha}(M_Z) = 0.06635(10)$ is due to the running of α , and $\rho_t = 3G_F m_t^2/8\sqrt{2}\pi^2 = 0.00943 (m_t/173.4 \text{ GeV})^2$ represents the dominant (quadratic) m_t dependence. There are additional contributions to Δr from bosonic loops, including those which depend logarithmically on M_H . One has $\Delta r = 0.0358 \mp 0.0004 \pm 0.00010$, where the first uncertainty is from m_t and the second is from $\alpha(M_Z)$. Thus the value of s_W^2 extracted from M_Z includes an uncertainty (∓ 0.00012) from the currently allowed range of m_t . This scheme is simple conceptually. However, the relatively large ($\sim 3\%$) correction from ρ_t causes large spurious contributions in higher orders.

(ii) A more precisely determined quantity s_{MZ}^2 [64] can be obtained from M_Z by removing the (m_t, M_H) dependent term from Δr [65], i.e.,

$$s_{M_Z}^2 (1 - s_{M_Z}^2) \equiv \frac{\pi \alpha(M_Z)}{\sqrt{2} G_F M_Z^2}$$
 (10.11)

Using $\alpha(M_Z)^{-1}=128.93\pm0.02$ yields $s_{M_Z}^2=0.23102\mp0.00005$. The small uncertainty in $s_{M_Z}^2$ compared to other schemes is because the m_t dependence has been removed by definition. However, the m_t uncertainty reemerges when other quantities (e.g., M_W or other Z pole observables) are predicted in terms of M_Z .

Both s_W^2 and $s_{M_Z}^2$ depend not only on the gauge couplings but also on the spontaneous-symmetry breaking, and both definitions are awkward in the presence of any extension of the SM which perturbs the value of M_Z (or M_W). Other definitions are motivated by the tree-level coupling constant definition $\theta_W = \tan^{-1}(g'/g)$:

(iii) In particular, the modified minimal subtraction ($\overline{\rm MS}$) scheme introduces the quantity $\sin^2 \widehat{\theta}_W(\mu) \equiv \widehat{g}^{\prime 2}(\mu)/[\widehat{g}^{\,2}(\mu)+\widehat{g}^{\prime 2}(\mu)]$, where the couplings \widehat{g} and \widehat{g}^\prime are defined by modified minimal subtraction and the scale μ is conveniently chosen to be M_Z for many EW processes. The value of $\hat{s}_Z^2 = \sin^2 \hat{\theta}_W(M_Z)$ extracted from M_Z is less sensitive than s_W^2 to m_t (by a factor of $\tan^2 \theta_W$), and is less sensitive to most types of new physics than s_W^2 or $s_{M_Z}^2$. It is also very useful for comparing with the predictions of grand unification. There are actually several variant definitions of $\sin^2 \theta_W(M_Z)$, differing according to whether or how finite $\alpha \ln(m_t/M_Z)$ terms are decoupled (subtracted from the couplings). One cannot entirely decouple the $\alpha \ln(m_t/M_Z)$ terms from all EW quantities because $m_t \gg m_b$ breaks SU(2) symmetry. The scheme that will be adopted here decouples the $\alpha \ln(m_t/M_Z)$ terms from the γ -Z mixing [18,66], essentially eliminating any $\ln(m_t/M_Z)$ dependence in the formulae for asymmetries at the Z pole when written in terms of \hat{s}_Z^2 . (A similar definition is used for $\hat{\alpha}$.) The various definitions are related by

$$\hat{s}_Z^2 = c(m_t, M_H) s_W^2 = \overline{c}(m_t, M_H) s_{M_Z}^2 , \qquad (10.12)$$

where $c=1.0362\pm0.0004$ and $\overline{c}=1.0009\mp0.0002$. The quadratic m_t dependence is given by $c\sim 1+\rho_t/\tan^2\theta_W$ and $\overline{c}\sim 1-\rho_t/(1-\tan^2\theta_W)$, respectively. The expressions for M_W and M_Z in the $\overline{\rm MS}$ scheme are

$$M_W = \frac{A_0}{\hat{s}_Z (1 - \Delta \hat{r}_W)^{1/2}} , \qquad M_Z = \frac{M_W}{\hat{\rho}^{1/2} \, \hat{c}_Z} , \quad (10.13)$$

and one predicts $\Delta \hat{r}_W = 0.06951 \pm 0.00001 \pm 0.00010$. $\Delta \hat{r}_W$ has no quadratic m_t dependence, because shifts in M_W are absorbed into the observed G_F , so that the error in $\Delta \hat{r}_W$ is dominated by $\Delta r_0 = 1 - \alpha/\hat{\alpha}(M_Z)$ which induces the second quoted uncertainty. The quadratic m_t dependence has been shifted into $\hat{\rho} \sim 1 + \rho_t$, where including bosonic loops, $\hat{\rho} = 1.01051 \pm 0.00011$. Quadratic M_H effects are deferred to two-loop order, while the leading logarithmic M_H effect is a good approximation only for large M_H values which are clearly disfavored by the precision data. As an illustration, the shift in M_W due to a large M_H (for fixed M_Z) is given by

$$\Delta_H M_W = -\frac{11}{96} \frac{\alpha}{\pi} \frac{M_W}{c_W^2 - s_W^2} \ln \frac{M_H^2}{M_W^2} + \mathcal{O}(\alpha^2)$$

$$\sim -200 \text{ MeV (for } M_H = 10 M_W). \tag{10.14}$$

(iv) A variant $\overline{\rm MS}$ quantity $\widehat{s}_{\rm ND}^2$ (used in the 1992 edition of this Review) does not decouple the $\alpha \ln(m_t/M_Z)$ terms [67]. It is related to \widehat{s}_Z^2 by

$$\widehat{s}_Z^2 = \widehat{s}_{ND}^2 / \left(1 + \frac{\widehat{\alpha}}{\pi} d\right), \tag{10.15a}$$

$$d = \frac{1}{3} \left(\frac{1}{\hat{s}^2} - \frac{8}{3} \right) \left[(1 + \frac{\alpha_s}{\pi}) \, \ln \frac{m_t}{M_Z} - \frac{15\alpha_s}{8\pi} \right], \ \ (10.15b)$$

Thus, $\hat{s}_Z^2 - \hat{s}_{ND}^2 \approx -0.0002$.

(v) Yet another definition, the effective angle [68–70] \overline{s}_f^2 for the Z vector coupling to fermion f, is based on Z pole observables and described below.

Experiments are at such level of precision that complete $\mathcal{O}(\alpha)$ radiative corrections must be applied. For neutral-current and Z pole processes, these corrections are conveniently divided into two classes:

- 1. QED diagrams involving the emission of real photons or the exchange of virtual photons in loops, but not including vacuum polarization diagrams. These graphs often yield finite and gaugeinvariant contributions to observable processes. However, they are dependent on energies, experimental cuts, etc., and must be calculated individually for each experiment.
- 2. EW corrections, including $\gamma\gamma$, γZ , ZZ, and WW vacuum polarization diagrams, as well as vertex corrections, box graphs,

etc., involving virtual W and Z bosons. The one-loop corrections are included for all processes, and certain two-loop corrections are also important. In particular, two-loop corrections involving the top quark modify ρ_t in $\hat{\rho}$, Δr , and elsewhere by

$$\rho_t \to \rho_t [1 + R(M_H, m_t)\rho_t/3].$$
(10.16)

 $R(M_H,m_t)$ is best described as an expansion in M_Z^2/m_t^2 . The unsuppressed terms were first obtained in Ref. 71, and are known analytically [72]. Contributions suppressed by M_Z^2/m_t^2 were first studied in Ref. 73 with the help of small and large Higgs mass expansions, which can be interpolated. These contributions are about as large as the leading ones in Refs. 71 and 72. The complete two-loop calculation of Δr (without further approximation) has been performed in Refs. 74 and 75 for fermionic and purely bosonic diagrams, respectively. Similarly, the EW two-loop calculation for the relation between \overline{s}_ℓ^2 and s_W^2 is complete [76] including the recently obtained purely bosonic contribution [77]. For M_H above its lower direct limit, -17 < R < -13.

Mixed QCD-EW contributions to gauge boson self-energies of order $\alpha\alpha_sm_t^2$ [78] and $\alpha\alpha_s^2m_t^2$ [79] increase the predicted value of m_t by 6%. This is, however, almost entirely an artifact of using the pole mass definition for m_t . The equivalent corrections when using the $\overline{\rm MS}$ definition $\widehat{m}_t(\widehat{m}_t)$ increase m_t by less than 0.5%. The subleading $\alpha\alpha_s$ corrections [80] are also included. Further three-loop corrections of order $\alpha\alpha_s^2$ [81], $\alpha^3m_t^6$ [82,83], and $\alpha^2\alpha_sm_t^4$ (for $M_H=0$) [82], are rather small. The same is true for $\alpha^3M_H^4$ [84] corrections unless M_H approaches 1 TeV. Also known are the singlet contributions (pure gluonic intermediate states) of order $\alpha\alpha_s^2$ [85] and $\alpha\alpha_s^3$ [86]. Recently, the corresponding non-singlet contributions have been computed as well [87].

The leading EW two-loop terms for the $Z \to b\bar{b}$ -vertex of $\mathcal{O}(\alpha^2 m_t^4)$ have been obtained in Refs. 71 and 72, and the mixed QCD-EW contributions in Refs. 88 and 89. The authors of Ref. 90 completed the two-loop EW fermionic corrections to \overline{s}_b^2 . The $\mathcal{O}(\alpha \alpha_s)$ -vertex corrections involving massless quarks [91] add coherently, resulting in a sizable effect and shift $\alpha_s(M_Z)$ when extracted from Z lineshape observables (see Sec. 10.4) by $\approx +0.0007$.

Many of the EW corrections are absorbed into the renormalized Fermi constant defined in Eq. (10.6). Others modify the tree-level expressions for Z pole observables and neutral-current amplitudes. In particular, the relations in Eq. (10.5) now read,

 $\overline{g}_{V}^{f} = \sqrt{\rho_{f}} \, (t_{3L}^{(f)} - 2q_{f} \kappa_{f} \sin^{2} \theta_{W}), \qquad \overline{g}_{A}^{f} = \sqrt{\rho_{f}} \, t_{3L}^{(f)}, \qquad (10)$ where the EW radiative corrections have been absorbed into corrections $\rho_f - 1$ and $\kappa_f - 1$, which depend on the fermion f and on the renormalization scheme. In the on-shell scheme, the quadratic m_t dependence is given by $\rho_f \sim 1 + \rho_t$, $\kappa_f \sim 1 + \rho_t / \tan^2 \theta_W$, while in $\overline{\text{MS}}$, $\widehat{\rho}_f \sim \widehat{\kappa}_f \sim 1$, for $f \neq b$ $(\widehat{\rho}_b \sim 1 - \frac{4}{3}\rho_t, \, \widehat{\kappa}_b \sim 1 + \frac{2}{3}\rho_t)$. In the $\overline{\rm MS}$ scheme the normalization is changed according to $G_F M_Z^2/2\sqrt{2}\pi \to \hat{\alpha}/4\hat{s}_Z^2\hat{c}_Z^2$. (If one continues to normalize amplitudes by $G_F M_Z^2/2\sqrt{2}\pi$, as in the 1996 edition of this Review, then $\hat{\rho}_f$ contains an additional factor of $\widehat{\rho}(1-\Delta \widehat{r}_W)\widehat{\alpha}/\alpha$.) In practice, additional bosonic and fermionic loops, vertex corrections, leading higher order contributions, etc., must be included. For example, in the $\overline{\text{MS}}$ scheme one has $\widehat{\rho}_{\ell} = 0.9981$, $\widehat{\kappa}_{\ell} = 1.0013$, $\widehat{\rho}_{b} = 0.9869$, and $\widehat{\kappa}_b$ = 1.0067. It is convenient to define an effective angle $\overline{s}_f^2 \equiv \sin^2 \overline{\theta}_{Wf} \equiv \widehat{\kappa}_f \widehat{s}_Z^2 = \kappa_f s_W^2$, in terms of which \overline{g}_V^f and \overline{g}_A^f are given by $\sqrt{\rho_f}$ times their tree-level formulae. Because \overline{g}_V^ℓ is very small, not only $A_{LR}^0 = A_e$, $A_{FB}^{(0,\ell)}$, and \mathcal{P}_{τ} , but also $A_{FB}^{(0,b)}$, $A_{FB}^{(0,c)}$, $A_{FB}^{(0,s)},$ and the hadronic asymmetries are mainly sensitive to $\overline{s}_{\ell}^2.$ One finds that $\hat{\kappa}_f$ $(f \neq b)$ is almost independent of (m_t, M_H) , so that one can write

$$\overline{s}_{\ell}^2 \sim \hat{s}_Z^2 + 0.00029 \ .$$
 (10.18)

Thus, the asymmetries determine values of \overline{s}_{ℓ}^2 and \widehat{s}_Z^2 almost independent of m_t , while the κ 's for the other schemes are m_t dependent.

Table 10.2: Standard Model expressions for the neutral-current parameters for ν -hadron, ν -e, and e^- -scattering processes. At tree level, $\rho=\kappa=1,\;\lambda=0.$ If radiative corrections are included, $\rho_{\nu N}=1.0082,\;\hat{\kappa}_{\nu N}(\langle Q^2\rangle=-20~{\rm GeV^2})=0.9972,\;\hat{\kappa}_{\nu N}(\langle Q^2\rangle=-35~{\rm GeV^2})=0.9965,\;\lambda_{uL}=-0.0031,\;\lambda_{dL}=-0.0025~{\rm and}\;\lambda_R=3.7\times10^{-5}.$ For ν -e scattering, $\rho_{\nu e}=1.0128$ and $\hat{\kappa}_{\nu e}=0.9963$ (at $\langle Q^2\rangle=0.$). For atomic parity violation and the polarized DIS experiment at SLAC, $\rho_e'=0.9887,\;\rho_e=1.0007,\;\hat{\kappa}_e'=1.0038,\;\hat{\kappa}_e=1.0297,\;\lambda'=-1.8\times10^{-5},\;\lambda_u=-0.0118$ and $\lambda_d=0.0029.$ And for polarized Møller scattering with SLAC (JLab) kinematics, $\lambda_e=-0.0002$ ($\lambda_e=-0.0004$). The dominant m_t dependence is given by $\rho\sim1+\rho_t,$ while $\hat{\kappa}\sim1~(\overline{\rm MS})$ or $\kappa\sim1+\rho_t/\tan^2\theta_W$ (on-shell).

| Quantity | Standard Model Expression |
|---------------------|--------------------------------------------------------------------------------------------------------------------|
| $\epsilon_L(u)$ | $\rho_{\nu N} \left(\frac{1}{2} - \frac{2}{3} \widehat{\kappa}_{\nu N} \widehat{s}_Z^2 \right) + \lambda_{uL}$ |
| $\epsilon_L(d)$ | $\rho_{\nu N} \left(-\frac{1}{2} + \frac{1}{3} \widehat{\kappa}_{\nu N} \widehat{s}_Z^2 \right) + \lambda_{dL}$ |
| $\epsilon_R(u)$ | $\rho_{\nu N} \left(-\frac{2}{3} \widehat{\kappa}_{\nu N} \widehat{s}_Z^2 \right) + \lambda_R$ |
| $\epsilon_R(d)$ | $\rho_{\nu N} \left(\frac{1}{3} \widehat{\kappa}_{\nu N} \widehat{s}_Z^2 \right) + 2 \lambda_R$ |
| $g_V^{ u e}$ | $\rho_{\nu e} \left(-\frac{1}{2} + 2 \widehat{\kappa}_{\nu e} \widehat{s}_Z^2 \right)$ |
| $g_A^{ u e}$ | $ \rho_{\nu e}\left(-\frac{1}{2}\right) $ |
| $\overline{C_{1u}}$ | $\rho_e'\left(-\frac{1}{2} + \frac{4}{3}\widehat{\kappa}_e'\widehat{s}_Z^2\right) + \lambda'$ |
| C_{1d} | $\rho_e'\left(\frac{1}{2} - \frac{2}{3}\widehat{\kappa}_e'\widehat{s}_Z^2\right) - 2\lambda'$ |
| C_{2u} | $\rho_e \left(-\frac{1}{2} + 2 \widehat{\kappa}_e \widehat{s}_Z^2 \right) + \lambda_u$ |
| C_{2d} | $\rho_e \left(\frac{1}{2} - 2 \widehat{\kappa}_e \widehat{s}_Z^2 \right) + \lambda_d$ |
| C_{2e} | $\rho_e \left(\frac{1}{2} - 2 \widehat{\kappa}_e \widehat{s}_Z^2 \right) + \lambda_e$ |

Throughout this *Review* we utilize EW radiative corrections from the program GAPP [21], which works entirely in the $\overline{\rm MS}$ scheme, and which is independent of the package ZFITTER [70]. Another resource is the recently developed modular fitting toolkit Gfitter [92].

10.3. Low energy electroweak observables

In the following we discuss EW precision observables obtained at low momentum transfers [6], i.e. $Q^2 \ll M_Z^2$. It is convenient to write the four-fermion interactions relevant to ν -hadron, ν -e, as well as parity violating e-hadron and e-e neutral-current processes in a form that is valid in an arbitrary gauge theory (assuming massless left-handed neutrinos). One has,

$$-\mathcal{L}^{\nu h} = \frac{G_F}{\sqrt{2}} \overline{\nu} \gamma^{\mu} (1 - \gamma^5) \nu$$

$$\times \sum_{i} [\epsilon_L(i) \overline{q}_i \gamma_{\mu} (1 - \gamma^5) q_i + \epsilon_R(i) \overline{q}_i \gamma_{\mu} (1 + \gamma^5) q_i], \qquad (10.19)$$

$$-\mathcal{L}^{\nu e} = \frac{G_F}{\sqrt{2}} \bar{\nu}_{\mu} \gamma^{\mu} (1 - \gamma^5) \nu_{\mu} \, \bar{e} \, \gamma_{\mu} (g_V^{\nu e} - g_A^{\nu e} \gamma^5) e, \qquad (10.20)$$

$$-\mathscr{L}^{eh} = -\,\frac{G_F}{\sqrt{2}}\,\sum_i \Big[C_{1i}\,\overline{e}\,\gamma_\mu\gamma^5 e\,\overline{q}_i\,\gamma^\mu q_i + C_{2i}\,\overline{e}\,\gamma_\mu e\,\overline{q}_i\,\,\gamma^\mu\gamma^5 q_i\Big], (10.21)$$

$$-\mathcal{L}^{ee} = -\frac{G_F}{\sqrt{2}} C_{2e} \,\overline{e} \,\gamma_{\mu} \gamma^5 e \,\overline{e} \,\gamma^{\mu} e, \qquad (10.22)$$

where one must include the charged-current contribution for ν_{e} -e and $\overline{\nu}_{e}$ -e and the parity-conserving QED contribution for electron scattering.

The SM expressions for $\epsilon_{L,R}(i)$, $g_{V,A}^{\nu e}$, and C_{ij} are given in Table 10.2. Note, that $g_{V,A}^{\nu e}$ and the other quantities are coefficients of effective four-Fermi operators, which differ from the quantities defined in Eq. (10.5) in the radiative corrections and in the presence of possible physics beyond the SM.

10.3.1. Neutrino scattering: For a general review on ν -scattering we refer to Ref. 93 (nonstandard neutrino scattering interactions are surveyed in Ref. 94).

The cross-section in the laboratory system for $\nu_{\mu}e \rightarrow \nu_{\mu}e$ or $\overline{\nu}_{\mu}e \rightarrow \overline{\nu}_{\mu}e$ elastic scattering [95] is

$$\frac{d\sigma_{\nu,\bar{\nu}}}{dy} = \frac{G_F^2 m_e E_{\nu}}{2\pi} \left[(g_V^{\nu e} \pm g_A^{\nu e})^2 + (g_V^{\nu e} \mp g_A^{\nu e})^2 (1-y)^2 - (g_V^{\nu e2} - g_A^{\nu e2}) \frac{y \, m_e}{E_{\nu}} \right]$$
(10.23)

where the upper (lower) sign refers to $\nu_{\mu}(\overline{\nu}_{\mu})$, and $y \equiv T_e/E_{\nu}$ (which runs from 0 to $(1+m_e/2E_{\nu})^{-1}$) is the ratio of the kinetic energy of the recoil electron to the incident ν or $\overline{\nu}$ energy. For $E_{\nu} \gg m_e$ this yields a total cross-section

$$\sigma = \frac{G_F^2 m_e E_{\nu}}{2\pi} \left[(g_V^{\nu e} \pm g_A^{\nu e})^2 + \frac{1}{3} (g_V^{\nu e} \mp g_A^{\nu e})^2 \right]. \tag{10.24}$$

The most accurate measurements [95–100] of $\sin^2 \theta_W$ from ν -lepton scattering (see Sec. 10.6) are from the ratio $R \equiv \sigma_{\nu\mu e}/\sigma_{\bar{\nu}\mu e}$ in which many of the systematic uncertainties cancel. Radiative corrections (other than m_t effects) are small compared to the precision of present experiments and have negligible effect on the extracted $\sin^2 \theta_W$. The most precise experiment (CHARM II) [98] determined not only $\sin^2 \theta_W$ but $g_{V,A}^{\nu e}$ as well, which are shown in Fig. 10.1. The cross-sections for ν_{e^-e} and $\overline{\nu}_{e^-e}$ may be obtained from Eq. (10.23) by replacing $g_{V,A}^{\nu e}$ by $g_{V,A}^{\nu e} + 1$, where the 1 is due to the charged-current contribution.

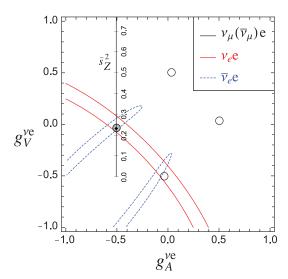

Figure 10.1: Allowed contours in $g_A^{\nu e}$ vs. $g_V^{\nu e}$ from neutrino-electron scattering and the SM prediction as a function of the weak mixing angle \hat{s}_Z^2 . (The SM best fit value $\hat{s}_Z^2=0.23116$ is also indicated.) The $\nu_e e$ [99] and $\bar{\nu}_e e$ [100] constraints are at 1 σ , while each of the four equivalent $\nu_\mu(\bar{\nu}_\mu)e$ [95–98] solutions $(g_{V,A} \to -g_{V,A})$ and $g_{V,A} \to g_{A,V}$ are at 90% C.L. The global best fit region (shaded) almost exactly coincides with the corresponding $\nu_\mu(\bar{\nu}_\mu)e$ region. The solution near $g_A=0,g_V=-0.5$ is eliminated by $e^+e^-\to \ell^+\ell^-$ data under the weak additional assumption that the neutral current is dominated by the exchange of a single Z boson.

A precise determination of the on-shell s_W^2 , which depends only very weakly on m_t and M_H , is obtained from deep inelastic scattering (DIS) of neutrinos from (approximately) isoscalar targets [101]. The ratio $R_{\nu} \equiv \sigma_{\nu N}^{NC}/\sigma_{\nu N}^{CC}$ of neutral-to-charged-current cross-sections has

been measured to 1% accuracy by CDHS [102] and CHARM [103] at CERN. CCFR [104] at Fermilab has obtained an even more precise result, so it is important to obtain theoretical expressions for R_{ν} and $R_{\bar{\nu}} \equiv \sigma_{\bar{\nu}N}^{NC}/\sigma_{\bar{\nu}N}^{CC}$ to comparable accuracy. Fortunately, many of the uncertainties from the strong interactions and neutrino spectra cancel in the ratio. A large theoretical uncertainty is associated with the c-threshold, which mainly affects σ^{CC} . Using the slow rescaling prescription [105] the central value of $\sin^2\theta_W$ from CCFR varies as 0.0111(m_c [GeV] - 1.31), where m_c is the effective mass which is numerically close to the $\overline{\rm MS}$ mass $\widehat{m}_c(\widehat{m}_c)$, but their exact relation is unknown at higher orders. For $m_c=1.31\pm0.24$ GeV (determined from ν -induced dimuon production [106]) this contributes ±0.003 to the total uncertainty $\Delta\sin^2\theta_W\sim\pm0.004$. (The experimental uncertainty is also ±0.003 .) This uncertainty largely cancels, however, in the Paschos-Wolfenstein ratio [107],

$$R^{-} = \frac{\sigma_{\nu N}^{NC} - \sigma_{\bar{\nu}N}^{NC}}{\sigma_{\nu N}^{CC} - \sigma_{\bar{\nu}N}^{CC}}.$$
 (10.25)

It was measured by Fermilab's NuTeV collaboration [108] for the first time, and required a high-intensity and high-energy anti-neutrino beam.

A simple zero th -order approximation is

$$R_{\nu} = g_L^2 + g_R^2 r$$
, $R_{\bar{\nu}} = g_L^2 + \frac{g_R^2}{r}$, $R^- = g_L^2 - g_R^2$, (10.26)

where

$$g_L^2 \equiv \epsilon_L(u)^2 + \epsilon_L(d)^2 \approx \frac{1}{2} - \sin^2 \theta_W + \frac{5}{9} \sin^4 \theta_W, (10.27a)$$

$$g_R^2 \equiv \epsilon_R(u)^2 + \epsilon_R(d)^2 \approx \frac{5}{9} \sin^4 \theta_W,$$
 (10.27b)

and $r \equiv \sigma^{CC}_{\bar{\nu}N}/\sigma^{CC}_{\nu N}$ is the ratio of $\bar{\nu}$ to ν charged-current cross-sections, which can be measured directly. (In the simple parton model, ignoring hadron energy cuts, $r \approx (\frac{1}{3}+\epsilon)/(1+\frac{1}{3}\epsilon)$, where $\epsilon \sim 0.125$ is the ratio of the fraction of the nucleon's momentum carried by antiquarks to that carried by quarks.) In practice, Eq. (10.26) must be corrected for quark mixing, quark sea effects, c-quark threshold effects, non-isoscalarity, W-Z propagator differences, the finite muon mass, QED and EW radiative corrections. Details of the neutrino spectra, experimental cuts, x and Q^2 dependence of structure functions, and longitudinal structure functions enter only at the level of these corrections and therefore lead to very small uncertainties. CCFR quotes $s^2_W = 0.2236 \pm 0.0041$ for $(m_t, M_H) = (175, 150)$ GeV with very little sensitivity to (m_t, M_H) .

The NuTeV collaboration found $s_W^2=0.2277\pm0.0016$ (for the same reference values), which was $3.0~\sigma$ higher than the SM prediction [108]. The deviation was in g_L^2 (initially $2.7~\sigma$ low) while g_R^2 was consistent with the SM. Since then a number of experimental and theoretical developments changed the interpretation of the measured cross section ratios, affecting the extracted $g_{L,R}^2$ (and thus s_W^2) including their uncertainties and correlation. In the following paragraph we give a semi-quantitative and preliminary discussion of these effects, but we stress that the precise impact of them needs to be evaluated carefully by the collaboration with a new and self-consistent set of PDFs, including new radiative corrections, while simultaneously allowing isospin breaking and asymmetric strange seas. This is an effort which is currently on its way and until it is completed we do not include the NuTeV constraints on $g_{L,R}^2$ in our default set of fits.

(i) In the original analysis NuTeV worked with a symmetric strange quark sea but subsequently measured [109] the difference between the strange and antistrange momentum distributions, $S^- \equiv \int_0^1 \mathrm{d}x x [s(x) - \bar{s}(x)] = 0.00196 \pm 0.00143$, from dimuon events utilizing the first complete next-to-leading order QCD description [110] and parton distribution functions (PDFs) according to Ref. 111. The global PDF fits in Ref. 112 give somewhat smaller values, $S^- = 0.0013(9)$ [$S^- = 0.0010(13)$], where the semi-leptonic charmed-hadron branching ratio, $B_\mu = 8.8 \pm 0.5\%$, has [not] been used as an external constraint. The resulting S^- also depends on the PDF

model used and on whether theoretical arguments (see Ref. 113 and references therein) are invoked favoring a zero crossing of $x[s(x) - \bar{s}(x)]$ at values much larger than seen by NuTeV and suggesting an effect of much smaller and perhaps negligible size. (ii) The measured branching ratio for K_{e3} decays enters crucially in the determination of the $\nu_e(\bar{\nu}_e)$ contamination of the $\nu_{\mu}(\bar{\nu}_{\mu})$ beam. This branching ratio has moved from $4.82 \pm 0.06\%$ at the time of the original publication [108] to the current value of $5.07 \pm 0.04\%$, i.e., a change by more than 4σ . This moves s_W^2 about one standard deviation further away from the SM prediction while reducing the $\nu_e(\bar{\nu}_e)$ uncertainty. (iii) PDFs seem to violate isospin symmetry at levels much stronger than generally expected [114]. A minimum χ^2 set of PDFs [115] allowing charge symmetry violation for both valence quarks $[d_V^p(x) \neq u_V^n(x)]$ and sea quarks $[\bar{d}^p(x) \neq \bar{u}^n(x)]$ shows a reduction in the NuTeV discrepancy by about 1σ . But isospin symmetry violating PDFs are currently not well constrained phenomenologically and within uncertainties the NuTeV anomaly could be accounted for in full or conversely made larger [115]. Still, the leading contribution from quark mass differences turns out to be largely model-independent [116] (at least in sign) and a shift, $\delta s_W^2 = -0.0015 \pm 0.0003$ [113], has been estimated. (iv) QED splitting effects also violate isospin symmetry with an effect on s_W^2 whose sign (reducing the discrepancy) is model-independent. The corresponding shift of $\delta s_W^2 = -0.0011$ has been calculated in Ref. 117 but has a large uncertainty. (v) Nuclear shadowing effects [118] are likely to affect the interpretation of the NuTeV result at some level, but the NuTeV collaboration argues that their data are dominated by values of Q^2 at which nuclear shadowing is expected to be relatively small. However, another nuclear effect, the isovector EMC effect [119], is much larger (because it affects all neutrons in the nucleus, not just the excess ones) and model-independently works to reduce the discrepancy. It is estimated to lead to a shift of $\delta s_W^2 = -0.0019 \pm 0.0006$ [113]. It would be important to verify and quantify this kind of effect experimentally, e.g., in polarized electron scattering. (vi) The extracted s_W^2 may also shift at the level of the quoted uncertainty when analyzed using the most recent QED and EW radiative corrections [120,121], as well as QCD corrections to the structure functions [122]. However, these are scheme-dependent and in order to judge whether they are significant they need to be adapted to the experimental conditions and kinematics of NuTeV, and have to be obtained in terms of observable variables and for the differential cross-sections. In addition, there is the danger of double counting some of the QED splitting effects. (vii) New physics could also affect $g_{L,R}^2$ [123] but it is difficult to convincingly explain the entire effect

${\bf 10.3.2.} \quad Parity\ violation:$

The SLAC polarized electron-deuteron DIS experiment [124] measured the right-left asymmetry,

$$A = \frac{\sigma_R - \sigma_L}{\sigma_R + \sigma_L} \,, \tag{10.28}$$

where $\sigma_{R,L}$ is the cross-section for the deep-inelastic scattering of a right- or left-handed electron: $e_{R,L}N \to e{\rm X}$. In the quark parton model,

$$\frac{A}{Q^2} = a_1 + a_2 \frac{1 - (1 - y)^2}{1 + (1 - y)^2} \,, \tag{10.29}$$

where $Q^2 > 0$ is the momentum transfer and y is the fractional energy transfer from the electron to the hadrons. For the deuteron or other isoscalar targets, one has, neglecting the s-quark and anti-quarks,

$$a_1 = \frac{3G_F}{5\sqrt{2}\pi\alpha} \left(C_{1u} - \frac{1}{2}C_{1d} \right) \approx \frac{3G_F}{5\sqrt{2}\pi\alpha} \left(-\frac{3}{4} + \frac{5}{3}\sin^2\theta_W \right), \quad (10.30a)$$

$$a_2 = \frac{3G_F}{5\sqrt{2}\pi\alpha} \left(C_{2u} - \frac{1}{2}C_{2d} \right) \approx \frac{9G_F}{5\sqrt{2}\pi\alpha} \left(\sin^2\theta_W - \frac{1}{4} \right).$$
 (10.30b)

In another polarized-electron scattering experiment on deuterons, but in the quasi-elastic kinematic regime, the SAMPLE experiment [125] at MIT-Bates extracted the combination $C_{2u} - C_{2d}$ at Q^2 values of 0.1 GeV² and 0.038 GeV². What was actually determined were

nucleon form factors from which the quoted results were obtained by the removal of a multi-quark radiative correction [126]. Other linear combinations of the C_{iq} have been determined in polarized-lepton scattering at CERN in μ -C DIS, at Mainz in e-Be (quasi-elastic), and at Bates in e-C (elastic). See the review articles in Refs. 127 and 128 for more details. Recent polarized electron asymmetry experiments, i.e., SAMPLE, the PVA4 experiment at Mainz, and the HAPPEX and G0 experiments at Jefferson Lab, have focussed on the strange quark content of the nucleon. These are reviewed in Ref. 129, where it is shown that they can also provide significant constraints on C_{1u} and C_{1d} which complement those from atomic parity violation (see Fig. 10.2).

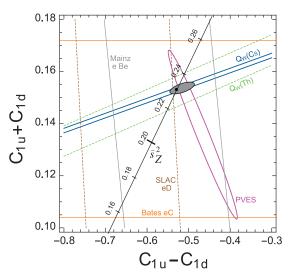

Figure 10.2: Constraints on the effective couplings, C_{1u} and C_{1d} , from recent (PVES) and older polarized parity violating electron scattering, and from atomic parity violation (APV) at 1 σ , as well as the 90% C.L. global best fit (shaded) and the SM prediction as a function of the weak mixing angle \hat{s}_Z^2 . (The SM best fit value $\hat{s}_Z^2 = 0.23116$ is also indicated.)

The parity violating asymmetry, A_{PV} , in fixed target polarized Møller scattering, $e^-e^- \rightarrow e^-e^-$, is defined as in Eq. (10.28) and reads [130],

$$\frac{A_{PV}}{Q^2} = -2 C_{2e} \frac{G_F}{\sqrt{2\pi\alpha}} \frac{1-y}{1+y^4+(1-y)^4} , \qquad (10.31)$$

where y is again the energy transfer. It has been measured at low $Q^2=0.026~{\rm GeV^2}$ in the SLAC E158 experiment [131], with the result $A_{PV}=(-1.31\pm0.14_{\rm stat.}\pm0.10_{\rm syst.})\times10^{-7}$. Expressed in terms of the weak mixing angle in the $\overline{\rm MS}$ scheme, this yields $\widehat{s}^2(Q^2)=0.2403\pm0.0013$, and established the scale dependence of the weak mixing angle (see Fig. 10.3) at the level of 6.4 standard deviations. One can also define the so-called weak charge of the electron (cf. Eq. (10.32) below) as $Q_W(e)\equiv -2\,C_{2e}=-0.0403\pm0.0053$ (the implications are discussed in Ref. 133).

In a similar experiment and at about the same Q^2 , Qweak at Jefferson Lab [136] will be able to measure the weak charge of the proton, $Q_W(p) = -2 [2 C_{1u} + C_{1d}]$, and $\sin^2 \theta_W$ in polarized ep scattering with relative precisions of 4% and 0.3%, respectively.

There are precise experiments measuring atomic parity violation (APV) [137] in cesium [138,139] (at the 0.4% level [138]), thallium [140], lead [141], and bismuth [142]. The EW physics is contained in the weak charges which are defined by,

$$Q_W(Z, N) \equiv -2 \left[C_{1u} \left(2Z + N \right) + C_{1d} (Z + 2N) \right] \approx Z (1 - 4 \sin^2 \theta_W) - N. \tag{10.32}$$

E.g., $Q_W(^{133}\mathrm{Cs})$ is extracted by measuring experimentally the ratio of the parity violating amplitude, E_{PNC} , to the Stark vector transition

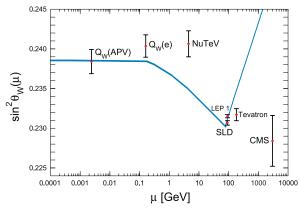

Figure 10.3: Scale dependence of the weak mixing angle defined in the $\overline{\text{MS}}$ scheme [132] (for the scale dependence of the weak mixing angle defined in a mass-dependent renormalization scheme, see Ref. 133). The minimum of the curve corresponds to $Q = M_W$, below which we switch to an effective theory with the W^{\pm} bosons integrated out, and where the β -function for the weak mixing angle changes sign. At the location of the W boson mass and each fermion mass there are also discontinuities arising from scheme dependent matching terms which are necessary to ensure that the various effective field theories within a given loop order describe the same physics. However, in the $\overline{\rm MS}$ scheme these are very small numerically and barely visible in the figure provided one decouples quarks at $Q = \hat{m}_q(\hat{m}_q)$. The width of the curve reflects the theory uncertainty from strong interaction effects which at low energies is at the level of $\pm 7 \times 10^{-5}$ [132]. Following the estimate [135] of the typical momentum transfer for parity violation experiments in Cs, the location of the APV data point is given by $\mu = 2.4$ MeV. For NuTeV we display the updated value from Ref. 134 and chose $\mu=\sqrt{20}$ GeV which is about half-way between the averages of $\sqrt{Q^2}$ for ν and $\overline{\nu}$ interactions at NuTeV. The Tevatron measurements are strongly dominated by invariant masses of the final state dilepton pair of $\mathcal{O}(M_Z)$ and can thus be considered as additional Z pole data points. However, for clarity we displayed the point horizontally to the right. Similar remarks apply to the first measurement at the LHC by the CMS collaboration.

polarizability, β , and by calculating theoretically $E_{\rm PNC}$ in terms of Q_W . One can then write,

$$Q_W = N \left(\frac{\operatorname{Im} E_{\text{PNC}}}{\beta} \right)_{\text{exp.}} \left(\frac{|e| \, a_B}{\operatorname{Im} E_{\text{PNC}}} \frac{Q_W}{N} \right)_{\text{th.}} \left(\frac{\beta}{a_B^3} \right)_{\text{exp.}+\text{th.}} \left(\frac{a_B^2}{|e|} \right).$$

The uncertainties associated with atomic wave functions are quite small for cesium [143]. The semi-empirical value of β used in early analyses added another source of theoretical uncertainty [144]. However, the ratio of the off-diagonal hyperfine amplitude to the polarizability was subsequently measured directly by the Boulder group [145]. Combined with the precisely known hyperfine amplitude [146] one finds, $\beta = 26.991 \pm 0.046$, in excellent agreement with the earlier results, reducing the overall theory uncertainty (while slightly increasing the experimental error). The recent stateof-the-art many body calculation [147] yields, $\operatorname{Im} E_{\text{PNC}} = (0.8906 \pm$ $0.0026) \times 10^{-11} |e| a_B Q_W/N$, while the two measurements [138,139] combine to give ${\rm Im}\,E_{\rm PNC}/\beta = -1.5924 \pm 0.0055$ mV/cm, and we obtain $Q_W(^{133}_{78}\text{Cs}) = -73.20 \pm 0.35$. Thus, the various theoretical efforts in Refs. 147 and 148 together with an update of the SM calculation [149] including a very recent dispersion analysis of the γZ -box contribution [150] removed an earlier 2.3 σ deviation from the SM (see the year 2000 edition of this Review). The theoretical uncertainties are 3% for thallium [151] but larger for the other atoms. The Boulder experiment in cesium also observed the parity-violating weak corrections to the nuclear electromagnetic vertex (the anapole moment [152]).

In the future it could be possible to further reduce the theoretical

wave function uncertainties by taking the ratios of parity violation in different isotopes [137,153]. There would still be some residual uncertainties from differences in the neutron charge radii, however [154]. Experiments in hydrogen and deuterium are another possibility for reducing the atomic theory uncertainties [155], while measurements of single trapped radium ions are promising [156] because of the much larger parity violating effect.

10.4. W and Z boson physics

10.4.1. e^+e^- scattering below the Z pole:

The forward-backward asymmetry for $e^+e^-\to \ell^+\ell^-,\,\ell=\mu$ or $\tau,$ is defined as

$$A_{FB} \equiv \frac{\sigma_F - \sigma_B}{\sigma_F + \sigma_B} \,, \tag{10.33}$$

where σ_F (σ_B) is the cross-section for ℓ^- to travel forward (backward) with respect to the e^- direction. A_{FB} and R, the total cross-section relative to pure QED, are given by

$$R = F_1 , A_{FB} = \frac{3}{4} \frac{F_2}{F_1} , (10.34)$$

where

$$F_1 = 1 - 2\chi_0 g_V^e g_V^\ell \cos \delta_R + \chi_0^2 \left(g_V^{e2} + g_A^{e2} \right) \left(g_V^{\ell2} + g_A^{\ell2} \right), \quad (10.35a)$$

$$F_2 = -2\chi_0 g_A^e g_A^\ell \cos \delta_R + 4\chi_0^2 g_A^e g_A^\ell g_V^\ell g_V^\ell , \qquad (10.35b)$$

$$\tan \delta_R = \frac{M_Z \Gamma_Z}{M_Z^2 - s} \; , \quad \chi_0 = \frac{G_F}{2\sqrt{2}\pi\alpha} \frac{sM_Z^2}{\left[(M_Z^2 - s)^2 + M_Z^2 \Gamma_Z^2\right]^{1/2}} \; , \eqno(10.36)$$

and where \sqrt{s} is the CM energy. Eqs. (10.35) are valid at tree level. If the data are radiatively corrected for QED effects (as described in Sec. 10.2), then the remaining EW corrections can be incorporated [157,158] (in an approximation adequate for existing PEP, PETRA, and TRISTAN data, which are well below the Z pole) by replacing χ_0 by $\chi(s) \equiv (1+\rho_t)\,\chi_0(s)\,\alpha/\alpha(s)$, where $\alpha(s)$ is the running QED coupling, and evaluating g_V in the $\overline{\rm MS}$ scheme. Reviews and formulae for $e^+e^-\to {\rm hadrons}$ may be found in Ref. 159.

10.4.2. Z pole physics:

At LEP 1 and the SLC, there were high-precision measurements of various Z pole observables [11,160–166], as summarized in Table 10.4. These include the Z mass and total width, Γ_Z , and partial widths $\Gamma(f\overline{f})$ for $Z \to f\overline{f}$ where fermion $f = e, \mu, \tau$, hadrons, b, or c. It is convenient to use the variables M_Z , Γ_Z , $R_{\ell} \equiv$ $\Gamma({\rm had})/\Gamma(\ell^+\ell^-)~(\ell=e,\mu,\tau),~\sigma_{\rm had}\equiv 12\pi\,\Gamma(e^+e^-)\,\Gamma({\rm had})/M_Z^2\,\Gamma_Z^2,~R_b\equiv\Gamma(b\overline{b})/\Gamma({\rm had}),~{\rm and}~R_c\equiv\Gamma(c\overline{c})/\Gamma({\rm had}),~{\rm most~of~which~are}$ weakly correlated experimentally. ($\Gamma(had)$ is the partial width into hadrons.) The three values for R_{ℓ} are not inconsistent with lepton universality (although R_{τ} is somewhat low compared to R_e and R_{μ}), but we use the general analysis in which the three observables are treated as independent. Similar remarks apply to $A_{FB}^{0,\ell}$ defined in Eq. (10.39) $(A_{FB}^{0,\tau})$ is somewhat high). $\mathcal{O}(\alpha^3)$ QED corrections introduce a large anti-correlation (-30%) between Γ_Z and $\sigma_{\rm had}$. The anti-correlation between R_b and R_c is -18% [11]. The R_ℓ are insensitive to m_t except for the $Z \to b\overline{b}$ vertex and final state corrections and the implicit dependence through $\sin^2 \theta_W$. Thus, they are especially useful for constraining α_s . The width for invisible decays [11], $\Gamma(\text{inv}) = \Gamma_Z - 3\Gamma(\ell^+\ell^-) - \Gamma(\text{had}) = 499.0 \pm 1.5 \text{ MeV},$ can be used to determine the number of neutrino flavors much lighter than $M_Z/2$, $N_{\nu} = \Gamma(\text{inv})/\Gamma^{\text{theory}}(\nu \overline{\nu}) = 2.984 \pm 0.009$ for $(m_t, M_H) = (173.4, 117) \text{ GeV}.$

There were also measurements of various Z pole asymmetries. These include the polarization or left-right asymmetry

$$A_{LR} \equiv \frac{\sigma_L - \sigma_R}{\sigma_L + \sigma_R} , \qquad (10.37)$$

where $\sigma_L(\sigma_R)$ is the cross-section for a left-(right-)handed incident electron. A_{LR} was measured precisely by the SLD collaboration at

the SLC [162], and has the advantages of being extremely sensitive to $\sin^2 \theta_W$ and that systematic uncertainties largely cancel. In addition, SLD extracted the final-state couplings (defined below), A_b , A_c [11], A_s [163], A_τ , and A_μ [164], from left-right forward-backward asymmetries, using

$$A_{LR}^{FB}(f) = \frac{\sigma_{LF}^{f} - \sigma_{LB}^{f} - \sigma_{RF}^{f} + \sigma_{RB}^{f}}{\sigma_{LF}^{f} + \sigma_{LB}^{f} + \sigma_{RF}^{f} + \sigma_{RB}^{f}} = \frac{3}{4} A_{f} , \qquad (10.38)$$

where, for example, σ_{LF}^f is the cross-section for a left-handed incident electron to produce a fermion f traveling in the forward hemisphere. Similarly, A_{τ} was measured at LEP 1 [11] through the negative total τ polarization, \mathcal{P}_{τ} , and A_e was extracted from the angular distribution of \mathcal{P}_{τ} . An equation such as (10.38) assumes that initial state QED corrections, photon exchange, $\gamma - Z$ interference, the tiny EW boxes, and corrections for $\sqrt{s} \neq M_Z$ are removed from the data, leaving the pure EW asymmetries. This allows the use of effective tree-level expressions,

$$A_{LR} = A_e P_e , \qquad A_{FB} = \frac{3}{4} A_f \frac{A_e + P_e}{1 + P_e A_e} , \qquad (10.39)$$

where

$$A_f \equiv \frac{2\overline{g}_V^f \, \overline{g}_A^f}{\overline{g}_V^{f_2} + \overline{g}_A^{f_2}} \,. \tag{10.40}$$

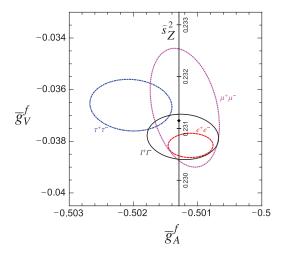

Figure 10.4: 1 σ (39.35% C.L.) contours for the Z-pole observables \bar{g}_A^f and \bar{g}_V^f , $f=e,\mu,\tau$ obtained at LEP and SLC [11], compared to the SM expectation as a function of \hat{s}_Z^2 . (The SM best fit value $\hat{s}_Z^2=0.23116$ is also indicated.) Also shown is the 90% CL allowed region in $\bar{g}_{A,V}^\ell$ obtained assuming lepton universality.

 P_e is the initial e^- polarization, so that the second equality in Eq. (10.38) is reproduced for $P_e=1$, and the Z pole forward-backward asymmetries at LEP 1 ($P_e=0$) are given by $A_{FB}^{(0,f)}=\frac{3}{4}A_eA_f$ where $f=e,~\mu,~\tau,~b,~c,~s~[165],~$ and q,~ and where $A_{FB}^{(0,q)}$ refers to the hadronic charge asymmetry. Corrections for t-channel exchange and s/t-channel interference cause $A_{FB}^{(0,e)}$ to be strongly anti-correlated with $R_e~(-37\%)$. The correlation between $A_{FB}^{(0,b)}$ and $A_{FB}^{(0,c)}$ amounts to 15%. The initial state coupling, A_e , was also determined through the left-right charge asymmetry [166] and in polarized Bhabba scattering [164] at the SLC.

As an example of the precision of the Z-pole observables, the values of \bar{g}_A^f and \bar{g}_J^V , $f=e,\mu,\tau,\ell$, extracted from the LEP and SLC lineshape and asymmetry data is shown in Fig. 10.4, which should be compared with Fig. 10.1. (The two sets of parameters coincide in the SM at tree-level.)

As for hadron colliders, the forward-backward asymmetry, A_{FB} , for e^+e^- final states (with invariant masses restricted to or dominated

by values around M_Z) in $p\bar{p}$ collisions has been measured by the DØ [167] and CDF [168] collaborations and values for \bar{s}_ℓ^2 were extracted, which combine to $\bar{s}_\ell^2 = 0.23200 \pm 0.00076$ (assuming common PDF uncertainties). By varying the invariant mass and the scattering angle (and assuming the electron couplings), information on the effective Z couplings to light quarks, $\bar{g}_{V,A}^{u,d}$, could also be obtained [167,169], but with large uncertainties and mutual correlations and not independently of \bar{s}_ℓ^2 above. Similar analyses have also been reported by the H1 and ZEUS collaborations at HERA [170] and by the LEP collaborations [11]. This kind of measurement is harder in the pp environment due to the difficulty to assign the initial quark and antiquark in the underlying Drell-Yan process to the protons. Nevertheless, the CMS collaboration [171] already reported a first measurement, $\bar{s}_Z^2 = 0.2287 \pm 0.0032$.

10.4.3. LEP 2:

LEP 2 [172] ran at several energies above the Z pole up to ~ 209 GeV. Measurements were made of a number of observables, including the cross-sections for $e^+e^- \to f\bar{f}$ for $f=q,\mu^-,\tau^-$; the differential cross-sections for $f=e^-,\mu^-,\tau^-$; R_q for q=b,c; $A_{FB}(f)$ for $f=\mu,\tau,b,c$; W branching ratios; and WW, $WW\gamma$, ZZ, single W, and single Z cross-sections. They are in good agreement with the SM predictions, with the exceptions of the total hadronic cross-section (1.7 σ high), R_b (2.1 σ low), and $A_{FB}(b)$ (1.6 σ low). Also, the negative result of the direct search for the SM Higgs boson excluded M_H values below 114.4 GeV at the 95% CL [173]. This result is complementary to and can be combined with [174] the limits inferred from the EW precision data.

The Z boson properties are extracted assuming the SM expressions for the $\gamma{-}Z$ interference terms. These have also been tested experimentally by performing more general fits [172,175] to the LEP 1 and LEP 2 data. Assuming family universality this approach introduces three additional parameters relative to the standard fit [11], describing the $\gamma{-}Z$ interference contribution to the total hadronic and leptonic cross-sections, $j_{\rm had}^{\rm tot}$ and $j_{\ell}^{\rm tot}$, and to the leptonic forward-backward asymmetry, $j_{\ell}^{\rm fb}$. E.g.,

$$j_{\rm had}^{\rm tot} \sim g_V^{\ell} g_V^{\rm had} = 0.277 \pm 0.065,$$
 (10.41)

which is in agreement with the SM expectation [11] of 0.21 ± 0.01 . These are valuable tests of the SM; but it should be cautioned that new physics is not expected to be described by this set of parameters, since (i) they do not account for extra interactions beyond the standard weak neutral-current, and (ii) the photonic amplitude remains fixed to its SM value.

Strong constraints on anomalous triple and quartic gauge couplings have been obtained at LEP 2 and the Tevatron as described in the Gauge & Higgs Bosons Particle Listings.

10.4.4. W and Z decays:

The partial decay width for gauge bosons to decay into massless fermions $f_1\overline{f}_2$ (the numerical values include the small EW radiative corrections and final state mass effects) is given by

$$\Gamma(W^+ \to e^+ \nu_e) = \frac{G_F M_W^3}{6\sqrt{2}\pi} \approx 226.36 \pm 0.05 \text{ MeV} ,$$
 (10.42a)

$$\Gamma(W^+ \to u_i \overline{d}_j) = \frac{CG_F M_W^3}{6\sqrt{2}\pi} |V_{ij}|^2 \approx 706.34 \pm 0.16 \text{ MeV } |V_{ij}|^2,$$
(10.42b)

$$\Gamma(Z \rightarrow \psi_i \overline{\psi}_i) = \frac{CG_F M_Z^3}{6\sqrt{2}\pi} \left[g_V^{i2} + g_A^{i2} \right]$$

$$\approx \begin{cases} 167.22 \pm 0.01 \text{ MeV } (\nu \overline{\nu}), \\ 84.00 \pm 0.01 \text{ MeV } (e^+e^-), \\ 300.26 \pm 0.05 \text{ MeV } (u\overline{u}), \\ 383.04 \pm 0.05 \text{ MeV } (d\overline{d}), \\ 375.08 \pm 0.03 \text{ MeV } (b\overline{b}) \end{cases}$$
(10.42c)

For leptons C = 1, while for quarks

$$C = 3 \left[1 + \frac{\alpha_s(M_V)}{\pi} + 1.409 \frac{\alpha_s^2}{\pi^2} - 12.77 \frac{\alpha_s^3}{\pi^3} - 80.0 \frac{\alpha_s^4}{\pi^4} \right], \quad (10.43)$$

where the 3 is due to color and the factor in brackets represents the universal part of the QCD corrections [176] for massless quarks [177]. The $\mathcal{O}(\alpha_s^4)$ contribution in Eq. (10.43) is recent [178]. The $Z \to f\bar{f}$ widths contain a number of additional corrections: which are different for vector and axial-vector partial widths and are included through order α_s^3 and $\widehat{m}_q^4(M_Z^2)$ unless they are tiny; and singlet contributions starting from two-loop order which are large, strongly top quark mass dependent, family universal, and flavor non-universal [181]. The QED factor $1 + 3\alpha q_f^2/4\pi$, as well as two-loop order $\alpha\alpha_s$ and α^2 self-energy corrections [182] are also included. Working in the on-shell scheme, i.e., expressing the widths in terms of $G_F M_{WZ}^3$, incorporates the largest radiative corrections from the running QED coupling [63,183]. $\stackrel{\smile}{\mathrm{EW}}$ corrections to the Z widths are then incorporated by replacing $g_{V,A}^{i2}$ by $\overline{g}_{V,A}^{i2}$. Hence, in the on-shell scheme the Z widths are proportional to $\rho_i \sim 1 + \rho_t$. The $\overline{\rm MS}$ normalization accounts also for the leading EW corrections [68]. There is additional (negative) quadratic m_t dependence in the $Z \to b\bar{b}$ vertex corrections [184] which causes $\Gamma(b\overline{b})$ to decrease with m_t . The dominant effect is to multiply $\Gamma(b\overline{b})$ by the vertex correction $1 + \delta \rho_{b\overline{b}}$, where $\delta \rho_{b\overline{b}} \sim 10^{-2} (-\frac{1}{2} \frac{m_t^2}{M_Z^2} + \frac{1}{5})$. In practice, the corrections are included in ρ_b and κ_b , as discussed in

For three fermion families the total widths are predicted to be

$$\Gamma_Z \approx 2.4960 \pm 0.0002 \; {\rm GeV} \; , \qquad \qquad \Gamma_W \approx 2.0915 \pm 0.0005 \; {\rm GeV} \; . \eqno(10.44)$$

We have assumed $\alpha_s(M_Z)=0.1200$. An uncertainty in α_s of ± 0.002 introduces an additional uncertainty of 0.06% in the hadronic widths, corresponding to ± 1 MeV in Γ_Z . These predictions are to be compared with the experimental results, $\Gamma_Z=2.4952\pm0.0023$ GeV [11] and $\Gamma_W=2.085\pm0.042$ GeV [185] (see the Gauge & Higgs Boson Particle Listings for more details).

10.5. Precision flavor physics

In addition to cross-sections, asymmetries, parity violation, W and Z decays, there is a large number of experiments and observables testing the flavor structure of the SM. These are addressed elsewhere in this Review, and are generally not included in this Section. However, we identify three precision observables with sensitivity to similar types of new physics as the other processes discussed here. The branching fraction of the flavor changing transition $b \to s \gamma$ is of comparatively low precision, but since it is a loop-level process (in the SM) its sensitivity to new physics (and SM parameters, such as heavy quark masses) is enhanced. A discussion can be found in earlier editions of this Review. The τ -lepton lifetime and leptonic branching ratios are primarily sensitive to α_s and not affected significantly by many types of new physics. However, having an independent and reliable low energy measurement of α_s in a global analysis allows the comparison with the Z lineshape determination of α_s which shifts easily in the presence of new physics contributions. By far the most precise observable discussed here is the anomalous magnetic moment of the muon (the electron magnetic moment is measured to even greater precision and can be used to determine α , but its new physics sensitivity is suppressed by an additional factor of m_e^2/m_μ^2). Its combined experimental and theoretical uncertainty is comparable to typical new physics contributions.

The extraction of α_s from the τ lifetime [186] is standing out from other determinations because of a variety of independent reasons: (i) the τ -scale is low, so that upon extrapolation to the Z scale (where it can be compared to the theoretically clean Z lineshape determinations) the α_s error shrinks by about an order of magnitude; (ii) yet, this scale is high enough that perturbation theory and the operator product expansion (OPE) can be applied; (iii) these observables are fully inclusive and thus free of fragmentation and hadronization effects that would have to be modeled or measured; (iv) duality violation (DV) effects are most problematic near the branch cut but there they are suppressed by a double zero at $s=m_{\tau}^2$; (v) there are data [43] to constrain non-perturbative effects both within $(\delta_{D=6,8})$ and breaking (δ_{DV}) the OPE; (vi) a complete four-loop order QCD calculation is available [178]; (vii) large effects associated

with the QCD β -function can be re-summed [187] in what has become known as contour improved perturbation theory (CIPT). However, while there is no doubt that CIPT shows faster convergence in the lower (calculable) orders, doubts have been cast on the method by the observation that at least in a specific model [188], which includes the exactly known coefficients and theoretical constraints on the large-order behavior, ordinary fixed order perturbation theory (FOPT) may nevertheless give a better approximation to the full result. We therefore use the expressions [54,177,178,189],

$$\tau_{\tau} = \hbar \frac{1 - \mathcal{B}_{\tau}^{s}}{\Gamma_{\tau}^{e} + \Gamma_{\tau}^{\mu} + \Gamma_{\tau}^{ud}} = 291.13 \pm 0.43 \text{ fs}, \qquad (10.45)$$

$$\Gamma_{\tau}^{ud} = \frac{G_F^2 m_{\tau}^5 |V_{ud}|^2}{64\pi^3} S(m_{\tau}, M_Z) \left(1 + \frac{3}{5} \frac{m_{\tau}^2 - m_{\mu}^2}{M_W^2} \right) \times$$

$$\left[1 + \frac{\alpha_s(m_\tau)}{\pi} + 5.202 \frac{\alpha_s^2}{\pi^2} + 26.37 \frac{\alpha_s^3}{\pi^3} + 127.1 \frac{\alpha_s^4}{\pi^4} + \frac{\widehat{\alpha}}{\pi} (\frac{85}{24} - \frac{\pi^2}{2}) + \delta_q\right],\tag{10.46}$$

and Γ_{τ}^{e} and Γ_{τ}^{μ} can be taken from Eq. (10.6) with obvious replacements. The relative fraction of decays with $\Delta S = -1$, $\mathcal{B}_{\tau}^{s} = 0.0286 \pm 0.0007$, is based on experimental data since the value for the strange quark mass, $\widehat{m}_s(m_\tau)$, is not well known and the QCD expansion proportional to \widehat{m}_s^2 converges poorly and cannot be trusted. $S(m_{\tau}, M_Z) = 1.01907 \pm 0.0003$ is a logarithmically enhanced EW correction factor with higher orders re-summed [190]. δ_q contains the dimension six and eight terms in the OPE, as well as DV effects, $\delta_{D=6,8} + \delta_{DV} = -0.004 \pm 0.012$ [191]. Depending on how $\delta_{D=6}$, $\delta_{D=8}$, and δ_{DV} are extracted, there are strong correlations not only between them, but also with the gluon condensate (D = 4) and possibly D > 8 terms. These latter are suppressed in Eq. (10.46) by additional factors of α_s , but not so for more general weight functions. A simultaneous fit to all non-perturbative terms [191] (as is necessary if one wants to avoid ad hoc assumptions) indicates that the α_s errors may have been underestimated in the past. Higher statistics τ decay data [45] and spectral functions from e^+e^- annihilation (providing a larger fit window and thus more discriminatory power and smaller correlations) are likely to reduce the δ_q error in the future. Also included in δ_q are quark mass effects and the D=4 condensate contributions. An uncertainty of similar size arises from the truncation of the FOPT series and is conservatively taken as the α_s^4 term (this is re-calculated in each call of the fits, leading to an α_s -dependent and thus asymmetric error) until a better understanding of the numerical differences between FOPT and CIPT has been gained. Our perturbative error covers almost the entire range from using CIPT to assuming that the nearly geometric series in Eq. (10.46) continues to higher orders. The experimental uncertainty in Eq. (10.45), is from the combination of the two leptonic branching ratios with the direct τ_{τ} . Included are also various smaller uncertainties (± 0.5 fs) from other sources which are dominated by the evolution from the Z scale. In total we obtain a $\sim 2\%$ determination of $\alpha_s(M_Z) = 0.1193^{+0.0022}_{-0.0020}$, which corresponds to $\alpha_s(m_\tau) = 0.327^{+0.019}_{-0.016}$, and updates the result of Refs. 54 and 192. For more details, see Refs. 191 and 193 where the τ spectral functions are used as additional input.

The world average of the muon anomalous magnetic moment $^{\frac{1}{4}}$,

$$a_{\mu}^{\rm exp} = \frac{g_{\mu} - 2}{2} = (1165920.80 \pm 0.63) \times 10^{-9},$$
 (10.47)

is dominated by the final result of the E821 collaboration at BNL [194]. The QED contribution has been calculated to four

 $^{^{\}dagger}$ In what follows, we summarize the most important aspects of $g_{\mu}-2,$ and give some details about the evaluation in our fits. For more details see the dedicated contribution by A. Höcker and W. Marciano in this Review. There are some small numerical differences (at the level of 0.1 standard deviation), which are well understood and mostly arise because internal consistency of the fits requires the calculation of all observables from analytical expressions and common inputs and fit parameters, so that an independent evaluation is necessary for this Section. Note, that in the spirit of a global analysis based on all available information we have chosen here to average in the τ decay data, as well.

loops [195] (fully analytically to three loops [196,197]) , and the leading logarithms are included to five loops [198,199]. The estimated SM EW contribution [200–202], $a_{\mu}^{\rm EW}=(1.52\pm0.03)\times10^{-9}$, which includes leading two-loop [201] and three-loop [202] corrections, is at the level of twice the current uncertainty.

The limiting factor in the interpretation of the result are the uncertainties from the two- and three-loop hadronic contribution. E.g., Ref. 20 obtained the value $a_{\mu}^{\rm had} = (69.23 \pm 0.42) \times 10^{-9}$ which combines CMD-2 [47] and SND [48] $e^+e^- \rightarrow$ hadrons cross-section data with radiative return results from BaBar [50] and KLOE [51]. This value suggests a 3.6 σ discrepancy between Eq. (10.47) and the SM prediction. An alternative analysis [20] using τ decay data and isospin symmetry (CVC) yields $a_{\mu}^{\rm had}=(70.15\pm0.47)\times10^{-9}$. This result implies a smaller conflict (2.4 σ) with Eq. (10.47). Thus, there is also a discrepancy between the spectral functions obtained from the two methods. For example, if one uses the e^+e^- data and CVC to predict the branching ratio for $\tau^- \to \nu_\tau \pi^- \pi^0$ decays [20] we obtain an average of $\mathcal{B}_{\text{CVC}} = 24.93 \pm 0.13 \pm 0.22_{\text{CVC}}$, while the average of the directly measured branching ratio yields 25.51 ± 0.09 , which is 2.3 σ higher. It is important to understand the origin of this difference, but two observations point to the conclusion that at least some of it is experimental: (i) There is also a direct discrepancy of $1.9~\sigma$ between $\mathcal{B}_{\mathrm{CVC}}$ derived from BaBar (which is not inconsistent with τ decays) and KLOE. (ii) Isospin violating corrections have been studied in detail in Ref. 203 and found to be largely under control. The largest effect is due to higher-order EW corrections [204] but introduces a negligible uncertainty [190]. Nevertheless, a_u^{had} is often evaluated excluding the τ decay data arguing [205] that CVC breaking effects (e.g., through a relatively large mass difference between the ρ^{\pm} and ρ^0 vector mesons) may be larger than expected. (This may also be relevant [205] in the context of the NuTeV result discussed above.) Experimentally [45], this mass difference is indeed larger than expected, but then one would also expect a significant width difference which is contrary to observation [45]. Fortunately, due to the suppression at large s (from where the conflicts originate) these problems are less pronounced as far as a_{μ}^{had} is concerned. In the following we view all differences in spectral functions as (systematic) fluctuations and average the results.

An additional uncertainty is induced by the hadronic three-loop light-by-light scattering contribution. Two recent and inherently different model calculations yield $a_\mu^{\rm LBLS}=(+1.36\pm0.25)\times10^{-9}$ [206] and $a_\mu^{\rm LBLS}=+1.37^{+0.15}_{-0.27}\times10^{-9}$ [207] which are higher than previous evaluations [208,209]. The sign of this effect is opposite [208] to the one quoted in the 2002 edition of this Review, and has subsequently been confirmed by two other groups [209]. There is also the upper bound $a_\mu^{\rm LBLS}<1.59\times10^{-9}$ [207] but this requires an $ad\ hoc$ assumption, too. The recent Ref. 210 quotes the value $a_\mu^{\rm LBLS}=(+1.05\pm0.26)\times10^{-9},$ which we shift by 2×10^{-11} to account for the more accurate charm quark treatment of Ref. 207. We also increase the error to cover all evaluations, and we will use $a_\mu^{\rm LBLS}=(+1.07\pm0.32)\times10^{-9}$ in the fits.

Other hadronic effects at three-loop order contribute [211] $a_{\mu}^{\rm had}(\alpha^3)=(-1.00\pm0.06)\times10^{-9}$. Correlations with the two-loop hadronic contribution and with $\Delta\alpha(M_Z)$ (see Sec. 10.2) were considered in Ref. 197 which also contains analytic results for the perturbative QCD contribution.

Altogether, the SM prediction is

$$a_{\mu}^{\text{theory}} = (1165918.41 \pm 0.48) \times 10^{-9} ,$$
 (10.48)

where the error is from the hadronic uncertainties excluding parametric ones such as from α_s and the heavy quark masses. Using a correlation of about 84% from the data input to the vacuum polarization integrals [20], we estimate the correlation of the total (experimental plus theoretical) uncertainty in a_μ with $\Delta\alpha(M_Z)$ as 24%. The overall 3.0 σ discrepancy between the experimental and theoretical a_μ values could be due to fluctuations (the E821 result is statistics dominated) or underestimates of the theoretical uncertainties. On the other hand, $g_\mu - 2$ is also affected by many types of new physics, such as supersymmetric models with large $\tan\beta$ and moderately light

Table 10.3: Principal non-Z pole observables, compared with the SM best fit predictions. The first M_W value is from the Tevatron [214] and the second one from LEP 2 [172]. e-DIS [129] and the ν -DIS constraints from CDHS [102], CHARM [103], and CCFR [104] are included, as well, but not shown in the Table. The world averages for $g_{V,A}^{\nu e}$ are dominated by the CHARM II [98] results, $g_V^{\nu e} = -0.035 \pm 0.017$ and $g_A^{\nu e} = -0.503 \pm 0.017$. The errors are the total (experimental plus theoretical) uncertainties. The τ_{τ} value is the τ lifetime world average computed by combining the direct measurements with values derived from the leptonic branching ratios [54]; in this case, the theory uncertainty is included in the SM prediction. In all other SM predictions, the uncertainty is from M_Z , M_H , m_t , m_b , m_c , $\widehat{\alpha}(M_Z)$, and α_s , and their correlations have been accounted for. The column denoted Pull gives the standard deviations for the principal fit with M_H free, while the column denoted Dev. (Deviation) is for $M_H = 124.5 \text{ GeV}$ [215] fixed.

| Quantity | Value | Standard Model | Pull | Dev. |
|---------------------------------------------|-------------------------------------|-------------------------------------|-------|------|
| m_t [GeV] | 173.4 ± 1.0 | 173.5 ± 1.0 | -0.1 | -0.3 |
| M_W [GeV] | 80.420 ± 0.031 | 80.381 ± 0.014 | 1.2 | 1.6 |

superparticle masses [212]. Thus, the deviation could also arise from physics beyond the SM.

10.6. Global fit results

In this section we present the results of global fits to the experimental data discussed in Sec. 10.3–Sec. 10.5. For earlier analyses see Refs. 128 and 213.

The values for m_t [56–58], M_W [172,214], neutrino scattering [96–104], the weak charges of the electron [131], cesium [138,139] and thallium [140], the muon anomalous magnetic moment [194], and the τ lifetime are listed in Table 10.3. Likewise, the principal Z pole observables can be found in Table 10.4 where the LEP 1 averages of the ALEPH, DELPHI, L3, and OPAL results include common systematic errors and correlations [11]. The heavy flavor results of LEP 1 and SLD are based on common inputs and correlated, as well [11]. Note that the values of $\Gamma(\ell^+\ell^-)$, $\Gamma(\text{had})$, and $\Gamma(\text{inv})$ are not independent of Γ_Z , the R_ℓ , and $\sigma_{\rm had}$ and that the SM errors in those latter are largely dominated by the uncertainty in α_s . Also shown in both Tables are the SM predictions for the values of M_Z , M_H , $\alpha_s(M_Z)$, $\Delta\alpha_{\rm had}^{(3)}$ and the heavy quark masses shown in Table 10.5. The predictions result from a global least-square (χ^2) fit to all data using the minimization package MINUIT [216] and the EW library GAPP [21]. In most cases, we treat all input errors (the uncertainties of the values) as Gaussian. The reason is not that we assume that theoretical and systematic errors are intrinsically bell-shaped (which they are not) but because in most cases the input errors are combinations of many different (including statistical) error sources, which should yield approximately Gaussian combined errors by the large number theorem. Thus, if either the statistical components dominate or there are many components of similar size. An exception is the theory dominated error on the τ lifetime, which we recalculate in each χ^2 -function call since it depends itself on α_s . Sizes and shapes of the output errors (the uncertainties of the predictions and the SM fit parameters) are fully determined by the fit, and 1 σ errors are defined to correspond to $\Delta \chi^2 = \chi^2 - \chi^2_{\min} = 1$, and do not necessarily correspond to the 68.3% probability range or the 39.3% probability contour (for 2 parameters).

Table 10.4: Principal Z pole observables and their SM predictions (cf. Table 10.3). The first $\overline{s}_\ell^2(A_{FB}^{(0,q)})$ is the effective angle extracted from the hadronic charge asymmetry, the second is the combined value from DØ [167] and CDF [168], and the third is from CMS [171]. The three values of A_e are (i) from A_{LR} for hadronic final states [162]; (ii) from A_{LR} for leptonic final states and from polarized Bhabba scattering [164]; and (iii) from the angular distribution of the τ polarization at LEP 1. The two A_τ values are from SLD and the total τ polarization, respectively.

| Quantity | Value | Standard Model | Pull Dev. |

| A_s | 0.895 ± 0.091 | 0.9357 ± 0.0001 | -0.4 - 0.4 |

The agreement is generally very good. Despite the few discrepancies discussed in the following, the fit describes well the data with a $\chi^2/\text{d.o.f.} = 45.0/42$. The probability of a larger χ^2 is 35%. Only the final result for $g_\mu - 2$ from BNL and $A_{FB}^{(0,b)}$ from LEP 1 are currently showing large (3.0 σ and 2.6 σ) deviations. In addition, A_{LR}^0 (SLD) from hadronic final states differs by 1.8 σ . g_L^2 from NuTeV is nominally in conflict with the SM, as well, but the precise status is under investigation (see Sec. 10.3).

 A_b can be extracted from $A_{FB}^{(0,b)}$ when $A_e=0.1501\pm0.0016$ is taken from a fit to leptonic asymmetries (using lepton universality). The result, $A_b=0.881\pm0.017$, is $3.2~\sigma$ below the SM prediction and also $1.6~\sigma$ below $A_b=0.923\pm0.020$ obtained from $A_{LR}^{FB}(b)$ at SLD. Thus, it appears that at least some of the problem in $A_{FB}^{(0,b)}$ is experimental. Note, however, that the uncertainty in $A_{FB}^{(0,b)}$ is strongly statistics dominated. The combined value, $A_b=0.899\pm0.013$ deviates by $2.8~\sigma$.

It would be difficult to account for this 4.0% deviation by new physics that enters only at the level of radiative corrections since about a 20% correction to $\widehat{\kappa}_b$ would be necessary to account for the central value of A_b [217]. If this deviation is due to new physics, it is most likely of tree-level type affecting preferentially the third generation. Examples include the decay of a scalar neutrino resonance [218], mixing of the b quark with heavy exotics [219], and a heavy Z' with family-nonuniversal couplings [220,221]. It is difficult, however, to simultaneously account for R_b , which has been measured on the Z peak and off-peak [222] at LEP 1. An average of R_b measurements at LEP 2 at energies between 133 and 207 GeV is 2.1 σ below the SM prediction, while $A_{EB}^{(b)}$ (LEP 2) is 1.6 σ low [172].

The left-right asymmetry, $A_{LR}^0=0.15138\pm0.00216$ [162], based on all hadronic data from 1992–1998 differs $1.8~\sigma$ from the SM expectation of 0.1475 ± 0.0010 . The combined value of $A_\ell=0.1513\pm0.0021$ from SLD (using lepton-family universality and including correlations) is also $1.8~\sigma$ above the SM prediction; but there is experimental agreement between this SLD value and the LEP 1 value, $A_\ell=0.1481\pm0.0027$, obtained from a fit to $A_{FB}^{(0,\ell)}$, $A_e(\mathcal{P}_\tau)$, and $A_\tau(\mathcal{P}_\tau)$, again assuming universality.

The observables in Table 10.3 and Table 10.4, as well as some other less precise observables, are used in the global fits described below. In all fits, the errors include full statistical, systematic, and theoretical uncertainties. The correlations on the LEP 1 lineshape and τ polarization, the LEP/SLD heavy flavor observables, the SLD lepton asymmetries, and the deep inelastic and $\nu\text{-}e$ scattering observables, are included. The theoretical correlations between $\Delta\alpha_{\rm had}^{(5)}$ and $g_{\mu}-2$, and between the charm and bottom quark masses, are also accounted for.

The data allow a simultaneous determination of M_Z , M_H , m_t , and the strong coupling $\alpha_s(M_Z)$. $(\widehat{m}_c,\,\widehat{m}_b,\,$ and $\Delta\alpha_{\rm had}^{(3)}$ are also allowed to float in the fits, subject to the theoretical constraints [19,54] described in Sec. 10.2. These are correlated with α_s .) α_s is determined mainly from R_ℓ , Γ_Z , $\sigma_{\rm had}$, and τ_τ and is only weakly correlated with the other variables. The global fit to all data, including the hadron collider average $m_t=173.4\pm1.0~{\rm GeV}$, yields the result in Table 10.5 (the $\overline{\rm MS}$ top quark mass given there corresponds to $m_t=173.5\pm1.0~{\rm GeV}$). The weak mixing angle is determined to

$$\hat{s}_Z^2 = 0.23116 \pm 0.00012,$$
 $s_W^2 = 0.22296 \pm 0.00028,$

while the corresponding effective angle is related by Eq. (10.18), *i.e.*, $\overline{s}_{\ell}^2 = 0.23146 \pm 0.00012$.

As described in Sec. 10.2 and the paragraph following Eq. (10.47) in Sec. 10.5, there is considerable stress in the experimental $e^+e^$ spectral functions and also conflict when these are compared with au decay spectral functions. These are below or above the 2σ level (depending on what is actually compared) but not larger than the deviations of some other quantities entering our analyses. The number and size or these deviations are not inconsistent with what one would expect to happen as a result of random fluctuations. It is nevertheless instructive to study the effect of doubling the uncertainty in $\Delta\alpha_{\rm had}^{(3)}(1.8~{\rm GeV}) = (55.50 \pm 0.78) \times 10^{-4}$, (see Sec. 10.2) on the extracted Higgs mass. The result, $M_H = 95^{+28}_{-23}$ GeV, demonstrates that the uncertainty in $\Delta\alpha_{\rm had}$ is currently of only secondary importance. Note also, that a shift of ± 0.0001 in $\Delta\alpha_{\rm had}^{(3)}(1.8~{\rm GeV})$ corresponds to a shift of ∓ 5 GeV in M_H or about one fifth of its total uncertainty. The hadronic contribution to $\alpha(M_Z)$ is correlated with $g_{\mu}-2$ (see Sec. 10.5). The measurement of the latter is higher than the SM prediction, and its inclusion in the fit favors a larger $\alpha(M_Z)$ and a lower M_H (currently by about 4 GeV).

The weak mixing angle can be determined from Z pole observables, M_W , and from a variety of neutral-current processes spanning a very wide Q^2 range. The results (for the older low energy neutral-current data see Refs. 128 and 213) shown in Table 10.6 are in reasonable agreement with each other, indicating the quantitative success of the SM. The largest discrepancy is the value $\hat{s}_Z^2 = 0.23193 \pm 0.00028$ from the forward-backward asymmetries into bottom and charm quarks, which is 2.8 σ above the value 0.23116 \pm 0.00012 from the

[§] Alternatively, one can use $A_{\ell}=0.1481\pm0.0027$, which is from LEP 1 alone and in excellent agreement with the SM, and obtain $A_{b}=0.893\pm0.022$ which is 1.9 σ low. This illustrates that some of the discrepancy is related to the one in A_{LR} .

global fit to all data. Similarly, $\hat{s}_Z^2 = 0.23067 \pm 0.00029$ from the SLD asymmetries (in both cases when combined with M_Z) is 1.8 σ low. The SLD result has the additional difficulty (within the SM) of implying very low and excluded [173] Higgs masses. This is also true for $\hat{s}_Z^2 = 0.23098 \pm 0.00022$ from M_W and M_Z and — as a consequence — for the global fit. We have therefore included in Table 10.3 and Table 10.4 an additional column (denoted Deviation) indicating the deviations if $M_H = 124.5$ GeV [215] is fixed.

 (0.1172 ± 0.0037) and lattice simulations $(0.1185\pm0.0007),$ whereas the DIS average (0.1150 ± 0.0021) is somewhat lower. For more details, other determinations, and references, see Section 9 on "Quantum Chromodynamics" in this Review. Using $\alpha(M_Z)$ and \hat{s}_Z^2 as inputs, one can predict $\alpha_s(M_Z)$ assuming grand unification. One predicts [223] $\alpha_s(M_Z)=0.130\pm0.001\pm0.01$ for the simplest theories based on the minimal supersymmetric extension of the SM, where the first (second) uncertainty is from the inputs (thresholds).

Table 10.5: Principal SM fit result including mutual correlations (all masses in GeV). Note that $\widehat{m}_c(\widehat{m}_c)$ induces a significant uncertainty in the running of α beyond $\Delta \alpha_{\rm had}^{(3)}(1.8 \text{ GeV})$ resulting in a relatively large correlation with M_H . Since this effect is proportional to the quark's electric charge squared it is much smaller for $\widehat{m}_b(\widehat{m}_b)$.

The extracted Z pole value of $\alpha_s(M_Z)$ is based on a formula with negligible theoretical uncertainty if one assumes the exact validity of the SM. One should keep in mind, however, that this value, $\alpha_s(M_Z)=0.1197\pm0.0028$, is very sensitive to such types of new physics as non-universal vertex corrections. In contrast, the value derived from τ decays, $\alpha_s(M_Z)=0.1193^{+0.0022}_{-0.0020}$, is theory dominated but less sensitive to new physics. The two values are in remarkable agreement with each other. They are also in perfect agreement with the averages from jet-event shapes in e^+e^- annihilation

This is slightly larger, but consistent with the experimental $\alpha_s(M_Z)=0.1196\pm0.0017$ from the Z lineshape and the τ lifetime, as well as with most other determinations. Non-supersymmetric unified theories predict the low value $\alpha_s(M_Z)=0.073\pm0.001\pm0.001$. See also the note on "Supersymmetry" in the Searches Particle Listings.

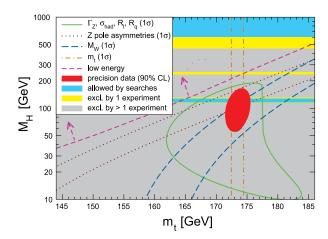

Figure 10.5: One-standard-deviation (39.35%) uncertainties in M_H as a function of m_t for various inputs, and the 90% CL region ($\Delta\chi^2 = 4.605$) allowed by all data. $\alpha_s(M_Z) = 0.1185$ is assumed except for the fits including the Z lineshape or low energy data. The bright (yellow) bands are excluded by one experiment and the remaining (gray) regions are ruled out by more than one experiment (95% CL).

The data indicate a preference for a small Higgs mass. There is a strong correlation between the quadratic m_t and logarithmic M_H terms in $\widehat{\rho}$ in all of the indirect data except for the $Z \to b\overline{b}$ vertex. Therefore, observables (other than R_b) which favor m_t values higher than the Tevatron range favor lower values of M_H . M_W has additional M_H dependence through $\Delta \widehat{r}_W$ which is not coupled to m_t^2 effects. The strongest individual pulls toward smaller M_H are from M_W and

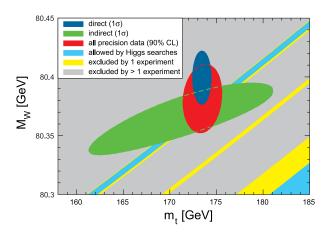

Figure 10.6: One-standard-deviation (39.35%) region in M_W as a function of m_t for the direct and indirect precision data, and the 90% CL region ($\Delta\chi^2=4.605$) allowed by all precision data. The SM predictions are also indicated, where the blue bands for Higgs masses between 115.5 and 127 GeV and beyond 600 GeV are currently allowed at the 95% CL. The yellow bands are excluded by one experiment and the remaining (gray) regions are ruled out by more than one experiment (95% CL).

 $A_{LR}^{0},$ while $A_{FB}^{(0,b)}$ favors higher values. The difference in χ^2 for the global fit is $\Delta\chi^2=\chi^2(M_H=314~{\rm GeV})-\chi^2_{\rm min}=25.$ Hence, the data favor a small value of $M_H,$ as in supersymmetric extensions of the SM. The central value of the global fit result, $M_H=99^{+28}_{-23}~{\rm GeV},$ is below the direct lower bound from LEP 2, $M_H\geq 114.4~{\rm GeV}$ (95% CL) [173], which was very recently extended slightly by ATLAS to $M_H\geq 115.5~{\rm GeV}$ [224].

The 90% central confidence range from all precision data is

$$68 \text{ GeV} \le M_H \le 155 \text{ GeV}.$$
 (10.49)

Including the results of the direct searches at LEP 2 [173] and the Tevatron [225] as extra contributions to the likelihood function reduces the 95% upper limit to $M_H \leq 150$ GeV. As two further refinements, we account for (i) theoretical uncertainties from uncalculated higher order contributions by allowing the T parameter (see next subsection) subject to the constraint $T=0\pm0.02$, (ii) the M_H dependence of the correlation matrix which gives slightly more weight to lower Higgs masses [226]. The resulting limits at 95 (90, 99)% CL are, respectively,

$$M_H \le 175 \text{ (148, 210) GeV.}$$
 (10.50)

In their Higgs searches in pp collisions with CM energy of 7 TeV, both ATLAS [224] and CMS [227] find results consistent with Eq. (10.50) and currently report $\gtrsim 2~\sigma$ excess fluctuation near $M_H=119.5~{\rm GeV}$ (CMS only), $M_H=124~{\rm GeV}$ (CMS), and $M_H=126~{\rm GeV}$ (ATLAS only). Of course, these excesses do not constitute a discovery. However, it is useful to take them at face value for comparison with the precision data in Table 10.3, Table 10.4, and Table 10.6. A combination of all available data yields (at the 68% CL) [215]

$$M_H = 124.5 \pm 0.8 \text{ GeV}.$$
 (10.51)

The resulting probability distribution has a twin peak structure (besides a smaller maximum at $M_H=118.5~{\rm GeV}$) with almost equal probability at $M_H=124~{\rm GeV}$ and $M_H=125~{\rm GeV}$ [215].

One can also carry out a fit to the indirect data alone, i.e., without including the constraint, $m_t=173.4\pm1.0$ GeV, from the hadron colliders. (The indirect prediction is for the $\overline{\rm MS}$ mass, $\widehat{m}_t(\widehat{m}_t)=167.5^{+8.9}_{-7.3}$ GeV, which is in the end converted to the pole mass). One obtains $m_t=177.5^{+9.4}_{-7.8}$ GeV, in perfect agreement with the direct Tevatron/LHC average. Using this indirect top mass value, the tendency for a light Higgs persists and Eq. (10.49) becomes 46 GeV $\leq M_H \leq 306$ GeV. The relations between M_H and m_t for various observables are shown in Fig. 10.5.

One can also determine the radiative correction parameters Δr : from the global fit one obtains $\Delta r = 0.0352 \pm 0.0009$ and $\Delta \hat{r}_W =$

Table 10.7: Values of the model-independent neutral-current parameters, compared with the SM predictions. There is a second $g_{VA}^{\nu e}$ solution, given approximately by $g_V^{\nu e} \leftrightarrow g_A^{\nu e}$, which is eliminated by e^+e^- data under the assumption that the neutral current is dominated by the exchange of a single Z boson. The ϵ_L , as well as the ϵ_R , are strongly correlated and non-Gaussian, so that for implementations we recommend the parametrization using g_i^2 and $\theta_i = \tan^{-1}[\epsilon_i(u)/\epsilon_i(d)]$, i=L or R. The analysis of more recent low energy experiments in polarized electron scattering performed in Ref. 129 is included by means of the two orthogonal constraints, $\cos \gamma \, C_{1d} - \sin \gamma \, C_{1u} = 0.342 \pm 0.063$ and $\sin \gamma \, C_{1d} + \cos \gamma \, C_{1u} = -0.0285 \pm 0.0043$, where $\tan \gamma \approx 0.445$. In the SM predictions, the uncertainty is from M_Z , M_H , m_t , m_b , m_c , $\widehat{\alpha}(M_Z)$, and α_s .

 $0.06945\pm0.00019.~M_W$ measurements [172,214] (when combined with $M_Z)$ are equivalent to measurements of $\Delta r=0.0342\pm0.0015,$ which is $0.9~\sigma$ below the result from all other data, $\Delta r=0.0358\pm0.0011.$ Fig. 10.6 shows the 1 σ contours in the M_W - m_t plane from the direct and indirect determinations, as well as the combined 90% CL region. The indirect determination uses M_Z from LEP 1 as input, which is defined assuming an s-dependent decay width. M_W then corresponds to the s-dependent width definition, as well, and can be directly compared with the results from the Tevatron and LEP 2 which have been obtained using the same definition. The difference to a constant width definition is formally only of $\mathcal{O}(\alpha^2)$, but is strongly enhanced since the decay channels add up coherently. It is about 34 MeV for M_Z and 27 MeV for M_W . The residual difference between working consistently with one or the other definition is about 3 MeV, i.e., of typical size for non-enhanced $\mathcal{O}(\alpha^2)$ corrections [74–77].

Most of the parameters relevant to ν -hadron, ν -e, e-hadron, and e^-e^\pm processes are determined uniquely and precisely from the data in "model-independent" fits (*i.e.*, fits which allow for an arbitrary EW gauge theory). The values for the parameters defined in Eqs. (10.19)–(10.22) are given in Table 10.7 along with the predictions of the SM. The agreement is very good. (The ν -hadron results including the original NuTeV data can be found in the 2006 edition of this Review, and fits with modified NuTeV constraints in the 2008 and 2010 editions.) The off Z pole e^+e^- results are difficult to present in a model-independent way because Z propagator effects are non-negligible at TRISTAN, PETRA, PEP, and LEP 2 energies. However, assuming e- μ - τ universality, the low energy lepton asymmetries imply [159] $4 (g_A^e)^2 = 0.99 \pm 0.05$, in good agreement with the SM prediction $\simeq 1$.

10.7. Constraints on new physics

The Z pole, W mass, and low energy data can be used to search for and set limits on deviations from the SM. We will mainly discuss the effects of exotic particles (with heavy masses $M_{\rm new}\gg M_Z$ in an expansion in $M_Z/M_{\rm new}$) on the gauge boson self-energies. (Brief remarks are made on new physics which is not of this type.) Most of the effects on precision measurements can be described by three gauge self-energy parameters $S,\ T,\ {\rm and}\ U.$ We will define these, as well as related parameters, such as $\rho_0,\ \epsilon_i,\ {\rm and}\ \hat{\epsilon}_i,$ to arise from new physics only. I.e., they are equal to zero $(\rho_0=1)$ exactly in the SM, and do not include any (loop induced) contributions that depend on m_t or M_H , which are treated separately. Our treatment differs from most of the original papers.

Many extensions of the SM can be described by the ρ_0 parameter,

$$\rho_0 \equiv \frac{M_W^2}{M_Z^2 \hat{c}_Z^2 \hat{\rho}} \,, \tag{10.52}$$

which describes new sources of SU(2) breaking that cannot be accounted for by the SM Higgs doublet or m_t effects. $\hat{\rho}$ is calculated as in Eq. (10.13) assuming the validity of the SM. In the presence of $\rho_0 \neq 1$, Eq. (10.52) generalizes the second Eq. (10.13) while the first remains unchanged. Provided that the new physics which yields $\rho_0 \neq 1$ is a small perturbation which does not significantly affect the radiative corrections, ρ_0 can be regarded as a phenomenological parameter which multiplies G_F in Eqs. (10.19)–(10.22), (10.36), and Γ_Z in Eq. (10.42c). There are enough data to determine ρ_0 , M_H , m_t , and α_s , simultaneously. From the global fit,

$$\rho_0 = 1.0004^{+0.0003}_{-0.0004}, \qquad (10.53)$$

$$115.5 \text{ GeV} \le M_H \le 127 \text{ GeV},$$
 (10.54)

$$m_t = 173.4 \pm 1.0 \text{ GeV},$$
 (10.55)

$$\alpha_s(M_Z) = 0.1195 \pm 0.0017,$$
 (10.56)

where the limits on M_H are nominal direct search bounds at the 95% CL [173,224,227]. In addition, the LHC is not yet sensitive to very large values of $M_H > 600$ GeV which are thus not ruled out either. In this very high mass scenario, we obtain,

$$\rho_0 = 1.0024^{+0.0010}_{-0.0003}, \qquad (10.57)$$

$$0.6 \text{ TeV} \le M_H \le 1.2 \text{ TeV},$$
 (10.58)

$$\alpha_s(M_Z) = 0.1191 \pm 0.0016,$$
 (10.59)

with the same m_t . Finally, if the direct search results are ignored entirely one finds $M_H=189^{+568}_{-114}$ GeV and $\rho_0=1.0008^{+0.0020}_{-0.0011}$. The result in Eq. (10.53) is slightly above but consistent with the SM expectation, $\rho_0=1$. It can be used to constrain higher-dimensional Higgs representations to have vacuum expectation values of less than a few percent of those of the doublets. Indeed, the relation between M_W and M_Z is modified if there are Higgs multiplets with weak isospin > 1/2 with significant vacuum expectation values. For a general (charge-conserving) Higgs structure,

$$\rho_0 = \frac{\sum_i [t(i)(t(i)+1) - t_3(i)^2] |v_i|^2}{2\sum_i t_3(i)^2 |v_i|^2},$$
(10.60)

where v_i is the expectation value of the neutral component of a Higgs multiplet with weak isospin t(i) and third component $t_3(i)$. In order to calculate to higher orders in such theories one must define a set of four fundamental renormalized parameters which one may conveniently choose to be α , G_F , M_Z , and M_W , since M_W and M_Z are directly measurable. Then \widehat{s}_Z^2 and ρ_0 can be considered dependent parameters.

Eq. (10.53) can also be used to constrain other types of new physics. For example, non-degenerate multiplets of heavy fermions or scalars break the vector part of weak SU(2) and lead to a decrease in the value of M_Z/M_W . A non-degenerate SU(2) doublet $\binom{f_1}{f_2}$ yields a positive contribution to ρ_0 [228] of

$$\frac{CG_F}{8\sqrt{2}\pi^2}\Delta m^2,\tag{10.61}$$

where

$$\Delta m^2 \equiv m_1^2 + m_2^2 - \frac{4m_1^2 m_2^2}{m_1^2 - m_2^2} \ln \frac{m_1}{m_2} \ge (m_1 - m_2)^2, \qquad (10.62)$$

and C=1 (3) for color singlets (triplets). Thus, in the presence of such multiplets,

$$\rho_0 = 1 + \frac{3G_F}{8\sqrt{2}\pi^2} \sum_i \frac{C_i}{3} \Delta m_i^2 , \qquad (10.63)$$

where the sum includes fourth-family quark or lepton doublets, $\binom{t'}{b'}$ or $\binom{E^0}{E^-}$, right-handed (mirror) doublets, non-degenerate vector-like fermion doublets (with an extra factor of 2), and scalar doublets such as $(\frac{\tilde{t}}{b})$ in Supersymmetry (in the absence of L-R mixing).

Eq. (10.53) taken together with Eq. (10.63) implies at the 95% CL,

$$\sum_{i} \frac{C_i}{3} \Delta m_i^2 \le (52 \text{ GeV})^2. \tag{10.64}$$

Non-degenerate multiplets usually imply $\rho_0 > 1$. Similarly, heavy Z' bosons decrease the prediction for M_Z due to mixing and generally lead to $\rho_0 > 1$ [229]. On the other hand, additional Higgs doublets which participate in spontaneous symmetry breaking [230] or heavy lepton doublets involving Majorana neutrinos [231], both of which have more complicated expressions, as well as the vacuum expectation values of Higgs triplets or higher-dimensional representations can contribute to ρ_0 with either sign. Allowing for the presence of heavy degenerate chiral multiplets (the S parameter, to be discussed below) affects the determination of ρ_0 from the data, at present leading to a larger value (for fixed M_H).

A number of authors [232–237] have considered the general effects on neutral-current and Z and W boson observables of various types of heavy (i.e., $M_{\rm new}\gg M_Z$) physics which contribute to the W and Z self-energies but which do not have any direct coupling to the ordinary fermions. In addition to non-degenerate multiplets, which break the vector part of weak SU(2), these include heavy degenerate multiplets of chiral fermions which break the axial generators. The effects of one degenerate chiral doublet are small, but in Technicolor theories there may be many chiral doublets and therefore significant effects [232].

Such effects can be described by just three parameters, S,T, and U, at the (EW) one-loop level. (Three additional parameters are needed if the new physics scale is comparable to M_Z [238]. Further generalizations, including effects relevant to LEP 2, are described in Ref. 239.) T is proportional to the difference between the W and Z self-energies at $Q^2=0$ (i.e., vector SU(2)-breaking), while S (S+U) is associated with the difference between the Z (W) self-energy at $Q^2=M_{Z,W}^2$ and $Q^2=0$ (axial SU(2)-breaking). Denoting the contributions of new physics to the various self-energies by $\Pi_{ij}^{\rm new}$, we have

$$\begin{split} \widehat{\alpha}(M_Z)T &\equiv \frac{\Pi_{WW}^{\text{new}}(0)}{M_W^2} - \frac{\Pi_{ZZ}^{\text{new}}(0)}{M_Z^2} \;, \\ \widehat{\alpha}(M_Z) \\ 4\,\widehat{s}_Z^2 \widehat{c}_Z^2 S &\equiv \frac{\Pi_{ZZ}^{\text{new}}(M_Z^2) - \Pi_{ZZ}^{\text{new}}(0)}{M_Z^2} - \\ &\qquad \qquad \frac{\widehat{c}_Z^2 - \widehat{s}_Z^2}{\widehat{c}_Z \widehat{s}_Z} \frac{\Pi_{Z\gamma}^{\text{new}}(M_Z^2)}{M_Z^2} - \frac{\Pi_{\gamma\gamma}^{\text{new}}(M_Z^2)}{M_Z^2} \;, \\ \widehat{\frac{\alpha}(M_Z)}{4\,\widehat{s}_Z^2} \left(S + U\right) &\equiv \frac{\Pi_{WW}^{\text{new}}(M_W^2) - \Pi_{WW}^{\text{new}}(0)}{M_W^2} - \\ &\qquad \qquad \frac{\widehat{c}_Z}{\widehat{s}_Z} \frac{\Pi_{Z\gamma}^{\text{new}}(M_Z^2)}{M_Z^2} - \frac{\Pi_{\gamma\gamma}^{\text{new}}(M_Z^2)}{M_Z^2} \;. \end{split} \tag{10.65c}$$

S, T, and U are defined with a factor proportional to $\widehat{\alpha}$ removed, so that they are expected to be of order unity in the presence of new physics. In the $\overline{\text{MS}}$ scheme as defined in Ref. 66, the last two terms in Eqs. (10.65b) and (10.65c) can be omitted (as was done in some earlier

editions of this *Review*). These three parameters are related to other parameters $(S_i, h_i, \widehat{\epsilon_i})$ defined in Refs. [66,233,234] by

$$\begin{split} T &= h_V = \widehat{\epsilon}_1/\widehat{\alpha}(M_Z), \\ S &= h_{AZ} = S_Z = 4\,\widehat{s}_Z^{\,2}\,\widehat{\epsilon}_3/\widehat{\alpha}(M_Z), \\ U &= h_{AW} - h_{AZ} = S_W - S_Z = -4\,\widehat{s}_Z^{\,2}\,\widehat{\epsilon}_2/\widehat{\alpha}(M_Z). \end{split} \ (10.66)$$

A heavy non-degenerate multiplet of fermions or scalars contributes positively to T as

$$\rho_0 - 1 = \frac{1}{1 - \widehat{\alpha}(M_Z)T} - 1 \simeq \widehat{\alpha}(M_Z)T, \tag{10.67}$$

where ρ_0 is given in Eq. (10.63). The effects of non-standard Higgs representations cannot be separated from heavy non-degenerate multiplets unless the new physics has other consequences, such as vertex corrections. Most of the original papers defined T to include the effects of loops only. However, we will redefine T to include all new sources of SU(2) breaking, including non-standard Higgs, so that T and ρ_0 are equivalent by Eq. (10.67).

A multiplet of heavy degenerate chiral fermions yields

$$S = \frac{C}{3\pi} \sum_{i} \left(t_{3L}(i) - t_{3R}(i) \right)^2, \tag{10.68}$$

where $t_{3L,R}(i)$ is the third component of weak isospin of the left-(right-)handed component of fermion i and C is the number of colors. For example, a heavy degenerate ordinary or mirror family would contribute $2/3\pi$ to S. In Technicolor models with QCD-like dynamics, one expects [232] $S \sim 0.45$ for an iso-doublet of techni-fermions, assuming $N_{TC}=4$ techni-colors, while $S\sim 1.62$ for a full techni-generation with $N_{TC} = 4$; T is harder to estimate because it is model-dependent. In these examples one has S > 0. However, the QCD-like models are excluded on other grounds (flavor changing neutral-currents, and too-light quarks and pseudo-Goldstone bosons [240]). In particular, these estimates do not apply to models of walking Technicolor [240], for which S can be smaller or even negative [241]. Other situations in which S < 0, such as loops involving scalars or Majorana particles, are also possible [242]. The simplest origin of S < 0 would probably be an additional heavy Z' boson [229], which could mimic S < 0. Supersymmetric extensions of the SM generally give very small effects. See Refs. 243 and 244 and the note on "Supersymmetry" in the Searches Particle Listings for a complete set of references.

Most simple types of new physics yield U=0, although there are counter-examples, such as the effects of anomalous triple gauge vertices [234].

The SM expressions for observables are replaced by

$$\begin{split} M_Z^2 &= M_{Z0}^2 \, \frac{1 - \widehat{\alpha}(M_Z)T}{1 - G_F M_{Z0}^2 S/2\sqrt{2}\pi} \;, \\ M_W^2 &= M_{W0}^2 \, \frac{1}{1 - G_F M_{W0}^2 (S+U)/2\sqrt{2}\pi} \;, \end{split} \tag{10.69}$$

where M_{Z0} and M_{W0} are the SM expressions (as functions of m_t and M_H) in the $\overline{\rm MS}$ scheme. Furthermore,

$$\Gamma_Z = \frac{M_Z^3 \beta_Z}{1 - \widehat{\alpha}(M_Z)T}, \quad \Gamma_W = M_W^3 \beta_W, \quad A_i = \frac{A_{i0}}{1 - \widehat{\alpha}(M_Z)T} , \quad (10.70)$$

where β_Z and β_W are the SM expressions for the reduced widths Γ_{Z0}/M_{Z0}^3 and Γ_{W0}/M_{W0}^3 , M_Z and M_W are the physical masses, and A_i (A_{i0}) is a neutral-current amplitude (in the SM).

The data allow a simultaneous determination of \widehat{s}_Z^2 (from the Z pole asymmetries), S (from M_Z), U (from M_W), T (mainly from Γ_Z), α_s (from R_ℓ , $\sigma_{\rm had}$, and τ_τ), and m_t (from the hadron colliders), with little correlation among the SM parameters:

$$S = 0.00^{+0.11}_{-0.10},$$

$$T = 0.02^{+0.11}_{-0.12},$$

$$U = 0.08 \pm 0.11,$$
 (10.71)

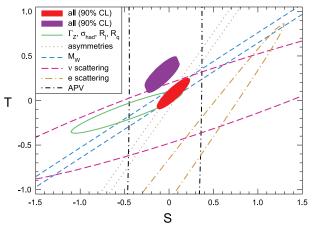

Figure 10.7: 1 σ constraints (39.35%) on S and T from various inputs combined with M_Z . S and T represent the contributions of new physics only. (Uncertainties from m_t are included in the errors.) The contours assume 115.5 GeV $< M_H < 127$ GeV except for the larger (violet) one for all data which is for $600~{\rm GeV} < M_H < 1~{\rm TeV}.$ Data sets not involving M_W are insensitive to U. Due to higher order effects, however, U=0 has to be assumed in all fits. α_s is constrained using the τ lifetime as additional input in all fits. The long-dashed (magenta) contour from ν scattering is now consistent with the global average (see Sec. 10.3). The long-dash-dotted (orange) contour from polarized e scattering [129,131] is the upper tip of an elongated ellipse centered at around S = -14 and T = -20. At first sight it looks as if it is deviating strongly but it is off by only 1.8 σ . This illusion arises because $\Delta \chi^2 > 0.77$ everywhere on the visible part of the contour.

and $\hat{s}_Z^2 = 0.23125 \pm 0.00016$, $\alpha_s(M_Z) = 0.1197 \pm 0.0018$, $m_t = 173.4 \pm 1.0$ GeV, where the uncertainties are from the inputs. We have used 115.5 GeV < M_H < 127 GeV which is the allowed low mass window from LEP and the LHC. The SM parameters (U) can be determined with no (little) M_H dependence. On the other hand, S, T, and M_H cannot be obtained simultaneously from the precision data alone, because the Higgs boson loops themselves are resembled approximately by oblique effects. Negative (positive) contributions to the S (T) parameter can weaken or entirely remove the strong constraints on M_H from the SM fits. Specific models in which a large M_H is compensated by new physics are reviewed in Ref. 245. The parameters in Eqs. (10.71), which by definition are due to new physics only, are in reasonable agreement with the SM values of zero. Fixing U=0 (as is also done in Fig. 10.7) moves S and T slightly upwards,

$$S = 0.04 \pm 0.09,$$

 $T = 0.07 \pm 0.08.$ (10.72)

The correlation between S and T in this fit amounts to 88%.

Using Eq. (10.67), the value of ρ_0 corresponding to T in Eq. (10.71) is 1.0001 ± 0.0009 , while the one corresponding to Eq. (10.72) is $1.0005^{+0.0007}_{-0.0006}$. The values of the $\hat{\epsilon}$ parameters defined in Eq. (10.66) are

$$\hat{\epsilon}_3 = 0.0000 \pm 0.0008,$$

$$\hat{\epsilon}_1 = 0.0001 \pm 0.0009$$

$$\hat{\epsilon}_2 = -0.0006 \pm 0.0009.$$
(10.73)

Unlike the original definition, we defined the quantities in Eqs. (10.73) to vanish identically in the absence of new physics and to correspond directly to the parameters $S,\ T,$ and U in Eqs. (10.71). There is a strong correlation (89%) between the S and T parameters. The U parameter is -49% (-70%) anti-correlated with S (T). The allowed regions in S-T are shown in Fig. 10.7. From Eqs. (10.71) one obtains $S \leq 0.17$ and $T \leq 0.20$ at 95% CL.

If one assumes that the excess Higgs candidates seen at the LHC are statistical fluctuations then (in the presence of new physics significantly affecting gauge boson self-energies) there is still the possibility for a heavy Higgs scenario. If one fixes $M_H=600~{\rm GeV}$ (as is still allowed by direct searches) and requires the constraint $S\geq 0$ (as is appropriate in QCD-like Technicolor models) then $S\leq 0.13$ (Bayesian) or $S\leq 0.11$ (frequentist). This rules out simple Technicolor models with many techni-doublets and QCD-like dynamics.

The S parameter can also be used to constrain the number of fermion families, under the assumption that there are no new contributions to T or U and therefore that any new families are degenerate; then an extra generation of SM fermions is excluded at the degenerate; then an extra generation of SN 161 model is consistent at $N_F = 2.91^{+0.19}_{-0.25}$ (with M_H in the allowed low mass window). This is in agreement with a fit to the number of light neutrinos, $N_{\nu} = 2.989 \pm 0.007$. However, the S parameter fits are valid even for a very heavy fourth family neutrino. This restriction can be relaxed by allowing T to vary as well, since T > 0 is expected from a non-degenerate extra family. Fixing $S=2/3\pi$, the global fit favors a fourth family contribution to T of 0.21 ± 0.04 . However, the quality of the fit deteriorates ($\Delta \chi^2 = 3.8$ relative to the SM fit with M_H forced not to drop below its ATLAS bound of 115.5 GeV) so that this tuned T scenario is also disfavored but less so than in the past. In fact, tuned mass splittings of the extra leptons and quarks [246] can yield fits with only moderately higher χ^2 values (by about 1 unit) than for the SM. A more detailed analysis is also required if the extra neutrino (or the extra down-type quark) is close to its direct mass limit [247]. Thus, a fourth family is disfavored but not excluded by the current EW precision data. Similar remarks apply to a heavy mirror family [248] involving right-handed SU(2) doublets and left-handed singlets. A more recent and detailed discussion can be found in Ref. 249. One important consequence of a heavy fourth family is to increase the Higgs production cross section by gluon fusion by a factor ~ 9 , which considerably strengthens the exclusion limits from direct searches at the Tevatron [250] and LHC [251]. Additional heavy ordinary or mirror generations may also require large Yukawa and Higgs couplings that may lead to Landau poles at low scales [252] In contrast, heavy degenerate non-chiral (also known as vector-like or exotic) multiplets, which are predicted in many grand unified theories [253] and other extensions of the SM, do not contribute to S, T, and U (or to ρ_0), and do not require large coupling constants. Such exotic multiplets may occur in partial families, as in E_6 models, or as complete vector-like families [254].

There is no simple parametrization to describe the effects of every type of new physics on every possible observable. The S, T, and Uformalism describes many types of heavy physics which affect only the gauge self-energies, and it can be applied to all precision observables. However, new physics which couples directly to ordinary fermions, such as heavy Z' bosons [229], mixing with exotic fermions [255], or leptoquark exchange [172,256] cannot be fully parametrized in the S, T, and U framework. It is convenient to treat these types of new physics by parameterizations that are specialized to that particular class of theories (e.g., extra Z' bosons), or to consider specific models (which might contain, e.g., Z' bosons and exotic fermions with correlated parameters). Fits to Supersymmetric models are described in Ref. 244. Models involving strong dynamics (such as (extended) Technicolor) for EW breaking are considered in Ref. 257. The effects of compactified extra spatial dimensions at the TeV scale are reviewed in Ref. 258, and constraints on Little Higgs models in Ref. 259. The implications of non-standard Higgs sectors, e.g., involving Higgs singlets or triplets, are discussed in Ref. 260, while additional Higgs doublets are considered in Ref. 230. Limits on new four-Fermi operators and on leptoquarks using LEP 2 and lower energy data are given in Refs. 172 and 261. Constraints on various types of new physics are reviewed in Refs. [7,128,149,161,262,263], and implications for the LHC in Ref. 264.

An alternate formalism [265] defines parameters, ϵ_1 , ϵ_2 , ϵ_3 , and ϵ_b in terms of the specific observables M_W/M_Z , $\Gamma_{\ell\ell}$, $A_{FB}^{(0,\ell)}$, and R_b . The definitions coincide with those for $\hat{\epsilon}_i$ in Eqs. (10.65) and (10.66) for physics which affects gauge self-energies only, but the ϵ 's now parametrize arbitrary types of new physics. However, the ϵ 's are not related to other observables unless additional model-dependent

Table 10.8: 95% CL lower mass limits (in GeV) from low energy and Z pole data on various extra Z' gauge bosons, appearing in models of unification and string theory. More general parametrizations are described in Refs. 267 and 272. The EW results [273] are for Higgs sectors consisting of doublets and singlets only ($\rho_0 = 1$) with unspecified U(1)' charges. The next two columns show the limits from ATLAS [274] and CMS [275] from the combination of both lepton channels. The CDF [276] and DØ [277] bounds from searches for $\bar{p}p \to \mu^+\mu^-$ and e^+e^- , respectively, are listed in the next two columns, followed by the LEP 2 $e^+e^- \to f\bar{f}$ bounds [172] (assuming $\theta = 0$). The Tevatron bounds would be moderately weakened if there are open supersymmetric or exotic decay channels [278]. The last column shows the 1 σ ranges for M_H when it is left unconstrained in the EW fits.

| Z' | EW | ATLAS | CMS | CDF | DØ | LEP 2 | M_H |
|-----------------------|------------------|-------|-------|-------|-------|-------|----------------------|
| $\overline{Z_{\chi}}$ | 1,141 | 1,640 | _ | 930 | 903 | 673 | 171^{+493}_{-89} |
| Z_{ψ} | 147 | 1,490 | 1,620 | 917 | 891 | 481 | $97^{+\ 31}_{-\ 25}$ |
| Z_{η} | 427 | 1,540 | _ | 938 | 923 | 434 | 423^{+577}_{-350} |
| Z_{LR} | 998 | _ | - | _ | _ | 804 | 804^{+174}_{-35} |
| Z_S | 1,257 | 1,600 | _ | 858 | 822 | _ | 149^{+353}_{-68} |
| Z_{SM} | 1,403 | 1,830 | 1,940 | 1,071 | 1,023 | 1,787 | 331^{+669}_{-246} |
| $Z_{ m string}$ | $_{\rm g}$ 1,362 | - | _ | _ | _ | _ | 134^{+209}_{-58} |

assumptions are made. Another approach [266] parametrizes new physics in terms of gauge-invariant sets of operators. It is especially powerful in studying the effects of new physics on non-Abelian gauge vertices. The most general approach introduces deviation vectors [262]. Each type of new physics defines a deviation vector, the components of which are the deviations of each observable from its SM prediction, normalized to the experimental uncertainty. The length (direction) of the vector represents the strength (type) of new physics.

One of the best motivated kinds of physics beyond the SM besides Supersymmetry are extra Z' bosons [267]. They do not spoil the observed approximate gauge coupling unification, and appear copiously in many Grand Unified Theories (GUTs), most Superstring models [268], as well as in dynamical symmetry breaking [257] and Little Higgs models [259]. For example, the SO(10) GUT contains an extra U(1) as can be seen from its maximal subgroup, $\mathrm{SU}(5) \times \mathrm{U}(1)_{\chi}$. Similarly, the E_6 GUT contains the subgroup $SO(10) \times U(1)_{\psi}$. The Z_{ψ} possesses only axial-vector couplings to the ordinary fermions, and its mass is generally less constrained. The Z_{η} boson is the linear combination $\sqrt{3/8} Z_{\chi} - \sqrt{5/8} Z_{\psi}$. The Z_{LR} boson occurs in left-right models with gauge group $\mathrm{SU}(3)_C\times\mathrm{SU}(2)_L\times\mathrm{SU}(2)_R\times\mathrm{U}(1)_{B-L}\subset\mathrm{SO}(10),$ and the secluded Z_S emerges in a supersymmetric bottom-up scenario [269]. The sequential Z_{SM} boson is defined to have the same couplings to fermions as the SM Z boson. Such a boson is not expected in the context of gauge theories unless it has different couplings to exotic fermions than the ordinary Z boson. However, it serves as a useful reference case when comparing constraints from various sources. It could also play the role of an excited state of the ordinary Z boson in models with extra dimensions at the weak scale [258]. Finally, we consider a Superstring motivated Z_{string} boson appearing in a specific model [270]. The potential Z' boson is in general a superposition of the SM Z and the new boson associated with the extra U(1). The mixing angle θ satisfies,

$$\tan^2\theta = \frac{M_{Z_1^0}^2 - M_Z^2}{M_{Z'}^2 - M_{Z_1^0}^2} \; ,$$

where $M_{Z_1^0}$ is the SM value for M_Z in the absence of mixing. Note, that $M_Z < M_{Z_1^0}$, and that the SM Z couplings are changed by the mixing. The couplings of the heavier Z' may also be modified by kinetic mixing [267,271]. If the Higgs U(1)' quantum numbers are

known, there will be an extra constraint,

$$\theta = C \, \frac{g_2}{g_1} \frac{M_Z^2}{M_{Z'}^2} \; ,$$

where $g_{1,2}$ are the U(1) and U(1)' gauge couplings with $g_2 =$ $\sqrt{\frac{5}{3}}\sin\theta_W\sqrt{\lambda}\,g_1$ and $g_1=\sqrt{g^2+g'^2}$. $\lambda\sim 1$ (which we assume) if the . GUT group breaks directly to SU(3) \times SU(2) \times U(1) \times U(1)'. C is a function of vacuum expectation values. For minimal Higgs sectors it can be found in Ref. 229. Table 10.8 shows the 95% CL lower mass limits [273] for $\rho_0 = 1$ and 114.4 GeV $\leq M_H \leq 1$ TeV. The last column shows the 1 σ ranges for M_H when it is left unconstrained. In cases of specific minimal Higgs sectors where C is known, the Z'mass limits from the EW precision data are generally pushed into the TeV region in which case they are still competitive with those from the LHC, and they are also competitive in the case of large g_2 [279]. The limits on $|\theta|$ are typically smaller than a few $\times 10^{-3}$. For more details see [267,273,280,281] and the note on "The Z' Searches" in the Gauge & Higgs Boson Particle Listings. Also listed in Table 10.8 are the direct lower limits on Z' production from the LHC [274,275] and the Tevatron [276,277], as well as the LEP 2 bounds [172].

11. THE CKM QUARK-MIXING MATRIX

Revised March 2012 by A. Ceccucci (CERN), Z. Ligeti (LBNL), and Y. Sakai (KEK).

11.1. Introduction

The masses and mixings of quarks have a common origin in the Standard Model (SM). They arise from the Yukawa interactions with the Higgs condensate,

$$\mathcal{L}_Y = -Y_{ij}^d \overline{Q_{Li}^I} \phi d_{Rj}^I - Y_{ij}^u \overline{Q_{Li}^I} \epsilon \phi^* u_{Rj}^I + \text{h.c.}, \qquad (11.1)$$

where $Y^{u,d}$ are 3×3 complex matrices, ϕ is the Higgs field, i,j are generation labels, and ϵ is the 2×2 antisymmetric tensor. Q_L^I are left-handed quark doublets, and d_R^I and u_R^I are right-handed down- and up-type quark singlets, respectively, in the weak-eigenstate basis. When ϕ acquires a vacuum expectation value, $\langle \phi \rangle = (0, v/\sqrt{2})$, Eq. (11.1) yields mass terms for the quarks. The physical states are obtained by diagonalizing $Y^{u,d}$ by four unitary matrices, $V_{L,R}^{u,d}$, as $M_{\mathrm{diag}}^f = V_L^f Y^f V_R^{\dagger\dagger}(v/\sqrt{2}), \ f = u,d.$ As a result, the charged-current W^\pm interactions couple to the physical u_{Lj} and d_{Lk} quarks with couplings given by

$$\frac{-g}{\sqrt{2}}(\overline{u_L},\,\overline{c_L},\,\overline{t_L})\gamma^{\mu}\,W_{\mu}^{+}\,V_{\rm CKM}\begin{pmatrix}d_L\\s_L\\b_L\end{pmatrix} + {\rm h.c.},$$

$$V_{\rm CKM} \equiv V_L^u V_L^{d\dagger} = \begin{pmatrix} V_{ud} & V_{us} & V_{ub} \\ V_{cd} & V_{cs} & V_{cb} \\ V_{td} & V_{ts} & V_{tb} \end{pmatrix}. \tag{11.2}$$

This Cabibbo-Kobayashi-Maskawa (CKM) matrix [1,2] is a 3×3 unitary matrix. It can be parameterized by three mixing angles and the CP-violating KM phase [2]. Of the many possible conventions, a standard choice has become [3]

$$V_{\text{CKM}} = \begin{pmatrix} c_{12}c_{13} & s_{12}c_{13} & s_{13}e^{-i\delta} \\ -s_{12}c_{23} - c_{12}s_{23}s_{13}e^{i\delta} & c_{12}c_{23} - s_{12}s_{23}s_{13}e^{i\delta} & s_{23}c_{13} \\ s_{12}s_{23} - c_{12}c_{23}s_{13}e^{i\delta} & -c_{12}s_{23} - s_{12}c_{23}s_{13}e^{i\delta} & c_{23}c_{13} \end{pmatrix}, \tag{11.3}$$

where $s_{ij} = \sin \theta_{ij}$, $c_{ij} = \cos \theta_{ij}$, and δ is the phase responsible for all CP-violating phenomena in flavor-changing processes in the SM. The angles θ_{ij} can be chosen to lie in the first quadrant, so $s_{ij}, c_{ij} \geq 0$.

It is known experimentally that $s_{13} \ll s_{23} \ll s_{12} \ll 1$, and it is convenient to exhibit this hierarchy using the Wolfenstein parameterization. We define [4–6]

$$s_{12} = \lambda = \frac{|V_{us}|}{\sqrt{|V_{ud}|^2 + |V_{us}|^2}}, \qquad s_{23} = A\lambda^2 = \lambda \left| \frac{V_{cb}}{V_{us}} \right|,$$

$$s_{13}e^{i\delta} = V_{ub}^* = A\lambda^3(\rho + i\eta) = \frac{A\lambda^3(\bar{\rho} + i\bar{\eta})\sqrt{1 - A^2\lambda^4}}{\sqrt{1 - \lambda^2}[1 - A^2\lambda^4(\bar{\rho} + i\bar{\eta})]}.(11.4)$$

These relations ensure that $\bar{\rho}+i\bar{\eta}=-(V_{ud}V_{ub}^*)/(V_{cd}V_{cb}^*)$ is phase-convention-independent, and the CKM matrix written in terms of λ , A, $\bar{\rho}$, and $\bar{\eta}$ is unitary to all orders in λ . The definitions of $\bar{\rho},\bar{\eta}$ reproduce all approximate results in the literature. For example, $\bar{\rho}=\rho(1-\lambda^2/2+\ldots)$ and we can write $V_{\rm CKM}$ to $\mathcal{O}(\lambda^4)$ either in terms of $\bar{\rho},\bar{\eta}$ or, traditionally.

$$V_{\text{CKM}} = \begin{pmatrix} 1 - \lambda^2/2 & \lambda & A\lambda^3(\rho - i\eta) \\ -\lambda & 1 - \lambda^2/2 & A\lambda^2 \\ A\lambda^3(1 - \rho - i\eta) & -A\lambda^2 & 1 \end{pmatrix} + \mathcal{O}(\lambda^4).$$
(11.5)

The CKM matrix elements are fundamental parameters of the SM, so their precise determination is important. The unitarity of the CKM matrix imposes $\sum_i V_{ij} V_{ik}^* = \delta_{jk}$ and $\sum_j V_{ij} V_{kj}^* = \delta_{ik}$. The six vanishing combinations can be represented as triangles in a complex plane, of which the ones obtained by taking scalar products of neighboring rows or columns are nearly degenerate. The areas of all triangles are the same, half of the Jarlskog invariant, J [7], which

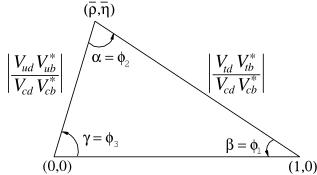

Figure 11.1: Sketch of the unitarity triangle.

is a phase-convention-independent measure of CP violation, defined by $\operatorname{Im} \left[V_{ij} V_{kl} V_{il}^* V_{kj}^* \right] = J \sum_{m,n} \varepsilon_{ikm} \varepsilon_{jln}$.

The most commonly used unitarity triangle arises from

$$V_{ud} V_{ub}^* + V_{cd} V_{cb}^* + V_{td} V_{tb}^* = 0, (11.6)$$

by dividing each side by the best-known one, $V_{cd}V_{cb}^*$ (see Fig. 1). Its vertices are exactly (0,0), (1,0), and, due to the definition in Eq. (11.4), $(\bar{\rho},\bar{\eta})$. An important goal of flavor physics is to overconstrain the CKM elements, and many measurements can be conveniently displayed and compared in the $\bar{\rho},\bar{\eta}$ plane.

Processes dominated by loop contributions in the SM are sensitive to new physics, and can be used to extract CKM elements only if the SM is assumed. We describe such measurements assuming the SM in Sec. 11.2 and 11.3, give the global fit results for the CKM elements in Sec. 11.4, and discuss implications for new physics in Sec. 11.5.

11.2. Magnitudes of CKM elements

11.2.1. $|V_{ud}|$:

The most precise determination of $|V_{ud}|$ comes from the study of superallowed $0^+ \to 0^+$ nuclear beta decays, which are pure vector transitions. Taking the average of the twenty most precise determinations [8] yields

$$|V_{ud}| = 0.97425 \pm 0.00022. \tag{11.7}$$

The error is dominated by theoretical uncertainties stemming from nuclear Coulomb distortions and radiative corrections. A precise determination of $|V_{ud}|$ is also obtained from the measurement of the neutron lifetime. The theoretical uncertainties are very small, but the determination is limited by the knowledge of the ratio of the axial-vector and vector couplings, $g_A = G_A/G_V$ [9]. The PIBETA experiment [10] has improved the measurement of the $\pi^+ \to \pi^0 e^+ \nu$ branching ratio to 0.6%, and quote $|V_{ud}| = 0.9728 \pm 0.0030$, in agreement with the more precise result listed above. The interest in this measurement is that the determination of $|V_{ud}|$ is very clean theoretically, because it is a pure vector transition and is free from nuclear-structure uncertainties.

11.2.2. $|V_{us}|$:

The product of $|V_{us}|$ and the form factor at $q^2=0$, $|V_{us}|\,f_+(0)$, has been extracted traditionally from $K_L^0\to\pi e\nu$ decays in order to avoid isospin-breaking corrections ($\pi^0-\eta$ mixing) that affect K^\pm semileptonic decay, and the complications induced by a second (scalar) form factor present in the muonic decays. The last round of measurements has lead to enough experimental constraints to justify the comparison between different decay modes. Systematic errors related to the experimental quantities, e.g., the lifetime of neutral or charged kaons, and the form factor determinations for electron and muonic decays, differ among decay modes, and the consistency between different determinations enhances the confidence in the final result. For this reason, we follow the prescription [11] to average $K_L^0\to\pi e\nu$, $K_L^0\to\pi \mu\nu$, $K^\pm\to\pi^0 e^\pm\nu$, $K^\pm\to\pi^0 \mu^\pm\nu$ and $K_S^0\to\pi e\nu$. The average of these five decay modes yields $|V_{us}|\,f_+(0)=0.21664\pm0.00048$. Results obtained from each decay

mode, and exhaustive references to the experimental data, are listed for instance in Ref. [9]. The form factor value $f_{+}(0) = 0.9644 \pm 0.0049$ [12] from a three-flavor unquenched lattice QCD calculation gives [9] $|V_{us}| = 0.2246 \pm 0.0012$. The broadly used classic calculation of $f_{+}(0)$ [13] is in good agreement with this value, while other calculations [14] differ by as much as 2%.

The calculation of the ratio of the kaon and pion decay constants enables one to extract $|V_{us}/V_{ud}|$ from $K \to \mu\nu(\gamma)$ and $\pi \to \mu\nu(\gamma)$, where (γ) indicates that radiative decays are included [15]. The KLOE measurement of the $K^+ \to \mu^+\nu(\gamma)$ branching ratio [16], combined with the lattice QCD calculation, $f_K/f_\pi=1.189\pm0.007$ [17], leads to $|V_{us}|=0.2259\pm0.0014$, where the accuracy is limited by the knowledge of the ratio of the decay constants. The average of these two determinations is quoted by Ref. 9 as

$$|V_{us}| = 0.2252 \pm 0.0009. \tag{11.8}$$

The latest determination from hyperon decays can be found in Ref. 19. The authors focus on the analysis of the vector form factor, protected from first order SU(3) breaking effects by the Ademollo-Gatto theorem [20], and treat the ratio between the axial and vector form factors g_1/f_1 as experimental input, thus avoiding first order SU(3) breaking effects in the axial-vector contribution. They find $|V_{us}| = 0.2250 \pm 0.0027$, although this does not include an estimate of the theoretical uncertainty due to second-order SU(3) breaking, contrary to Eq. (11.8). Concerning hadronic τ decays to strange particles, the latest determinations based on LEP, BABAR, and Belle data yield $|V_{us}| = 0.2208 \pm 0.0039$ [21]. A measurement of the ratio of branching fractions $\mathcal{B}(\tau \to K\nu)/\mathcal{B}(\tau \to \pi\nu)$ by BABAR [22] combined with the above f_K/f_π value gives $|V_{us}| = 0.2255 \pm 0.0024$.

11.2.3. $|V_{cd}|$:

The magnitude of V_{cd} can be extracted from semileptonic charm decays if theoretical knowledge of the form factors is available. Three-flavor unquenched lattice QCD calculations for $D \to K\ell\nu$ and $D \to \pi\ell\nu$ have been published [23]. Using these estimates and the average of recent CLEO-c [24] and Belle [25] measurements of $D \to \pi\ell\nu$ decays, one obtains $|V_{cd}| = 0.229 \pm 0.006 \pm 0.024$, where the first uncertainty is experimental, and the second is from the theoretical uncertainty of the form factor.

This determination is not yet as precise as the one based on neutrino and antineutrino interactions. The difference of the ratio of double-muon to single-muon production by neutrino and antineutrino beams is proportional to the charm cross section off valence d quarks, and therefore to $|V_{cd}|^2$ times the average semileptonic branching ratio of charm mesons, \mathcal{B}_{μ} . The method was used first by CDHS [26] and then by CCFR [27,28] and CHARM II [29]. Averaging these results is complicated, not only because it requires assumptions about the scale of the QCD corrections, but also because \mathcal{B}_{μ} is an effective quantity, which depends on the specific neutrino beam characteristics. Given that no new experimental input is available, we quote the average provided in a previous review, $\mathcal{B}_{\mu}|V_{cd}|^2=(0.463\pm0.034)\times10^{-2}$ [30] Analysis cuts make these experiments insensitive to neutrino energies smaller than 30 GeV. Thus, \mathcal{B}_{μ} should be computed using only neutrino interactions with visible energy larger than 30 GeV. An appraisal [31] based on charm-production fractions measured in neutrino interactions [32,33] gives $\mathcal{B}_{\mu} = 0.088 \pm 0.006$. Data from the CHORUS experiment [34] are sufficiently precise to extract \mathcal{B}_{μ} directly, by comparing the number of charm decays with a muon to the total number of charmed hadrons found in the nuclear emulsions. Requiring the visible energy to be larger than 30 GeV, CHORUS finds $\mathcal{B}_{\mu} = 0.085 \pm 0.009 \pm 0.006$. To extract $|V_{cd}|$, we use the average of these two determinations, $\mathcal{B}_{\mu} = 0.087 \pm 0.005$, and obtain

$$|V_{cd}| = 0.230 \pm 0.011. \tag{11.9}$$

11.2.4. $|V_{cs}|$:

The determination of $|V_{cs}|$ from neutrino and antineutrino scattering suffers from the uncertainty of the s-quark sea content. Measurements sensitive to $|V_{cs}|$ from on-shell W^{\pm} decays were performed at LEP-2. The branching ratios of the W depend on the six CKM matrix elements involving quarks with masses smaller than M_W . The W branching ratio to each lepton flavor is given by $1/\mathcal{B}(W \to \ell \bar{\nu}_{\ell}) = 3\left[1 + \sum_{u,c,d,s,b} |V_{ij}|^2 \left(1 + \alpha_s(m_W)/\pi\right)\right]$. The measurement assuming lepton universality, $\mathcal{B}(W \to \ell \bar{\nu}_{\ell}) = (10.83 \pm 0.07 \pm 0.07)\%$ [35], implies $\sum_{u,c,d,s,b} |V_{ij}|^2 = 2.002 \pm 0.027$. This is a precise test of unitarity, but only flavor-tagged W-decay measurements determine $|V_{cs}|$ directly. DELPHI measured tagged $W^+ \to c\bar{s}$ decays, obtaining $|V_{cs}| = 0.94^{+0.32}_{-0.26} \pm 0.13$ [36]. Hereafter, the first error is statistical and the second is systematic, unless mentioned otherwise.

The direct determination of $|V_{cs}|$ is possible from semileptonic D or leptonic D_s decays, using unquenched lattice QCD calculations of the semileptonic D form factor or the D_s decay constant. For muonic decays, the average of Belle [37], CLEO-c [38] and BABAR [39] gives $\mathcal{B}(D_s^+\to\mu^+\nu)=(5.90\pm0.33)\times10^{-3}$ [41]. For decays with τ leptons, the average of CLEO-c [38,42,43] and BABAR [39] gives $\mathcal{B}(D_s^+ \to \tau^+ \nu) = (5.29 \pm 0.28) \times 10^{-2}$ [41]. From each of these values, determinations of $|V_{cs}|$ can be obtained by using the PDG values for the mass and lifetime of the D_s , the masses of the leptons, and $f_{D_8} = (248.6 \pm 3.0) \,\mathrm{MeV}$ [44]. The average of these determinations gives $|V_{cs}| = 1.008 \pm 0.024$, where the error is dominated by the lattice QCD determination of f_{D_s} . In semileptonic D decays, unquenched lattice QCD calculations have predicted the normalization and the shape (dependence on the invariant mass of the lepton pair, q^2) of the form factors in $D \to K\ell\nu$ and $D \to \pi\ell\nu$ [23]. Using these theoretical results and the average of recent CLEO-c [24], Belle [25] and BABAR [45] measurements of $B \to K \ell \nu$ decays, one obtains $|V_{cs}| = 0.98 \pm 0.01 \pm 0.10$, where the first error is experimental and the second, which is dominant, is from the theoretical uncertainty of the form factor. Averaging the determinations from leptonic and semileptonic decays, we find

$$|V_{cs}| = 1.006 \pm 0.023. \tag{11.10}$$

11.2.5. $|V_{cb}|$:

This matrix element can be determined from exclusive and inclusive semileptonic decays of B mesons to charm. The inclusive determinations use the semileptonic decay rate measurement, together with the leptonic energy and the hadronic invariant-mass spectra. The theoretical foundation of the calculation is the operator product expansion [46,47]. It expresses the total rate and moments of differential energy and invariant-mass spectra as expansions in α_s , and inverse powers of the heavy quark mass. The dependence on m_b , m_c , and the parameters that occur at subleading order is different for different moments, and a large number of measured moments overconstrains all the parameters, and tests the consistency of the determination. The precise extraction of $|V_{cb}|$ requires using a "threshold" quark mass definition [48,49]. Inclusive measurements have been performed using B mesons from Z^0 decays at LEP, and at e^+e^- machines operated at the $\Upsilon(4S)$. At LEP, the large boost of B mesons from the Z^0 allows the determination of the moments throughout phase space, which is not possible otherwise, but the large statistics available at the B factories lead to more precise determinations. An average of the measurements and a compilation of the references are provided by Ref. [50]: $|V_{cb}| = (41.9 \pm 0.7) \times 10^{-3}$.

Exclusive determinations are based on semileptonic B decays to D and D^* . In the $m_{b,c}\gg \Lambda_{\rm QCD}$ limit, all form factors are given by a single Isgur-Wise function [51], which depends on the product of the four-velocities of the B and $D^{(*)}$ mesons, $w=v\cdot v'$. Heavy quark symmetry determines the normalization of the rate at w=1, the maximum momentum transfer to the leptons, and $|V_{cb}|$ is obtained from an extrapolation to w=1. The exclusive determination, $|V_{cb}|=(39.6\pm0.9)\times10^{-3}$ [50], is less precise than the inclusive one because of the theoretical uncertainty in the form factor and the experimental uncertainty in the rate near w=1. The V_{cb} and V_{ub} minireview [50] quotes a combination with a scaled error as

$$|V_{cb}| = (40.9 \pm 1.1) \times 10^{-3}.$$
 (11.11)

11.2.6. $|V_{ub}|$:

The determination of $|V_{ub}|$ from inclusive $B \to X_u \ell \bar{\nu}$ decay is complicated due to large $B \to X_c \ell \bar{\nu}$ backgrounds. In most regions of phase space where the charm background is kinematically forbidden, the hadronic physics enters via unknown nonperturbative functions, so-called shape functions. (In contrast, the nonperturbative physics for $|V_{ch}|$ is encoded in a few parameters.) At leading order in $\Lambda_{\rm OCD}/m_b$, there is only one shape function, which can be extracted from the photon energy spectrum in $B \to X_s \gamma$ [52,53], and applied to several spectra in $B \to X_u \ell \bar{\nu}$. The subleading shape functions are modeled in the current determinations. Phase space cuts for which the rate has only subleading dependence on the shape function are also possible [54]. The measurements of both the hadronic and the leptonic systems are important for an optimal choice of phase space. A different approach is to make the measurements more inclusive by extending them deeper into the $B \to X_c \ell \bar{\nu}$ region, and thus reduce the theoretical uncertainties. Analyses of the electron-energy endpoint from CLEO [55], BABAR [56], and Belle [57] quote $B \to X_u e \bar{\nu}$ partial rates for $|\vec{p}_e| \geq 2.0 \,\mathrm{GeV}$ and 1.9 GeV, which are well below the charm endpoint. The large and pure $B\overline{B}$ samples at the B factories permit the selection of $B \to X_u \ell \bar{\nu}$ decays in events where the other B is fully reconstructed [58]. With this full-reconstruction tag method, the four-momenta of both the leptonic and the hadronic systems can be measured. It also gives access to a wider kinematic region because of improved signal purity. Ref. 50 quotes an inclusive average as $|V_{ub}|=(4.41\pm0.15~^{+0.15}_{-0.19})\times10^{-3}$.

To extract $|V_{ub}|$ from an exclusive channel, the form factors have to be known. Experimentally, better signal-to-background ratios are offset by smaller yields. The $B\to\pi\ell\bar\nu$ branching ratio is now known to 5%. Unquenched lattice QCD calculations of the $B\to\pi\ell\bar\nu$ form factor are available [59,60] for the high q^2 region ($q^2>16$ or $18~{\rm GeV}^2$). A simultaneous fit to the experimental partial rates and lattice points versus q^2 yields $|V_{ub}|=(3.23\pm0.31)\times10^{-3}$ [60]. Light-cone QCD sum rules are applicable for $q^2<14~{\rm GeV}^2$ [61] and yield similar results.

The theoretical uncertainties in extracting $|V_{ub}|$ from inclusive and exclusive decays are different. A combination of the determinations is quoted by Ref. [50] as

$$|V_{ub}| = (4.15 \pm 0.49) \times 10^{-3}. (11.12)$$

A determination of $|V_{ub}|$ not included in this average is obtained from $\mathcal{B}(B \to \tau \bar{\nu}) = (1.67 \pm 0.30) \times 10^{-4}$ [40]. Using $f_B = (190.6 \pm 4.6) \,\mathrm{MeV}$ [44], we find $|V_{ub}| = (5.10 \pm 0.47) \times 10^{-3}$. This decay rate is sensitive, for example, to tree-level charged Higgs contributions, and is higher than other $|V_{ub}|$ determinations or the SM fit value.

11.2.7. $|V_{td}|$ and $|V_{ts}|$:

The CKM elements $|V_{td}|$ and $|V_{ts}|$ are not likely to be precisely measurable in tree-level processes involving top quarks, so one has to rely on determinations from $B-\overline{B}$ oscillations mediated by box diagrams with top quarks, or loop-mediated rare K and B decays. Theoretical uncertainties in hadronic effects limit the accuracy of the current determinations. These can be reduced by taking ratios of processes that are equal in the flavor SU(3) limit to determine $|V_{td}/V_{ts}|$.

The mass difference of the two neutral B meson mass eigenstates is very well measured, $\Delta m_d = (0.507 \pm 0.004)\,\mathrm{ps^{-1}}$ [62]. In the B_s^0 system, the average of the CDF [63] and recent LHCb [64] measurements yields $\Delta m_s = (17.719 \pm 0.043)\,\mathrm{ps^{-1}}$. Using the unquenched lattice QCD calculations [44], $f_{B_d}\sqrt{\widehat{B}_{B_d}} = (211 \pm 12)\,\mathrm{MeV},\,f_{B_s}\sqrt{\widehat{B}_{B_s}} = (248 \pm 15)\,\mathrm{MeV},\,\mathrm{and}$ assuming $|V_{tb}| = 1$, one finds

$$|V_{td}| = (8.4 \pm 0.6) \times 10^{-3}, \qquad |V_{ts}| = (42.9 \pm 2.6) \times 10^{-3}. \quad (11.13)$$

The uncertainties are dominated by lattice QCD. Several uncertainties are reduced in the calculation of the ratio $\xi = (f_{Bs}\sqrt{\widehat{B}_{Bs}})/(f_{Bd}\sqrt{\widehat{B}_{Bd}}) = 1.237 \pm 0.032$ [44], and therefore the constraint on $|V_{td}/V_{ts}|$ from $\Delta m_d/\Delta m_s$ is more reliable theoretically. These provide a new, theoretically clean, and significantly improved constraint

$$|V_{td}/V_{ts}| = 0.211 \pm 0.001 \pm 0.006.$$
 (11.14)

The inclusive branching ratio $\mathcal{B}(B \to X_s \gamma) = (3.55 \pm 0.26) \times 10^{-4}$ extrapolated to $E_{\gamma} > E_0 = 1.6 \,\mathrm{GeV}$ [65] is also sensitive to $V_{tb}V_{ts}^*$. In addition to t-quark penguins, a large part of the sensitivity comes from charm contributions proportional to $V_{cb}V_{cs}^*$ via the application of $3 \times 3 \,\mathrm{CKM}$ unitarity (which is used here; any CKM determination from loop processes necessarily assumes the SM). With the NNLO calculation of $\mathcal{B}(B \to X_s \gamma)_{E_{\gamma} > E_0} / \mathcal{B}(B \to X_c e \bar{\nu})$ [66], we obtain $|V_{ts}/V_{cb}| = 1.04 \pm 0.05$. The same CKM elements also determine the $B_s \to \mu^+\mu^-$ decay rate in the SM, and with the bounds approaching the SM level [67], this mode can soon provide a strong constraint.

A complementary determination of $|V_{td}/V_{ts}|$ is possible from the ratio of $B\to\rho\gamma$ and $K^*\gamma$ rates. The ratio of the neutral modes is theoretically cleaner than that of the charged ones, because the poorly known spectator-interaction contribution is expected to be smaller (W-exchange vs. weak annihilation). For now, because of low statistics we average the charged and neutral rates assuming the isospin symmetry and heavy quark limit motivated relation, $|V_{td}/V_{ts}|^2/\xi_\gamma^2 = [\Gamma(B^+\to\rho^+\gamma) + 2\Gamma(B^0\to\rho^0\gamma)]/[\Gamma(B^+\to K^{*+}\gamma) + \Gamma(B^0\to K^{*0}\gamma)] = (3.19\pm0.46)\%$ [65]. Here ξ_γ contains the poorly known hadronic physics. Using $\xi_\gamma = 1.2\pm0.2$ [68], and combining the experimental and theoretical errors in quadrature, gives $|V_{td}/V_{ts}| = 0.21\pm0.04$.

A theoretically clean determination of $|V_{td}V_{ts}^*|$ is possible from $K^+ \to \pi^+ \nu \bar{\nu}$ decay [69]. Experimentally, only seven events have been observed [70] and the rate is consistent with the SM with large uncertainties. Much more data are needed for a precision measurement.

11.2.8. $|V_{tb}|$:

The determination of $|V_{tb}|$ from top decays uses the ratio of branching fractions $R=\mathcal{B}(t\to Wb)/\mathcal{B}(t\to Wq)=|V_{tb}|^2/(\sum_q|V_{tq}|^2)=|V_{tb}|^2$, where q=b,s,d. The CDF and DØ measurements performed on data collected during Run II of the Tevatron give $|V_{tb}|>0.78$ [71] and $0.99>|V_{tb}|>0.90$ [72], respectively, at 95% CL. CMS recently measured the same quantity at 7 TeV and gives $|V_{tb}|>0.92$ [73] at 95% CL. The direct determination of $|V_{tb}|$ without assuming unitarity is possible from the single top-quark-production cross section. The $(2.71^{+0.44}_{-0.43})$ pb average cross section measured by DØ [74] and CDF [75,76] implies $|V_{tb}|=0.87\pm0.07$. The recent CMS measurement, (83.6 ± 29.8) pb [77] at 7 TeV, implies $|V_{tb}|=1.14\pm0.22$. The average of above gives

$$|V_{tb}| = 0.89 \pm 0.07. (11.15)$$

An attempt at constraining $|V_{tb}|$ from the precision electroweak data was made in Ref. 78. The result, mostly driven by the top-loop contributions to $\Gamma(Z \to b\bar{b})$, gives $|V_{tb}| = 0.77^{+0.18}_{-0.24}$.

11.3. Phases of CKM elements

As can be seen from Fig. 11.1, the angles of the unitarity triangle are

$$\beta = \phi_1 = \arg\left(-\frac{V_{cd}V_{cb}^*}{V_{td}V_{tb}^*}\right),$$

$$\alpha = \phi_2 = \arg\left(-\frac{V_{td}V_{tb}^*}{V_{ud}V_{ub}^*}\right),$$

$$\gamma = \phi_3 = \arg\left(-\frac{V_{ud}V_{ub}^*}{V_{cd}V_{cb}^*}\right).$$
(11.16)

Since CP violation involves phases of CKM elements, many measurements of CP-violating observables can be used to constrain these angles and the $\bar{\rho}, \bar{\eta}$ parameters.

11.3.1. ϵ and ϵ' :

The measurement of CP violation in K^0 – \overline{K}^0 mixing, $|\epsilon|=(2.233\pm0.015)\times10^{-3}$ [79], provides important information about the CKM matrix. In the SM, in the basis where $V_{ud}V_{us}^*$ is real [80]

$$\begin{split} |\epsilon| &= \frac{G_F^2 f_K^2 m_K m_W^2}{12\sqrt{2} \, \pi^2 \Delta m_K} \, \widehat{B}_K \Big\{ \eta_1 S(x_c) \, \mathrm{Im}[(V_{cs} V_{cd}^*)^2] \\ &+ \eta_2 S(x_t) \, \mathrm{Im}[(V_{ts} V_{td}^*)^2] + 2 \eta_3 S(x_c, x_t) \, \mathrm{Im}(V_{cs} V_{cd}^* V_{ts} V_{td}^*) \Big\}, (11.17) \end{split}$$

where S is an Inami-Lim function [81], $x_q=m_q^2/m_W^2$, and η_i are perturbative QCD corrections. The constraint from ϵ in the $\bar{\rho},\bar{\eta}$ plane is bounded by approximate hyperbolas. The dominant uncertainties are due to the bag parameter, for which we use $\hat{B}_K=0.7674\pm0.0099$ from lattice QCD [44], and the parametric uncertainty proportional to $\sigma(A^4)$ from $(V_{ts}V_{ts}^*)^2$, which is approximately $\sigma(|V_{cb}|^4)$.

The measurement of $6 \operatorname{Re}(\epsilon'/\epsilon) = 1 - |\eta_{00}/\eta_{+-}|^2$, where η_{00} and η_{+-} are the CP-violating amplitude ratios of K_S^0 and K_L^0 decays to two pions, provides a qualitative test of the CKM mechanism. Its nonzero experimental average, $\operatorname{Re}(\epsilon'/\epsilon) = (1.67 \pm 0.23) \times 10^{-3}$ [79], demonstrates the existence of direct CP violation, a prediction of the KM ansatz. While $\operatorname{Re}(\epsilon'/\epsilon) \propto \operatorname{Im}(V_{td}V_{ts}^*)$, this quantity cannot easily be used to extract CKM parameters, because the electromagnetic penguin contributions tend to cancel the gluonic penguins for large m_t [82], thereby significantly increasing the hadronic uncertainties. Most estimates [83–86] agree with the observed value, indicating that $\bar{\eta}$ is positive. Progress in lattice QCD, in particular finite-volume calculations [87,88], may eventually provide a determination of the $K \to \pi\pi$ matrix elements.

11.3.2. β / ϕ_1 :

11.3.2.1. Charmonium modes:

CP-violation measurements in B-meson decays provide direct information on the angles of the unitarity triangle, shown in Fig. 11.1. These overconstraining measurements serve to improve the determination of the CKM elements, or to reveal effects beyond the SM.

The time-dependent CP asymmetry of neutral B decays to a final state f common to B^0 and \overline{B}^0 is given by [89,90]

$$\mathcal{A}_f = \frac{\Gamma(\overline{B}^0(t) \to f) - \Gamma(B^0(t) \to f)}{\Gamma(\overline{B}^0(t) \to f) + \Gamma(B^0(t) \to f)} = S_f \sin(\Delta m_d t) - C_f \cos(\Delta m_d t), \tag{11.18}$$

where

$$S_f = \frac{2 \operatorname{Im} \lambda_f}{1 + |\lambda_f|^2}, \qquad C_f = \frac{1 - |\lambda_f|^2}{1 + |\lambda_f|^2}, \qquad \lambda_f = \frac{q}{p} \frac{\bar{A}_f}{A_f}.$$
 (11.19)

Here, q/p describes $B^0-\overline{B}{}^0$ mixing and, to a good approximation in the SM, $q/p = V_{tb}^*V_{td}/V_{tb}V_{td}^* = e^{-2i\beta+\mathcal{O}(\lambda^4)}$ in the usual phase convention. A_f (\bar{A}_f) is the amplitude of the $B^0\to f$ $(\overline{B}^0\to f)$ decay. If f is a CP eigenstate, and amplitudes with one CKM phase dominate the decay, then $|A_f|=|\bar{A}_f|,\,C_f=0,$ and $S_f=\sin(\arg\lambda_f)=\eta_f\sin2\phi,$ where η_f is the CP eigenvalue of f and 2ϕ is the phase difference between the $B^0\to f$ and $B^0\to \overline{B}^0\to f$ decay paths. A contribution of another amplitude to the decay with a different CKM phase makes the value of S_f sensitive to relative strong interaction phases between the decay amplitudes (it also makes $C_f\neq 0$ possible).

The $b\to c\bar cs$ decays to CP eigenstates $(B^0\to {\rm charmonium}\ K^0_{S,L})$ are the theoretically cleanest examples, measuring $S_f=-\eta_f\sin2\beta$. The $b\to sq\bar q$ penguin amplitudes have dominantly the same weak phase as the $b\to c\bar cs$ tree amplitude. Since only λ^2 -suppressed penguin amplitudes introduce a new CP-violating phase, amplitudes with a single weak phase dominate, and we expect $\left||\bar A_{\psi K}/A_{\psi K}|-1\right|<0.01$. The e^+e^- asymmetric-energy B-factory experiments, BABAR [92] and Belle [93], provide precise measurements. The world average is [94]

$$\sin 2\beta = 0.679 \pm 0.020. \tag{11.20}$$

This measurement has a four-fold ambiguity in β , which can be resolved by a global fit as mentioned in Sec. 11.4. Experimentally, the two-fold ambiguity $\beta \to \pi/2 - \beta$ (but not $\beta \to \pi + \beta$) can be resolved by a time-dependent angular analysis of $B^0 \to J/\psi K^{*0}$ [95,96], or a time-dependent Dalitz plot analysis of $B^0 \to \overline{D}^0 h^0$ ($h^0 = \pi^0, \eta, \omega$) with $\overline{D}^0 \to K_S^0 \pi^+ \pi^-$ [97,98]. These results indicate that negative $\cos 2\beta$ solutions are very unlikely, in agreement with the global CKM fit result.

The $b \to c\bar{c}d$ mediated transitions, such as $B^0 \to J/\psi\pi^0$ and $B^0 \to D^{(*)+}D^{(*)-}$, also measure approximately $\sin 2\beta$. However,

the dominant component of the $b\to d$ penguin amplitude has a different CKM phase $(V_{tb}^*V_{td})$ than the tree amplitude $(V_{cb}^*V_{cd})$, and its magnitudes are of the same order in λ . Therefore, the effect of penguins could be large, resulting in $S_f\neq -\eta_f\sin2\beta$ and $C_f\neq 0$. These decay modes have also been measured by BABAR and Belle. The world averages [94], $S_{J/\psi\pi^0}=-0.93\pm0.15$, $S_{D^+D^-}=-0.96\pm0.19$, and $S_{D^*+D^*-}=-0.77\pm0.14$ ($\eta_f=+1$ for these modes), are consistent with $\sin2\beta$ obtained from $B^0\to$ charmonium K^0 decays, and the C_f 's are consistent with zero, although the uncertainties are sizable.

The $b\to c\bar u d$ decays, $B^0\to \overline D^0 h^0$ with $\overline D^0\to CP$ eigenstates, have no penguin contributions and provide theoretically clean $\sin 2\beta$ measurements. BABAR measured $S_{D(*)h^0}=-0.56\pm0.25$ [91].

${\bf 11.3.2.2.} \quad \textit{Penguin-dominated modes:} \\$

The $b\to s\bar qq$ penguin-dominated decays have the same CKM phase as the $b\to c\bar cs$ tree level decays, up to corrections suppressed by λ^2 , since $V_{tb}^*V_{ts}=-V_{cb}^*V_{cs}[1+\mathcal{O}(\lambda^2)]$. Therefore, decays such as $B^0\to\phi K^0$ and $\eta'K^0$ provide $\sin 2\beta$ measurements in the SM. Any new physics contribution to the amplitude with a different weak phase would give rise to $S_f\neq -\eta_f\sin 2\beta$, and possibly $C_f\neq 0$. Therefore, the main interest in these modes is not simply to measure $\sin 2\beta$, but to search for new physics. Measurements of many other decay modes in this category, such as $B\to\pi^0K_S^0$, $K_S^0K_S^0$, etc., have also been performed by BABAR and Belle. The results and their uncertainties are summarized in Fig. 12.3 and Table 12.1 of Ref. 90.

11.3.3. α / ϕ_2 :

Since α is the phase between $V_{tb}^*V_{td}$ and $V_{ub}^*V_{ud}$, only time-dependent CP asymmetries in $b \to u\bar{u}d$ decay dominated modes can directly measure $\sin 2\alpha$, in contrast to $\sin 2\beta$, where several different transitions can be used. Since $b \to d$ penguin amplitudes have a different CKM phase than $b \to u\bar{u}d$ tree amplitudes, and their magnitudes are of the same order in λ , the penguin contribution can be sizable, which makes the determination of α complicated. To date, α has been measured in $B \to \pi\pi$, $\rho\pi$ and $\rho\rho$ decay modes.

11.3.3.1. $B \to \pi \pi$:

It is now experimentally well established that there is a sizable contribution of $b\to d$ penguin amplitudes in $B\to\pi\pi$ decays. Thus, $S_{\pi^+\pi^-}$ in the time-dependent $B^0\to\pi^+\pi^-$ analysis does not measure $\sin2\alpha$, but

$$S_{\pi^{+}\pi^{-}} = \sqrt{1 - C_{\pi^{+}\pi^{-}}^{2}} \sin(2\alpha + 2\Delta\alpha),$$
 (11.21)

where $2\Delta\alpha$ is the phase difference between $e^{2i\gamma}\bar{A}_{\pi^+\pi^-}$ and $A_{\pi^+\pi^-}$. The value of $\Delta\alpha$, hence α , can be extracted using the isospin relation among the amplitudes of $B^0\to\pi^+\pi^-$, $B^0\to\pi^0\pi^0$, and $B^+\to\pi^+\pi^0$ decays [99],

$$\frac{1}{\sqrt{2}}A_{\pi^{+}\pi^{-}} + A_{\pi^{0}\pi^{0}} - A_{\pi^{+}\pi^{0}} = 0, \tag{11.22}$$

and a similar expression for the $\bar{A}_{\pi\pi}$'s. This method utilizes the fact that a pair of pions from $B\to\pi\pi$ decay must be in a zero angular momentum state, and, because of Bose statistics, they must have even isospin. Consequently, $\pi^0\pi^\pm$ is in a pure isospin-2 state, while the penguin amplitudes only contribute to the isospin-0 final state. The latter does not hold for the electroweak penguin amplitudes, but their effect is expected to be small. The isospin analysis uses the world averages [94,100] $S_{\pi^+\pi^-} = -0.65 \pm 0.07$, $C_{\pi^+\pi^-} = -0.38 \pm 0.06$, the branching fractions of all three modes, and the direct CP asymmetry $C_{\pi^0\pi^0} = -0.43^{+0.25}_{-0.24}$. This analysis leads to 16 mirror solutions for $0 \le \alpha < 2\pi$. Because of this, and the sizable experimental error of the $B^0 \to \pi^0\pi^0$ rate and CP asymmetry, only a loose constraint on α can be obtained at present [101], $0^\circ < \alpha < 7^\circ$, $81^\circ < \alpha < 103^\circ$, $121^\circ < \alpha < 150^\circ$, and $166^\circ < \alpha < 180^\circ$ at 68% CL.

11.3.3.2. $B \to \rho \rho$:

The decay $B^0 \to \rho^+ \rho^-$ contains two vector mesons in the final state, which in general is a mixture of CP-even and CP-odd components. Therefore, it was thought that extracting α from this mode would be complicated.

However, the longitudinal polarization fractions (f_L) in $B^+ \to \rho^+ \rho^0$ and $B^0 \to \rho^+ \rho^-$ decays were measured to be close to unity [102], which implies that the final states are almost purely CP-even. Furthermore, $\mathcal{B}(B^0 \to \rho^0 \rho^0) = (0.73^{+0.27}_{-0.28}) \times 10^{-6}$ is much smaller than $\mathcal{B}(B^0 \to \rho^+ \rho^-) = (24.2^{+3.1}_{-3.2}) \times 10^{-6}$ and $\mathcal{B}(B^+ \to \rho^+ \rho^0) = (24.0^{+1.9}_{-2.0}) \times 10^{-6}$ [40], which implies that the effect of the penguin diagrams is small. The isospin analysis using the world averages, $S_{\rho^+ \rho^-} = -0.05 \pm 0.17$ and $C_{\rho^+ \rho^-} = -0.06 \pm 0.13$ [40], together with the time-dependent CP asymmetry, $S_{\rho^0 \rho^0} = -0.3 \pm 0.7$ and $C_{\rho^0 \rho^0} = -0.2 \pm 0.9$ [103], and the above-mentioned branching fractions, gives $\alpha = (89.9 \pm 5.4)^\circ$ [101], with a mirror solution at $3\pi/2 - \alpha$. A possible small violation of Eq. (11.22) due to the finite width of the ρ [104] is neglected.

11.3.3.3. $B \to \rho \pi$:

The final state in $B^0 \to \rho^+\pi^-$ decay is not a CP eigenstate, but this decay proceeds via the same quark-level diagrams as $B^0 \to \pi^+\pi^-$, and both B^0 and \overline{B}^0 can decay to $\rho^+\pi^-$. Consequently, mixing-induced CP violations can occur in four decay amplitudes, $B^0 \to \rho^\pm\pi^\mp$ and $\overline{B}^0 \to \rho^\pm\pi^\mp$. The time-dependent Dalitz plot analysis of $B^0 \to \pi^+\pi^-\pi^0$ decays permits the extraction of α with a single discrete ambiguity, $\alpha \to \alpha + \pi$, since one knows the variation of the strong phases in the interference regions of the $\rho^+\pi^-$, $\rho^-\pi^+$, and $\rho^0\pi^0$ amplitudes in the Dalitz plot [105]. The combination of Belle [106] and BABAR [107] measurements gives $\alpha = (120^{+11}_{-7})^{\circ}$ [101]. This constraint is still moderate, and there are also solutions around 30° and 90° within 2σ significance level.

Combining the above-mentioned three decay modes [101], α is constrained as

$$\alpha = (89.0^{+4.4}_{-4.2})^{\circ}. \tag{11.23}$$

A different statistical approach [108] gives similar constraint from the combination of these measurements.

11.3.4. γ / ϕ_3 :

By virtue of Eq. (11.16), γ does not depend on CKM elements involving the top quark, so it can be measured in tree-level B decays. This is an important distinction from the measurements of α and β , and implies that the measurements of γ are unlikely to be affected by physics beyond the SM.

11.3.4.1. $B^{\pm} \to DK^{\pm}$:

The interference of $B^- \to D^0 K^ (b \to c \bar{u} s)$ and $B^- \to \overline{D}{}^0 K^ (b \to u \bar{c} s)$ transitions can be studied in final states accessible in both D^0 and $\overline{D}{}^0$ decays [89]. In principle, it is possible to extract the B and D decay amplitudes, the relative strong phases, and the weak phase γ from the data.

A practical complication is that the precision depends sensitively on the ratio of the interfering amplitudes

$$r_B = \left| A(B^- \to \overline{D}{}^0 K^-) / A(B^- \to D^0 K^-) \right|,$$
 (11.24)

which is around 0.1–0.2. The original GLW method [109,110] considers D decays to CP eigenstates, such as $B^{\pm} \to D_{CP}^{(*)}(\to \pi^+\pi^-)K^{\pm(*)}$. To alleviate the smallness of r_B and make the interfering amplitudes (which are products of the B and D decay amplitudes) comparable in magnitude, the ADS method [111] considers final states where Cabibbo-allowed \overline{D}^0 and doubly-Cabibbo-suppressed D^0 decays interfere. Extensive measurements have been made by the B factories [112,113], CDF [114] and LHCb [115] using both methods.

It was realized that both D^0 and \overline{D}^0 have large branching fractions to certain three-body final states, such as $K_S\pi^+\pi^-$, and the analysis can be optimized by studying the Dalitz plot dependence of the interferences [116,117]. The best present determination of γ comes from this method. Belle [118] and BABAR [119] obtained

 $\gamma=(78^{+11}_{-12}\pm4\pm9)^\circ$ and $\gamma=(68\pm14\pm4\pm3)^\circ$, respectively, where the last uncertainty is due to the D-decay modeling. The error is sensitive to the central value of the amplitude ratio r_B (and r_B^* for the D^*K mode), for which Belle found somewhat larger central values than BABAR. The same values of $r_B^{(*)}$ enter the ADS analyses, and the data can be combined to fit for $r_B^{(*)}$ and γ . The $D^0-\overline{D}^0$ mixing has been neglected in all measurements, but its effect on γ is far below the present experimental accuracy [120], unless $D^0-\overline{D}^0$ mixing is due to CP-violating new physics, in which case it can be included in the analysis [121].

Combining the GLW, ADS, and Dalitz analyses [101], γ is constrained as

$$\gamma = (68^{+10}_{-11})^{\circ}. \tag{11.25}$$

Similar results are found in Ref. [108].

11.3.4.2. $B^0 \to D^{(*)\pm}\pi^{\mp}$:

The interference of $b \to u$ and $b \to c$ transitions can be studied in $\overline B{}^0 \to D^{(*)+}\pi^-$ ($b \to c \overline u d$) and $\overline B{}^0 \to B^0 \to D^{(*)+}\pi^-$ ($\overline b \to \overline u c \overline d$) decays and their CP conjugates, since both B^0 and $\overline B{}^0$ decay to $D^{(*)\pm}\pi^\mp$ (or $D^\pm \rho^\mp$, etc.). Since there are only tree and no penguin contributions to these decays, in principle, it is possible to extract from the four time-dependent rates the magnitudes of the two hadronic amplitudes, their relative strong phase, and the weak phase between the two decay paths, which is $2\beta + \gamma$.

A complication is that the ratio of the interfering amplitudes is very small, $r_{D\pi}=A(B^0\to D^+\pi^-)/A(\overline B^0\to D^+\pi^-)=\mathcal O(0.01)$ (and similarly for $r_{D^*\pi}$ and $r_{D\rho}$), and therefore it has not been possible to measure it. To obtain $2\beta+\gamma$, SU(3) flavor symmetry and dynamical assumptions have been used to relate $A(\overline B^0\to D^-\pi^+)$ to $A(\overline B^0\to D_s^-\pi^+)$, so this measurement is not model-independent at present. Combining the $D^\pm\pi^\mp$, $D^{*\pm}\pi^\mp$ and $D^\pm\rho^\mp$ measurements [122] gives $\sin(2\beta+\gamma)>0.68$ at 68% CL [101], consistent with the previously discussed results for β and γ . The amplitude ratio is much larger in the analogous $B_s^0\to D_s^\pm K^\mp$ decays, so it will be possible at LHCb to measure it and model-independently extract $\gamma-2\beta_s$ [123] (where $\beta_s=\arg(-V_{ts}V_{tb}^*/V_{cs}V_{cb}^*)$ is related to the phase of B_s mixing).

11.4. Global fit in the Standard Model

Using the independently measured CKM elements mentioned in the previous sections, the unitarity of the CKM matrix can be checked. We obtain $|V_{ud}|^2+|V_{us}|^2+|V_{ub}|^2=0.9999\pm0.0006$ (1st row), $|V_{cd}|^2+|V_{cs}|^2+|V_{cb}|^2=1.067\pm0.047$ (2nd row), $|V_{ud}|^2+|V_{cd}|^2+|V_{td}|^2=1.002\pm0.005$ (1st column), and $|V_{us}|^2+|V_{cs}|^2+|V_{ts}|^2=1.065\pm0.046$ (2nd column), respectively. The uncertainties in the second row and column are dominated by that of $|V_{cs}|$. For the second row, a more stringent check is obtained from the measurement of $\sum_{u,c,d,s,b}|V_{ij}|^2$ in Sec. 11.2.4 minus the sum in the first row above: $|V_{cd}|^2+|V_{cs}|^2+|V_{cb}|^2=1.002\pm0.027$. These provide strong tests of the unitarity of the CKM matrix. The sum of the three angles of the unitarity triangle, $\alpha+\beta+\gamma=(178^{+11}_{-12})^\circ$, is also consistent with the SM expectation.

The CKM matrix elements can be most precisely determined by a global fit that uses all available measurements and imposes the SM constraints (*i.e.*, three generation unitarity). The fit must also use theory predictions for hadronic matrix elements, which sometimes have significant uncertainties. There are several approaches to combining the experimental data. CKMfitter [6,101] and Ref. 124 (which develops [125,126] further) use frequentist statistics, while UTfit [108,127] uses a Bayesian approach. These approaches provide similar results.

The constraints implied by the unitarity of the three generation CKM matrix significantly reduce the allowed range of some of the CKM elements. The fit for the Wolfenstein parameters defined in Eq. (11.4) gives

$$\begin{split} \lambda &= 0.22535 \pm 0.00065 \,, \qquad A = 0.811^{+0.022}_{-0.012} \,, \\ \bar{\rho} &= 0.131^{+0.026}_{-0.013} \,, \qquad \qquad \bar{\eta} = 0.345^{+0.013}_{-0.014} \,. \end{split} \tag{11.26}$$

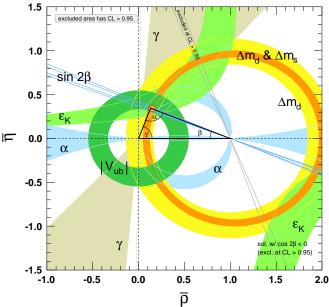

Figure 11.2: Constraints on the $\bar{\rho},\bar{\eta}$ plane. The shaded areas have 95% CL.

These values are obtained using the method of Refs. [6,101]. Using the prescription of Refs. [108,127] gives $\lambda=0.22535\pm0.00065,$ $A=0.817\pm0.015,$ $\bar{\rho}=0.136\pm0.018,$ $\bar{\eta}=0.348\pm0.014$ [128]. The fit results for the magnitudes of all nine CKM elements are

and the Jarlskog invariant is $J=(2.96^{+0.20}_{-0.16})\times 10^{-5}.$

Figure 11.2 illustrates the constraints on the $\bar{\rho}, \bar{\eta}$ plane from various measurements and the global fit result. The shaded 95% CL regions all overlap consistently around the global fit region. This consistency gets noticeably worse if $B \to \tau \bar{\nu}$ is included in the fit.

11.5. Implications beyond the SM

The effects in B, K, and D decays and mixings due to high-scale physics (W, Z, t, h) in the SM, and new physics particles) can be parameterized by operators made of SM fields, obeying the $SU(3) \times SU(2) \times U(1)$ gauge symmetry. The beyond SM (BSM) contributions to the coefficients of these operators are suppressed by powers of the scale of new physics. At lowest order, there are of order a hundred flavor-changing operators of dimension-6, and the observable effects of BSM interactions are encoded in their coefficients. In the SM, these coefficients are determined by just the four CKM parameters, and the W, Z, and quark masses. For example, Δm_d , $\Gamma(B \to \rho \gamma)$, and $\Gamma(B \to X_d \ell^+ \ell^-)$ are all proportional to $|V_{td}V_{tb}^*|^2$ in the SM, however, they may receive unrelated contributions from new physics. The new physics contributions may or may not obey the SM relations. (For example, the flavor sector of the MSSM contains 69 CP-conserving parameters and 41 CP-violating phases, i.e., 40 new ones [129]). Thus, similar to the measurements of $\sin 2\beta$ in tree- and loop-dominated decay modes, overconstraining measurements of the magnitudes and phases of flavor-changing neutral-current amplitudes give good sensitivity to new physics.

To illustrate the level of suppression required for BSM contributions, consider a class of models in which the unitarity of the CKM matrix is maintained, and the dominant effect of new physics is to modify the neutral meson mixing amplitudes [130] by $(z_{ij}/\Lambda^2)(\overline{q}_i\gamma^\mu P_L q_j)^2$ (for recent reviews, see [131,132]). It is only known since the measurements of γ and α that the SM gives the leading contribution to $B^0-\overline{B}^0$ mixing [6,133]. Nevertheless, new physics with a generic weak phase may still contribute to neutral meson mixings at a significant fraction of the SM [134,127]. The existing data imply that $\Lambda/|z_{ij}|^{1/2}$ has to

exceed about 10^4 TeV for $K^0-\overline{K}^0$ mixing, 10^3 TeV for $D^0-\overline{D}^0$ mixing, 500 TeV for $B^0-\overline{B}^0$ mixing, and 100 TeV for $B^0_s-\overline{B}^0_s$ mixing [127,132]. (Some other operators are even better constrained [127].) The constraints are the strongest in the kaon sector, because the CKM suppression is the most severe. Thus, if there is new physics at the TeV scale, $|z_{ij}| \ll 1$ is required. Even if $|z_{ij}|$ are suppressed by a loop factor and $|V^*_{ti}V_{tj}|^2$ (in the down quark sector), similar to the SM, one expects percent-level effects, which may be observable in forthcoming flavor physics experiments. To constrain such extensions of the SM, many measurements irrelevant for the SM-CKM fit, such as the CP asymmetry in semileptonic $B^0_{d,s}$ decays, $A^{d,s}_{\rm SL}$, are important [135]. A DØ measurement sensitive to the approximate linear combination $0.6A^d_{\rm SL}+0.4A^s_{\rm SL}$ shows a 3.9σ hint of a deviation from the SM [136].

Many key measurements which are sensitive to BSM flavor physics are not useful to think about in terms of constraining the unitarity triangle in Fig. 11.1. For example, besides the angles in Eq. (11.16), a key quantity in the B_s system is $\beta_s = \arg(-V_{ts}V_{tb}^*/V_{cs}V_{cb}^*)$, which is the small, λ^2 -suppressed, angle of a "squashed" unitarity triangle, obtained by taking the scalar product of the second and third columns. This angle can be measured via time-dependent CP violation in $B_s^0 \to J/\psi \phi$, similar to β in $B^0 \to J/\psi K^0$. Since the $J/\psi \phi$ final state is not a CP eigenstate, an angular analysis of the decay products is needed to separate the CP-even and CP-odd components, which give opposite asymmetries. In the SM, the asymmetry for the CP-even part is $2\beta_s$ (sometimes the notation $\phi_s = -2\beta_s$ plus a possible BSM contribution to the B_s mixing phase is used). Checking if the data agrees with the SM prediction, $\beta_s = 0.018 \pm 0.001$ [101], is another sensitive test of the SM. After the first CP-asymmetry measurements of $B_s^0 \to J/\psi \phi$ hinted at a possible large deviation from the SM, the latest Tevatron results [137] are consistent with the SM, within the sizable uncertainties. So is the much more precise LHCb measurement obtained from 1 fb⁻¹ data, including the $J/\psi \pi\pi$ mode, yielding $\beta_s = 0.001 \pm 0.044$ [138]. This uncertainty is still more than twice the SM central value and 40 times the SM uncertainty; thus a lot will be learned from higher precision measurements in the future.

In the kaon sector, the two measured CP-violating observables ϵ and ϵ' are tiny, so models in which all sources of CP violation are small were viable before the B-factory measurements. Since the measurement of $\sin 2\beta$, we know that CP violation can be an $\mathcal{O}(1)$ effect, and only flavor mixing is suppressed between the three quark generations. Thus, many models with spontaneous CP violation are excluded. In the kaon sector, a very clean test of the SM will come from measurements of $K^+ \to \pi^+ \nu \bar{\nu}$ and $K^0_L \to \pi^0 \nu \bar{\nu}$. These loop-induced rare decays are sensitive to new physics, and will allow a determination of β independent of its value measured in B decays [139].

The CKM elements are fundamental parameters, so they should be measured as precisely as possible. The overconstraining measurements of CP asymmetries, mixing, semileptonic, and rare decays have started to severely constrain the magnitudes and phases of possible new physics contributions to flavor-changing interactions. When new particles are observed at the LHC, it will be important to know the flavor parameters as precisely as possible to understand the underlying physics.

12. CP VIOLATION IN MESON DECAYS

Revised May 2012 by D. Kirkby (UC Irvine) and Y. Nir (Weizmann Institute).

The CP transformation combines charge conjugation C with parity P. Under C, particles and antiparticles are interchanged, by conjugating all internal quantum numbers, e.g., $Q \to -Q$ for electromagnetic charge. Under P, the handedness of space is reversed, $\vec{x} \to -\vec{x}$. Thus, for example, a left-handed electron e_L^- is transformed under CP into a right-handed positron, e_R^+ .

If CP were an exact symmetry, the laws of Nature would be the same for matter and for antimatter. We observe that most phenomena are C- and P-symmetric, and therefore, also CP-symmetric. In particular, these symmetries are respected by the gravitational, electromagnetic, and strong interactions. The weak interactions, on the other hand, violate C and P in the strongest possible way. For example, the charged W bosons couple to left-handed electrons, e_L^- , and to their CP-conjugate right-handed positrons, e_R^+ , but to neither their C-conjugate left-handed positrons, e_L^+ , nor their P-conjugate right-handed electrons, e_R^- . While weak interactions violate C and Pseparately, CP is still preserved in most weak interaction processes. The CP symmetry is, however, violated in certain rare processes, as discovered in neutral K decays in 1964 [1], and observed in recent years in B decays. A K_L meson decays more often to $\pi^- e^+ \overline{\nu}_e$ than to $\pi^+e^-\nu_e$, thus allowing electrons and positrons to be unambiguously distinguished, but the decay-rate asymmetry is only at the 0.003 level. The CP-violating effects observed in B decays are larger: the CPasymmetry in B^0/\overline{B}^0 meson decays to CP eigenstates like $J/\psi K_S$ is about 0.7 [2.3]. These effects are related to $K^0 - \overline{K}^0$ and $B^0 - \overline{B}^0$ mixing, but CP violation arising solely from decay amplitudes has also been observed, first in $K \to \pi\pi$ decays [4–6], and more recently in various neutral B [7,8] and charged B [9–11] decays. Evidence for CPviolation in the decay amplitude at a level higher than 3σ (but still lower than 5σ) has also been achieved in neutral D [12] and B_s [13] decays. CP violation has not yet been observed in the lepton sector.

In addition to parity and to continuous Lorentz transformations, there is one other spacetime operation that could be a symmetry of the interactions: time reversal $T, t \to -t$. Violations of T symmetry have been observed in neutral K decays [14], and are expected as a corollary of CP violation if the combined CPT transformation is a fundamental symmetry of Nature [15]. All observations indicate that CPT is indeed a symmetry of Nature. Furthermore, one cannot build a Lorentz-invariant quantum field theory with a Hermitian Hamiltonian that violates CPT. (At several points in our discussion, we avoid assumptions about CPT, in order to identify cases where evidence for CP violation relies on assumptions about CPT.)

Within the Standard Model, CP symmetry is broken by complex phases in the Yukawa couplings (that is, the couplings of the Higgs scalar to quarks). When all manipulations to remove unphysical phases in this model are exhausted, one finds that there is a single CP-violating parameter [16]. In the basis of mass eigenstates, this single phase appears in the 3×3 unitary matrix that gives the W-boson couplings to an up-type antiquark and a down-type quark. (If the Standard Model is supplemented with Majorana mass terms for the neutrinos, the analogous mixing matrix for leptons has three CP-violating phases.) The beautifully consistent and economical Standard-Model description of CP violation in terms of Yukawa couplings, known as the Kobayashi-Maskawa (KM) mechanism [16]. agrees with all measurements to date. (The measurement of the dimuon asymmetry in semi-leptonic b-hadron decays deviates from the Standard Model prediction by 3.9σ [17]. Pending confirmation, we do not discuss it further in this review.) Furthermore, one can fit the data allowing new physics contributions to loop processes to compete with, or even dominate over, the Standard Model ones [18,19]. Such an analysis provides a model-independent proof that the KM phase is different from zero, and that the matrix of three-generation quark mixing is the dominant source of CP violation in meson decays.

The current level of experimental accuracy and the theoretical uncertainties involved in the interpretation of the various observations leave room, however, for additional subdominant sources of CP violation from new physics. Indeed, almost all extensions of the

Standard Model imply that there are such additional sources. Moreover, CP violation is a necessary condition for baryogenesis, the process of dynamically generating the matter-antimatter asymmetry of the Universe [20]. Despite the phenomenological success of the KM mechanism, it fails (by several orders of magnitude) to accommodate the observed asymmetry [21]. This discrepancy strongly suggests that Nature provides additional sources of CP violation beyond the KM mechanism. (The evidence for neutrino masses implies that CP can be violated also in the lepton sector. This situation makes leptogenesis [22], a scenario where CP-violating phases in the Yukawa couplings of the neutrinos play a crucial role in the generation of the baryon asymmetry, a very attractive possibility.) The expectation of new sources motivates the large ongoing experimental effort to find deviations from the predictions of the KM mechanism.

CP violation can be experimentally searched for in a variety of processes, such as meson decays, electric dipole moments of neutrons, electrons and nuclei, and neutrino oscillations. Meson decays probe flavor-changing CP violation. The search for electric dipole moments may find (or constrain) sources of CP violation that, unlike the KM phase, are not related to flavor-changing couplings. Future searches for CP violation in neutrino oscillations might provide further input on leptogenesis.

The present measurements of CP asymmetries provide some of the strongest constraints on the weak couplings of quarks. Future measurements of CP violation in K, D, B, and B_s meson decays will provide additional constraints on the flavor parameters of the Standard Model, and can probe new physics. In this review, we give the formalism and basic physics that are relevant to present and near future measurements of CP violation in meson decays.

Before going into details, we list here the observables where CP violation has been observed at a level above 5σ [23–25]:

• Indirect CP violation in $K\to\pi\pi$ and $K\to\pi\ell\nu$ decays, and in the $K_L\to\pi^+\pi^-e^+e^-$ decay, is given by

$$|\epsilon| = (2.228 \pm 0.011) \times 10^{-3}$$
 (12.1)

• Direct CP violation in $K \to \pi\pi$ decays is given by

$$\Re(\epsilon'/\epsilon) = (1.65 \pm 0.26) \times 10^{-3}.$$
 (12.2)

• CP violation in the interference of mixing and decay in the tree-dominated $b \to c\bar{c}s$ transitions, such as $B \to \psi K^0$, is given by (we use K^0 throughout to denote results that combine K_S and K_L modes, but use the sign appropriate to K_S):

$$S_{\psi K^0} = +0.679 \pm 0.020. \tag{12.3} \label{eq:spike}$$

• CP violation in the interference of mixing and decay in various modes related to $b \to q\bar{q}s$ (penguin) transitions is given by

$$S_{n'K^0} = +0.59 \pm 0.07,$$
 (12.4)

$$S_{\phi K^0} = +0.74^{+0.11}_{-0.13},$$
 (12.5)

$$S_{f_0K^0} = +0.69^{+0.10}_{-0.12},$$
 (12.6)

$$S_{K^+K^-K_S} = +0.68^{+0.09}_{-0.10}, \tag{12.7} \label{eq:12.7}$$

• CP violation in the interference of mixing and decay in the $B\to \pi^+\pi^-$ mode is given by

$$S_{\pi^{+}\pi^{-}} = -0.65 \pm 0.07.$$
 (12.8)

• Direct CP violation in the $B \to \pi^+\pi^-$ mode is given by

$$C_{\pi^{+}\pi^{-}} = -0.36 \pm 0.06.$$
 (12.9)

• CP violation in the interference of mixing and decay in various modes related to $b\to c\bar cd$ transitions is given by

$$S_{\psi\pi^0} = -0.93 \pm 0.15,$$
 (12.10)

$$S_{D^+D^-} = -0.98 \pm 0.17.$$
 (12.11)

$$S_{D^{*+}D^{*-}} = -0.77 \pm 0.10.$$
 (12.12)

• Direct CP violation in the $\overline{B}{}^0 \to K^-\pi^+$ mode is given by

$$A_{K^{\mp}\pi^{\pm}} = -0.087 \pm 0.008. \tag{12.13}$$

• Direct CP violation in $B^{\pm} \to D_+ K^{\pm}$ decays (D_+ is the CP-even neutral D state) is given by

$$A_{D+K^{\pm}} = +0.19 \pm 0.03.$$
 (12.14)

12.1. Formalism

The phenomenology of CP violation is superficially different in K, D, B, and B_s decays. This is primarily because each of these systems is governed by a different balance between decay rates, oscillations, and lifetime splitting. However, the underlying mechanisms of CP violation are identical for all pseudoscalar mesons.

In this section, we present a general formalism for, and classification of, CP violation in the decay of a pseudoscalar meson M that might be a charged or neutral K, D, B, or B_s meson. Subsequent sections describe the CP-violating phenomenology, approximations, and alternative formalisms that are specific to each system.

12.1.1. Charged- and neutral-meson decays: We define decay amplitudes of M (which could be charged or neutral) and its CP conjugate \overline{M} to a multi-particle final state f and its CP conjugate \overline{f} as

$$A_f = \langle f | \mathcal{H} | M \rangle$$
 , $\overline{A}_f = \langle f | \mathcal{H} | \overline{M} \rangle$,
 $A_{\overline{f}} = \langle \overline{f} | \mathcal{H} | M \rangle$, $\overline{A}_{\overline{f}} = \langle \overline{f} | \mathcal{H} | \overline{M} \rangle$, (12.15)

where \mathcal{H} is the Hamiltonian governing weak interactions. The action of CP on these states introduces phases ξ_M and ξ_f that depend on their flavor content, according to

$$CP|M\rangle = e^{+i\xi_M}|\overline{M}\rangle$$
 , $CP|f\rangle = e^{+i\xi_f}|\overline{f}\rangle$, (12.16)

with

$$CP|\overline{M}\rangle = e^{-i\xi_M}|M\rangle$$
 , $CP|\overline{f}\rangle = e^{-i\xi_f}|f\rangle$ (12.17)

so that $(CP)^2=1$. The phases ξ_M and ξ_f are arbitrary and unphysical because of the flavor symmetry of the strong interaction. If CP is conserved by the dynamics, $[CP,\mathcal{H}]=0$, then A_f and $\overline{A}_{\overline{f}}$ have the same magnitude and an arbitrary unphysical relative phase

$$\overline{A_f} = e^{i(\xi_f - \xi_M)} A_f . \qquad (12.18)$$

12.1.2. Neutral-meson mixing: A state that is initially a superposition of M^0 and \overline{M}^0 , say

$$|\psi(0)\rangle = a(0)|M^0\rangle + b(0)|\overline{M}^0\rangle, \qquad (12.19)$$

will evolve in time acquiring components that describe all possible decay final states $\{f_1, f_2, \ldots\}$, that is,

$$|\psi(t)\rangle = a(t)|M^{0}\rangle + b(t)|\overline{M}^{0}\rangle + c_{1}(t)|f_{1}\rangle + c_{2}(t)|f_{2}\rangle + \cdots$$
 (12.20)

If we are interested in computing only the values of a(t) and b(t) (and not the values of all $c_i(t)$), and if the times t in which we are interested are much larger than the typical strong interaction scale, then we can use a much simplified formalism [26]. The simplified time evolution is determined by a 2×2 effective Hamiltonian ${\bf H}$ that is not Hermitian, since otherwise the mesons would only oscillate and not decay. Any complex matrix, such as ${\bf H}$, can be written in terms of Hermitian matrices ${\bf M}$ and ${\bf \Gamma}$ as

$$\mathbf{H} = \mathbf{M} - \frac{i}{2} \mathbf{\Gamma} . \tag{12.21}$$

M and Γ are associated with $(M^0, \overline{M}^0) \leftrightarrow (M^0, \overline{M}^0)$ transitions via off-shell (dispersive), and on-shell (absorptive) intermediate states, respectively. Diagonal elements of **M** and Γ are associated with

the flavor-conserving transitions $M^0 \to M^0$ and $\overline{M}^0 \to \overline{M}^0$, while off-diagonal elements are associated with flavor-changing transitions $M^0 \leftrightarrow \overline{M}^0$.

The eigenvectors of \mathbf{H} have well-defined masses and decay widths. To specify the components of the strong interaction eigenstates, M^0 and \overline{M}^0 , in the light (M_L) and heavy (M_H) mass eigenstates, we introduce three complex parameters: p, q, and, for the case that both CP and CPT are violated in mixing, z:

$$|M_L\rangle \propto p\sqrt{1-z} |M^0\rangle + q\sqrt{1+z} |\overline{M}^0\rangle$$

 $|M_H\rangle \propto p\sqrt{1+z} |M^0\rangle - q\sqrt{1-z} |\overline{M}^0\rangle$, (12.22)

with the normalization $|q|^2 + |p|^2 = 1$ when z = 0. (Another possible choice, which is in standard usage for K mesons, defines the mass eigenstates according to their lifetimes: K_S for the short-lived and K_L for the long-lived state. The K_L is experimentally found to be the heavier state.)

The real and imaginary parts of the eigenvalues $\omega_{L,H}$ corresponding to $|M_{L,H}\rangle$ represent their masses and decay widths, respectively. The mass and width splittings are

$$\Delta m \equiv m_H - m_L = \Re e(\omega_H - \omega_L) \quad ,$$

$$\Delta \Gamma \equiv \Gamma_H - \Gamma_L = -2 \mathcal{I} m(\omega_H - \omega_L) \ . \tag{12.23}$$

Note that here Δm is positive by definition, while the sign of $\Delta \Gamma$ is to be experimentally determined. The sign of $\Delta \Gamma$ has not yet been established for the B mesons, while $\Delta \Gamma < 0$ is established for K and B_s mesons and $\Delta \Gamma > 0$ is established for D mesons. The Standard Model predicts $\Delta \Gamma < 0$ also for B mesons (for this reason, $\Delta \Gamma = \Gamma_L - \Gamma_H$, which is still a signed quantity, is often used in the B and B_s literature and is the convention used in the PDG experimental summaries).

Solving the eigenvalue problem for H vields

$$\left(\frac{q}{p}\right)^2 = \frac{\mathbf{M}_{12}^* - (i/2)\mathbf{\Gamma}_{12}^*}{\mathbf{M}_{12} - (i/2)\mathbf{\Gamma}_{12}}$$
(12.24)

and

$$z \equiv \frac{\delta m - (i/2)\delta\Gamma}{\Delta m - (i/2)\Delta\Gamma} , \qquad (12.25)$$

where

$$\delta m \equiv \mathbf{M}_{11} - \mathbf{M}_{22} \quad , \quad \delta \Gamma \equiv \mathbf{\Gamma}_{11} - \mathbf{\Gamma}_{22}$$
 (12.26)

are the differences in effective mass and decay-rate expectation values for the strong interaction states M^0 and \overline{M}^0 .

If either CP or CPT is a symmetry of \mathbf{H} (independently of whether T is conserved or violated), then the values of δm and $\delta \Gamma$ are both zero, and hence z=0. We also find that

$$\omega_H - \omega_L = 2\sqrt{\left(\mathbf{M}_{12} - \frac{i}{2}\mathbf{\Gamma}_{12}\right)\left(\mathbf{M}_{12}^* - \frac{i}{2}\mathbf{\Gamma}_{12}^*\right)}$$
 (12.27)

If either CP or T is a symmetry of \mathbf{H} (independently of whether CPT is conserved or violated), then $\Gamma_{12}/\mathbf{M}_{12}$ is real, leading to

$$\left(\frac{q}{p}\right)^2 = e^{2i\xi_M} \quad \Rightarrow \quad \left|\frac{q}{p}\right| = 1 , \qquad (12.28)$$

where ξ_M is the arbitrary unphysical phase introduced in Eq. (12.17). If, and only if, CP is a symmetry of \mathbf{H} (independently of CPT and T), then both of the above conditions hold, with the result that the mass eigenstates are orthogonal

$$\langle M_H | M_L \rangle = |p|^2 - |q|^2 = 0.$$
 (12.29)

12.1.3. CP-violating observables: All CP-violating observables in M and \overline{M} decays to final states f and \overline{f} can be expressed in terms of phase-convention-independent combinations of A_f , $\overline{A_f}$, and $\overline{A_f}$, together with, for neutral-meson decays only, q/p. CP violation in charged-meson decays depends only on the combination $|\overline{A_f}/A_f|$, while CP violation in neutral-meson decays is complicated by $M^0 \leftrightarrow \overline{M}^0$ oscillations, and depends, additionally, on |q/p| and on $\lambda_f \equiv (q/p)(\overline{A_f}/A_f)$.

The decay rates of the two neutral K mass eigenstates, K_S and K_L , are different enough $(\Gamma_S/\Gamma_L\sim 500)$ that one can, in most cases, actually study their decays independently. For neutral D, B, and B_s mesons, however, values of $\Delta\Gamma/\Gamma$ (where $\Gamma\equiv (\Gamma_H+\Gamma_L)/2$) are relatively small, and so both mass eigenstates must be considered in their evolution. We denote the state of an initially pure $|M^0\rangle$ or $|\overline{M}^0\rangle$ after an elapsed proper time t as $|M^0_{\rm phys}(t)\rangle$ or $|\overline{M}^0_{\rm phys}(t)\rangle$, respectively. Using the effective Hamiltonian approximation, but not assuming CPT is a good symmetry, we obtain

$$|M_{\rm phys}^{0}(t)\rangle = (g_{+}(t) + z g_{-}(t)) |M^{0}\rangle - \sqrt{1 - z^{2}} \frac{q}{p} g_{-}(t) |\overline{M}^{0}\rangle,$$

$$|\overline{M}_{\rm phys}^{0}(t)\rangle = (g_{+}(t) - z g_{-}(t)) |\overline{M}^{0}\rangle - \sqrt{1 - z^{2}} \frac{p}{q} g_{-}(t) |M^{0}\rangle,$$
(12.30)

where

$$g_{\pm}(t) \equiv \frac{1}{2} \left(e^{-im_H t - \frac{1}{2}\Gamma_H t} \pm e^{-im_L t - \frac{1}{2}\Gamma_L t} \right)$$
 (12.31)

and z = 0 if either CPT or CP is conserved.

Defining $x \equiv \Delta m/\Gamma$ and $y \equiv \Delta \Gamma/(2\Gamma)$, and assuming z=0, one obtains the following time-dependent decay rates:

$$\begin{split} \frac{d\Gamma\big[M_{\rm phys}^0(t) \to f\big]/dt}{e^{-\Gamma t} \mathcal{N}_f} &= \\ & \left(|A_f|^2 + |(q/p)\overline{A}_f|^2\right) \cosh(y\Gamma t) + \left(|A_f|^2 - |(q/p)\overline{A}_f|^2\right) \cos(x\Gamma t) \\ &+ 2 \,\mathcal{R}e((q/p)A_f^*\overline{A}_f) \sinh(y\Gamma t) - 2 \,\mathcal{I}m((q/p)A_f^*\overline{A}_f) \sin(x\Gamma t) \;, \end{split}$$

$$(12.32)$$

$$\begin{split} \frac{d\Gamma[\overline{M}_{\rm phys}^0(t) \to f]/dt}{e^{-\Gamma t} \mathcal{N}_f} &= \\ & \left(|(p/q)A_f|^2 + |\overline{A}_f|^2 \right) \cosh(y\Gamma t) - \left(|(p/q)A_f|^2 - |\overline{A}_f|^2 \right) \cos(x\Gamma t) \\ &+ 2 \mathcal{R}e((p/q)A_f \overline{A}_f^*) \sinh(y\Gamma t) - 2 \mathcal{I}m((p/q)A_f \overline{A}_f^*) \sin(x\Gamma t) \;, \end{split}$$

where \mathcal{N}_f is a common, time-independent, normalization factor. Decay rates to the CP-conjugate final state \overline{f} are obtained analogously, with $\mathcal{N}_f = \mathcal{N}_{\overline{f}}$ and the substitutions $A_f \to A_{\overline{f}}$ and $\overline{A}_f \to \overline{A}_{\overline{f}}$ in Eqs. (12.32, 12.33). Terms proportional to $|A_f|^2$ or $|\overline{A}_f|^2$ are associated with decays that occur without any net $M \to \overline{M}$ oscillation, while terms proportional to $|(q/p)\overline{A}_f|^2$ or $|(p/q)A_f|^2$ are associated with decays following a net oscillation. The $\sin(y\Gamma t)$ and $\sin(x\Gamma t)$ terms of Eqs. (12.32, 12.33) are associated with the interference between these two cases. Note that, in multi-body decays, amplitudes are functions of phase-space variables. Interference may be present in some regions but not others, and is strongly influenced by resonant substructure.

When neutral pseudoscalar mesons are produced coherently in pairs from the decay of a vector resonance, $V \to M^0 \overline{M}^0$ (for example, $\Upsilon(4S) \to B^0 \overline{B}^0$ or $\phi \to K^0 \overline{K}^0$), the time-dependence of their subsequent decays to final states f_1 and f_2 has a similar form to Eqs. (12.32, 12.33):

$$\begin{split} \frac{d\Gamma \big[V_{\rm phys}(t_1,t_2) \to f_1 f_2 \big] / d(\Delta t)}{e^{-\Gamma |\Delta t|} \mathcal{N}_{f_1 f_2}} &= \\ \Big(|a_+|^2 + |a_-|^2 \Big) \cosh(y \Gamma \Delta t) + \Big(|a_+|^2 - |a_-|^2 \Big) \cos(x \Gamma \Delta t) \\ &- 2 \, \mathcal{R}e(a_+^* a_-) \sinh(y \Gamma \Delta t) + 2 \, \mathcal{I}m(a_+^* a_-) \sin(x \Gamma \Delta t) \;, \end{split}$$
(12.34)

where $\Delta t \equiv t_2 - t_1$ is the difference in the production times, t_1 and t_2 , of f_1 and f_2 , respectively, and the dependence on the average decay time and on decay angles has been integrated out. The coefficients in Eq. (12.34) are determined by the amplitudes for no net oscillation from $t_1 \rightarrow t_2$, $\overline{A}_{f_1} A_{f_2}$, and $A_{f_1} \overline{A}_{f_2}$, and for a net oscillation, $(q/p)\overline{A}_{f_1} \overline{A}_{f_2}$ and $(p/q)A_{f_1} A_{f_2}$, via

$$a_{+} \equiv \overline{A}_{f_{1}} A_{f_{2}} - A_{f_{1}} \overline{A}_{f_{2}} ,$$
 (12.35)

$$a_- \equiv \; - \sqrt{1-z^2} \left(\frac{q}{p} \overline{A}_{f_1} \overline{A}_{f_2} - \frac{p}{q} A_{f_1} A_{f_2} \right) + z \left(\overline{A}_{f_1} A_{f_2} + A_{f_1} \overline{A}_{f_2} \right) \; . \label{alpha}$$

Assuming CPT conservation, z=0, and identifying $\Delta t \to t$ and $f_2 \to f$, we find that Eqs. (12.34) and (12.35) reduce to Eq. (12.32) with $A_{f_1}=0$, $\overline{A}_{f_1}=1$, or to Eq. (12.33) with $\overline{A}_{f_1}=0$, $A_{f_1}=1$. Indeed, such a situation plays an important role in experiments. Final states f_1 with $A_{f_1}=0$ or $\overline{A}_{f_1}=0$ are called tagging states, because they identify the decaying pseudoscalar meson as, respectively, \overline{M}^0 or M^0 . Before one of M^0 or \overline{M}^0 decays, they evolve in phase, so that there is always one M^0 and one \overline{M}^0 present. A tagging decay of one meson sets the clock for the time evolution of the other: it starts at t_1 as purely M^0 or \overline{M}^0 , with time evolution that depends only on t_2-t_1 .

When f_1 is a state that both M^0 and \overline{M}^0 can decay into, then Eq. (12.34) contains interference terms proportional to $A_{f_1}\overline{A}_{f_1}\neq 0$ that are not present in Eqs. (12.32, 12.33). Even when f_1 is dominantly produced by M^0 decays rather than \overline{M}^0 decays, or vice versa, $A_{f_1}\overline{A}_{f_1}$ can be non-zero owing to doubly-CKM-suppressed decays (with amplitudes suppressed by at least two powers of λ relative to the dominant amplitude, in the language of Section 12.3), and these terms should be considered for precision studies of CP violation in coherent $V \to M^0\overline{M}^0$ decays [27].

12.1.4. Classification of CP-violating effects: We distinguish three types of CP-violating effects in meson decays:

I. CP violation in decay is defined by

$$|\overline{A_f}/A_f| \neq 1. \tag{12.36}$$

In charged meson decays, where mixing effects are absent, this is the only possible source of CP asymmetries:

$$A_{f\pm} \equiv \frac{\Gamma(M^{-} \to f^{-}) - \Gamma(M^{+} \to f^{+})}{\Gamma(M^{-} \to f^{-}) + \Gamma(M^{+} \to f^{+})} = \frac{|\overline{A}_{f^{-}}/A_{f^{+}}|^{2} - 1}{|\overline{A}_{f^{-}}/A_{f^{+}}|^{2} + 1} . \quad (12.37)$$

II. CP (and T) violation in mixing is defined by

$$|q/p| \neq 1$$
. (12.38)

In charged-current semileptonic neutral meson decays $M, \overline{M} \to \ell^{\pm} X$ (taking $|A_{\ell^+ X}| = |\overline{A}_{\ell^- X}|$ and $A_{\ell^- X} = \overline{A}_{\ell^+ X} = 0$, as is the case in the Standard Model, to lowest order in G_F , and in most of its reasonable extensions), this is the only source of CP violation, and can be measured via the asymmetry of "wrong-sign" decays induced by oscillations:

$$\mathcal{A}_{\rm SL}(t) \equiv \frac{d\Gamma/dt \left[\overline{M}_{\rm phys}^{0}(t) \to \ell^{+} X\right] - d\Gamma/dt \left[M_{\rm phys}^{0}(t) \to \ell^{-} X\right]}{d\Gamma/dt \left[\overline{M}_{\rm phys}^{0}(t) \to \ell^{+} X\right] + d\Gamma/dt \left[M_{\rm phys}^{0}(t) \to \ell^{-} X\right]}$$
$$= \frac{1 - |q/p|^{4}}{1 + |q/p|^{4}}. \tag{12.39}$$

Note that this asymmetry of time-dependent decay rates is actually time-independent. $\,$

III. CP violation in interference between a decay without mixing, $M^0 \to f$, and a decay with mixing, $M^0 \to \overline{M}^0 \to f$ (such an effect occurs only in decays to final states that are common to M^0 and \overline{M}^0 , including all CP eigenstates), is defined by

$$\mathcal{I}m(\lambda_f) \neq 0 , \qquad (12.40)$$

with

$$\lambda_f \equiv \frac{q}{p} \frac{\overline{A}_f}{A_f} \ . \tag{12.41}$$

This form of CP violation can be observed, for example, using the asymmetry of neutral meson decays into final CP eigenstates f_{CP}

$$\mathcal{A}_{f_{CP}}(t) \equiv \frac{d\Gamma/dt \left[\overline{M}_{\text{phys}}^{0}(t) \to f_{CP} \right] - d\Gamma/dt \left[M_{\text{phys}}^{0}(t) \to f_{CP} \right]}{d\Gamma/dt \left[\overline{M}_{\text{phys}}^{0}(t) \to f_{CP} \right] + d\Gamma/dt \left[M_{\text{phys}}^{0}(t) \to f_{CP} \right]}. \tag{12.4}$$

If $\Delta\Gamma=0$ and |q/p|=1, as expected to a good approximation for B_d mesons, but not for K and B_s mesons, then \mathcal{A}_{fCP} has a particularly simple form (see Eq. (12.86), below). If, in addition, the decay amplitudes fulfill $|\overline{A}_{fCP}|=|A_{fCP}|,$ the interference between decays with and without mixing is the only source of the asymmetry and $\mathcal{A}_{fCP}(t)=\mathcal{I}m(\lambda_{fCP})\sin(x\Gamma t).$

Examples of these three types of CP violation will be given in Sections 12.4, 12.5, and 12.6.

12.2. Theoretical Interpretation: General Considerations

Consider the $M \to f$ decay amplitude A_f , and the CP conjugate process, $\overline{M} \to \overline{f}$, with decay amplitude $\overline{A}_{\overline{f}}$. There are two types of phases that may appear in these decay amplitudes. Complex parameters in any Lagrangian term that contributes to the amplitude will appear in complex conjugate form in the ${\it CP}$ -conjugate amplitude. Thus, their phases appear in A_f and $\overline{A_f}$ with opposite signs. In the Standard Model, these phases occur only in the couplings of the W^{\pm} bosons, and hence, are often called "weak phases." The weak phase of any single term is convention-dependent. However, the difference between the weak phases in two different terms in A_f is conventionindependent. A second type of phase can appear in scattering or decay amplitudes, even when the Lagrangian is real. Their origin is the possible contribution from intermediate on-shell states in the decay process. Since these phases are generated by CP-invariant interactions, they are the same in A_f and $\overline{A_f}$. Usually the dominant rescattering is due to strong interactions; hence the designation "strong phases" for the phase shifts so induced. Again, only the relative strong phases between different terms in the amplitude are physically meaningful.

The 'weak' and 'strong' phases discussed here appear in addition to the 'spurious' CP-transformation phases of Eq. (12.18). Those spurious phases are due to an arbitrary choice of phase convention, and do not originate from any dynamics or induce any CP violation. For simplicity, we set them to zero from here on.

It is useful to write each contribution a_i to A_f in three parts: its magnitude $|a_i|$, its weak phase ϕ_i , and its strong phase δ_i . If, for example, there are two such contributions, $A_f = a_1 + a_2$, we have

$$A_f = |a_1|e^{i(\delta_1 + \phi_1)} + |a_2|e^{i(\delta_2 + \phi_2)},$$

$$\overline{A_f} = |a_1|e^{i(\delta_1 - \phi_1)} + |a_2|e^{i(\delta_2 - \phi_2)}.$$
(12.43)

Similarly, for neutral meson decays, it is useful to write

$$\mathbf{M}_{12} = |\mathbf{M}_{12}|e^{i\phi_M} \quad , \quad \mathbf{\Gamma}_{12} = |\mathbf{\Gamma}_{12}|e^{i\phi_{\Gamma}} .$$
 (12.44)

Each of the phases appearing in Eqs. (12.43, 12.44) is convention-dependent, but combinations such as $\delta_1-\delta_2,\ \phi_1-\phi_2,\ \phi_M-\phi_\Gamma,$ and $\phi_M+\phi_1-\overline{\phi}_1$ (where $\overline{\phi}_1$ is a weak phase contributing to \overline{A}_f) are physical.

It is now straightforward to evaluate the various asymmetries in terms of the theoretical parameters introduced here. We will do so with approximations that are often relevant to the most interesting measured asymmetries.

1. The CP asymmetry in charged meson decays [Eq. (12.37)] is given by

$$\mathcal{A}_{f^{\pm}} = -\frac{2|a_1 a_2| \sin(\delta_2 - \delta_1) \sin(\phi_2 - \phi_1)}{|a_1|^2 + |a_2|^2 + 2|a_1 a_2| \cos(\delta_2 - \delta_1) \cos(\phi_2 - \phi_1)}.$$
 (12.45)

The quantity of most interest to theory is the weak phase difference $\phi_2 - \phi_1$. Its extraction from the asymmetry requires, however, that the amplitude ratio $|a_2/a_1|$ and the strong phase difference $\delta_2 - \delta_1$ are known. Both quantities depend on non-perturbative hadronic parameters that are difficult to calculate.

2. In the approximation that $|\Gamma_{12}/M_{12}| \ll 1$ (valid for B and B_s mesons), the CP asymmetry in semileptonic neutral-meson decays [Eq. (12.39)] is given by

$$\mathcal{A}_{SL} = -\left|\frac{\Gamma_{12}}{\mathbf{M}_{12}}\right| \sin(\phi_M - \phi_\Gamma). \tag{12.46}$$

The quantity of most interest to theory is the weak phase $\phi_M - \phi_\Gamma$. Its extraction from the asymmetry requires, however, that $|\Gamma_{12}/\mathbf{M}_{12}|$ is known. This quantity depends on long-distance physics that is difficult to calculate.

3. In the approximations that only a single weak phase contributes to decay, $A_f = |a_f|e^{i(\delta_f + \phi_f)}$, and that $|\Gamma_{12}/\mathbf{M}_{12}| = 0$, we obtain $|\lambda_f| = 1$, and the CP asymmetries in decays to a final CP eigenstate f [Eq. (12.42)] with eigenvalue $\eta_f = \pm 1$ are given by

$$\mathcal{A}_{f_{CP}}(t) = \mathcal{I}m(\lambda_f) \sin(\Delta m t) \text{ with } \mathcal{I}m(\lambda_f) = \eta_f \sin(\phi_M + 2\phi_f). \tag{12.47}$$

Note that the phase so measured is purely a weak phase, and no hadronic parameters are involved in the extraction of its value from $\mathcal{I}m(\lambda_f)$.

The discussion above allows us to introduce another classification of ${\cal CP}\text{-}{\rm violating}$ effects:

- 1. Indirect CP violation is consistent with taking $\phi_M \neq 0$ and setting all other CP violating phases to zero. CP violation in mixing (type II) belongs to this class.
- 2. Direct CP violation cannot be accounted for by just $\phi_M \neq 0$. CP violation in decay (type I) belongs to this class.

As concerns type III CP violation, observing $\eta_{f_1} Im(\lambda_{f_1}) \neq \eta_{f_2} Im(\lambda_{f_2})$ (for the same decaying meson and two different final CP eigenstates f_1 and f_2) would establish direct CP violation. The significance of this classification is related to theory. In superweak models [28], CP violation appears only in diagrams that contribute to \mathbf{M}_{12} , hence they predict that there is no direct CP violation. In most models and, in particular, in the Standard Model, CP violation is both direct and indirect. The experimental observation of $\epsilon' \neq 0$ (see Section 12.4) excluded the superweak scenario.

12.3. Theoretical Interpretation: The KM Mechanism

Of all the Standard Model quark parameters, only the Kobayashi-Maskawa (KM) phase is CP-violating. Having a single source of CP violation, the Standard Model is very predictive for CP asymmetries: some vanish, and those that do not are correlated.

To be precise, CP could be violated also by strong interactions. The experimental upper bound on the electric-dipole moment of the neutron implies, however, that $\theta_{\rm QCD}$, the non-perturbative parameter that determines the strength of this type of CP violation, is tiny, if not zero. (The smallness of $\theta_{\rm QCD}$ constitutes a theoretical puzzle, known as 'the strong CP problem.') In particular, it is irrelevant to our discussion of meson decays.

The charged current interactions (that is, the W^{\pm} interactions) for quarks are given by

$$-\mathcal{L}_{W^{\pm}} = \frac{g}{\sqrt{2}} \overline{u_{Li}} \gamma^{\mu} (V_{\text{CKM}})_{ij} d_{Lj} W_{\mu}^{+} + \text{h.c.}$$
 (12.48)

Here i,j=1,2,3 are generation numbers. The Cabibbo-Kobayashi-Maskawa (CKM) mixing matrix for quarks is a 3×3 unitary matrix [29] Ordering the quarks by their masses, *i.e.*, $(u_1,u_2,u_3) \rightarrow (u,c,t)$ and $(d_1,d_2,d_3) \rightarrow (d,s,b)$, the elements of V_{CKM} are written as follows:

$$V_{\text{CKM}} = \begin{pmatrix} V_{ud} & V_{us} & V_{ub} \\ V_{cd} & V_{cs} & V_{cb} \\ V_{td} & V_{ts} & V_{tb} \end{pmatrix} . \tag{12.49}$$

While a general 3×3 unitary matrix depends on three real angles and six phases, the freedom to redefine the phases of the quark mass eigenstates can be used to remove five of the phases, leaving a single physical phase, the Kobayashi-Maskawa phase, that is responsible for all CP violation in meson decays in the Standard Model.

The fact that one can parametrize $V_{\rm CKM}$ by three real and only one imaginary physical parameters can be made manifest by choosing an explicit parametrization. The Wolfenstein parametrization [30,31] is particularly useful:

$$V_{CKM} =$$

$$\begin{pmatrix} 1 - \frac{1}{2}\lambda^2 - \frac{1}{8}\lambda^4 & \lambda & A\lambda^3(\rho - i\eta) \\ -\lambda + \frac{1}{2}A^2\lambda^5[1 - 2(\rho + i\eta)] & 1 - \frac{1}{2}\lambda^2 - \frac{1}{8}\lambda^4(1 + 4A^2) & A\lambda^2 \\ A\lambda^3[1 - (1 - \frac{1}{2}\lambda^2)(\rho + i\eta)] & -A\lambda^2 + \frac{1}{2}A\lambda^4[1 - 2(\rho + i\eta)] & 1 - \frac{1}{2}A^2\lambda^4 \end{pmatrix}$$
(12.50)

Here $\lambda \approx 0.23$ (not to be confused with λ_f), the sine of the Cabibbo angle, plays the role of an expansion parameter, and η represents the CP-violating phase. Terms of $\mathcal{O}(\lambda^6)$ were neglected.

The unitarity of the CKM matrix, $(VV^{\dagger})_{ij} = (V^{\dagger}V)_{ij} = \delta_{ij}$, leads to twelve distinct complex relations among the matrix elements. The six relations with $i \neq j$ can be represented geometrically as triangles in the complex plane. Two of these,

$$\begin{split} V_{ud}V_{ub}^* + V_{cd}V_{cb}^* + V_{td}V_{tb}^* &= 0 \\ V_{td}V_{ud}^* + V_{ts}V_{us}^* + V_{tb}V_{ub}^* &= 0 \ , \end{split}$$

have terms of equal order, $\mathcal{O}(A\lambda^3)$, and so have corresponding triangles whose interior angles are all $\mathcal{O}(1)$ physical quantities that can be independently measured. The angles of the first triangle (see Fig. 12.1) are given by

$$\alpha \equiv \varphi_2 \equiv \arg\left(-\frac{V_{td}V_{tb}^*}{V_{ud}V_{ub}^*}\right) \simeq \arg\left(-\frac{1-\rho-i\eta}{\rho+i\eta}\right),$$

$$\beta \equiv \varphi_1 \equiv \arg\left(-\frac{V_{cd}V_{cb}^*}{V_{td}V_{tb}^*}\right) \simeq \arg\left(\frac{1}{1-\rho-i\eta}\right),$$

$$\gamma \equiv \varphi_3 \equiv \arg\left(-\frac{V_{ud}V_{ub}^*}{V_{cd}V_{cb}^*}\right) \simeq \arg\left(\rho+i\eta\right). \tag{12.51}$$

The angles of the second triangle are equal to (α, β, γ) up to corrections of $\mathcal{O}(\lambda^2)$. The notations (α, β, γ) and $(\varphi_1, \varphi_2, \varphi_3)$ are both in common usage but, for convenience, we only use the first convention in the following.

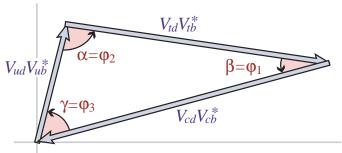

Figure 12.1: Graphical representation of the unitarity constraint $V_{ud}V_{ub}^* + V_{cd}V_{cb}^* + V_{td}V_{tb}^* = 0$ as a triangle in the complex plane.

Another relation that can be represented as a triangle,

$$V_{us}V_{ub}^* + V_{cs}V_{cb}^* + V_{ts}V_{tb}^* = 0 , \qquad (12.52)$$

and, in particular, its small angle, of $\mathcal{O}(\lambda^2)$,

$$\beta_s \equiv \arg\left(-\frac{V_{ts}V_{tb}^*}{V_{cs}V_{cb}^*}\right),\tag{12.53}$$

is convenient for analyzing CP violation in the B_s sector.

All unitarity triangles have the same area, commonly denoted by J/2 [32]. If CP is violated, J is different from zero and can be taken as the single CP-violating parameter. In the Wolfenstein parametrization of Eq. (12.50), $J \simeq \lambda^6 A^2 \eta$.

12.4. K Decays

CP violation was discovered in $K \to \pi\pi$ decays in 1964 [1]. The same mode provided the first evidence for direct CP violation [4–6].

The decay amplitudes actually measured in neutral K decays refer to the mass eigenstates K_L and K_S , rather than to the K and \overline{K} states referred to in Eq. (12.15). The final $\pi^+\pi^-$ and $\pi^0\pi^0$ states are CP-even. In the CP limit, $K_S(K_L)$ would be CP-even (odd), and therefore would (would not) decay to two pions. We define CP-violating amplitude ratios for two-pion final states,

$$\eta_{00} \equiv \frac{\langle \pi^0 \pi^0 | \mathcal{H} | K_L \rangle}{\langle \pi^0 \pi^0 | \mathcal{H} | K_S \rangle} \quad , \quad \eta_{+-} \equiv \frac{\langle \pi^+ \pi^- | \mathcal{H} | K_L \rangle}{\langle \pi^+ \pi^- | \mathcal{H} | K_S \rangle} \ . \tag{12.54}$$

Another important observable is the asymmetry of time-integrated semileptonic decay rates:

$$\delta_L \equiv \frac{\Gamma(K_L \to \ell^+ \nu_\ell \pi^-) - \Gamma(K_L \to \ell^- \overline{\nu}_\ell \pi^+)}{\Gamma(K_L \to \ell^+ \nu_\ell \pi^-) + \Gamma(K_L \to \ell^- \overline{\nu}_\ell \pi^+)} \ . \tag{12.55}$$

CP violation has been observed as an appearance of K_L decays to two-pion final states [23],

$$|\eta_{00}| = (2.221 \pm 0.011) \times 10^{-3}$$
 $|\eta_{+-}| = (2.232 \pm 0.011) \times 10^{-3}$ (12.56)
 $|\eta_{00}/\eta_{+-}| = 0.9951 \pm 0.0008$, (12.57)

where the phase ϕ_{ij} of the amplitude ratio η_{ij} has been determined both assuming CPT invariance:

$$\phi_{00} = (43.52 \pm 0.06)^{\circ}, \qquad \phi_{+-} = (43.51 \pm 0.05)^{\circ}, \qquad (12.58)$$

and without assuming CPT invariance:

$$\phi_{00} = (43.7 \pm 0.8)^{\circ}, \qquad \phi_{+-} = (43.4 \pm 0.7)^{\circ}.$$
 (12.59)

CP violation has also been observed in semileptonic K_L decays [23]

$$\delta_L = (3.32 \pm 0.06) \times 10^{-3} \,, \tag{12.60}$$

where δ_L is a weighted average of muon and electron measurements, as well as in K_L decays to $\pi^+\pi^-\gamma$ and $\pi^+\pi^-e^+e^-$ [23]. CP violation in $K \to 3\pi$ decays has not yet been observed [23,33].

Historically, CP violation in neutral K decays has been described in terms of parameters ϵ and ϵ' . The observables η_{00} , η_{+-} , and δ_L are related to these parameters, and to those of Section 12.1, by

$$\eta_{00} = \frac{1 - \lambda_{\pi^0 \pi^0}}{1 + \lambda_{\pi^0 \pi^0}} = \epsilon - 2\epsilon' ,$$

$$\eta_{+-} = \frac{1 - \lambda_{\pi^+ \pi^-}}{1 + \lambda_{\pi^+ \pi^-}} = \epsilon + \epsilon' ,$$

$$\delta_L = \frac{1 - |q/p|^2}{1 + |q/p|^2} = \frac{2\Re e(\epsilon)}{1 + |\epsilon|^2} ,$$
(12.61)

where, in the last line, we have assumed that $\left|A_{\ell^+\nu_\ell\pi^-}\right|=\left|\overline{A}_{\ell^-\overline{\nu}_\ell\pi^+}\right|$ and $\left|A_{\ell^-\overline{\nu}_\ell\pi^+}\right|=\left|\overline{A}_{\ell^+\nu_\ell\pi^-}\right|=0$. (The convention-dependent parameter $\tilde{\epsilon}\equiv (1-q/p)/(1+q/p)$, sometimes used in the literature, is, in general, different from ϵ but yields a similar expression, $\delta_L=2\mathcal{R}e(\tilde{\epsilon})/(1+|\tilde{\epsilon}|^2)$.) A fit to the $K\to\pi\pi$ data yields [23]

$$|\epsilon| = (2.228 \pm 0.011) \times 10^{-3}$$
,
 $\Re e(\epsilon'/\epsilon) = (1.65 \pm 0.26) \times 10^{-3}$. (12.62)

In discussing two-pion final states, it is useful to express the amplitudes $A_{\pi^0\pi^0}$ and $A_{\pi^+\pi^-}$ in terms of their isospin components via

$$\begin{split} A_{\pi^0\pi^0} &= \sqrt{\frac{1}{3}} \, |A_0| \, e^{i(\delta_0 + \phi_0)} - \sqrt{\frac{2}{3}} \, |A_2| \, e^{i(\delta_2 + \phi_2)}, \\ A_{\pi^+\pi^-} &= \sqrt{\frac{2}{3}} \, |A_0| \, e^{i(\delta_0 + \phi_0)} + \sqrt{\frac{1}{3}} \, |A_2| \, e^{i(\delta_2 + \phi_2)} \,, \end{split}$$
 (12.63)

where we parameterize the amplitude $A_I(\overline{A}_I)$ for $K^0(\overline{K}^0)$ decay into two pions with total isospin I=0 or 2 as

$$\begin{split} A_I &\equiv \langle (\pi\pi)_I \, | \mathcal{H} | \, K^0 \rangle = |A_I| \, e^{i(\delta_I + \phi_I)} \; , \\ \overline{A}_I &\equiv \langle (\pi\pi)_I \, | \mathcal{H} | \, \overline{K}^0 \rangle = |A_I| \, e^{i(\delta_I - \phi_I)} \; . \end{split} \tag{12.64}$$

The smallness of $|\eta_{00}|$ and $|\eta_{+-}|$ allows us to approximate

$$\epsilon \simeq \frac{1}{2} (1 - \lambda_{(\pi\pi)_{I=0}}), \qquad \epsilon' \simeq \frac{1}{6} (\lambda_{\pi^0 \pi^0} - \lambda_{\pi^+ \pi^-}) .$$
 (12.65)

The parameter ϵ represents indirect CP violation, while ϵ' parameterizes direct CP violation: $\mathcal{R}e(\epsilon')$ measures CP violation in decay (type I), $\mathcal{R}e(\epsilon)$ measures CP violation in mixing (type II), and $\mathcal{I}m(\epsilon)$ and $\mathcal{I}m(\epsilon')$ measure the interference between decays with and without mixing (type III).

The following expressions for ϵ and ϵ' are useful for theoretical evaluations:

$$\epsilon \simeq \frac{e^{i\pi/4}}{\sqrt{2}} \frac{\mathcal{I}m(\mathbf{M}_{12})}{\Delta m}, \qquad \epsilon' = \frac{i}{\sqrt{2}} \left| \frac{A_2}{A_0} \right| e^{i(\delta_2 - \delta_0)} \sin(\phi_2 - \phi_0). \tag{12.66}$$

The expression for ϵ is only valid in a phase convention where $\phi_2=0$, corresponding to a real $V_{ud}V_{us}^*$, and in the approximation that also $\phi_0=0$. The phase of ϵ , $\arg(\epsilon)\approx\arctan(-2\Delta m/\Delta\Gamma)$, is independent of the electroweak model and is experimentally determined to be about $\pi/4$. The calculation of ϵ benefits from the fact that $\mathcal{I}m(\mathbf{M}_{12})$ is dominated by short distance physics. Consequently, the main source of uncertainty in theoretical interpretations of ϵ are the values of matrix elements, such as $\langle K^0 | (\overline{sd})_{V-A}(\overline{sd})_{V-A}| \overline{K^0} \rangle$. The expression for ϵ' is valid to first order in $|A_2/A_0| \sim 1/20$. The phase of ϵ' is experimentally determined, $\pi/2 + \delta_2 - \delta_0 \approx \pi/4$, and is independent of the electroweak model. Note that, accidentally, ϵ'/ϵ is real to a good approximation.

A future measurement of much interest is that of CP violation in the rare $K \to \pi \nu \overline{\nu}$ decays. The signal for CP violation is simply observing the $K_L \to \pi^0 \nu \overline{\nu}$ decay. The effect here is that of interference between decays with and without mixing (type III) [34]:

$$\frac{\Gamma(K_L \to \pi^0 \nu \overline{\nu})}{\Gamma(K^+ \to \pi^+ \nu \overline{\nu})} = \frac{1}{2} \left[1 + |\lambda_{\pi \nu \overline{\nu}}|^2 - 2 \, \Re e(\lambda_{\pi \nu \overline{\nu}}) \right] \simeq 1 - \Re e(\lambda_{\pi \nu \overline{\nu}}), \tag{12.6}$$

where in the last equation we neglect CP violation in decay and in mixing (expected, model-independently, to be of order 10^{-5} and 10^{-3} , respectively). Such a measurement would be experimentally very challenging and theoretically very rewarding [35]. Similar to the CP asymmetry in $B \to J/\psi K_S$, the CP violation in $K \to \pi \nu \overline{\nu}$ decay is predicted to be large (that is, the ratio in Eq. (12.67) is neither CKM- nor loop-suppressed) and can be very cleanly interpreted.

Within the Standard Model, the $K_L \to \pi^0 \nu \overline{\nu}$ decay is dominated by an intermediate top quark contribution and, consequently, can be interpreted in terms of CKM parameters [36]. (For the charged mode, $K^+ \to \pi^+ \nu \overline{\nu}$, the contribution from an intermediate charm quark is not negligible, and constitutes a source of hadronic uncertainty.) In particular, $\mathcal{B}(K_L \to \pi^0 \nu \overline{\nu})$ provides a theoretically clean way to determine the Wolfenstein parameter η [37]:

$$\mathcal{B}(K_L \to \pi^0 \nu \overline{\nu}) = \kappa_L [X(m_t^2/m_W^2)]^2 A^4 \eta^2,$$
 (12.68)

where $\kappa_L \sim 2 \times 10^{-10}$ incorporates the value of the four-fermion matrix element which is deduced, using isospin relations, from $\mathcal{B}(K^+ \to \pi^0 e^+ \nu)$, and $X(m_t^2/m_W^2)$ is a known function of the top mass.

12.5. D Decays

Evidence for $D^0-\overline{D}^0$ mixing has been obtained in recent years [38–40]. The experimental constraints read [25,41] $x\equiv \Delta m/\Gamma=0.0063\pm0.0019$ and $y\equiv \Delta\Gamma/(2\Gamma)=0.0075\pm0.0012$. Long-distance contributions make it difficult to calculate the Standard Model prediction for the $D^0-\overline{D}^0$ mixing parameters. Therefore, the goal of the search for $D^0-\overline{D}^0$ mixing is not to constrain the CKM parameters, but rather to probe new physics. Here CP violation plays an important role. Within the Standard Model, the CP-violating effects are predicted to be small, since the mixing and the relevant decays are described, to an excellent approximation, by physics of the first two generations. The expectation is that the Standard Model size of CP violation in D decays is of $\mathcal{O}(10^{-3})$ or less, but theoretical work is ongoing to understand whether QCD effects can significantly enhance it. At present, the most sensitive searches involve the $D\to K^+K^-$, $D\to \pi^+\pi^-$ and $D\to K^\pm\pi^\mp$ modes.

The neutral D mesons decay via a singly-Cabibbo-suppressed transition to the CP eigenstates K^+K^- and $\pi^+\pi^-$. These decays are dominated by Standard-Model tree diagrams. Thus, we can write, for $f=K^+K^-$ or $\pi^+\pi^-$,

$$\begin{split} A_f &= A_f^T e^{+i\phi_f^T} \left[1 + r_f e^{i(\delta_f + \phi_f)} \right] , \\ \bar{A}_f &= A_f^T e^{-i\phi_f^T} \left[1 + r_f e^{i(\delta_f - \phi_f)} \right] , \end{split} \tag{12.69}$$

where $A_f^T e^{\pm i\phi_f^T}$ is the SM tree level contribution, ϕ_f^T and ϕ_f are weak, CP violating phases, δ_f is a strong phase, and r_f is the ratio between a subleading $(r_f \ll 1)$ contribution with a weak phase different from ϕ_f^T and the SM tree level contribution. Neglecting r_f , λ_f is universal, and we can define a phase ϕ_D via

$$\lambda_f \equiv -|q/p|e^{i\phi_D}.\tag{12.70}$$

(In the limit of CP conservation, choosing $\phi_D = 0$ is equivalent to defining the mass eigenstates by their CP eigenvalue: $|D_{\mp}\rangle = p|D^0\rangle \pm q|\overline{D}^0\rangle$, with $D_-(D_+)$ being the CP-odd (CP-even) state; that is, the state that does not (does) decay into K^+K^- .)

We define the time integrated ${\cal CP}$ asymmetry for a final ${\cal CP}$ eigenstate f as follows:

$$a_f \equiv \frac{\int_0^\infty \Gamma(D_{\rm phys}^0(t) \to f) dt - \int_0^\infty \Gamma(\overline{D}_{\rm phys}^0(t) \to f) dt}{\int_0^\infty \Gamma(D_{\rm phys}^0(t) \to f) dt + \int_0^\infty \Gamma(\overline{D}_{\rm phys}^0(t) \to f) dt}.$$
 (12.71)

(This expression corresponds to the D meson being tagged at production, hence the integration goes from 0 to $+\infty$; measurements are also possible with $\psi(3770) \to D\bar{D}$, in which case the integration goes from $-\infty$ to $+\infty$.) We take $x,y,r_f\ll 1$ and expand to leading order in these parameters. Then, we can separate the contribution to a_f to three parts [42],

$$a_f = a_f^d + a_f^m + a_f^i, (12.72)$$

with the following underlying mechanisms:

1. a_f^d signals CP violation in decay (similar to Eq. (12.37)):

$$a_f^d = 2r_f \sin \phi_f \sin \delta_f. \tag{12.73}$$

2. a_f^m signals CP violation in mixing (similar to Eq. (12.46)). With our approximations, it is universal:

$$a^{m} = -\frac{y}{2} \left(\left| \frac{q}{p} \right| - \left| \frac{p}{q} \right| \right) \cos \phi_{D}. \tag{12.74}$$

3. a_f^i signals CP violation in the interference of mixing and decay (similar to Eq. (12.47)). With our approximations, it is universal:

$$a^{i} = \frac{x}{2} \left(\left| \frac{q}{p} \right| + \left| \frac{p}{q} \right| \right) \sin \phi_{D}. \tag{12.75}$$

One can isolate the effects of direct CP violation by taking the difference between the CP asymmetries in the K^+K^- and $\pi^+\pi^-$ modes:

$$\Delta a_{CP} \equiv a_{K^+K^-} - a_{\pi^+\pi^-} = a_{K^+K^-}^d - a_{\pi^+\pi^-}^d, \eqno(12.76)$$

where we neglected a residual, experiment-dependent, contribution from indirect CP violation due to the fact that there is a time dependent acceptance function that can be different for the K^+K^- and $\pi^+\pi^-$ channels. Recently, evidence for such direct CP violation has been obtained [25]:

$$a_{K^+K^-}^d - a_{\pi^+\pi^-}^d = (-6.4 \pm 1.8) \times 10^{-3}.$$
 (12.77)

One can also isolate the effects of indirect CP violation in the following way. Consider the time dependent decay rates in Eq. (12.32) and Eq. (12.33). The mixing processes modify the time dependence from a pure exponential. However, given the small values of x and y, the time dependences can be recast, to a good approximation, into purely exponential form, but with modified decay-rate parameters [43]:

$$\begin{split} &\Gamma_{D^0 \to K^+K^-} = \Gamma \times \left[1 + |q/p| \left(y\cos\phi_D - x\sin\phi_D\right)\right] \;, \\ &\Gamma_{\overline{D^0 \to K^+K^-}} = \Gamma \times \left[1 + |p/q| \left(y\cos\phi_D + x\sin\phi_D\right)\right] \;. \end{split} \tag{12.78}$$

One can define CP-conserving and CP-violating combinations of these two observables (normalized to the true width Γ):

$$\begin{split} y_{CP} &\equiv \frac{\Gamma_{\overline{D}^0 \to K^+ K^-} + \Gamma_{D^0 \to K^+ K^-}}{2\Gamma} - 1 \\ &= (y/2) \left(|q/p| + |p/q| \right) \cos \phi_D - (x/2) \left(|q/p| - |p/q| \right) \sin \phi_D \;, \\ A_{\Gamma} &\equiv \frac{\Gamma_{D^0 \to K^+ K^-} - \Gamma_{\overline{D}^0 \to K^+ K^-}}{2\Gamma} \\ &= - \left(a^m + a^i \right) \;. \end{split} \tag{12.79}$$

In the limit of CP conservation (and, in particular, within the Standard Model), $y_{CP}=(\Gamma_+-\Gamma_-)/2\Gamma$ (where $\Gamma_+(\Gamma_-)$ is the decay width of the CP-even (-odd) mass eigenstate) and $A_\Gamma=0$. Indeed, present measurements imply that CP violation is small [25],

$$y_{CP} = + (1.06 \pm 0.21) \times 10^{-2},$$

 $A_{\Gamma} = + (0.03 \pm 0.23) \times 10^{-2}.$

The $K^{\pm}\pi^{\mp}$ states are not CP eigenstates, but they are still common final states for D^0 and \overline{D}^0 decays. Since $D^0(\overline{D}^0) \to K^-\pi^+$ is a Cabibbo-favored (doubly-Cabibbo-suppressed) process, these processes are particularly sensitive to x and/or $y=\mathcal{O}(\lambda^2)$. Taking into account that $\left|\lambda_{K^-\pi^+}\right|, \left|\lambda_{K^+\pi^-}^{-1}\right| \ll 1$ and $x,y \ll 1$, assuming that there is no direct CP violation (these are Standard Model tree-level decays dominated by a single weak phase, and there is no contribution from penguin-like and chromomagnetic operators), and expanding the time-dependent rates for $xt,yt\lesssim \Gamma^{-1}$, one obtains

$$\Gamma[D^{0}_{\text{phys}}(t) \to K^{+}\pi^{-}] = e^{-\Gamma t} |\overline{A}_{K^{-}\pi^{+}}|^{2}$$

$$\times \left[r_{d}^{2} + r_{d} \left| \frac{q}{p} \right| (y' \cos \phi_{D} - x' \sin \phi_{D}) \Gamma t + \left| \frac{q}{p} \right|^{2} \frac{y^{2} + x^{2}}{4} (\Gamma t)^{2} \right] ,$$

$$\Gamma[\overline{D}^{0}_{\text{phys}}(t) \to K^{-}\pi^{+}] = e^{-\Gamma t} |\overline{A}_{K^{-}\pi^{+}}|^{2}$$

$$\times \left[r_{d}^{2} + r_{d} \left| \frac{p}{q} \right| (y' \cos \phi_{D} + x' \sin \phi_{D}) \Gamma t + \left| \frac{p}{q} \right|^{2} \frac{y^{2} + x^{2}}{4} (\Gamma t)^{2} \right] ,$$

$$(12.86)$$

where

$$y' \equiv y \cos \delta - x \sin \delta$$
,
 $x' \equiv x \cos \delta + y \sin \delta$. (12.81)

The weak phase ϕ_D is the same as that of Eq. (12.70) (a consequence of neglecting direct CP violation), δ is a strong-phase difference for these processes, and $r_d = \mathcal{O}(\tan^2\theta_c)$ is the amplitude ratio, $r_d = \left|\overline{A}_{K^-\pi^+}/A_{K^-\pi^+}\right| = \left|A_{K^+\pi^-}/\overline{A}_{K^+\pi^-}\right|$, that is, $\lambda_{K^-\pi^+} = r_d|q/p|e^{-i(\delta-\phi_D)}$ and $\lambda_{K^+\pi^-}^{-1} = r_d|p/q|e^{-i(\delta+\phi_D)}$. By fitting to the six coefficients of the various time-dependences, one can extract r_d , |q/p|, (x^2+y^2) , $y'\cos\phi_D$, and $x'\sin\phi_D$. In particular, finding CP violation $(|q/p|\neq 1$ and/or $\sin\phi_D\neq 0$) at a level much higher than 10^{-3} would constitute evidence for new physics.

A fit to all data [25] yields no evidence for indirect CP violation:

$$1 - |q/p| = +0.12 \pm 0.17,$$

$$\phi_D = -0.18 \pm 0.16.$$

More details on various theoretical and experimental aspects of $D^0 - \overline{D}^0$ mixing can be found in Ref. [44].

12.6. B and B_s Decays

The upper bound on the CP asymmetry in semileptonic B decays [24] implies that CP violation in $B^0 - \overline{B}^0$ mixing is a small effect (we use $\mathcal{A}_{\mathrm{SL}}/2 \approx 1 - |q/p|$, see Eq. (12.39)):

$$\mathcal{A}_{\mathrm{SL}}^d = (-3.3 \pm 3.3) \times 10^{-3} \implies |q/p| = 1.0017 \pm 0.0017. \quad (12.82)$$

The Standard Model prediction is

$$\mathcal{A}_{\mathrm{SL}}^{d} = \mathcal{O}\left[(m_{c}^{2}/m_{t}^{2})\sin\beta\right] \lesssim 0.001. \tag{12.83}$$

In models where $\Gamma_{12}/\mathbf{M}_{12}$ is approximately real, such as the Standard Model, an upper bound on $\Delta\Gamma/\Delta m \approx \mathcal{R}e(\Gamma_{12}/\mathbf{M}_{12})$ provides yet another upper bound on the deviation of |q/p| from one. This constraint does not hold if $\Gamma_{12}/\mathbf{M}_{12}$ is approximately imaginary. (An alternative parameterization uses $q/p = (1-\tilde{\epsilon}_B)/(1+\tilde{\epsilon}_B)$, leading to $\mathcal{A}_{\mathrm{SL}} \simeq 4\mathcal{R}e(\tilde{\epsilon}_B)$.)

The small deviation (less than one percent) of |q/p| from 1 implies that, at the present level of experimental precision, CP violation in B mixing is a negligible effect. Thus, for the purpose of analyzing CP asymmetries in hadronic B decays, we can use

$$\lambda_f = e^{-i\phi_M(B)} (\overline{A}_f/A_f) , \qquad (12.84)$$

where $\phi_{M(B)}$ refers to the phase of \mathbf{M}_{12} appearing in Eq. (12.44) that is appropriate for $B^0 - \overline{B}^0$ oscillations. Within the Standard Model, the corresponding phase factor is given by

$$e^{-i\phi_{M(B)}} = (V_{tb}^* V_{td})/(V_{tb} V_{td}^*)$$
 (12.85)

Some of the most interesting decays involve final states that are common to B^0 and \overline{B}^0 [45,46]. It is convenient to rewrite Eq. (12.42) for B decays as [47–49]

$$\mathcal{A}_f(t) = S_f \sin(\Delta m t) - C_f \cos(\Delta m t),$$

$$S_f \equiv \frac{2\mathcal{I}m(\lambda_f)}{1 + |\lambda_f|^2}, \quad C_f \equiv \frac{1 - |\lambda_f|^2}{1 + |\lambda_f|^2},$$
 (12.86)

where we assume that $\Delta\Gamma=0$ and |q/p|=1. An alternative notation in use is $A_f\equiv -C_f$, but this A_f should not be confused with the A_f of Eq. (12.15).

A large class of interesting processes proceed via quark transitions of the form $\overline{b} \to \overline{q}q\overline{q}'$ with q'=s or d. For q=c or u, there are contributions from both tree (t) and penguin $(p^{qu},$ where $q_u=u,c,t$ is the quark in the loop) diagrams (see Fig. 12.2) which carry different weak phases:

$$A_f = \left(V_{qb}^* V_{qq'}\right) t_f + \sum_{q_u = u, c, t} \left(V_{qub}^* V_{quq'}\right) p_f^{q_u} . \tag{12.87}$$

(The distinction between tree and penguin contributions is a heuristic one; the separation by the operator that enters is more precise. For a detailed discussion of the more complete operator product approach, which also includes higher order QCD corrections, see, for example, Ref. [50].) Using CKM unitarity, these decay amplitudes can always be written in terms of just two CKM combinations. For example, for $f=\pi\pi$, which proceeds via $\overline{b} \to \overline{u}u\overline{d}$ transition, we can write

$$A_{\pi\pi} = (V_{ub}^* V_{ud}) T_{\pi\pi} + (V_{tb}^* V_{td}) P_{\pi\pi}^t, \tag{12.88}$$

where $T_{\pi\pi} = t_{\pi\pi} + p_{\pi\pi}^u - p_{\pi\pi}^c$ and $P_{\pi\pi}^t = p_{\pi\pi}^t - p_{\pi\pi}^c$. *CP*-violating phases in Eq. (12.88) appear only in the CKM elements, so that

$$\frac{\overline{A}_{\pi\pi}}{A_{\pi\pi}} = \frac{\left(V_{ub}V_{ud}^*\right)T_{\pi\pi} + \left(V_{tb}V_{td}^*\right)P_{\pi\pi}^t}{\left(V_{ub}^*V_{ud}\right)T_{\pi\pi} + \left(V_{tb}^*V_{td}\right)P_{\pi\pi}^t}.$$
(12.89)

For $f = J/\psi K$, which proceeds via $\overline{b} \to \overline{c}c\overline{s}$ transition, we can write

$$A_{\psi K} = (V_{cb}^* V_{cs}) T_{\psi K} + (V_{ub}^* V_{us}) P_{\psi K}^u, \tag{12.90}$$

where $T_{\psi K} = t_{\psi K} + p^c_{\psi K} - p^t_{\psi K}$ and $P^u_{\psi K} = p^u_{\psi K} - p^t_{\psi K}$. A subtlety arises in this decay that is related to the fact that B^0 decays into a final $J/\psi K^0$ state while \overline{B}^0 decays into a final $J/\psi \overline{K}^0$ state. A common final state, e.g., $J/\psi K_S$, is reached only via $K^0 - \overline{K}^0$ mixing. Consequently, the phase factor (defined in Eq. (12.44)) corresponding to neutral K mixing, $e^{-i\phi_M(K)} = (V^*_{cd}V_{cs})/(V_{cd}V^*_{cs})$, plays a role:

$$\frac{\overline{A}_{\psi K_S}}{A_{\psi K_S}} = -\frac{\left(V_{cb}V_{cs}^*\right)T_{\psi K} + \left(V_{ub}V_{us}^*\right)P_{\psi K}^u}{\left(V_{cb}^*V_{cs}\right)T_{\psi K} + \left(V_{ub}^*V_{us}\right)P_{\psi K}^u} \times \frac{V_{cd}^*V_{cs}}{V_{cd}V_{cs}^*}. \tag{12.91}$$

For q=s or d, there are only penguin contributions to A_f , that is, $t_f=0$ in Eq. (12.87). (The tree $\overline{b} \to \overline{u}u\overline{q}'$ transition followed by $\overline{u}u \to \overline{q}q$ rescattering is included below in the P^u terms.) Again, CKM unitarity allows us to write A_f in terms of two CKM combinations. For example, for $f=\phi K_S$, which proceeds via $\overline{b} \to \overline{s}s\overline{s}$ transition, we can write

$$\frac{\overline{A}_{\phi K_S}}{A_{\phi K_S}} = -\frac{\left(V_{cb}V_{cs}^*\right)P_{\phi K}^c + \left(V_{ub}V_{us}^*\right)P_{\phi K}^u}{\left(V_{cb}^*V_{cs}\right)P_{\phi K}^c + \left(V_{ub}^*V_{us}\right)P_{\phi K}^u} \times \frac{V_{cd}^*V_{cs}}{V_{cd}V_{cs}^*}, \tag{12.92}$$

where
$$P_{\phi K}^c = p_{\phi K}^c - p_{\phi K}^t$$
 and $P_{\phi K}^u = p_{\phi K}^u - p_{\phi K}^t$.

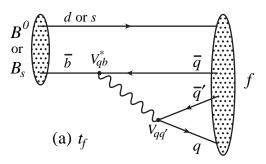

Since the amplitude A_f involves two different weak phases, the corresponding decays can exhibit both CP violation in the interference of decays with and without mixing, $S_f \neq 0$, and CP violation in decays, $C_f \neq 0$. (At the present level of experimental precision, the contribution to C_f from CP violation in mixing is negligible, see Eq. (12.82).) If the contribution from a second weak phase is suppressed, then the interpretation of S_f in terms of Lagrangian CP-violating parameters is clean, while C_f is small. If such a second contribution is not suppressed, S_f depends on hadronic parameters and, if the relevant strong phase is large, C_f is large.

A summary of $\overline{b} \to \overline{q}\overline{q}q'$ modes with q'=s or d is given in Table 12.1. The $\overline{b} \to \overline{d}d\overline{q}$ transitions lead to final states that are similar to the $\overline{b} \to \overline{u}u\overline{q}$ transitions and have similar phase dependence. Final states that consist of two-vector mesons $(\psi\phi$ and $\phi\phi)$ are not CP eigenstates, and angular analysis is needed to separate the CP-even from the CP-odd contributions.

The cleanliness of the theoretical interpretation of S_f can be assessed from the information in the last column of Table 12.1. In case of small uncertainties, the expression for S_f in terms of CKM phases can be deduced from the fourth column of Table 12.1 in combination with Eq. (12.85) (and, for $b \to q \overline{q} s$ decays, the example in Eq. (12.91)). Here we consider several interesting examples.

For $B \to J/\psi K_S$ and other $\overline{b} \to \overline{c}c\overline{s}$ processes, we can neglect the P^u contribution to A_f , in the Standard Model, to an approximation that is better than one percent:

$$\lambda_{\psi K_S} = -e^{-2i\beta} \implies S_{\psi K_S} = \sin 2\beta, \quad C_{\psi K_S} = 0.$$
 (12.93)

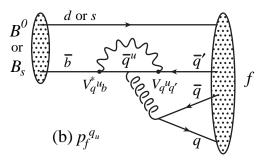

Figure 12.2: Feynman diagrams for (a) tree and (b) penguin amplitudes contributing to $B^0 \to f$ or $B_s \to f$ via a $\overline{b} \to \overline{q}q\overline{q}$ quark-level process.

Table 12.1: Summary of $\overline{b} \to \overline{q}q\overline{q}'$ modes with q'=s or d. The second and third columns give examples of final hadronic states. The fourth column gives the CKM dependence of the amplitude A_f , using the notation of Eqs. (12.88, 12.90,12.92), with the dominant term first and the subdominant second. The suppression factor of the second term compared to the first is given in the last column. "Loop" refers to a penguin versus tree-suppression factor (it is mode-dependent and roughly $\mathcal{O}(0.2-0.3)$) and $\lambda=0.23$ is the expansion parameter of Eq. (12.50).

| $\overline{b} 	o \overline{q} q \overline{q}'$ | $B^0 \to f$ | $B_s \to f$ | CKM dependence of A_f | Suppression |
|------------------------------------------------|--------------|--------------|---------------------------------------------|----------------------------------|
| $\bar{b} \to \bar{c}c\bar{s}$ | ψK_S | $\psi\phi$ | $(V_{cb}^*V_{cs})T + (V_{ub}^*V_{us})P^u$ | $\mathrm{loop} \times \lambda^2$ |
| $\bar{b} \to \bar{s} s \bar{s}$ | ϕK_S | $\phi\phi$ | $(V_{cb}^*V_{cs})P^c + (V_{ub}^*V_{us})P^u$ | λ^2 |
| $\bar{b} \to \bar{u} u \bar{s}$ | $\pi^0 K_S$ | K^+K^- | $(V_{cb}^*V_{cs})P^c + (V_{ub}^*V_{us})T$ | λ^2/loop |
| $\bar{b} \to \bar{c} c \bar{d}$ | D^+D^- | ψK_S | $(V_{cb}^*V_{cd})T + (V_{tb}^*V_{td})P^t$ | loop |
| $\bar{b} \to \bar{s} s \bar{d}$ | K_SK_S | ϕK_S | $(V_{tb}^*V_{td})P^t + (V_{cb}^*V_{cd})P^c$ | $\lesssim 1$ |
| $\bar{b} \to \bar{u}u\bar{d}$ | $\pi^+\pi^-$ | $\rho^0 K_S$ | $(V_{ub}^*V_{ud})T + (V_{tb}^*V_{td})P^t$ | loop |

In the presence of new physics, A_f is still likely to be dominated by the T term, but the mixing amplitude might be modified. We learn that, model-independently, $C_f \approx 0$ while S_f cleanly determines the mixing phase $(\phi_M - 2 \arg(V_{cb}V_{cd}^*))$. The experimental measurement [25], $S_{\psi K} = 0.665 \pm 0.022$, gave the first precision test of the Kobayashi-Maskawa mechanism, and its consistency with the predictions for $\sin 2\beta$ makes it very likely that this mechanism is indeed the dominant source of CP violation in meson decays.

For $B\to \phi K_S$ and other $\overline{b}\to \overline{s}s\overline{s}$ processes (as well as some $\overline{b}\to \overline{u}u\overline{s}$ processes), we can neglect the subdominant contributions, in the Standard Model, to an approximation that is good on the order of

a few percent:

$$\lambda_{\phi K_S} = -e^{-2i\beta} \ \Rightarrow \ S_{\phi K_S} = \sin 2\beta, \quad C_{\phi K_S} = 0 \ . \eqno(12.94)$$

In the presence of new physics, both A_f and \mathbf{M}_{12} can get contributions that are comparable in size to those of the Standard Model and carry new weak phases. Such a situation gives several interesting consequences for penguin-dominated $b \to q\overline{q}s$ decays (q=u,d,s) to a final state f:

- 1. The value of $-\eta_f S_f$ may be different from $S_{\psi K_S}$ by more than a few percent, where η_f is the CP eigenvalue of the final state.
- 2. The values of $\eta_f S_f$ for different final states f may be different from each other by more than a few percent (for example, $S_{\phi K_S} \neq S_{\eta' K_S}$).
- 3. The value of C_f may be different from zero by more than a few percent.

While a clear interpretation of such signals in terms of Lagrangian parameters will be difficult because, under these circumstances, hadronic parameters do play a role, any of the above three options will clearly signal new physics. Fig. 12.3 summarizes the present experimental results: none of the possible signatures listed above is unambiguously established, but there is definitely still room for new physics.

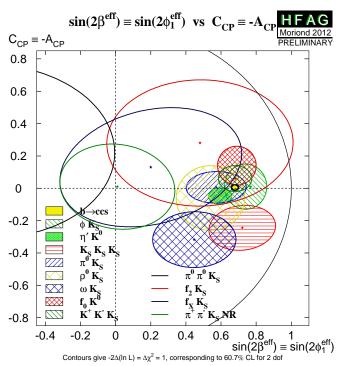

Figure 12.3: Summary of the results [25] of time-dependent analyses of $b\to q\overline{q}s$ decays, which are potentially sensitive to new physics.

For $B\to\pi\pi$ and other $\overline{b}\to\overline{u}u\overline{d}$ processes, the penguin-to-tree ratio can be estimated using SU(3) relations and experimental data on related $B\to K\pi$ decays. The result is that the suppression is on the order of 0.2-0.3 and so cannot be neglected. The expressions for $S_{\pi\pi}$ and $C_{\pi\pi}$ to leading order in $R_{PT}\equiv (|V_{tb}V_{td}|\,P_{\pi\pi}^t)/(|V_{ub}V_{ud}|\,T_{\pi\pi})$ are:

$$\lambda_{\pi\pi} = e^{2i\alpha} \left[(1 - R_{PT}e^{-i\alpha}) / (1 - R_{PT}e^{+i\alpha}) \right] \Rightarrow$$

 $S_{\pi\pi} \approx \sin 2\alpha + 2 \, \mathcal{R}e(R_{PT}) \cos 2\alpha \sin \alpha, \quad C_{\pi\pi} \approx 2 \, \mathcal{I}m(R_{PT}) \sin \alpha.$ (12.95)

Note that R_{PT} is mode-dependent and, in particular, could be different for $\pi^+\pi^-$ and $\pi^0\pi^0$. If strong phases can be neglected, then R_{PT} is real, resulting in $C_{\pi\pi} = 0$. The size of $C_{\pi\pi}$ is an indicator of how large the strong phase is. The present experimental range is

 $C_{\pi\pi} = -0.38 \pm 0.06$ [25]. As concerns $S_{\pi\pi}$, it is clear from Eq. (12.95) that the relative size or strong phase of the penguin contribution must be known to extract α . This is the problem of penguin pollution.

The cleanest solution involves isospin relations among the $B\to\pi\pi$ amplitudes [51]:

$$\frac{1}{\sqrt{2}}A_{\pi^{+}\pi^{-}} + A_{\pi^{0}\pi^{0}} = A_{\pi^{+}\pi^{0}}.$$
 (12.96)

The method exploits the fact that the penguin contribution to $P^t_{\pi\pi}$ is pure $\Delta I = \frac{1}{2}$ (this is not true for the electroweak penguins which, however, are expected to be small), while the tree contribution to $T_{\pi\pi}$ contains pieces which are both $\Delta I = \frac{1}{2}$ and $\Delta I = \frac{3}{2}$. A simple geometric construction then allows one to find R_{PT} and extract α cleanly from $S_{\pi^+\pi^-}$. The key experimental difficulty is that one must measure accurately the separate rates for $B^0, \overline{B}^0 \to \pi^0\pi^0$.

CP asymmetries in $B \to \rho \pi$ and $B \to \rho \rho$ can also be used to determine α . In particular, the $B \to \rho \rho$ measurements are presently very significant in constraining α . The extraction proceeds via isospin analysis similar to that of $B \to \pi\pi$. There are, however, several important differences. First, due to the finite width of the ρ mesons, a final $(\rho\rho)_{I=1}$ state is possible [52]. The effect is, however, small, on the order of $(\Gamma_{\rho}/m_{\rho})^2 \sim 0.04$. Second, due to the presence of three helicity states for the two-vector mesons, angular analysis is needed to separate the CP-even and CP-odd components. The theoretical expectation is, however, that the CP-odd component is small. This expectation is supported by experiments which find that the $\rho^+\rho^-$ and $\rho^{\pm}\rho^0$ modes are dominantly longitudinally polarized. Third, an important advantage of the $\rho\rho$ modes is that the penguin contribution is expected to be small due to different hadronic dynamics. This expectation is confirmed by the smallness of $\mathcal{B}(B^0 \to \rho^0 \rho^0) = (0.73 \pm 0.28) \times 10^{-6}$ compared to $\mathcal{B}(B^0 \to \rho^+ \rho^-) = (24.2 \pm 3.1) \times 10^{-6}$. Thus, $S_{\rho^+ \rho^-}$ is not far from $\sin 2\alpha$. Finally, both $S_{\rho^0\rho^0}$ and $C_{\rho^0\rho^0}$ are experimentally accessible, which may allow a precision determination of α . The consistency between the range of α determined by the $B \to \pi\pi, \rho\pi, \rho\rho$ measurements and the range allowed by CKM fits (excluding these direct determinations) provides further support to the Kobayashi-Maskawa mechanism.

An interesting class of decay modes is that of the tree level decays $B^{\pm} \to D^{(*)0} K^{\pm}$. These decays provide golden methods for a clean determination of the angle γ [53–56]. The method uses the decays $B^+ \to D^0 K^+$, which proceeds via the quark transition $\overline{b} \to \overline{u} c \overline{s}$, and $B^+ \to \overline{D}^0 K^+$, which proceeds via the quark transition $\overline{b} \to \overline{c} u \overline{s}$, with the D^0 and \overline{D}^0 decaying into a common final state. The decays into common final states, such $(\pi^0 K_S)_D K^+$, involve interference effects between the two amplitudes, with sensitivity to the relative phase, $\delta + \gamma$ (δ is the relevant strong phase). The *CP*-conjugate processes are sensitive to $\delta - \gamma$. Measurements of branching ratios and CP asymmetries allow an extraction of γ and δ from amplitude triangle relations. The extraction suffers from discrete ambiguities but involves no hadronic uncertainties. However, the smallness of the CKM-suppressed $b \rightarrow u$ transitions makes it difficult at present to use the simplest methods [53–55] to determine γ . These difficulties are overcome (and the discrete ambiguities are removed) by performing a Dalitz plot analysis for multi-body D decays [56]. The consistency between the range of γ determined by the $B \to DK$ measurements and the range allowed by CKM fits (excluding these direct determinations) provides further support to the Kobayashi-Maskawa mechanism.

The upper bound on the CP asymmetry in semileptonic B_s decays [25] implies that CP violation in $B_s - \overline{B_s}$ mixing is a small effects:

$$\mathcal{A}_{\mathrm{SL}}^{s} = (-10.5 \pm 6.4) \times 10^{-3} \implies |q/p| = 1.0052 \pm 0.0032. (12.97)$$

Neglecting the deviation of |q/p| from 1, implies that we can use

$$\lambda_f = e^{-i\phi_M(B_s)} (\overline{A}_f / A_f). \tag{12.98}$$

Within the Standard Model,

$$e^{-i\phi_{M}(B_{s})} = (V_{th}^{*}V_{ts})/(V_{th}V_{ts}^{*}).$$
 (12.99)

Note that $\Delta\Gamma/\Gamma=0.15\pm0.02$ [25] and therefore y should not be put to zero in Eqs. (12.32, 12.33). However, |q/p|=1 is expected to hold to an even better approximation than for B mesons. The $B_s\to J/\psi\phi$ decay proceeds via the $b\to c\bar cs$ transition. The CP asymmetry in in this mode thus determines (with angular analysis to disentangle the CP-even and CP-odd components of the final state) $\sin 2\beta_s$, where β_s is defined in Eq. (12.53). The combination of CDF, D0 and LHCb measurements yields [25]

$$\beta_s = 0.07^{+0.06}_{-0.08},$$
 (12.100)

consistent with the Standard Model prediction, $\beta_s = 0.018 \pm 0.001$ [18].

12.7. Summary and Outlook

CP violation has been experimentally established in K and B meson decays. A full list of CP asymmetries that have been measured at a level higher than 5σ is given in the introduction to this review. In Section 12.1.4 we introduced three types of CP-violating effects. Examples of these three types include the following:

1. All three types of CP violation have been observed in $K \to \pi\pi$ decays:

$$\mathcal{R}e(\epsilon') = \frac{1}{6} \left(\left| \frac{\overline{A}_{\pi^0 \pi^0}}{A_{\pi^0 \pi^0}} \right| - \left| \frac{\overline{A}_{\pi^+ \pi^-}}{A_{\pi^+ \pi^-}} \right| \right) = (2.5 \pm 0.4) \times 10^{-6} (I)$$

$$\mathcal{R}e(\epsilon) = \frac{1}{2} \left(1 - \left| \frac{q}{p} \right| \right) = (1.66 \pm 0.02) \times 10^{-3}$$
 (II)

$$\mathcal{I}m(\epsilon) = -\frac{1}{2}\mathcal{I}m(\lambda_{(\pi\pi)I=0}) = (1.57 \pm 0.02) \times 10^{-3} . \quad \text{(III)}$$
(12.101)

2. Direct CP violation has been observed in, for example, the $B^0 \to K^+\pi^-$ decays, while CP violation in interference of decays with and without mixing has been observed in, for example, the $B \to J/\psi K_S$ decay:

$$\begin{split} \mathcal{A}_{K^{+}\pi^{-}} &= \frac{|\overline{A}_{K^{-}\pi^{+}}/A_{K^{+}\pi^{-}}|^{2} - 1}{|\overline{A}_{K^{-}\pi^{+}}/A_{K^{+}\pi^{-}}|^{2} + 1} = -0.087 \pm 0.008 \quad \text{(I)} \\ S_{\psi K} &= \mathcal{I}m(\lambda_{\psi K}) = +0.679 \pm 0.020 \; . \end{split} \tag{III)} \tag{12.102} \end{split}$$

Based on Standard Model predictions, further observation of CP violation in D, B and B_s decays seems promising for the near future, at both LHCb and a possible higher-luminosity asymmetric-energy B factory [58]. Observables that are subject to clean theoretical interpretation, such as $S_{\psi K_S}$, $\mathcal{B}(K_L \to \pi^0 \nu \overline{\nu})$ and CP violation in $B \to DK$ decays, are of particular value for constraining the values of the CKM parameters and probing the flavor sector of extensions to the Standard Model. Other probes of CP violation now being pursued experimentally include the electric dipole moments of the neutron and electron, and the decays of tau leptons. Additional processes that are likely to play an important role in future CP studies include top-quark production and decay, and neutrino oscillations.

All measurements of CP violation to date are consistent with the predictions of the Kobayashi-Maskawa mechanism of the Standard Model. Actually, it is now established that the KM mechanism plays a major role in the CP violation measured in meson decays. However, a dynamically-generated matter-antimatter asymmetry of the universe requires additional sources of CP violation, and such sources are naturally generated by extensions to the Standard Model. New sources might eventually reveal themselves as small deviations from the predictions of the KM mechanism in meson decay rates, or else might not be observable in meson decays at all, but observable with future probes such as neutrino oscillations or electric dipole moments. We cannot guarantee that new sources of CP violation will ever be found experimentally, but the fundamental nature of CP violation demands a vigorous effort.

A number of excellent reviews of CP violation are available [59–67], where the interested reader may find a detailed discussion of the various topics that are briefly reviewed here.

We thank Tim Gershon for significant contributions to the 2012 update.

13. NEUTRINO MASS, MIXING, AND OSCILLATIONS

Updated May 2012 by K. Nakamura (Kavli IPMU (WPI), U. Tokyo, KEK) and S.T. Petcov (SISSA/INFN Trieste, Kavli IPMU (WPI), U. Tokyo, Bulgarian Academy of Sciences).

The experiments with solar, atmospheric, reactor and accelerator neutrinos have provided compelling evidences for oscillations of neutrinos caused by nonzero neutrino masses and neutrino mixing. The data imply the existence of 3-neutrino mixing in vacuum. We review the theory of neutrino oscillations, the phenomenology of neutrino mixing, the problem of the nature - Dirac or Majorana, of massive neutrinos, the issue of CP violation in the lepton sector, and the current data on the neutrino masses and mixing parameters. The open questions and the main goals of future research in the field of neutrino mixing and oscillations are outlined.

13.1. Introduction: Massive neutrinos and neutrino mixing

It is a well-established experimental fact that the neutrinos and antineutrinos which take part in the standard charged current (CC) and neutral current (NC) weak interaction are of three varieties (types) or flavours: electron, ν_e and $\bar{\nu}_e$, muon, ν_μ and $\bar{\nu}_\mu$, and tauon, ν_τ and $\bar{\nu}_\tau$. The notion of neutrino type or flavour is dynamical: ν_e is the neutrino which is produced with e^+ , or produces an e^- in CC weak interaction processes; ν_μ is the neutrino which is produced with μ^+ , or produces μ^- , etc. The flavour of a given neutrino is Lorentz invariant. Among the three different flavour neutrinos and antineutrinos, no two are identical. Correspondingly, the states which describe different flavour neutrinos must be orthogonal (within the precision of the current data): $\langle \nu_{\ell'} | \nu_{\ell} \rangle = \delta_{\ell' \ell}$, $\langle \bar{\nu}_{\ell'} | \bar{\nu}_{\ell} \rangle = \delta_{\ell' \ell}$, $\langle \bar{\nu}_{\ell'} | \nu_{\ell} \rangle = 0$.

It is also well-known from the existing data (all neutrino experiments were done so far with relativistic neutrinos or antineutrinos), that the flavour neutrinos ν_l (antineutrinos $\bar{\nu}_l$), are always produced in weak interaction processes in a state that is predominantly left-handed (LH) (right-handed (RH)). To account for this fact, ν_l and $\bar{\nu}_l$ are described in the Standard Model (SM) by a chiral LH flavour neutrino field $\nu_{lL}(x)$, $l = e, \mu, \tau$. For massless ν_l , the state of ν_l ($\bar{\nu}_l$) which the field $\nu_{lL}(x)$ annihilates (creates) is with helicity (-1/2) (helicity +1/2). If ν_l has a non-zero mass $m(\nu_l)$, the state of ν_l ($\bar{\nu}_l$) is a linear superposition of the helicity (-1/2) and (+1/2) states, but the helicity +1/2 state (helicity (-1/2) state) enters into the superposition with a coefficient $\propto m(\nu_l)/E$, E being the neutrino energy, and thus is strongly suppressed. Together with the LH charged lepton field $l_L(x)$, $\nu_{lL}(x)$ forms an $SU(2)_L$ doublet. In the absence of neutrino mixing and zero neutrino masses, $\nu_{lL}(x)$ and $l_L(x)$ can be assigned one unit of the additive lepton charge L_l and the three charges L_l , $l=e,\mu,\tau,$ are conserved by the weak interaction.

At present there is no compelling evidence for the existence of states of relativistic neutrinos (antineutrinos), which are predominantly righthanded, ν_R (left-handed, $\bar{\nu}_L$). If RH neutrinos and LH antineutrinos exist, their interaction with matter should be much weaker than the weak interaction of the flavour LH neutrinos ν_l and RH antineutrinos $\bar{\nu}_l, i.e., \nu_R \ (\bar{\nu}_L)$ should be "sterile" or "inert" neutrinos (antineutrinos) [1]. In the formalism of the Standard Model, the sterile ν_R and $\bar{\nu}_L$ can be described by $SU(2)_L$ singlet RH neutrino fields $\nu_R(x)$. In this case, ν_R and $\bar{\nu}_L$ will have no gauge interactions, *i.e.*, will not couple to the weak W^\pm and Z^0 bosons. If present in an extension of the Standard Model, the RH neutrinos can play a crucial role i) in the generation of neutrino masses and mixing, ii) in understanding the remarkable disparity between the magnitudes of neutrino masses and the masses of the charged leptons and quarks, and iii) in the generation of the observed matter-antimatter asymmetry of the Universe (via the leptogenesis mechanism [2]) . In this scenario which is based on the see-saw theory [3], there is a link between the generation of neutrino masses and the generation of the baryon asymmetry of the Universe. The simplest hypothesis (based on symmetry considerations) is that to each LH flavour neutrino field $\nu_{lL}(x)$ there corresponds a RH neutrino field $\nu_{lR}(x)$, $l=e,\mu,\tau$, although schemes with less (more) than three RH neutrinos are also being considered.

The experiments with solar, atmospheric and reactor neutrinos [4–16] have provided compelling evidences for the existence of neutrino oscillations [17,18], transitions in flight between the different flavour neutrinos ν_e , ν_μ , ν_τ (antineutrinos $\bar{\nu}_e$, $\bar{\nu}_\mu$, $\bar{\nu}_\tau$), caused by nonzero neutrino masses and neutrino mixing.

The existence of flavour neutrino oscillations implies that if a neutrino of a given flavour, say ν_{μ} , with energy E is produced in some weak interaction process, at a sufficiently large distance L from the ν_{μ} source the probability to find a neutrino of a different flavour, say ν_{τ} , $P(\nu_{\mu} \to \nu_{\tau}; E, L)$, is different from zero. $P(\nu_{\mu} \to \nu_{\tau}; E, L)$ is called the $\nu_{\mu} \to \nu_{\tau}$ oscillation or transition probability. If $P(\nu_{\mu} \to \nu_{\tau}; E, L) \neq 0$, the probability that ν_{μ} will not change into a neutrino of a different flavour, i.e., the " ν_{μ} survival probability" $P(\nu_{\mu} \rightarrow \nu_{\mu}; E, L)$, will be smaller than one. If only muon neutrinos ν_{μ} are detected in a given experiment and they take part in oscillations, one would observe a "disappearance" of muon neutrinos on the way from the ν_{μ} source to the detector. Disappearance of the solar ν_{e} , reactor $\bar{\nu}_e$ and of atmospheric ν_μ and $\bar{\nu}_\mu$ due to the oscillations have been observed respectively, in the solar neutrino [4-12], KamLAND [15,16] and Super-Kamokande [13,14] experiments. Strong evidences for disappearance of muon neutrinos due to oscillations were obtained also in the long-baseline accelerator neutrino experiments K2K [19] and MINOS [20,21]. As a consequence of the results of the experiments quoted above the existence of oscillations or transitions of the solar ν_e , atmospheric ν_μ and $\bar{\nu}_\mu$, accelerator ν_μ (at $L\sim 250$ km and $L \sim 730$ km) and reactor $\bar{\nu}_e$ (at $L \sim 180$ km), driven by nonzero neutrino masses and neutrino mixing, was firmly established. There are strong indications that the solar ν_e transitions are affected by the solar matter [22,23]. In June of 2011, the T2K [24] Collaboration reported indication of $\nu_{\mu} \rightarrow \nu_{e}$ oscillations, i.e., "appearance" of ν_{e} in a beam of ν_{μ} at a significance of 2.5 σ . Also MINOS [25] Collaboration obtained data consistent with $\nu_{\mu} \rightarrow \nu_{e}$ oscillations. In March and April, 2012, the Daya Bay [26] and RENO [27] experiments reported strong evidence for reactor $\bar{\nu}_e$ disappearance respectively at $L\sim 1.65$ km and $L\sim 1.38$ km and with statistical significance of 5.2σ and $4.9\sigma.$

Oscillations of neutrinos are a consequence of the presence of flavour neutrino mixing, or lepton mixing, in vacuum. In the formalism of local quantum field theory, used to construct the Standard Model, this means that the LH flavour neutrino fields $\nu_{\text{IL}}(x)$, which enter into the expression for the lepton current in the CC weak interaction Lagrangian, are linear combinations of the fields of three (or more) neutrinos ν_j , having masses $m_j \neq 0$:

$$\nu_{lL}(x) = \sum_{j} U_{lj} \nu_{jL}(x), \quad l = e, \mu, \tau,$$
 (13.1)

where $\nu_{j{\rm L}}(x)$ is the LH component of the field of ν_{j} possessing a mass m_{j} and U is a unitary matrix - the neutrino mixing matrix [1,17,18]. The matrix U is often called the Pontecorvo-Maki-Nakagawa-Sakata (PMNS) or Maki-Nakagawa-Sakata (MNS) mixing matrix. Obviously, Eq. (13.1) implies that the individual lepton charges $L_{l},\ l=e,\mu,\tau,$ are not conserved.

All existing neutrino oscillation data, except for the LSND [28] and the MiniBooNE [29] results (see below), can be described assuming 3-flavour neutrino mixing in vacuum. The data on the invisible decay width of the Z^0 -boson is compatible with only 3 light flavour neutrinos coupled to Z^0 [30]. The number of massive neutrinos ν_j , n, can, in general, be bigger than 3, n>3, if, for instance, there exist sterile neutrinos and they mix with the flavour neutrinos. It follows from the existing data that at least 3 of the neutrinos ν_j , say ν_1 , ν_2 , ν_3 , must be light, $m_{1,2,3} \lesssim 1$ eV, and must have different masses, $m_1 \neq m_2 \neq m_3$.

The short-baseline accelerator experiment LSND [28] observed a possible indication of $\bar{\nu}_{\mu} \to \bar{\nu}_{e}$ oscillations. Performing a $\bar{\nu}_{\mu} \to \bar{\nu}_{e}$ oscillation search, the MiniBooNE Collaboration reported a 1.5σ excess of $\bar{\nu}_{e}$ events [29], which is marginally consistent with the LSND indication of $\bar{\nu}_{\mu} \to \bar{\nu}_{e}$ oscillations. However, in the MiniBooNE experiment no indications of $\nu_{\mu} \to \nu_{e}$ oscillations were found so far [31]. Interpreting the LSND [28] and the MiniBooNE [29,31] results in terms of neutrino oscillations requires the introduction of at least two more light neutrinos with masses in the 1 eV range [32], and thus of two sterile neutrino fields which mix with the ν_{e} and ν_{μ} fields.

However, further experimental investigations are definitely needed since the excess of $\bar{\nu}_e$ events observed in the MiniBooNE experiment has a relatively low statistical significance.

Hints (at $\sim 2.5\sigma$) for existence of additional light neutrinos beyond the three firmly established were obtained in the re-analysis [33] of the old short baseline (SBL) reactor $\bar{\nu}_e$ oscillation data using the results of a new and very detailed calculation of the reactor $\bar{\nu}_e$ fluxes [34]. The latter were found in Ref. 34 to be by approximately 3% larger than the fluxes calculated in Ref. 35 and widely used in the interpretation of the results of the SBL reactor $\bar{\nu}_e$ oscillation experiments. It should be added that the results for the reactor $\bar{\nu}_e$ fluxes have an uncertainty associated, e.g., with the weak magnetism term contribution to the corresponding β -decay rates, which can be larger than the 3% difference between the "old" and "new" fluxes [36].

On the basis of the preceding discussion we can conclude that at present there are no compelling experimental evidences for the existence of more than 3 light neutrinos.

Being electrically neutral, the neutrinos with definite mass ν_j can be Dirac fermions or Majorana particles [37,38]. The first possibility is realised when there exists a lepton charge carried by the neutrinos ν_j , which is conserved by the particle interactions. This could be, e.g., the total lepton charge $L = L_e + L_{\mu} + L_{\tau}$: $L(\nu_j) = 1$, j = 1, 2, 3. In this case the neutrino ν_j has a distinctive antiparticle $\bar{\nu}_j$: $\bar{\nu}_j$ differs from ν_j by the value of the lepton charge L it carries, $L(\bar{\nu}_j) = -1$. The massive neutrinos ν_j can be Majorana particles if no lepton charge is conserved (see, e.g., Ref. 39). A massive Majorana particle χ_j is identical with its antiparticle $\bar{\chi}_j$: $\chi_j \equiv \bar{\chi}_j$. On the basis of the existing neutrino data it is impossible to determine whether the massive neutrinos are Dirac or Majorana fermions.

In the case of n neutrino flavours and n massive neutrinos, the $n\times n$ unitary neutrino mixing matrix U can be parametrised by n(n-1)/2 Euler angles and n(n+1)/2 phases. If the massive neutrinos ν_j are Dirac particles, only (n-1)(n-2)/2 phases are physical and can be responsible for CP violation in the lepton sector. In this respect the neutrino (lepton) mixing with Dirac massive neutrinos is similar to the quark mixing. For n=3 there is just one CP violating phase in U, which is usually called "the Dirac CP violating phase." CP invariance holds if (in a certain standard convention) U is real, $U^* = U$.

If, however, the massive neutrinos are Majorana fermions, $\nu_j \equiv \chi_j$, the neutrino mixing matrix U contains n(n-1)/2 CP violation phases [40,41], *i.e.*, by (n-1) phases more than in the Dirac neutrino case: in contrast to Dirac fields, the massive Majorana neutrino fields cannot "absorb" phases. In this case U can be cast in the form [40]

$$U = V P \tag{13.2}$$

where the matrix V contains the (n-1)(n-2)/2 Dirac CP violation phases, while P is a diagonal matrix with the additional (n-1) Majorana CP violation phases $\alpha_{21}, \alpha_{31}, ..., \alpha_{n1}$,

$$P = diag\left(1, e^{i\frac{\alpha_{21}}{2}}, e^{i\frac{\alpha_{31}}{2}}, ..., e^{i\frac{\alpha_{n1}}{2}}\right). \tag{13.3}$$

The Majorana phases will conserve CP if [42] $\alpha_{j1} = \pi q_j$, $q_j = 0, 1, 2$, j = 2, 3, ..., n. In this case $\exp[i(\alpha_{j1} - \alpha_{k1})] = \pm 1$ has a simple physical interpretation: this is the relative CP-parity of Majorana neutrinos χ_j and χ_k . The condition of CP invariance of the leptonic CC weak interaction in the case of mixing and massive Majorana neutrinos reads [39]:

$$U_{lj}^* = U_{lj} \rho_j, \quad \rho_j = \frac{1}{i} \eta_{CP}(\chi_j) = \pm 1,$$
 (13.4)

where $\eta_{CP}(\chi_j)=i\rho_j=\pm i$ is the CP parity of the Majorana neutrino χ_j [42]. Thus, if CP invariance holds, the elements of U are either real or purely imaginary.

In the case of n=3 there are altogether 3 CP violation phases - one Dirac and two Majorana. Even in the mixing involving only 2 massive Majorana neutrinos there is one physical CP violation Majorana phase. In contrast, the CC weak interaction is automatically CP-invariant in the case of mixing of two massive Dirac neutrinos or of two quarks.

13.2. Neutrino oscillations in vacuum

Neutrino oscillations are a quantum mechanical consequence of the existence of nonzero neutrino masses and neutrino (lepton) mixing, Eq. (13.1), and of the relatively small splitting between the neutrino masses. The neutrino mixing and oscillation phenomena are analogous to the $K^0 - \bar{K^0}$ and $B^0 - \bar{B^0}$ mixing and oscillations.

In what follows we will present a simplified version of the derivation of the expressions for the neutrino and antineutrino oscillation probabilities. The complete derivation would require the use of the wave packet formalism for the evolution of the massive neutrino states, or, alternatively, of the field-theoretical approach, in which one takes into account the processes of production, propagation and detection of neutrinos [43].

Suppose the flavour neutrino ν_l is produced in a CC weak interaction process and after a time T it is observed by a neutrino detector, located at a distance L from the neutrino source and capable of detecting also neutrinos $\nu_{l'}$, $l' \neq l$. We will consider the evolution of the neutrino state $|\nu_l\rangle$ in the frame in which the detector is at rest (laboratory frame). The oscillation probability, as we will see, is a Lorentz invariant quantity. If lepton mixing, Eq. (13.1), takes place and the masses m_j of all neutrinos ν_j are sufficiently small, the state of the neutrino ν_l , $|\nu_l\rangle$, will be a coherent superposition of the states $|\nu_j\rangle$ of neutrinos ν_j :

$$|\nu_l\rangle = \sum_j U_{lj}^* |\nu_j; \tilde{p}_j\rangle, \quad l = e, \mu, \tau,$$
 (13.5)

where U is the neutrino mixing matrix and \tilde{p}_j is the 4-momentum of ν_j [44].

We will consider the case of relativistic neutrinos ν_j , which corresponds to the conditions in both past and currently planned future neutrino oscillation experiments [46]. In this case the state $|\nu_j, \tilde{p}_j\rangle$ practically coincides with the helicity (-1) state $|\nu_j, L; \tilde{p}_j\rangle$ of the neutrino ν_j , the admixture of the helicity (+1) state $|\nu_j, R; \tilde{p}_j\rangle$ in $|\nu_j; \tilde{p}_j\rangle$ being suppressed due to the factor $\sim m_j/E_j$, where E_j is the energy of ν_j . If ν_j are Majorana particles, $\nu_j \equiv \chi_j$, due to the presence of the helicity (+1) state $|\chi_j, R; \tilde{p}_j\rangle$ in $|\chi_j; \tilde{p}_j\rangle$, the neutrino ν_l can produce an l^+ (instead of l^-) when it interacts with nucleons. The cross section of such a $|\Delta L_l| = 2$ process is suppressed by the factor $(m_j/E_j)^2$, which renders the process unobservable at present.

If the number n of massive neutrinos ν_j is bigger than 3 due to a mixing between the active flavour and sterile neutrinos, one will have additional relations similar to that in Eq. (13.5) for the state vectors of the (predominantly LH) sterile antineutrinos. In the case of just one RH sterile neutrino field $\nu_{sR}(x)$, for instance, we will have in addition to Eq. (13.5):

$$|\bar{\nu}_{sL}\rangle = \sum_{j=1}^{4} U_{sj}^{*} |\nu_{j}; \tilde{p}_{j}\rangle \cong \sum_{j=1}^{4} U_{sj}^{*} |\nu_{j}, L; \tilde{p}_{j}\rangle,$$
 (13.6)

where the neutrino mixing matrix U is now a 4×4 unitary matrix.

For the state vector of RH flavour antineutrino $\bar{\nu}_l$, produced in a CC weak interaction process we similarly get:

$$|\bar{\nu}_l\rangle = \sum_j U_{lj} \, |\bar{\nu}_j; \tilde{p}_j\rangle \cong \sum_{j=1} U_{lj} \, |\bar{\nu}_j, R; \tilde{p}_j\rangle, \quad l = e, \mu, \tau \,, \eqno(13.7)$$

where $|\bar{\nu}_j, R; \tilde{p}_j\rangle$ is the helicity (+1) state of the antineutrino $\bar{\nu}_j$ if ν_j are Dirac fermions, or the helicity (+1) state of the neutrino $\nu_j \equiv \bar{\nu}_j \equiv \chi_j$ if the massive neutrinos are Majorana particles. Thus, in the latter case we have in Eq. (13.7): $|\bar{\nu}_j; \tilde{p}_j\rangle \cong |\nu_j, R; \tilde{p}_j\rangle \equiv |\chi_j, R; \tilde{p}_j\rangle$. The presence of the matrix U in Eq. (13.7) (and not of U^*) follows directly from Eq. (13.1).

We will assume in what follows that the spectrum of masses of neutrinos is not degenerate: $m_j \neq m_k, j \neq k$. Then the states $|\nu_j; \tilde{p}_j\rangle$ in the linear superposition in the r.h.s. of Eq. (13.5) will have, in general, different energies and different momenta, independently of whether they are produced in a decay or interaction process: $\tilde{p}_j \neq \tilde{p}_k$,

or
$$E_j \neq E_k$$
, $\mathbf{p}_j \neq \mathbf{p}_k$, $j \neq k$, where $E_j = \sqrt{p_j^2 + m_j^2}$, $p_j \equiv |\mathbf{p}_j|$.

The deviations of E_j and p_j from the values for a massless neutrino E and p=E are proportional to m_j^2/E_0 , E_0 being a characteristic energy of the process, and are extremely small. In the case of $\pi^+ \to \mu^+ + \nu_\mu$ decay at rest, for instance, we have: $E_j = E + m_j^2/(2m_\pi)$, $p_j = E - \xi m_j^2/(2E)$, where $E = (m_\pi/2)(1 - m_\mu^2/m_\pi^2) \cong 30$ MeV, $\xi = (1 + m_\mu^2/m_\pi^2)/2 \cong 0.8$, and m_μ and m_π are the μ^+ and π^+ masses. Taking $m_j = 1$ eV we find: $E_j \cong E (1 + 1.2 \times 10^{-16})$ and $p_j \cong E (1 - 4.4 \times 10^{-16})$.

Suppose that the neutrinos are observed via a CC weak interaction process and that in the detector's rest frame they are detected after time T after emission, after traveling a distance L. Then the amplitude of the probability that neutrino ν_l will be observed if neutrino ν_l was produced by the neutrino source can be written as [43,45,47]:

$$A(\nu_l \to \nu_{l'}) = \sum_j U_{l'j} D_j U_{jl}^{\dagger}, \quad l, l' = e, \mu, \tau,$$
 (13.8)

where $D_j = D_j(p_j; L, T)$ describes the propagation of ν_j between the source and the detector, U_{jl}^{\dagger} and $U_{l'j}$ are the amplitudes to find ν_j in the initial and in the final flavour neutrino state, respectively. It follows from relativistic Quantum Mechanics considerations that [43,45]

$$D_j \equiv D_j(\tilde{p}_j; L, T) = e^{-i\tilde{p}_j(x_f - x_0)} = e^{-i(E_j T - p_j L)}, \qquad p_j \equiv |\mathbf{p}_j|,$$
(13.9)

where [48] x_0 and x_f are the space-time coordinates of the points of neutrino production and detection, $T=(t_f-t_0)$ and $L=\mathbf{k}(\mathbf{x}_f-\mathbf{x}_0)$, \mathbf{k} being the unit vector in the direction of neutrino momentum, $\mathbf{p}_j=\mathbf{k}\mathbf{p}_j$. What is relevant for the calculation of the probability $P(\nu_l\to\nu_{l'})=|A(\nu_l\to\nu_{l'})|^2$ is the interference factor $D_jD_k^*$ which depends on the phase

$$\delta\varphi_{jk} = (E_j - E_k)T - (p_j - p_k)L = (E_j - E_k)\left[T - \frac{E_j + E_k}{p_j + p_k}L\right] + \frac{m_j^2 - m_k^2}{p_j + p_k}L.$$
(13.10)

Some authors [49] have suggested that the distance traveled by the neutrinos L and the time interval T are related by $T=(E_j+E_k)\,L/(p_j+p_k)=L/\bar{v},\,\bar{v}=(E_j/(E_j+E_k))v_j+(E_k/(E_j+E_k))v_k$ being the "average" velocity of ν_j and ν_k , where $\nu_{j,k}=p_{j,k}/E_{j,k}$. In this case the first term in the r.h.s. of Eq. (13.10) vanishes. The indicated relation has not emerged so far from any dynamical wave packet calculations. We arrive at the same conclusion concerning the term under discussion in Eq. (13.10) if one assumes [50] that $E_j=E_k=E_0$. Finally, it was proposed in Ref. 47 and Ref. 51 that the states of ν_j and $\bar{\nu}_j$ in Eq. (13.5) and Eq. (13.7) have the same 3-momentum, $p_j=p_k=p$. Under this condition the first term in the r.h.s. of Eq. (13.10) is negligible, being suppressed by the additional factor $(m_j^2+m_k^2)/p^2$ since for relativistic neutrinos L=T up to terms $\sim m_{j,k}^2/p^2$. We arrive at the same conclusion if $E_j\neq E_k$, $p_j\neq p_k$, $j\neq k$, and we take into account that neutrinos are relativistic and therefore, up to corrections $\sim m_{j,k}^2/E_{j,k}^2$, we have $L\cong T$ (see, e.g., C. Giunti quoted in Ref. 43).

Although the cases considered above are physically quite different, they lead to the same result for the phase difference $\delta\varphi_{jk}$. Thus, we have:

$$\delta \varphi_{jk} \cong \frac{m_j^2 - m_k^2}{2p} L = 2\pi \frac{L}{L_{jk}^v} \operatorname{sgn}(m_j^2 - m_k^2),$$
 (13.11)

where $p = (p_j + p_k)/2$ and

$$L_{jk}^{v} = 4\pi \frac{p}{|\Delta m_{jk}^{2}|} \cong 2.48 \text{ m} \frac{p[MeV]}{|\Delta m_{jk}^{2}|[eV^{2}]}$$
 (13.12)

is the neutrino oscillation length associated with Δm_{jk}^2 . We can safely neglect the dependence of p_j and p_k on the masses m_j and m_k and

consider p to be the zero neutrino mass momentum, p=E. The phase difference $\delta\varphi_{jk}$, Eq. (13.11), is Lorentz-invariant.

Eq. (13.9) corresponds to a plane-wave description of the propagation of neutrinos ν_i . It accounts only for the movement of the center of the wave packet describing ν_j . In the wave packet treatment of the problem, the interference between the states of ν_i and ν_k is subject to a number of conditions [43], the localisation condition and the condition of overlapping of the wave packets of ν_i and ν_k at the detection point being the most important. For relativistic neutrinos, the localisation condition in space, for instance, reads: $\sigma_{xP}, \sigma_{xD} < L^{v}_{jk}/(2\pi), \ \sigma_{xP(D)}$ being the spatial width of the production (detection) wave packet. Thus, the interference will not be suppressed if the spatial width of the neutrino wave packets determined by the neutrino production and detection processes is smaller than the corresponding oscillation length in vacuum. In order for the interference to be nonzero, the wave packets describing ν_i and ν_k should also overlap in the point of neutrino detection. This requires that the spatial separation between the two wave packets at the point of neutrinos detection, caused by the two wave packets having different group velocities $v_i \neq v_k$, satisfies $|(v_i - v_k)T| \ll \max(\sigma_{xP}, \sigma_{xD})$. If the interval of time T is not measured, T in the preceding condition must be replaced by the distance L between the neutrino source and the detector (for further discussion see, e.g., Refs. [43,45,47])

For the $\nu_l \to \nu_{l'}$ and $\bar{\nu}_l \to \bar{\nu}_{l'}$ oscillation probabilities we get from Eq. (13.8), Eq. (13.9), and Eq. (13.11):

$$P(\nu_l \to \nu_{l'}) = \sum_{j} |U_{l'j}|^2 |U_{lj}|^2 + 2 \sum_{j>k} |U_{l'j} U_{l'j}^* U_{lk} U_{l'k}^*|$$

$$\cos(\frac{\Delta m_{jk}^2}{2p} L - \phi_{l'l;jk}), \qquad (13.13)$$

$$P(\bar{\nu}_l \to \bar{\nu}_{l'}) = \sum_j |U_{l'j}|^2 |U_{lj}|^2 + 2 \sum_{j>k} |U_{l'j} U_{lj}^* U_{lk} U_{l'k}^*|$$

$$\cos(\frac{\Delta m_{jk}^2}{2n} L + \phi_{l'l;jk}), \qquad (13.14)$$

where $l,l'=e,\mu,\tau$ and $\phi_{l'l;jk}=\arg\left(U_{l'j}\,U_{lj}^*\,U_{lk}\,U_{l'k}^*\right)$. It follows from Eq. (13.8) - Eq. (13.10) that in order for neutrino oscillations to occur, at least two neutrinos ν_j should not be degenerate in mass and lepton mixing should take place, $U\neq \mathbf{1}$. The neutrino oscillations effects can be large if we have

$$\frac{|\Delta m_{jk}^2|}{2p} L = 2\pi \frac{L}{L_{jk}^v} \gtrsim 1 \,, \ j \neq k \,. \tag{13.15}$$

at least for one Δm_{jk}^2 . This condition has a simple physical interpretation: the neutrino oscillation length L_{jk}^v should be of the order of, or smaller, than source-detector distance L, otherwise the oscillations will not have time to develop before neutrinos reach the detector.

We see from Eq. (13.13) and Eq. (13.14) that $P(\nu_l \to \nu_{l'}) = P(\bar{\nu}_{l'} \to \bar{\nu}_{l}), \ l, l' = e, \mu, \tau$. This is a consequence of CPT invariance. The conditions of CP and T invariance read [40,52,53]: $P(\nu_l \to \nu_{l'}) = P(\bar{\nu}_l \to \bar{\nu}_{l'}), \ l, l' = e, \mu, \tau$ (CP), $P(\nu_l \to \nu_{l'}) = P(\nu_{l'} \to \nu_{l'}), \ l, l' = e, \mu, \tau$ (T). In the case of CPT invariance, which we will assume to hold throughout this article, we get for the survival probabilities: $P(\nu_l \to \nu_l) = P(\bar{\nu}_l \to \bar{\nu}_l), \ l, l' = e, \mu, \tau$. Thus, the study of the "disappearance" of ν_l and $\bar{\nu}_l$, caused by oscillations in vacuum, cannot be used to test whether CP invariance holds in the lepton sector. It follows from Eq. (13.13) and Eq. (13.14) that we can have CP violation effects in neutrino oscillations only if $\phi_{l'l;jk} \neq \pi q, q = 0, 1, 2, i.e.$, if $U_{l'j}U_{l'j}^*U_{lk}U_{l'k}^*$, and therefore U itself, is not real. As a measure of CP and T violation in neutrino oscillations we can consider the asymmetries:

$$A_{\rm CP}^{(l'l)} \equiv P(\nu_l \to \nu_{l'}) - P(\bar{\nu}_l \to \bar{\nu}_{l'}) \,, \quad A_{\rm T}^{(l'l)} \equiv P(\nu_l \to \nu_{l'}) - P(\nu_{l'} \to \nu_l) \,. \tag{13.16}$$

CPT invariance implies: $A_{\rm CP}^{(l'l)} = -A_{\rm CP}^{(ll')}, A_{\rm T}^{(l'l)} = P(\bar{\nu}_{l'} \to \bar{\nu}_l) - P(\bar{\nu}_l \to \bar{\nu}_{l'}) = A_{\rm CP}^{(l'l)}$. It follows further directly from Eq. (13.13) and Eq. (13.14) that

$$A_{\text{CP}}^{(l'l)} = 4 \sum_{j>k} \text{Im} \left(U_{l'j} U_{lj}^* U_{lk} U_{l'k}^* \right) \sin \frac{\Delta m_{jk}^2}{2p} L, \quad l, l' = e, \mu, \tau.$$
(13.1)

Eq. (13.2) and Eq. (13.13) - Eq. (13.14) imply that $P(\nu_l \to \nu_{l'})$ and $P(\bar{\nu}_l \to \bar{\nu}_{l'})$ do not depend on the Majorana CP violation phases in the neutrino mixing matrix U [40]. Thus, the experiments investigating the $\nu_l \to \nu_{l'}$ and $\bar{\nu}_l \to \bar{\nu}_{l'}$ oscillations, $l, l' = e, \mu, \tau$, cannot provide information on the nature - Dirac or Majorana, of massive neutrinos. The same conclusions hold also when the $\nu_l \to \nu_{l'}$ and $\bar{\nu}_l \to \bar{\nu}_{l'}$ oscillations take place in matter [54]. In the case of $\nu_l \leftrightarrow \nu_{l'}$ and $\bar{\nu}_l \leftrightarrow \bar{\nu}_{l'}$ oscillations in vacuum, only the Dirac phase(s) in U can cause CP violating effects leading to $P(\nu_l \to \nu_{l'}) \neq P(\bar{\nu}_l \to \bar{\nu}_{l'}), l \neq l'$.

In the case of 3-neutrino mixing all different $\text{Im}(U_{l'j}U_{lj}^*U_{lk}U_{l'k}^*) \neq 0$, $l' \neq l = e, \mu, \tau, j \neq k = 1, 2, 3$, coincide up to a sign as a consequence of the unitarity of U. Therefore one has [55]:

$$A_{\text{CP}}^{(\mu e)} = -A_{\text{CP}}^{(\tau e)} = A_{\text{CP}}^{(\tau \mu)} = 4 J_{\text{CP}} \left(\sin \frac{\Delta m_{32}^2}{2p} L + \sin \frac{\Delta m_{21}^2}{2p} L + \sin \frac{\Delta m_{13}^2}{2p} L \right) (13.18)$$

where

$$J_{\rm CP} = {\rm Im} \left(U_{\mu 3} U_{e3}^* U_{e2} U_{\mu 2}^* \right),$$
 (13.19)

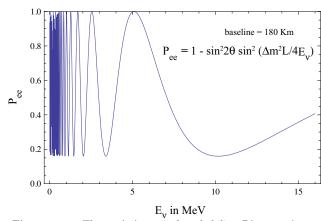

Figure 13.1: The ν_e ($\bar{\nu}_e$) survival probability $P(\nu_e \to \nu_e) = P(\bar{\nu}_e \to \bar{\nu}_e)$, Eq. (13.30), as a function of the neutrino energy for L=180 km, $\Delta m^2=7.0\times 10^{-5}~{\rm eV}^2$ and $\sin^2 2\theta=0.84$ (from Ref. 62).

is the "rephasing invariant" associated with the Dirac CP violation phase in U. It is analogous to the rephasing invariant associated with the Dirac CP violating phase in the CKM quark mixing matrix [56]. It is clear from Eq. (13.18) that $J_{\rm CP}$ controls the magnitude of CP violation effects in neutrino oscillations in the case of 3-neutrino mixing. If $\sin(\Delta m_{ij}^2/(2p))L\cong 0$ for (ij)=(32), or (21), or (13),

we get $A_{\mathrm{CP}}^{(l'l)}\cong 0$. Thus, if as a consequence of the production, propagation and/or detection of neutrinos, effectively oscillations due only to one non-zero neutrino mass squared difference take place, the CP violating effects will be strongly suppressed. In particular, we get $A_{\mathrm{CP}}^{(l'l)}=0$, unless all three $\Delta m_{ij}^2\neq 0$, (ij)=(32),(21),(13).

If the number of massive neutrinos n is equal to the number of neutrino flavours, n=3, one has as a consequence of the unitarity of the neutrino mixing matrix: $\sum_{l'=e,\mu,\tau} P(\nu_l \to \nu_{l'}) = 1$, $l=e,\mu,\tau$, $\sum_{l=e,\mu,\tau} P(\nu_l \to \nu_{l'}) = 1$, $l'=e,\mu,\tau$. Similar "probability conservation" equations hold for $P(\bar{\nu}_l \to \bar{\nu}_{l'})$. If, however, the number of light massive neutrinos is bigger than the number of flavour

neutrinos as a consequence, e.g., of a flavour neutrino - sterile neutrino mixing, we would have $\sum_{l'=e,\mu,\tau} P(\nu_l \to \nu_{l'}) = 1 - P(\nu_l \to \bar{\nu}_{sL})$, $l=e,\mu,\tau$, where we have assumed the existence of just one sterile neutrino. Obviously, in this case $\sum_{l'=e,\mu,\tau} P(\nu_l \to \nu_{l'}) < 1$ if $P(\nu_l \to \bar{\nu}_{sL}) \neq 0$. The former inequality is used in the searches for oscillations between active and sterile neutrinos.

Consider next neutrino oscillations in the case of one neutrino mass squared difference "dominance": suppose that $|\Delta m_{j1}^2| \ll |\Delta m_{n1}^2|$, $j=2,...,(n-1),\,|\Delta m_{n1}^2|\,L/(2p)\gtrsim 1$ and $|\Delta m_{j1}^2|\,L/(2p)\ll 1$, so that $\exp[i(\Delta m_{j1}^2\,L/(2p)]\cong 1,\,j=2,...,(n-1)$. Under these conditions we obtain from Eq. (13.13) and Eq. (13.14), keeping only the oscillating terms involving Δm_{n1}^2 :

$$P(\nu_{l(l')} \to \nu_{l'(l)}) \cong P(\bar{\nu}_{l(l')} \to \bar{\nu}_{l'(l)}) \cong \delta_{ll'} - 2|U_{ln}|^2 \left[\delta_{ll'} - |U_{l'n}|^2 \right]$$

$$(1 - \cos \frac{\Delta m_{n1}^2}{2p} L).$$
(13.20)

It follows from the neutrino oscillation data (Sections 13.4 and 13.5) that in the case of 3-neutrino mixing, one of the two independent neutrino mass squared differences, say Δm_{21}^2 , is much smaller in absolute value than the second one, Δm_{31}^2 : $|\Delta m_{21}^2| \ll |\Delta m_{31}^2|$. The data imply:

$$\begin{split} |\Delta m_{21}^2| &\cong 7.6 \times 10^{-5} \text{ eV}^2 \,, \\ |\Delta m_{31}^2| &\cong 2.4 \times 10^{-3} \text{ eV}^2 \,, \\ |\Delta m_{21}^2| / |\Delta m_{31}^2| &\cong 0.032 \,. \end{split} \tag{13.21}$$

Neglecting the effects due to Δm^2_{21} we get from Eq. (13.20) by setting n=3 and choosing, e.g., i) l=l'=e and ii) $l=e(\mu), \, l'=\mu(e)$ [57]:

$$P(\nu_e \to \nu_e) = P(\bar{\nu}_e \to \bar{\nu}_e) \cong 1 - 2|U_{e3}|^2 \left(1 - |U_{e3}|^2\right) \left(1 - \cos\frac{\Delta m_{31}^2}{2p} L\right),$$
(13.22)

$$P(\nu_{\mu(e)} \to \nu_{e(\mu)}) \cong 2 |U_{\mu 3}|^2 |U_{e 3}|^2 \left(1 - \cos \frac{\Delta m_{31}^2}{2p} L\right)$$

$$= \frac{|U_{\mu 3}|^2}{1 - |U_{e 3}|^2} P^{2\nu} \left(|U_{e 3}|^2, m_{31}^2\right), \qquad (13.23)$$

Table 13.1: Sensitivity of different oscillation experiments.

| Source | Type of ν | $\overline{E}[\mathrm{MeV}]$ | $L[\mathrm{km}]$ | $\min(\Delta m^2)[\mathrm{eV}^2]$ |
|----------------------|-------------------------------------|------------------------------|---------------------|-----------------------------------|
| Reactor | $\overline{ u}_e$ | ~ 1 | 1 | $\sim 10^{-3}$ |
| Reactor | $\overline{ u}_e$ | ~ 1 | 100 | $\sim 10^{-5}$ |
| Accelerator | $ u_{\mu}, \overline{ u}_{\mu}$ | $\sim 10^3$ | 1 | ~ 1 |
| Accelerator | $ u_{\mu}, \overline{ u}_{\mu}$ | $\sim 10^3$ | 1000 | $\sim 10^{-3}$ |
| Atmospheric ν 's | $ u_{\mu,e}, \overline{ u}_{\mu,e}$ | $\sim 10^3$ | 10^{4} | $\sim 10^{-4}$ |
| Sun | $ u_e$ | ~ 1 | 1.5×10^{8} | $\sim 10^{-11}$ |

and $P(\bar{\nu}_{\mu(e)} \to \bar{\nu}_{e(\mu)}) = P(\nu_{\mu(e)} \to \nu_{e(\mu)})$. Here $P^{2\nu}(|U_{e3}|^2, m_{31}^2)$ is the probability of the 2-neutrino transition $\nu_e \to (s_{23}\nu_\mu + c_{23}\nu_\tau)$ due to Δm_{31}^2 and a mixing with angle θ_{13} , where

$$\sin^2 \theta_{13} = |U_{e3}|^2, \quad s_{23}^2 \equiv \sin^2 \theta_{23} = \frac{|U_{\mu 3}|^2}{1 - |U_{e3}|^2},$$

$$c_{23}^2 \equiv \cos^2 \theta_{23} = \frac{|U_{\tau 3}|^2}{1 - |U_{e3}|^2}.$$
(13.24)

Eq. (13.22) describes with a relatively high precision the oscillations of reactor $\bar{\nu}_e$ on a distance $L\sim 1$ km in the case of 3-neutrino mixing. It was used in the analysis of the data of the Chooz [58], Double Chooz [59], Daya Bay [26] and RENO [27] experiments. Eq. (13.20) with n=3 and $l=l'=\mu$ describes with a relatively good precision the effects of oscillations of the accelerator ν_μ , seen in the K2K [19]

and MINOS [20,21] experiments. The $\nu_{\mu} \to \nu_{\tau}$ oscillations, which the OPERA experiment [60,61] is aiming to detect, can be described by Eq. (13.20) with n=3 and $l=\mu$, $l'=\tau$. Finally, the probability Eq. (13.23) describes with a good precision the $\nu_{\mu} \to \nu_{e}$ and $\bar{\nu}_{\mu} \to \bar{\nu}_{e}$ oscillations under the conditions of the K2K experiment.

In certain cases the dimensions of the neutrino source, ΔL , are not negligible in comparison with the oscillation length. Similarly, when analyzing neutrino oscillation data one has to include the energy resolution of the detector, ΔE , etc. in the analysis. As can be shown [39], if $2\pi\Delta L/L_{jk}^v\gg 1$, and/or $2\pi(L/L_{jk}^v)(\Delta E/E)\gg 1$, the oscillating terms in the neutrino oscillation probabilities will be strongly suppressed. In this case (as well as in the case of sufficiently large separation of the ν_j and ν_k wave packets at the detection point) the interference terms in $P(\nu_l \to \nu_{l'})$ and $P(\bar{\nu}_{l'} \to \bar{\nu}_{l})$ will be negligibly small and the neutrino flavour conversion will be determined by the average probabilities:

$$\bar{P}(\nu_l \to \nu_{l'}) = \bar{P}(\bar{\nu}_l \to \bar{\nu}_{l'}) \cong \sum_j |U_{l'j}|^2 |U_{lj}|^2.$$
 (13.25)

Suppose next that in the case of 3-neutrino mixing, $|\Delta m_{21}^2| L/(2p) \sim 1$, while at the same time $|\Delta m_{31(32)}^2| L/(2p) \gg 1$, and the oscillations due to Δm_{31}^2 and Δm_{32}^2 are strongly suppressed (averaged out) due to integration over the region of neutrino production, the energy resolution function, etc. In this case we get for the ν_e and $\bar{\nu}_e$ survival probabilities:

$$P(\nu_e \to \nu_e) = P(\bar{\nu}_e \to \bar{\nu}_e) \cong |U_{e3}|^4 + (1 - |U_{e3}|^2)^2 P^{2\nu}(\nu_e \to \nu_e),$$
(13.26)

$$\begin{split} P^{2\nu}(\nu_e \to \nu_e) &= P^{2\nu}(\bar{\nu}_e \to \bar{\nu}_e) \equiv P_{ee}^{2\nu}(\theta_{12}, \Delta m_{21}^2) \\ &= 1 - \frac{1}{2} \sin^2 2\theta_{12} \left(1 - \cos \frac{\Delta m_{21}^2}{2p} L \right) \quad (13.27) \end{split}$$

being the ν_e and $\bar{\nu}_e$ survival probability in the case of 2-neutrino oscillations "driven" by the angle θ_{12} and Δm_{21}^2 , with θ_{12} determined by

$$\cos^2 \theta_{12} = \frac{|U_{e1}|^2}{1 - |U_{e3}|^2}, \quad \sin^2 \theta_{12} = \frac{|U_{e2}|^2}{1 - |U_{e3}|^2}.$$
 (13.28)

Eq. (13.26) with $P^{2\nu}(\bar{\nu}_e \to \bar{\nu}_e)$ given by Eq. (13.27) describes the effects of neutrino oscillations of reactor $\bar{\nu}_e$ observed by the KamLAND experiment.

In the case of 3-neutrino mixing with $0 < \Delta m_{21}^2 < |\Delta m_{31(32)}^2|$ and $|U_{e3}|^2 = |\sin\theta_{13}|^2 \ll 1$ (see Section 13.6), one can identify Δm_{21}^2 and θ_{12} as the neutrino mass squared difference and mixing angle responsible for the solar ν_e oscillations, and Δm_{31}^2 and θ_{23} as those associated with the dominant atmospheric ν_μ and $\bar{\nu}_\mu$ oscillations. Thus, θ_{12} and θ_{23} are often called "solar" and "atmospheric" neutrino mixing angles and denoted as $\theta_{12} = \theta_{\odot}$ and $\theta_{23} = \theta_{\rm A}$ (or $\theta_{\rm atm}$), while Δm_{21}^2 and Δm_{31}^2 are often referred to as the "solar" and "atmospheric" neutrino mass squared differences and denoted as $\Delta m_{21}^2 \equiv \Delta m_{\odot}^2$ and $\Delta m_{31}^2 \equiv \Delta m_{\rm A}^2$ (or $\Delta m_{\rm atm}^2$).

The data of ν -oscillations experiments is often analyzed assuming 2-neutrino mixing:

$$|\nu_l\rangle = |\nu_1\rangle\cos\theta + |\nu_2\rangle\sin\theta$$
, $|\nu_x\rangle = -|\nu_1\rangle\sin\theta + |\nu_2\rangle\cos\theta$, (13.29)

where θ is the neutrino mixing angle in vacuum and ν_x is another flavour neutrino or sterile (anti-) neutrino, $x = l' \neq l$ or $\nu_x \equiv \bar{\nu}_{sL}$. In this case we have [51]:

$$P^{2\nu}(\nu_l \to \nu_l) = 1 - \frac{1}{2}\sin^2 2\theta \left(1 - \cos 2\pi \frac{L}{L^v}\right),$$

$$P^{2\nu}(\nu_l \to \nu_x) = 1 - P^{2\nu}(\nu_l \to \nu_l),$$
(13.30)

where $L^v = 4\pi p/\Delta m^2$, $\Delta m^2 = m_2^2 - m_1^2 > 0$. Combining the CPT invariance constraints with the probability conservation one obtains: $P(\nu_l \to \nu_x) = P(\bar{\nu}_l \to \bar{\nu}_x) = P(\nu_x \to \nu_l) = P(\bar{\nu}_x \to \bar{\nu}_l)$.

These equalities and Eq. (13.30) with $l=\mu$ and $x=\tau$ were used, for instance, in the analysis of the Super-K atmospheric neutrino data [13], in which the first compelling evidence for oscillations of neutrinos was obtained. The probability $P^{2\nu}(\nu_l\to\nu_x)$, Eq. (13.30), depends on two factors: on $(1-\cos 2\pi L/L^v)$, which exhibits oscillatory dependence on the distance L and on the neutrino energy p=E (hence the name "neutrino oscillations"), and on $\sin^2 2\theta$, which determines the amplitude of the oscillations. In order to have $P^{2\nu}(\nu_l\to\nu_x)\cong 1$, two conditions have to be fulfilled: one should have $\sin^2 2\theta\cong 1$ and $L^v\lesssim 2\pi L$ with $\cos 2\pi L/L^v\cong -1$. If $L^v\gg 2\pi L$, the oscillations do not have enough time to develop on the way to the neutrino detector and $P(\nu_l\to\nu_x)\cong 0$. This is illustrated in Fig. 1 showing the dependence of the probability $P^{2\nu}(\nu_e\to\nu_e)=P^{2\nu}(\bar{\nu}_e\to\bar{\nu}_e)$ on the neutrino energy.

A given experiment searching for neutrino oscillations is specified, in particular, by the average energy of the neutrinos being studied, \bar{E} , and by the source-detector distance L. The requirement $L^v_{jk}\lesssim 2\pi L$ determines the minimal value of a generic neutrino mass squared difference $\Delta m^2>0$, to which the experiment is sensitive (figure of merit of the experiment): $\min(\Delta m^2)\sim 2\bar{E}/L$. Because of the interference nature of neutrino oscillations, experiments can probe, in general, rather small values of Δm^2 (see, e.g., Ref. 47). Values of $\min(\Delta m^2)$, characterizing qualitatively the sensitivity of different experiments are given in Table 1. They correspond to the reactor experiments Chooz ($L\sim 1~{\rm km}$) and KamLAND ($L\sim 100~{\rm km}$), to accelerator experiments - past ($L\sim 1~{\rm km}$), recent, current and future (K2K, MINOS, OPERA, T2K, NO ν A [63]), $L\sim (300\div 1000)~{\rm km}$), to the Super-Kamiokande experiment studying atmospheric neutrino oscillations, and to the solar neutrino experiments.

13.3. Matter effects in neutrino oscillations

The presence of matter can change drastically the pattern of neutrino oscillations: neutrinos can interact with the particles forming the matter. Accordingly, the Hamiltonian of the neutrino system in matter H_m , differs from the Hamiltonian in vacuum H_0 , $H_m = H_0 + H_{int}$, where H_{int} describes the interaction of neutrinos with the particles of matter. When, for instance, ν_e and ν_μ propagate in matter, they can scatter (due to H_{int}) on the electrons (e⁻), protons (p) and neutrons (n) present in matter. The incoherent elastic and the quasi-elastic scattering, in which the states of the initial particles change in the process (destroying the coherence between the neutrino states), are not of interest - they have a negligible effect on the solar neutrino propagation in the Sun and on the solar, atmospheric and reactor neutrino propagation in the Earth [64]: even in the center of the Sun, where the matter density is relatively high ($\sim 150 \text{ g/cm}^3$), a ν_e with energy of 1 MeV has a mean free path with respect to the indicated scattering processes $\sim 10^{10}$ km. We recall that the solar radius is much smaller: $R_{\odot} = 6.96 \times 10^5$ km. The oscillating ν_e and ν_{μ} can scatter also elastically in the forward direction on the e⁻, p and n, with the momenta and the spin states of the particles remaining unchanged. In such a process the coherence of the neutrino states is

The ν_e and ν_μ coherent elastic scattering on the particles of matter generates nontrivial indices of refraction of the ν_e and ν_μ in matter [22]: $\kappa(\nu_e) \neq 1$, $\kappa(\nu_\mu) \neq 1$. Most importantly, we have $\kappa(\nu_e) \neq \kappa(\nu_\mu)$. The difference $\kappa(\nu_e) - \kappa(\nu_\mu)$ is determined essentially by the difference of the real parts of the forward $\nu_e - e^-$ and $\nu_\mu - e^$ elastic scattering amplitudes [22] Re $[F_{\nu_e-e^-}(0)]-Re~[F_{\nu_\mu-e^-}(0)]:$ due to the flavour symmetry of the neutrino - quark (neutrino - nucleon) neutral current interaction, the forward $\nu_e - p, n$ and $\nu_{\mu} - p, n$ elastic scattering amplitudes are equal and therefore do not contribute to the difference of interest [65]. The imaginary parts of the forward scattering amplitudes (responsible, in particular, for decoherence effects) are proportional to the corresponding total scattering cross-sections and in the case of interest are negligible in comparison with the real parts. The real parts of the amplitudes $F_{\nu_{\rm e}-{\rm e}^-}(0)$ and $F_{\nu_{\mu}-{\rm e}^-}(0)$ can be calculated in the Standard Model. To leading order in the Fermi constant G_F , only the term in ${\cal F}_{\nu_{
m e}-{
m e}^-}(0)$ due to the diagram with exchange of a virtual W^\pm -boson contributes to ${\cal F}_{\nu_{
m e}-{
m e}^-}(0)-{\cal F}_{\nu_{\mu}-{
m e}^-}(0)$. One finds the following result for $\kappa(\nu_e) - \kappa(\nu_\mu)$ in the rest frame of the scatters [22,67,68]:

$$\kappa(\nu_e) - \kappa(\nu_\mu) = \frac{2\pi}{p^2} \left(\text{Re } [F_{\nu_e - e^-}(0)] - \text{Re } [F_{\nu_\mu - e^-}(0)] \right)$$
$$= -\frac{1}{p} \sqrt{2} G_F N_e , \qquad (13.31)$$

where N_e is the electron number density in matter. Given $\kappa(\nu_e) - \kappa(\nu_\mu)$, the system of evolution equations describing the $\nu_e \leftrightarrow \nu_\mu$ oscillations in matter reads [22]:

$$i\frac{d}{dt}\begin{pmatrix} A_e(t,t_0) \\ A_\mu(t,t_0) \end{pmatrix} = \begin{pmatrix} -\epsilon(t) & \epsilon' \\ \epsilon' & \epsilon(t) \end{pmatrix} \begin{pmatrix} A_e(t,t_0) \\ A_\mu(t,t_0) \end{pmatrix}$$
(13.32)

where $A_e(t,t_0)$ $(A_{\mu}(t,t_0))$ is the amplitude of the probability to find ν_e (ν_{μ}) at time t of the evolution of the system if at time $t_0 \leq t$ the neutrino ν_e or ν_{μ} has been produced and

$$\epsilon(t) = \frac{1}{2} \left[\frac{\Delta m^2}{2E} \cos 2\theta - \sqrt{2}G_F N_e(t) \right], \quad \epsilon' = \frac{\Delta m^2}{4E} \sin 2\theta. \quad (13.33)$$

The term $\sqrt{2}G_FN_e(t)$ in $\epsilon(t)$ accounts for the effects of matter on neutrino oscillations. The system of evolution equations describing the oscillations of antineutrinos $\bar{\nu}_e \leftrightarrow \bar{\nu}_\mu$ in matter has exactly the same form except for the matter term in $\epsilon(t)$ which changes sign. The effect of matter in neutrino oscillations is usually called the Mikheyev, Smirnov, Wolfenstein (or MSW) effect.

Consider first the case of $\nu_e \leftrightarrow \nu_\mu$ oscillations in matter with constant density: $N_e(t) = N_e = const.$ Due to the interaction term H_{int} in H_m , the eigenstates of the Hamiltonian of the neutrino system in vacuum, $|\nu_{1,2}\rangle$ are not eigenstates of H_m . For the eigenstates $|\nu_{1,2}^m\rangle$ of H_m , which diagonalize the evolution matrix in the r.h.s. of the system Eq. (13.32) we have:

$$|\nu_e\rangle = |\nu_1^m\rangle \cos\theta_m + |\nu_2^m\rangle \sin\theta_m , \quad |\nu_\mu\rangle = -|\nu_1^m\rangle \sin\theta_m + |\nu_2^m\rangle \cos\theta_m .$$
(13.34)

Here θ_m is the neutrino mixing angle in matter [22]

$$\sin 2\theta_m = \frac{\tan 2\theta}{\sqrt{(1 - \frac{N_e}{N_e^{res}})^2 + \tan^2 2\theta}}, \cos 2\theta_m = \frac{1 - N_e/N_e^{res}}{\sqrt{(1 - \frac{N_e}{N_e^{res}})^2 + \tan^2 2\theta}},$$
(13.35)

where the quantity

$$N_e^{res} = \frac{\Delta m^2 \cos 2\theta}{2E\sqrt{2}G_F} \cong 6.56 \times 10^6 \ \frac{\Delta m^2 [\text{eV}^2]}{E[\text{MeV}]} \ \cos 2\theta \ \text{cm}^{-3} \ \text{N}_\text{A} \,, \eqno(13.36)$$

is called (for $\Delta m^2\cos 2\theta>0$) "resonance density" [23,67], N_A being Avogadro's number. The "adiabatic" states $|\nu_{1,2}^m\rangle$ have energies $E_{1,2}^m$ whose difference is given by

$$E_2^m - E_1^m = \frac{\Delta m^2}{2E} \left((1 - \frac{N_e}{N_e^{res}})^2 \cos^2 2\theta + \sin^2 2\theta \right)^{\frac{1}{2}} \equiv \frac{\Delta M^2}{2E}.$$
(13.3)

The probability of $\nu_e \to \nu_\mu$ transition in matter with $N_e = const.$ has the form [22,67]

$$\begin{split} P_m^{2\nu}(\nu_e \to \nu_\mu) &= |A_\mu(t)|^2 = \frac{1}{2} \sin^2 2\theta_m \ [1 - \cos 2\pi \frac{L}{L_m} \] \\ L_m &= 2\pi/(E_2^m - E_1^m) \,, \end{split} \tag{13.38}$$

where L_m is the oscillation length in matter. As Eq. (13.35) indicates, the dependence of $\sin^2 2\theta_m$ on N_e has a resonance character [23]. Indeed, if $\Delta m^2 \cos 2\theta > 0$, for any $\sin^2 2\theta \neq 0$ there exists a value of N_e given by N_e^{res} , such that when $N_e = N_e^{res}$ we have $\sin^2 2\theta_m = 1$ independently of the value of $\sin^2 2\theta < 1$. This implies that the presence of matter can lead to a strong enhancement of the oscillation probability $P_m^{2\nu}(\nu_e \to \nu_\mu)$ even when the $\nu_e \leftrightarrow \nu_\mu$ oscillations in vacuum are suppressed due to a small value of $\sin^2 2\theta$. For obvious reasons

$$N_e = N_e^{res} \equiv \frac{\Delta m^2 \cos 2\theta}{2E\sqrt{2}G_F} \,, \tag{13.39}$$

is called the "resonance condition" [23,67], while the energy at which Eq. (13.39) holds for given N_e and $\Delta m^2\cos 2\theta$, is referred to as the "resonance energy", E^{res} . The oscillation length at resonance is given by [23] $L_m^{res} = L^v/\sin 2\theta$, while the width in N_e of the resonance at half height reads $\Delta N_e^{res} = 2N_e^{res}\tan 2\theta$. Thus, if the mixing angle in vacuum is small, the resonance is narrow, $\Delta N_e^{res} \ll N_e^{res}$, and $L_m^{res} \gg L^v$. The energy difference $E_2^m - E_1^m$ has a minimum at the resonance: $(E_2^m - E_1^m)^{res} = \min (E_2^m - E_1^m) = (\Delta m^2/(2E)) \sin 2\theta$.

It is instructive to consider two limiting cases. If $N_e \ll N_e^{res}$, we have from Eq. (13.35) and Eq. (13.37), $\theta_m \cong \theta$, $L_m \cong L^v$ and neutrinos oscillate practically as in vacuum. In the limit $N_e \gg N_e^{res}$, $N_e^{res} \tan^2 2\theta$, one finds $\theta_m \cong \pi/2$ ($\cos 2\theta_m \cong -1$) and the presence of matter suppresses the $\nu_e \leftrightarrow \nu_\mu$ oscillations. In this case $|\nu_e\rangle \cong |\nu_2^m\rangle$, $|\nu_\mu\rangle = -|\nu_1^m\rangle$, i.e., ν_e practically coincides with the heavier matter-eigenstate, while ν_μ coincides with the lighter one.

Since the neutral current weak interaction of neutrinos in the Standard Model is flavour symmetric, the formulae and results we have obtained are valid for the case of $\nu_e - \nu_\tau$ mixing and $\nu_e \leftrightarrow \nu_\tau$ oscillations in matter as well. The case of $\nu_\mu - \nu_\tau$ mixing, however, is different: to a relatively good precision we have [69] $\kappa(\nu_\mu) \cong \kappa(\nu_\tau)$ and the $\nu_\mu \leftrightarrow \nu_\tau$ oscillations in the matter of the Earth and the Sun proceed practically as in vacuum [70].

The analogs of Eq. (13.35) to Eq. (13.38) for oscillations of antineutrinos, $\bar{\nu}_e \leftrightarrow \bar{\nu}_\mu$, in matter can formally be obtained by replacing N_e with $(-N_e)$ in the indicated equations. It should be clear that depending on the sign of $\Delta m^2 \cos 2\theta$, the presence of matter can lead to resonance enhancement either of the $\nu_e \leftrightarrow \nu_\mu$ or of the $\bar{\nu}_e \leftrightarrow \bar{\nu}_\mu$ oscillations, but not of both types of oscillations [67]. For $\Delta m^2 \cos 2\theta < 0$, for instance, the matter can only suppress the $\nu_e \to \nu_\mu$ oscillations, while it can enhance the $\bar{\nu}_e \to \bar{\nu}_\mu$ transitions. This disparity between the behavior of neutrinos and that of antineutrinos is a consequence of the fact that the matter in the Sun or in the Earth we are interested in is not charge-symmetric (it contains e^- , p and n, but does not contain their antiparticles) and therefore the oscillations in matter are neither CP- nor CPT- invariant [54]. Thus, even in the case of 2-neutrino mixing and oscillations we have, e.g., $P_m^{2\nu}(\nu_e \to \nu_{\mu(\tau)}) \neq P_m^{2\nu}(\bar{\nu}_e \to \bar{\nu}_{\mu(\tau)})$.

The matter effects in the $\nu_e \leftrightarrow \nu_{\mu(\tau)}$ ($\bar{\nu}_e \leftrightarrow \bar{\nu}_{\mu(\tau)}$) oscillations will be invariant with respect to the operation of time reversal if the N_e distribution along the neutrino path is symmetric with respect to this operation [55,71]. The latter condition is fulfilled (to a good approximation) for the N_e distribution along a path of a neutrino crossing the Earth [72].

13.3.1. Effects of Earth matter on oscillations of neutrinos:

The formalism we have developed can be applied, e.g., to the study of matter effects in the $\nu_e \leftrightarrow \nu_{\mu(\tau)} \ (\nu_{\mu(\tau)} \leftrightarrow \nu_e)$ and $\bar{\nu}_e \leftrightarrow \bar{\nu}_{\mu(\tau)}$ $(\bar{\nu}_{\mu(\tau)} \leftrightarrow \bar{\nu}_e)$ oscillations of neutrinos which traverse the Earth [73] Indeed, the Earth density distribution in the existing Earth models [72] is assumed to be spherically symmetric and there are two major density structures - the core and the mantle, and a certain number of substructures (shells or layers). The Earth radius is $R_{\oplus} = 6371$ km; the Earth core has a radius of $R_c = 3486$ km, so the Earth mantle depth is 2885 km. For a spherically symmetric Earth density distribution, the neutrino trajectory in the Earth is specified by the value of the nadir angle θ_n of the trajectory. For $\theta_n \leq 33.17^o$, or path lengths $L \geq 10660$ km, neutrinos cross the Earth core. The path length for neutrinos which cross only the Earth mantle is given by $L=2R_{\oplus}\cos\theta_n$. If neutrinos cross the Earth core, the lengths of the paths in the mantle, $2L^{\text{man}}$, and in the core, L^{core} , are determined by: $L^{\text{man}} = R_{\oplus} \cos \theta_n - (R_c^2 - R_{\oplus}^2 \sin^2 \theta_n)^{\frac{1}{2}}, L^{\text{core}} = 2(R_c^2 - R_{\oplus}^2 \sin^2 \theta_n)^{\frac{1}{2}}.$ The mean electron number densities in the mantle and in the core according to the PREM model read [72]: $\bar{N}_e^{man} \cong 2.2 \text{ cm}^{-3} \text{ N}_A$, $\bar{N}_e^c \cong 5.4 \text{ cm}^{-3} \text{ N}_A$. Thus, we have $\bar{N}_e^c \cong 2.5 \ \bar{N}_e^{man}$. The change of N_e from the mantle to the core can well be approximated by a step function [72]. The electron number density N_e changes relatively little around the indicated mean values along the trajectories of neutrinos which cross a substantial part of the Earth mantle, or the mantle and the core, and the two-layer constant density approximation, $N_e^{man} = const. = \tilde{N}_e^{man}, N_e^c = const. = \tilde{N}_e^c, \tilde{N}_e^{man}$ and \tilde{N}_e^c being the mean densities along the given neutrino path in

the Earth, was shown to be sufficiently accurate in what concerns the calculation of neutrino oscillation probabilities [55,75,76] (and references quoted in [75,76]) in a large number of specific cases. This is related to the fact that the relatively small changes of density along the path of the neutrinos in the mantle (or in the core) take place over path lengths which are typically considerably smaller than the corresponding oscillation length in matter.

In the case of 3-neutrino mixing and for neutrino energies of $E \gtrsim 2$ GeV, the effects due to Δm_{21}^2 ($|\Delta m_{21}^2| \ll |\Delta m_{31}^2|$, see Eq. (13.21)) in the neutrino oscillation probabilities are sub-dominant and to leading order can be neglected: the corresponding resonance density $|N_{e21}^{res}| \lesssim 0.25~cm^{-3}~N_A \ll \bar{N}_e^{man,c}$ and the Earth matter strongly suppresses the oscillations due to Δm_{21}^2 . For oscillations in vacuum this approximation is valid as long as the leading order contribution due to Δm_{31}^2 in the relevant probabilities is bigger than approximately 10^{-3} . In this case the 3-neutrino $\nu_e \to \nu_{\mu(\tau)} \ (\bar{\nu}_e \to \bar{\nu}_{\mu(\tau)})$ and $\nu_{\mu(\tau)} \rightarrow \nu_e \ (\bar{\nu}_{\mu(\tau)} \rightarrow \bar{\nu}_e)$ transition probabilities for neutrinos traversing the Earth, reduce effectively to a 2-neutrino transition probability (see, e.g., Refs. [76–78]), with Δm_{31}^2 and θ_{13} playing the role of the relevant 2-neutrino vacuum oscillation parameters. As will be discussed in Sections 13.6 and 13.7, the value of $\sin^2 2\theta_{13}$ has been determined recently with a rather high precision in the Daya Bay [26] and RENO [27] experiments. The best fit values found in the two experiments read, respectively, $\sin^2 2\theta_{13} = 0.092$ and 0.113, while the 3σ allowed range reported in [26] is $0.04 \lesssim \sin^2 2\theta_{13} \lesssim 0.14$. The 3-neutrino oscillation probabilities of the atmospheric and accelerator $\nu_{e,\mu}$ having energy E and crossing the Earth along a trajectory characterized by a nadir angle θ_n , for instance, have the following

$$P_m^{3\nu}(\nu_e \to \nu_e) \cong 1 - P_m^{2\nu},$$
 (13.40)

$$P_{m}^{3\nu}(\nu_{e} \to \nu_{\mu}) \cong P_{m}^{3\nu}(\nu_{\mu} \to \nu_{e}) \cong s_{23}^{23} P_{m}^{2\nu}, \quad P_{m}^{3\nu}(\nu_{e} \to \nu_{\tau}) \cong c_{23}^{23} P_{m}^{2\nu},$$

$$(13.41)$$

$$P_m^{3\nu}(\nu_{\mu} \to \nu_{\mu}) \cong 1 - s_{23}^4 \ P_m^{2\nu} - 2c_{23}^2 s_{23}^2 \ \left[1 - Re \ \left(e^{-i\kappa} A_m^{2\nu}(\nu' \to \nu') \right) \right], \tag{13.42}$$

$$P_m^{3\nu}(\nu_\mu \to \nu_\tau) = 1 - P_m^{3\nu}(\nu_\mu \to \nu_\mu) - P_m^{3\nu}(\nu_\mu \to \nu_e). \tag{13.43}$$

Here $P_m^{2\nu} \equiv P_m^{2\nu}(\Delta m_{31}^2, \theta_{13}; E, \theta_n)$ is the probability of the 2-neutrino $\nu_e \to \nu' \equiv (s_{23}\nu_\mu + c_{23}\nu_\tau)$ oscillations in the Earth, and κ and $A_m^{2\nu}(\nu' \to \nu') \equiv A_m^{2\nu}$ are known phase and 2-neutrino transition probability amplitude (see, e.g., Refs. [76,77]). We note that Eq. (13.40) to Eq. (13.42) are based only on the assumptions that $|N_e^{res}|$ is much smaller than the densities in the Earth mantle and core and that $|\Delta m_{21}^2| \ll |\Delta m_{31}^2|$, and does not rely on the constant density approximation. Similar results are valid for the corresponding antineutrino oscillation probabilities: one has just to replace $P_m^{2\nu}$, κ and $A_m^{2\nu}$ in the expressions given above with the corresponding quantities for antineutrinos (the latter are obtained from those for neutrinos by changing the sign in front of N_e). Obviously, we have: $P(\nu_{e(\mu)} \to \nu_{\mu(e)})$, $P(\bar{\nu}_{e(\mu)} \to \bar{\nu}_{\mu(e)}) \leq \sin^2\theta_{23}$, and $P(\nu_e \to \nu_\tau)$, $P(\bar{\nu}_e \to \bar{\nu}_\tau) \leq \cos^2\theta_{23}$. The one Δm^2 dominance approximation and correspondingly Eq. (13.40) to Eq. (13.43) were used by the Super-Kamiokande Collaboration in their 2006 neutrino oscillation analysis of the multi-GeV atmospheric neutrino data [79].

In the case of neutrinos crossing only the Earth mantle and in the constant density approximation, $P_m^{2\nu}$ is given by the r.h.s. of Eq. (13.38) with θ and Δm^2 replaced by θ_{13} and Δm_{31}^2 , while for κ and $A_m^{2\nu}$ we have (see, e.g., Ref. 76):

$$\begin{split} \kappa &\cong \frac{1}{2} [\frac{\Delta m_{31}^2}{2E} \ L + \sqrt{2} G_F \bar{N}_e^{man} L - \frac{\Delta M^2 L}{2E}], \\ A_m^{2\nu} &= 1 + (e^{-i\frac{\Delta M^2 L}{2E}} - 1) \cos^2 \theta_m' \ , \end{split} \tag{13.44}$$

where ΔM^2 is defined in Eq. (13.37) (with $\theta=\theta_{13}$ and $\Delta m^2=\Delta m_{31}^2$), θ_m' is the mixing angle in the mantle which coincides in vacuum with θ_{13} (Eq. (13.35) with $N_e=\bar{N}_e^{man}$ and $\theta=\theta_{13}$), and $L=2R_\oplus\cos\theta_n$ is the distance the neutrino travels in the mantle.

It follows from Eq. (13.40) and Eq. (13.41) that for $\Delta m_{31}^2 \cos 2\theta_{13} > 0$, the oscillation effects of interest, e.g., in the $\nu_{e(\mu)} \to \nu_{\mu(e)}$ and $\nu_e \to \nu_\tau$ transitions will be maximal if $P_n^{2\nu} \cong 1$, i.e., if Eq. (13.39)

leading to $\sin^2 2\theta_m \cong 1$ is fulfilled, and ii) $\cos(\Delta M^2 L/(2E)) \cong -1$. Given the value of \bar{N}_n^{man} , the first condition determines the neutrino's energy, while the second determines the path length L, for which one can have $P_m^{2\nu} \cong 1$. For $\Delta m_{31}^2 \cong 2.4 \times 10^{-3} \text{ eV}^2$, $\sin^2 2\theta_{13} \lesssim 0.14$ and $\bar{N}_n^{man} \cong 2.2 \text{ N}_A \text{cm}^{-3}$, one finds that $E_{res} \cong 7.2 \text{ GeV}$ and $L \cong 2370/\sin 2\theta_{13} \text{ km} \gtrsim 6267.3 \text{ km}$. Since for neutrinos crossing only the mantle $L \lesssim 10660 \text{ km}$, the second condition can be satisfied only if $\sin \theta_{13} \gtrsim 0.11$, which falls in the range of the experimentally allowed values of $\sin \theta_{13}$. Thus, for $\Delta m_{31}^2 > 0$, the Earth matter effects can amplify P_m^2 , and therefore $P(\nu_{e(\mu)} \to \nu_{\mu(e)})$ and $P(\nu_e \to \nu_\tau)$, maximally when the neutrinos cross only the mantle for $E \sim 7$ GeV and $L \gtrsim 5400 \text{ km}$, or $\cos \theta_n \gtrsim 0.43$, provided $\sin \theta_{13} \gtrsim 0.1$. If $\Delta m_{31}^2 < 0$ the same considerations apply for the corresponding antineutrino oscillation probabilities $\bar{P}_m^{2\nu} = \bar{P}_m^{2\nu} (\bar{\nu}_e \to (s_{23}\bar{\nu}_\mu + c_{23}\bar{\nu}_\tau))$ and correspondingly for $P(\bar{\nu}_{e(\mu)} \to \bar{\nu}_{\mu(e)})$ and $P(\bar{\nu}_e \to \bar{\nu}_\tau)$. For $\Delta m_{31}^2 > 0$, the $\bar{\nu}_{e(\mu)} \to \bar{\nu}_{\mu(e)}$ and $\bar{\nu}_e \to \bar{\nu}_\tau$ oscillations are suppressed by the Earth matter, while if $\Delta m_{31}^2 < 0$, the same conclusion holds for the $\nu_{e(\mu)} \to \nu_{\mu(e)}$ and $\nu_e \to \nu_\tau$, oscillations.

In the case of neutrinos crossing the Earth core, new resonance-like effects become possible in the $\nu_{\mu} \rightarrow \nu_{e}$ and $\nu_{e} \rightarrow \nu_{\mu(\tau)}$ (or $\bar{\nu}_{\mu} \rightarrow \bar{\nu}_{e}$ and $\bar{\nu}_e \to \bar{\nu}_{\mu(\tau)}$) transitions [75–77,80–82]. For $\sin^2 \theta_{13} \lesssim 0.05$ and $\Delta m_{31}^2>0$, we can have [81] $P_m^{2\nu}(\Delta m_{31}^2,\theta_{13})\cong 1$, and correspondingly maximal $P_m^{3\nu}(\nu_e\to\nu_\mu)=P_m^{3\nu}(\nu_\mu\to\nu_e)\cong s_{23}^2$, only due to the effect of maximal constructive interference between the amplitudes of the $\nu_e \to \nu'$ transitions in the Earth mantle and in the Earth core. The effect differs from the MSW one and the enhancement happens in the case of interest at a value of the energy between the MSW resonance energies corresponding to the density in the mantle and that of the core, or at a value of the resonance density N_e^{res} which lies between the values of N_e in the mantle and in the core [75]. In Refs. [75,76] the enhancement was called "neutrino oscillation length resonance", while in Refs. [77,80] the term "parametric resonance" for the same effect was used [83]. The mantle-core enhancement effect is caused by the existence (for a given neutrino trajectory through the Earth core) of points of resonance-like maximal neutrino conversion, $P_m^{2\nu}(\Delta m_{31}^2, \theta_{13})=1$, in the corresponding space of neutrino oscillation parameters [81]. For $\Delta m_{31}^2<0$ the mantle-core enhancement can take place for the antineutrino transitions, $\bar{\nu}_{\mu} \to \bar{\nu}_{e}$ and $\bar{\nu}_{e} \to \bar{\nu}_{\mu(\tau)}$.

A rather complete set of values of $\Delta m_{31}^2/E>0$ and $\sin^22\theta_{13}$ for which $P_m^{2\nu}(\Delta m_{31}^2,\theta_{13})=1$ was found in Ref. 81. The location of these points in the $\Delta m_{31}^2/E-\sin^22\theta_{13}$ plane determines the regions in the plane where $P_m^{2\nu}(\Delta m_{31}^2,\theta_{13})$ is large, $P_m^{2\nu}(\Delta m_{31}^2,\theta_{13})\gtrsim 0.5$. These regions vary slowly with the nadir angle, being remarkably wide in the nadir angle and rather wide in the neutrino energy [81], so that the transitions of interest can produce noticeable effects in the measured observables. For $\sin^2\theta_{13}\lesssim 0.05$, there are two sets of values of $(\Delta m_{31}^2/E,\sin^2\theta_{13})$ for which $P_m^{2\nu}(\Delta m_{31}^2,\theta_{13})=1$, and thus two regions in $\Delta m_{31}^2/E-\sin^22\theta_{13}$ plane where $P_m^{2\nu}(\Delta m_{31}^2,\theta_{13})\gtrsim 0.5$. For $\Delta m_{31}^2=2.4\times 10^{-3}$ eV² and nadir angle, e.g., θ_n =0 (Earth center crossing neutrinos), we have $P_m^{2\nu}(\Delta m_{31}^2,\theta_{13})=1$ at $(E,\sin^22\theta_{13})=(3.3~{\rm GeV},0.034)$ and (5.0 ${\rm GeV},0.15$). At the same time for $E=3.3~{\rm GeV}$ (5.0 ${\rm Gev}$), the probability $P_m^{2\nu}(\Delta m_{31}^2,\theta_{13})\gtrsim 0.5$ for the values of $\sin^22\theta_{13}\lesssim 0.26$). Similar results hold for neutrinos crossing the Earth core along the trajectories with $\theta_n\neq 0$ (for further details see the last article in Ref. 81; see also the last article in Ref. 82).

The mantle-core enhancement of $P_m^{2\nu}$ (or $\bar{P}_m^{2\nu}$) is relevant, in particular, for the searches of sub-dominant $\nu_{e(\mu)} \to \nu_{\mu(e)}$ (or $\bar{\nu}_{e(\mu)} \to \bar{\nu}_{\mu(e)}$) oscillations of atmospheric neutrinos having energies $E \gtrsim 2$ GeV and crossing the Earth core on the way to the detector (see Ref. 75 to Ref. 82 and the references quoted therein). The effects of Earth matter on the oscillations of atmospheric and accelerator neutrinos have not been observed so far. At present there are no compelling evidences for oscillations of the atmospheric ν_e and/or $\bar{\nu}_e$.

The expression for the probability of the $\nu_e \rightarrow \nu_\mu$ oscillations taking place in the Earth mantle in the case of 3-neutrino mixing, in which both neutrino mass squared differences Δm_{21}^2 and Δm_{31}^2 contribute and the CP violation effects due to the Dirac phase in the neutrino mixing matrix are taken into account, has the following

form in the constant density approximation and keeping terms up to second order in the two small parameters $|\alpha| \equiv |\Delta m_{21}^2|/|\Delta m_{31}^2| \ll 1$ and $\sin^2\theta_{13} \ll 1$ [84]:

$$P_m^{3\nu \ man}(\nu_e \to \nu_\mu) \cong P_0 + P_{\sin \delta} + P_{\cos \delta} + P_3.$$
 (13.45)

Here

$$P_0 = \sin^2 \theta_{23} \frac{\sin^2 2\theta_{13}}{(A-1)^2} \sin^2[(A-1)\Delta]$$

$$P_3 = \alpha^2 \cos^2 \theta_{23} \frac{\sin^2 2\theta_{12}}{A^2} \sin^2(A\Delta), \qquad (13.46)$$

$$P_{\sin\delta} = \alpha \; \frac{8 \, J_{CP}}{A(1-A)} \left(\sin\Delta\right) \left(\sin A\Delta\right) \, \left(\sin[(1-A)\Delta]\right) \, , \qquad (13.47)$$

$$P_{\cos\delta} = \alpha \; \frac{8 \, J_{CP} \cot \delta}{A(1-A)} \left(\cos \Delta\right) \left(\sin A\Delta\right) \; \left(\sin[(1-A)\Delta]\right) \; , \quad \ (13.48)$$

where

$$\alpha = \frac{\Delta m_{21}^2}{\Delta m_{31}^2} \,, \ \ \Delta = \frac{\Delta m_{31}^2 \, L}{4E} \,, \ \ A = \sqrt{2} G_{\rm F} N_e^{man} \frac{2E}{\Delta m_{31}^2} \,, \eqno(13.49)$$

and $\cot\delta=J_{CP}^{-1}{\rm Re}(U_{\mu3}U_{e3}^*U_{e2}U_{\mu2}^*),\ J_{CP}={\rm Im}(U_{\mu3}U_{e3}^*U_{e2}U_{\mu2}^*).$ The analytic expression for $P_m^{3\nu}$ $^{man}(\nu_e\to\nu_\mu)$ given above is valid for [84] neutrino path lengths in the mantle $(L\le 10660~{\rm km})$ satisfying $L\lesssim 10560~{\rm km}~E[{\rm GeV}]~(7.6\times 10^{-5}~{\rm eV}^2/\Delta m_{21}^2),$ and energies $E\gtrsim 0.34~{\rm GeV}(\Delta m_{21}^2/7.6\times 10^{-5}~{\rm eV}^2)~(1.4~{\rm cm}^{-3}N_A/N_e^{man}).$ The expression for the $\bar{\nu}_e\to\bar{\nu}_\mu$ oscillation probability can be obtained formally from that for $P_m^{3\nu}$ $^{man}(\nu_e\to\nu_\mu)$ by making the changes $A\to -A$ and $J_{CP}\to -J_{CP}$, with $J_{CP}\cot\delta\equiv{\rm Re}(U_{\mu3}U_{e3}^*U_{e2}U_{\mu2}^*)$ remaining unchanged. The term $P_{\sin\delta}$ in $P_m^{3\nu}$ $^{man}(\nu_e\to\nu_\mu)$ would be equal to zero if the Dirac phase in the neutrino mixing matrix U possesses a CP-conserving value. Even in this case, however, we have $A_{CP}^{(\mu e)}$ $^{man}\equiv(P_m^{3\nu}$ $^{man}(\nu_e\to\nu_\mu)-P_m^{3\nu}$ $^{man}(\bar{\nu}_e\to\bar{\nu}_\mu))\neq 0$ due to the effects of the Earth matter. It will be important to experimentally disentangle the effects of the Earth matter and of J_{CP} in $A_{CP}^{(\mu e)}$ man : this will allow to get information about the Dirac CP violation phase in U. In the vacuum limit of $N_e^{man}=0$ (A=0) we have $A_{CP}^{(\mu e)}$ $^{man}=A_{CP}^{(\mu e)}$ (see Eq. (13.18)) and only the term $P_{\sin\delta}$ contributes to the asymmetry $A_{CP}^{(\mu e)}$.

13.3.2. Oscillations of solar neutrinos:

Consider next the oscillations of solar ν_e while they propagate from the central part of the Sun, where they are produced, to the surface of the Sun [23,74](see also Ref. 22 and, e.g., Ref. 85) Details concerning the production, spectrum, magnitude and particularities of the solar neutrino flux, the methods of detection of solar neutrinos, description of solar neutrino experiments and of the data they provided will be discussed in the next section (see also Ref. 86). The electron number density N_e changes considerably along the neutrino path in the Sun: it decreases monotonically from the value of $\sim 100~{\rm cm}^{-3}~N_A$ in the center of the Sun to 0 at the surface of the Sun. According to the contemporary solar models (see, e.g., Ref. [86,87]), N_e decreases approximately exponentially in the radial direction towards the surface of the Sun:

$$N_e(t) = N_e(t_0) \exp\left\{-\frac{t - t_0}{r_0}\right\} ,$$
 (13.50)

where $(t-t_0)\cong d$ is the distance traveled by the neutrino in the Sun, $N_e(t_0)$ is the electron number density at the point of ν_e production in the Sun, r_0 is the scale-height of the change of $N_e(t)$ and one has [86,87] $r_0\sim 0.1R_{\odot}$.

Consider the case of 2-neutrino mixing, Eq. (13.34). Obviously, if N_e changes with t (or equivalently with the distance) along the neutrino trajectory, the matter-eigenstates, their energies, the mixing angle and the oscillation length in matter, become, through their dependence on N_e , also functions of $t: |\nu_{1,2}^m\rangle = |\nu_{1,2}^m(t)\rangle$, $E_{1,2}^m = E_{1,2}^m(t)$, $\theta_m = \theta_m(t)$ and $L_m = L_m(t)$. It is not difficult to understand qualitatively the possible behavior of the neutrino system when solar neutrinos propagate from the center to the surface of the

Sun if one realizes that one is dealing effectively with a two-level system whose Hamiltonian depends on time and admits "jumps" from one level to the other (see Eq. (13.32)). Consider the case of $\Delta m^2 \cos 2\theta > 0$. Let us assume first for simplicity that the electron number density at the point of a solar ν_e production in the Sun is much bigger than the resonance density, $N_e(t_0) \gg N_e^{res}$. Actually, this is one of the cases relevant to the solar neutrinos. In this case we have $\theta_m(t_0) \cong \pi/2$ and the state of the electron neutrino in the initial moment of the evolution of the system practically coincides with the heavier of the two matter-eigenstates:

$$|\nu_e\rangle \cong |\nu_2^m(t_0)\rangle. \tag{13.51}$$

Thus, at t_0 the neutrino system is in a state corresponding to the "level" with energy $E_2^m(t_0)$. When neutrinos propagate to the surface of the Sun they cross a layer of matter in which $N_e=N_e^{res}$: in this layer the difference between the energies of the two "levels" $(E_2^m(t)-E_1^m(t))$ has a minimal value on the neutrino trajectory (Eq. (13.37) and Eq. (13.39)). Correspondingly, the evolution of the neutrino system can proceed basically in two ways. First, the system can stay on the "level" with energy $E_2^m(t)$, i.e., can continue to be in the state $|\nu_2^m(t)\rangle$ up to the final moment t_s , when the neutrino reaches the surface of the Sun. At the surface of the Sun $N_e(t_s)=0$ and therefore $\theta_m(t_s)=\theta$, $|\nu_{1,2}^m(t_s)\rangle\equiv |\nu_{1,2}\rangle$ and $E_{1,2}^m(t_s)=E_{1,2}$. Thus, in this case the state describing the neutrino system at t_0 will evolve continuously into the state $|\nu_2\rangle$ at the surface of the Sun. Using Eq. (13.29) with l=e and $x=\mu$, it is easy to obtain the probabilities to find ν_e and ν_μ at the surface of the Sun:

$$P(\nu_e \to \nu_e; t_s, t_0) \cong |\langle \nu_e | \nu_2 \rangle|^2 = \sin^2 \theta$$

$$P(\nu_e \to \nu_\mu; t_s, t_0) \cong |\langle \nu_\mu | \nu_2 \rangle|^2 = \cos^2 \theta.$$
 (13.52)

It is clear that under the assumption made and if $\sin^2\theta \ll 1$, practically a total $\nu_e \to \nu_\mu$ conversion is possible. This type of evolution of the neutrino system and the $\nu_e \to \nu_\mu$ transitions taking place during the evolution, are called [23] "adiabatic." They are characterized by the fact that the probability of the "jump" from the upper "level" (having energy $E_2^m(t)$) to the lower "level" (with energy $E_1^m(t)$), P', or equivalently the probability of the $\nu_2^m(t_0) \to \nu_1^m(t_s)$ transition, $P' \equiv P'(\nu_2^m(t_0) \to \nu_1^m(t_s))$, on the whole neutrino trajectory is negligible:

$$P' \equiv P'(\nu_2^m(t_0) \to \nu_1^m(t_s)) \cong 0$$
 : adiabatic transitions. (13.53)

The second possibility is realized if in the resonance region, where the two "levels" approach each other closest the system "jumps" from the upper "level" to the lower "level" and after that continues to be in the state $|\nu_1^m(t)\rangle$ until the neutrino reaches the surface of the Sun. Evidently, now we have $P'\equiv P'(\nu_2^m(t_0)\to\nu_1^m(t_s))\sim 1$. In this case the neutrino system ends up in the state $|\nu_1^m(t_s)\rangle\equiv |\nu_1\rangle$ at the surface of the Sun and

$$P(\nu_e \to \nu_e; t_s, t_0) \cong |\langle \nu_e | \nu_1 \rangle|^2 = \cos^2 \theta$$

$$P(\nu_e \to \nu_\mu; t_s, t_0) \cong |\langle \nu_\mu | \nu_1 \rangle|^2 = \sin^2 \theta.$$
 (13.54)

Obviously, if $\sin^2\theta \ll 1$, practically no transitions of the solar ν_e into ν_μ will occur. The considered regime of evolution of the neutrino system and the corresponding $\nu_e \to \nu_\mu$ transitions are usually referred to as "extremely nonadiabatic."

Clearly, the value of the "jump" probability P' plays a crucial role in the the $\nu_e \to \nu_\mu$ transitions: it fixes the type of the transition and determines to a large extent the $\nu_e \to \nu_\mu$ transition probability [74,88,89]. We have considered above two limiting cases. Obviously, there exists a whole spectrum of possibilities since P' can have any value from 0 to $\cos^2\theta$ [90,91]. In general, the transitions are called "nonadiabatic" if P' is non-negligible.

Numerical studies have shown [23] that solar neutrinos can undergo both adiabatic and nonadiabatic $\nu_e \to \nu_\mu$ transitions in the Sun and the matter effects can be substantial in the solar neutrino oscillations for $10^{-8}~{\rm eV}^2 \lesssim \Delta m^2 \lesssim 10^{-4}~{\rm eV}^2, 10^{-4} \lesssim \sin^2 2\theta < 1.0.$

The condition of adiabaticity of the solar ν_e transitions in Sun can be written as [74.88]

$$\gamma(t) \equiv \sqrt{2}G_F \frac{(N_e^{res})^2}{|\dot{N}_e(t)|} \tan^2 2\theta \left(1 + \tan^{-2} 2\theta_m(t)\right)^{\frac{3}{2}} \gg 1$$
adiabatic transitions, (13.55)

while if $\gamma(t) \lesssim 1$ the transitions are nonadiabatic (see also Ref. 91), where $\dot{N}_e(t) \equiv \frac{d}{dt} N_e(t)$. Condition in Eq. (13.55) implies that the $\nu_e \to \nu_{\mu(\tau)}$ transitions in the Sun will be adiabatic if $N_e(t)$ changes sufficiently slowly along the neutrino path. In order for the transitions to be adiabatic, condition in Eq. (13.55) has to be fulfilled at any point of the neutrino's path in the Sun.

Actually, the system of evolution equations Eq. (13.32) can be solved exactly for N_e changing exponentially, Eq. (13.50), along the neutrino path in the Sun [90,92]. More specifically, the system in Eq. (13.32) is equivalent to one second order differential equation (with appropriate initial conditions). The latter can be shown [93] to coincide in form, in the case of N_e given by Eq. (13.50), with the Schroedinger equation for the radial part of the nonrelativistic wave function of the Hydrogen atom [94]. On the basis of the exact solution, which is expressed in terms of confluent hypergeometric functions, it was possible to derive a complete, simple and very accurate analytic description of the matter-enhanced transitions of solar neutrinos in the Sun for any values of Δm^2 and θ [22,90,91,95,96] (see also Refs. [23,74,89,97,98]).

The probability that a ν_e , produced at time t₀ in the central part of the Sun, will not transform into $\nu_{\mu(\tau)}$ on its way to the surface of the Sun (reached at time t_s) is given by

$$P_{\odot}^{2\nu}(\nu_e \to \nu_e; t_s, t_0) = \bar{P}_{\odot}^{2\nu}(\nu_e \to \nu_e; t_s, t_0) + Oscillating terms.$$
(13.56)

Here

$$\bar{P}_{\odot}^{2\nu}(\nu_{e} \to \nu_{e}; t_{s}, t_{0}) \equiv \bar{P}_{\odot} = \frac{1}{2} + \left(\frac{1}{2} - P'\right) \cos 2\theta_{m}(t_{0}) \cos 2\theta ,$$
(13.5)

is the average survival probability for ν_e having energy E \cong p [89],

$$P' = \frac{\exp\left[-2\pi r_0 \frac{\Delta m^2}{2E} \sin^2 \theta\right] - \exp\left[-2\pi r_0 \frac{\Delta m^2}{2E}\right]}{1 - \exp\left[-2\pi r_0 \frac{\Delta m^2}{2E}\right]},$$
 (13.58)

is [90] the "jump" probability for exponentially varying N_e , and $\theta_m(t_0)$ is the mixing angle in matter at the point of ν_e production [97]. The expression for $\bar{P}_{\odot}^{2\nu}(\nu_e \to \nu_e; t_s, t_0)$ with P' given by Eq. (13.58) is valid for $\Delta m^2 > 0$, but for both signs of $\cos 2\theta \neq 0$ [90,98]; it is valid for any given value of the distance along the neutrino trajectory and does not take into account the finite dimensions of the region of ν_e production in the Sun. This can be done by integrating over the different neutrino paths, *i.e.*, over the region of ν_e production.

The oscillating terms in the probability $P_{\odot}^{2\nu}(\nu_e \to \nu_e; t_s, t_0)$ [95,93] were shown [96] to be strongly suppressed for $\Delta m^2 \gtrsim 10^{-7} \text{ eV}^2$ by the various averagings one has to perform when analyzing the solar neutrino data. The current solar neutrino and KamLAND data suggest that $\Delta m^2 \cong 7.6 \times 10^{-5} \text{ eV}^2$. For $\Delta m^2 \gtrsim 10^{-7} \text{ eV}^2$, the averaging over the region of neutrino production in the Sun etc. renders negligible all interference terms which appear in the probability of ν_e survival due to the $\nu_e \leftrightarrow \nu_{\mu(\tau)}$ oscillations in vacuum taking place on the way of the neutrinos from the surface of the Sun to the surface of the Earth. Thus, the probability that ν_e will remain ν_e while it travels from the central part of the Sun to the surface of the Earth is effectively equal to the probability of survival of the ν_e while it propagates from the central part to the surface of the Sun and is given by the average probability $\bar{P}_{\odot}(\nu_e \to \nu_e; t_s, t_0)$ (determined by Eq. (13.57) and Eq. (13.58)).

If the solar ν_e transitions are adiabatic $(P'\cong 0)$ and $\cos 2\theta_m(t_0)\cong -1$ (i.e., $N_e(t_0)/|N_e^{res}|\gg 1$, $|\tan 2\theta|$, the ν_e are born "above" (in N_e) the resonance region), one has [23]

$$\bar{P}^{2\nu}(\nu_e \to \nu_e; t_s, t_0) \cong \frac{1}{2} - \frac{1}{2}\cos 2\theta.$$
 (13.59)

The regime under discussion is realised for $\sin^2 2\theta \cong 0.8$ (suggested by the data, Section 13.4), if $E/\Delta m^2$ lies approximately in the range $(2\times 10^4-3\times 10^7)~{\rm MeV/eV^2}$ (see Ref. 91). This result is relevant for the interpretation of the Super-Kamiokande and SNO solar neutrino data. We see that depending on the sign of $\cos 2\theta \neq 0$, $\bar{P}^{2\nu}(\nu_e \to \nu_e)$ is either bigger or smaller than 1/2. It follows from the solar neutrino data that in the range of validity (in $E/\Delta m^2$) of Eq. (13.59) we have $\bar{P}^{2\nu}(\nu_e \to \nu_e) \cong 0.3$. Thus, the possibility of $\cos 2\theta \leq 0$ is ruled out by the data. Given the choice $\Delta m^2 > 0$ we made, the data imply that $\Delta m^2 \cos 2\theta > 0$.

If $E/\Delta m^2$ is sufficiently small so that $N_e(t_0)/|N_e^{res}| \ll 1$, we have $P' \cong 0$, $\theta_m(t_0) \cong \theta$ and the oscillations take place in the Sun as in vacuum [23]:

$$\bar{P}^{2\nu}(\nu_e \to \nu_e; t_s, t_0) \cong 1 - \frac{1}{2}\sin^2 2\theta,$$
 (13.60)

which is the average two-neutrino vacuum oscillation probability. This expression describes with good precision the transitions of the solar pp neutrinos (Section 13.4). The extremely nonadiabatic ν_e transitions in the Sun, characterised by $\gamma(t) \ll 1$, are also described by the average vacuum oscillation probability (Eq. (13.60)) (for $\Delta m^2 \cos 2\theta > 0$ in this case we have (see e.g., Refs. [90,91]) $\cos 2\theta_m(t_0) \cong -1$ and $P' \cong \cos^2 \theta$).

The probability of ν_e survival in the case 3-neutrino mixing takes a simple form for $|\Delta m_{31}^2| \cong 2.4 \times 10^{-3} \ {\rm eV}^2 \gg |\Delta m_{21}^2|$. Indeed, for the energies of solar neutrinos $E \lesssim 10$ MeV, N^{res} corresponding to $|\Delta m_{31}^2|$ satisfies $N_{e31}^{res} \gtrsim 10^3 \ {\rm cm}^{-3} \ {\rm N_A}$ and is by a factor of 10 bigger than N_e in the center of the Sun. As a consequence, the oscillations due to Δm_{31}^2 proceed as in vacuum. The oscillation length associated with $|\Delta m_{31}^2|$ satisfies $L_{31}^v \lesssim 10 \ {\rm km} \ll \Delta R$, ΔR being the dimension of the region of ν_e production in the Sun. We have for the different components of the solar ν_e flux [86] $\Delta R \cong (0.04-0.20)R_{\odot}$. Therefore the averaging over ΔR strongly suppresses the oscillations due to Δm_{31}^2 and we get [78,99]:

$$P_{\odot}^{3\nu} \cong \sin^4 \theta_{13} + \cos^4 \theta_{13} \ P_{\odot}^{2\nu}(\Delta m_{21}^2, \theta_{12}; N_e \cos^2 \theta_{13}),$$
 (13.61)

where $P_{\odot}^{2\nu}(\Delta m_{21}^2, \theta_{12}; N_e \cos^2\theta_{13})$ is given by Eq. (13.56) to Eq. (13.58) in which $\Delta m^2 = \Delta m_{21}^2$, $\theta = \theta_{12}$ and the solar e^- number density N_e is replaced by $N_e \cos^2\theta_{13}$. Thus, the solar ν_e transitions observed by the Super-Kamiokande and SNO experiments are described approximately by:

$$P_{\odot}^{3\nu} \cong \sin^4 \theta_{13} + \cos^4 \theta_{13} \sin^2 \theta_{12}$$
. (13.62)

The data show that $P_{\odot}^{3\nu} \cong 0.3$, which is a strong evidence for matter effects in the solar ν_e transitions [100] since in the case of oscillations in vacuum $P_{\odot}^{3\nu} \cong \sin^4\theta_{13} + (1-0.5\sin^22\theta_{12})\cos^4\theta_{13} \gtrsim 0.49$, where we have used $\sin^2\theta_{13} \lesssim 0.040$ and $\sin^22\theta_{12} \lesssim 0.93$ (see Section 13.7).

13.4. Measurements of Δm_{\odot}^2 and θ_{\odot}

13.4.1. Solar neutrino observations:

Observation of solar neutrinos directly addresses the theory of stellar structure and evolution, which is the basis of the standard solar model (SSM). The Sun as a well-defined neutrino source also provides extremely important opportunities to investigate nontrivial neutrino properties such as nonzero mass and mixing, because of the wide range of matter density and the great distance from the Sun to the Earth.

The solar neutrinos are produced by some of the fusion reactions in the pp chain or CNO cycle. The combined effect of these reactions is written as

$$4p \to {}^{4}\text{He} + 2e^{+} + 2\nu_{e}.$$
 (13.63)

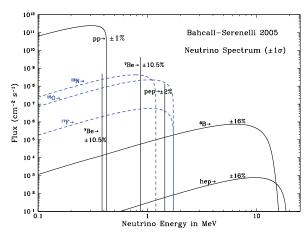

Figure 13.2: The solar neutrino spectrum predicted by the BS05(OP) standard solar model [101]. The neutrino fluxes are given in units of ${\rm cm}^{-2}{\rm s}^{-1}{\rm MeV}^{-1}$ for continuous spectra and ${\rm cm}^{-2}{\rm s}^{-1}$ for line spectra. The numbers associated with the neutrino sources show theoretical errors of the fluxes. This figure is taken from the late John Bahcall's web site, http://www.sns.ias.edu/~jnb/.

Positrons annihilate with electrons. Therefore, when considering the solar thermal energy generation, a relevant expression is

$$4p + 2e^- \rightarrow {}^{4}\text{He} + 2\nu_e + 26.73 \text{ MeV} - E_{\nu} ,$$
 (13.64)

where E_{ν} represents the energy taken away by neutrinos, with an average value being $\langle E_{\nu} \rangle \sim 0.6$ MeV. There have been efforts to calculate solar neutrino fluxes from these reactions on the basis of SSM. A variety of input information is needed in the evolutionary calculations. The most elaborate SSM calculations have been developed by Bahcall and his collaborators, who define their SSM as the solar model which is constructed with the best available physics and input data. Therefore, their SSM calculations have been rather frequently updated. SSM's labelled as BS05(OP) [101], BSB06(GS) and BSB06(AGS) [87], and BPS08(GS) and BPS08(AGS) [102] represent some of recent model calculations. Here, "OP" means that newly calculated radiative opacities from the "Opacity Project" are used. The later models are also calculated with OP opacities. "GS" and "AGS" refer to old and new determinations of solar abundances of heavy elements. There are significant differences between the old, higher heavy element abundances (GS) and the new, lower heavy element abundances (AGS). The models with GS are consistent with helioseismological data, but the models with AGS are not.

The prediction of the BPS08(GS) model for the fluxes from neutrino-producing reactions is given in Table 13.2. Fig. 13.2 shows the solar-neutrino spectra calculated with the BS05(OP) model which is similar to the BPS08(GS) model. Here we note that in Ref. 103 the authors point out that electron capture on ¹³N, ¹⁵O, and ¹⁷F produces line spectra of neutrinos, which have not been considered in the SSM calculations quoted above.

In 2011, a new SSM calculations [104] have been presented by A.M. Serenelli, W.C. Haxton, and C. Peña-Garay, by adopting the newly analyzed nuclear fusion cross sections. Their high metalicity SSM is labelled as SHP11(GS). For the same solar abundances as used in Ref. 101 and Ref. 87, the most significant change is a decrease of $^8{\rm B}$ flux by $\sim 5\%$.

So far, solar neutrinos have been observed by chlorine (Homestake) and gallium (SAGE, GALLEX, and GNO) radiochemical detectors and water Cherenkov detectors using light water (Kamiokande and Super-Kamiokande) and heavy water (SNO). Recently, a liquid scintillation detector (Borexino) successfully observed low energy solar neutrinos

A pioneering solar neutrino experiment by Davis and collaborators at Homestake using the 37 Cl - 37 Ar method proposed by Pontecorvo [105] started in the late 1960's. This experiment exploited

Table 13.2: Neutrino-producing reactions in the Sun (first column) and their abbreviations (second column). The neutrino fluxes predicted by the BPS08(GS) model [102] are listed in the third column.

| Reaction | Abbr. | Flux $(cm^{-2} s^{-1})$ |
|--------------------------------------------------------|-------------------|---------------------------------------|
| $pp \to d e^+ \nu$ | pp | $5.97(1 \pm 0.006) \times 10^{10}$ |
| $pe^-p \to d \nu$ | pep | $1.41(1 \pm 0.011) \times 10^8$ |
| ${}^{3}\mathrm{He}\;p^{4}\mathrm{He}\;e^{+}\nu$ | hep | $7.90(1 \pm 0.15) \times 10^3$ |
| $^{7}\mathrm{Be}\;e^{-}^{7}\mathrm{Li}\;\nu+(\gamma)$ | $^7\mathrm{Be}$ | $5.07(1 \pm 0.06) \times 10^9$ |
| $^8\mathrm{B} \to {}^8\mathrm{Be^*}\; e^+\nu$ | $^8\mathrm{B}$ | $5.94(1 \pm 0.11) \times 10^6$ |
| $^{13}\mathrm{N} \rightarrow ^{13}\mathrm{C}~e^{+}\nu$ | $^{13}\mathrm{N}$ | $2.88(1 \pm 0.15) \times 10^8$ |
| $^{15}{ m O} \to ^{15}{ m N}\; e^+ u$ | $^{15}\mathrm{O}$ | $2.15(1^{+0.17}_{-0.16}) \times 10^8$ |
| $^{17}\mathrm{F} \rightarrow ^{17}\mathrm{O}~e^{+}\nu$ | $^{17}\mathrm{F}$ | $5.82(1_{-0.17}^{+0.19}) \times 10^6$ |

 ν_e absorption on $^{37}{\rm Cl}$ nuclei followed by the produced $^{37}{\rm Ar}$ decay through orbital e^- capture,

$$\nu_e + ^{37} \mathrm{Cl} \rightarrow ^{37} \mathrm{Ar} + e^- \text{ (threshold 814 keV)}.$$
 (13.65)

The $^{37}\mathrm{Ar}$ atoms produced are radioactive, with a half life $(\tau_{1/2})$ of 34.8 days. After an exposure of the detector for two to three times $\tau_{1/2},$ the reaction products were chemically extracted and introduced into a low-background proportional counter, where they were counted for a sufficiently long period to determine the exponentially decaying signal and a constant background. Solar-model calculations predict that the dominant contribution in the chlorine experiment came from $^8\mathrm{B}$ neutrinos, but $^7\mathrm{Be},~pep,~^{13}\mathrm{N},$ and $^{15}\mathrm{O}$ neutrinos also contributed (for notations, refer to Table 13.2).

From the very beginning of the solar-neutrino observation [106], it was recognized that the observed flux was significantly smaller than the SSM prediction, provided nothing happens to the electron neutrinos after they are created in the solar interior. This deficit has been called "the solar-neutrino problem."

Table 13.3: Results from radiochemical solar-neutrino experiments. The predictions of a recent standard solar model BPS08(GS) are also shown. The first and the second errors in the experimental results are the statistical and systematic errors, respectively. SNU (Solar Neutrino Unit) is defined as 10^{-36} neutrino captures per atom per second.

| | $^{37}\text{Cl}\rightarrow^{37}\text{Ar} (\text{SNU})$ | $^{71}\mathrm{Ga} \rightarrow ^{71}\mathrm{Ge} \ (\mathrm{SNU})$ |
|-----------------------|--------------------------------------------------------|------------------------------------------------------------------|
| Homestake [4] | $2.56 \pm 0.16 \pm 0.16$ | _ |
| GALLEX [8] | _ | $77.5 \pm 6.2^{+4.3}_{-4.7}$ |
| GALLEX- | | |
| Reanalysis [107] | = | $73.4^{+6.1+3.7}_{-6.0-4.1}$ |
| GNO [9] | _ | $62.9^{+5.5}_{-5.3} \pm 2.5$ |
| GNO+GALLEX [9] | = | $69.3 \pm 4.1 \pm 3.6$ |
| GNO+GALLEX- | | |
| Reanalysis [107] | _ | $67.6^{+4.0+3.2}_{-4.0-3.2}$ |
| SAGE [6] | _ | $65.4_{-3.0-2.8}^{+3.1+2.6}$ |
| SSM [BPS08(GS)] [102] | $8.46^{+0.87}_{-0.88}$ | $127.9^{+8.1}_{-8.2}$ |

Gallium experiments (GALLEX and GNO at Gran Sasso in Italy and SAGE at Baksan in Russia) utilize the reaction

$$\nu_e + {}^{71}\text{Ga} \rightarrow {}^{71}\text{Ge} + e^- \text{ (threshold 233 keV)}.$$
 (13.66)

They are sensitive to the most abundant pp solar neutrinos. The solar-model calculations predict that more than 80% of the capture

rate in gallium is due to low energy pp and $^7\mathrm{Be}$ solar neutrinos with the pp rate being about twice the $^7\mathrm{Be}$ rate. SAGE reported the first results in 1991 [108]. They observed the capture rate to be $20^{+15}_{-20} \pm 32$ SNU, or a 90% confidence-level upper limit of 79 SNU. In 1992, GALLEX reported the observed capture rate of $83 \pm 19 \pm 8$ SNU [7]. It was the first evidence for low-energy solar-neutrino observation. Later, SAGE observed similar flux [109] to GALLEX. The latest SAGE results are published in Ref. 6. The GALLEX Collaboration finished observations in early 1997 [8,107]. Since April, 1998, a newly defined collaboration, GNO (Gallium Neutrino Observatory) continued the observations until April 2003. The GNO results are published in Ref. 9. The GNO + GALLEX joint analysis results are also presented in Ref. 9 and Ref. 107. The results from radiochemical solar neutrino experiments are shown in Table 13.3.

In 1987, the Kamiokande experiment in Japan succeeded in real-time solar neutrino observation, utilizing νe scattering,

$$\nu_x + e^- \to \nu_x + e^-$$
, (13.67)

in a large water-Cherenkov detector. This experiment takes advantage of the directional correlation between the incoming neutrino and the recoil electron. This feature greatly helps the clear separation of the solar-neutrino signal from the background. The Kamiokande result gave the first direct evidence that neutrinos come from the direction of the Sun [110]. Later, the high-statistics Super-Kamiokande experiment [111–114] with a 50-kton water Cherenkov detector replaced the Kamiokande experiment. Due to the high thresholds (7 MeV in Kamiokande and 5 MeV at present in Super-Kamiokande) the experiments observe pure ⁸B solar neutrinos. It should be noted that the reaction (Eq. (13.67)) is sensitive to all active neutrinos, $x = e, \mu$, and τ . However, the sensitivity to ν_{μ} and ν_{τ} is much smaller than the sensitivity to ν_{e} , $\sigma(\nu_{\mu,\tau}e) \approx 0.16 \, \sigma(\nu_{e}e)$.

In 1999, a new real time solar-neutrino experiment, SNO (Sudbury Neutrino Observatory), in Canada started observation. This experiment used 1000 tons of ultra-pure heavy water ($\rm D_2O$) contained in a spherical acrylic vessel, surrounded by an ultra-pure $\rm H_2O$ shield. SNO measured $^8\rm B$ solar neutrinos via the charged-current (CC) and neutral-current (NC) reactions

$$\nu_e + d \to e^- + p + p$$
 (CC), (13.68)

and

$$\nu_x + d \to \nu_x + p + n \tag{NC}, \tag{13.69}$$

as well as νe scattering, (Eq. (13.67)). The CC reaction, (Eq. (13.68)), is sensitive only to ν_e , while the NC reaction, (Eq. (13.69)), is sensitive to all active neutrinos. This is a key feature to solve the solar neutrino problem. If it is caused by flavour transitions such as neutrino oscillations, the solar neutrino fluxes measured by CC and NC reactions would show a significant difference.

The Q-value of the CC reaction is -1.4 MeV and the e^- energy is strongly correlated with the ν_e energy. Thus, the CC reaction provides an accurate measure of the shape of the $^8\mathrm{B}$ neutrino spectrum. The contributions from the CC reaction and ν_e scattering can be distinguished by using different $\cos\theta$ distributions, where θ is the angle of the e^- momentum with respect to the Sun-Earth axis. While the ν_e scattering events have a strong forward peak, CC events have an approximate angular distribution of $1-1/3\cos\theta$.

The neutrino energy threshold of the NC reaction is 2.2 MeV. In the pure D_2O [11,12], the signal of the NC reaction was neutron capture in deuterium, producing a 6.25-MeV γ -ray. In this case, the capture efficiency was low and the deposited energy was close to the detection threshold of 5 MeV. In order to enhance both the capture efficiency and the total γ -ray energy (8.6 MeV), 2 tons of NaCl were added to the heavy water in the second phase of the experiment [115]. Subsequently NaCl was removed and an array of ³He neutron counters were installed for the third phase measurement [116]. These neutron counters provided independent NC measurement with different systematics from that of the second phase, and thus strengthened the reliability of the NC measurement. The SNO experiment completed data acquisition in 2006. Recently, the SNO group presented the

results of Phase I and Phase II joint analysis [117] as well as the results of a combined analysis of all three phases [118].

Table 13.4 shows the ⁸B solar neutrino results from real time experiments. The standard solar model predictions are also shown. Table 13.4 includes the results from the SNO group's recent joint analysis of the SNO Phase I and Phase II data with the analysis threshold as low as 3.5 MeV (effective electron kinetic energy) and significantly improved systematic uncertainties [117]. Also, the recent result from a combined analysis of all three phases [118] is included. It is seen from these tables that the results from all the solar-neutrino experiments, except SNO's NC result, indicate significantly less flux than expected from the solar-model predictions.

Table 13.4: ⁸B solar neutrino results from real time experiments. The predictions of BPS08(GS) and SHP11(GS) standard solar models are also shown. The first and the second errors in the experimental results are the statistical and systematic errors, respectively.

| | Reaction | $^{8}\text{B }\nu \text{ flux}$ $(10^{6}\text{cm}^{-2}\text{s}^{-1})$ |
|-----------------------------|----------------------------------------|-----------------------------------------------------------------------|
| Kamiokande [5] | νe | $2.80 \pm 0.19 \pm 0.33$ |
| Super-K I [112,114] | νe | $2.38 \pm 0.02 \pm 0.08$ |

| SSM [BPS08(GS)] [102] | _ | $5.94(1 \pm 0.11)$ |
| SSM [SHP11(GS)] [104] | _ | $5.58(1 \pm 0.14)$ |

Another real time solar neutrino experiment, Borexino at Gran Sasso in Italy, started solar neutrino observation in 2007. This experiment measures solar neutrinos via νe scattering in 300 tons of ultra-pure liquid scintillator. With a detection threshold as low as 250 keV, the flux of monochromatic 0.862 MeV $^7\mathrm{Be}$ solar neutrinos has been directly observed for the first time (see Table 13.5). The observed energy spectrum shows the characteristic Comptonedge over the background [119,120]. Borexino also reported an observation of null day-night asymmetry of the $^7\mathrm{Be}$ neutrino flux, $A_{dn} = 2(R_N - R_D)/(R_N + R_D) = 0.001 \pm 0.012 \pm 0.007$ [121], where R_N and R_D are the night and day count rates of $^7\mathrm{Be}$ neutrinos.

Further, Borexino measured the flux of monochromatic 1.44 MeV pep solar neutrinos [122]. The absence of the pep solar neutrino signal is disfavored at 98% CL. The pep solar neutrino flux measured via νe scattering (calculated from the measured interaction rate and the expected one with the assumption of no neutrino oscillations and the SHP11(GS) SSM [104], both given in [122]) is shown in Table 13.6 and compared with the SSM predictions. Also, an upper limit of the "unoscillated" CNO solar neutrino flux is determined [122] as $<7.7\times10^8~{\rm cm}^{-2}{\rm s}^{-1}$ (95% CL) by assuming the MSW large mixing angle solution with $\Delta m_{\odot}^2=(7.6\pm0.2)\times10^{-5}~{\rm eV}^2$ and

 $\tan^2\!\theta_\odot=0.47^{+0.05}_{-0.04}$ and the SHP11(GS) SSM prediction [104] for the $pep~\nu$ flux.

Borexino also measured ⁸B solar neutrinos with an energy threshold of 3 MeV [123]. Measurements of low energy solar neutrinos are important not only to test the SSM further, but also to study the MSW effect over the energy region spanning from sub-MeV to 10 MeV.

Table 13.5: ⁷Be solar neutrino result from Borexino [120]. The predictions of BPS08(GS) and SHP11(GS) standard solar models are also shown.

| | Reaction | $^{7}{\rm Be} \ \nu \ {\rm flux}$ $(10^{9}{\rm cm}^{-2}{\rm s}^{-1})$ |
|------------------------------------------------|----------|-----------------------------------------------------------------------|
| Borexino [120] | νe | 3.10 ± 0.15 |
| SSM [BPS08(GS)] [102] SSM [SHP11(GS)] [104] | - | $5.07(1 \pm 0.06)$ $5.00(1 \pm 0.07)$ |

Table 13.6: pep solar neutrino result from Borexino [122]. The predictions of BPS08(GS) and SHP11(GS) standard solar models are also shown.

| | Reaction | $pep \ \nu \ flux$ $(10^8 cm^{-2} s^{-1})$ |
|-----------------------|----------|--------------------------------------------|
| Borexino [122] | νe | 1.0 ± 0.2 |
| SSM [BPS08(GS)] [102] | = | $1.41(1 \pm 0.011)$ |
| SSM [SHP11(GS)] [104] | _ | $1.44(1\pm 0.012)$ |

$13.4.2. \ \ Evidence\ for\ solar\ neutrino\ flavour\ conversion:$

Solar neutrino experiments achieved remarkable progress in the past ten years, and the solar-neutrino problem, which had remained unsolved for more than 30 years, has been understood as due to neutrino flavour conversion. In 2001, the initial SNO CC result combined with the Super-Kamiokande's high-statistics νe elastic scattering result [124] provided direct evidence for flavour conversion of solar neutrinos [11]. Later, SNO's NC measurements further strengthened this conclusion [12,115,116]. From the salt-phase measurement [115], the fluxes measured with CC, ES, and NC events were obtained as

$$\phi_{\text{SNO}}^{\text{CC}} = (1.68 \pm 0.06_{-0.09}^{+0.08}) \times 10^{6} \text{cm}^{-2} \text{s}^{-1} ,$$
 (13.70)

$$\phi_{\rm SNO}^{\rm ES} = (2.35 \pm 0.22 \pm 0.15) \times 10^6 {\rm cm}^{-2} {\rm s}^{-1} \; , \eqno (13.71)$$

$$\phi_{\text{SNO}}^{\text{NC}} = (4.94 \pm 0.21^{+0.38}_{-0.34}) \times 10^6 \text{cm}^{-2} \text{s}^{-1} ,$$
 (13.72)

where the first errors are statistical and the second errors are systematic. In the case of $\nu_e \to \nu_{\mu,\tau}$ transitions, Eq. (13.72) is a mixing-independent result and therefore tests solar models. It shows good agreement with the ⁸B solar-neutrino flux predicted by the solar model [101]. Fig. 13.3 shows the salt phase result of $\phi(\nu_{\mu} \text{ or } \tau)$ versus the flux of electron neutrinos $\phi(\nu_e)$ with the 68%, 95%, and 99% joint probability contours. The flux of non- ν_e active neutrinos, $\phi(\nu_{\mu} \text{ or } \tau)$, can be deduced from these results. It is

$$\phi(\nu_{\mu \text{ or } \tau}) = \left(3.26 \pm 0.25^{+0.40}_{-0.35}\right) \times 10^6 \text{cm}^{-2} \text{s}^{-1}. \tag{13.73}$$

The non-zero $\phi(\nu_{\mu}\ _{\rm or}\ _{\tau})$ is strong evidence for neutrino flavor conversion. These results are consistent with those expected from the LMA (large mixing angle) solution of solar neutrino oscillation in matter [22,23] with $\Delta m_{\odot}^2 \sim 5 \times 10^{-5}\ {\rm eV}^2$ and $\tan^2\!\theta_{\odot} \sim 0.45$. However, with the SNO data alone, the possibility of other solutions cannot be excluded with sufficient statistical significance.

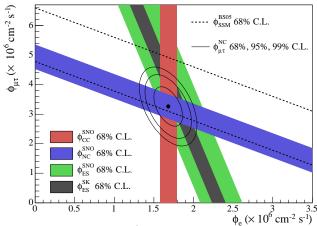

Figure 13.3: Fluxes of ^8B solar neutrinos, $\phi(\nu_e)$, and $\phi(\nu_{\mu} \text{ or } \tau)$, deduced from the SNO's CC, ES, and NC results of the salt phase measurement [115]. The Super-Kamiokande ES flux is from Ref. 125. The BS05(OP) standard solar model prediction [101] is also shown. The bands represent the 1σ error. The contours show the 68%, 95%, and 99% joint probability for $\phi(\nu_e)$ and $\phi(\nu_{\mu} \text{ or } \tau)$. The figure is from Ref. 115.

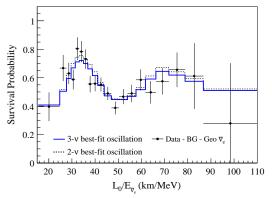

Figure 1.4: The ratio of the background and geoneutrino-subtracted $\bar{\nu}_e$ spectrum to the predicted one without oscillations (survival probability) as a function of L₀/E, where L₀=180 km. The histograms show the expected distributions based on the best-fit parameter values from the two- and three-flavor neutrino oscillation analyses. The figure is from Ref. 128.

$13.4.3. \quad KamLAND \ experiment:$

KamLAND is a 1-kton ultra-pure liquid scintillator detector located at the old Kamiokande's site in Japan. The primary goal of the KamLAND experiment was a long-baseline (flux-weighted average distance of ~ 180 km) neutrino oscillation studies using $\bar{\nu}_e$'s emitted from nuclear power reactors. The reaction $\bar{\nu}_e+p\to e^++n$ is used to detect reactor $\bar{\nu}_e$'s and a delayed coincidence of the positron with a 2.2 MeV γ -ray from neutron capture on a proton is used to reduce the backgrounds. With the reactor $\bar{\nu}_e$'s energy spectrum (< 8 MeV) and a prompt-energy analysis threshold of 2.6 MeV, this experiment has a sensitive Δm^2 range down to $\sim 10^{-5}$ eV². Therefore, if the LMA solution is the real solution of the solar neutrino problem, KamLAND should observe reactor $\bar{\nu}_e$ disappearance, assuming CPT invariance.

The first KamLAND results [15] with 162 ton-yr exposure were reported in December 2002. The ratio of observed to expected (assuming no $\bar{\nu}_e$ oscillations) number of events was

$$\frac{N_{\rm obs} - N_{\rm BG}}{N_{\rm NoOsc}} = 0.611 \pm 0.085 \pm 0.041 \tag{13.74}$$

with obvious notation. This result showed clear evidence of an event deficit expected from neutrino oscillations. The 95% CL allowed

regions are obtained from the oscillation analysis with the observed event rates and positron spectrum shape. A combined global solar + KamLAND analysis showed that the LMA is a unique solution to the solar neutrino problem with > 5σ CL [126]. With increased statistics [16,127,128], KamLAND observed not only the distortion of the $\bar{\nu}_e$ spectrum, but also for the first time the periodic feature of the $\bar{\nu}_e$ survival probability expected from neutrino oscillations (see Fig. 13.4).

13.5. Measurements of $|\Delta m_{\rm A}^2|$ and $\theta_{\rm A}$

13.5.1. Atmospheric neutrino results:

The first compelling evidence for the neutrino oscillation was presented by the Super-Kamiokande Collaboration in 1998 [13] from the observation of atmospheric neutrinos produced by cosmic-ray interactions in the atmosphere. The zenith-angle distributions of the μ -like events which are mostly muon-neutrino and muon antineutrino initiated charged-current interactions, showed a clear deficit compared to the no-oscillation expectation. Note that a water Cherenkov detector cannot measure the charge of the final-state leptons, and therefore neutrino and antineutrino induced events cannot be discriminated. Neutrino events having their vertex in the 22.5 kton fiducial volume in Super-Kamiokande are classified into fully contained (FC) events and partially contained (PC) events. The FC events are required to have no activity in the anti-counter. Single-ring events have only one charged lepton which radiates Cherenkov light in the final state, and particle identification is particularly clean for single-ring FC events. A ring produced by an e-like (e^{\pm}, γ) particle exhibits a more diffuse pattern than that produced by a μ -like (μ^{\pm} , π^{\pm}) particle, since an e-like particle produces an electromagnetic shower and low-energy electrons suffer considerable multiple Coulomb scattering in water. All the PC events were assumed to be μ -like since the PC events comprise a 98% pure charged-current ν_{μ} sample.

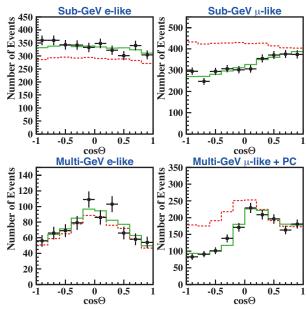

Figure 13.5: The zenith angle distributions for fully contained 1-ring e-like and μ -like events with visible energy < 1.33 GeV (sub-GeV) and > 1.33 GeV (multi-GeV). For multi-GeV μ -like events, a combined distribution with partially contained (PC) events is shown. The dotted histograms show the non-oscillated Monte Carlo events, and the solid histograms show the best-fit expectations for $\nu_{\mu} \leftrightarrow \nu_{\tau}$ oscillations. (This figure is provided by the Super-Kamiokande Collab.)

Fig. 13.5 shows the zenith-angle distributions of e-like and μ -like events from the SK-I measurement [129]. $\cos\theta = 1$ corresponds to the downward direction, while $\cos\theta = -1$ corresponds to the upward

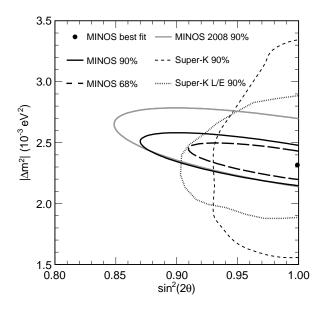

Figure 13.6: Allowed region for the $\nu_{\mu} \leftrightarrow \nu_{\tau}$ oscillation parameters from the MINOS results published in 2011. The 68 % and 90 % CL allowed regions are shown together with the Super-Kamiokande and MINOS 2008 90% CL allowed regions. This figure is taken from Ref. 130.

direction. Events included in these plots are single-ring FC events subdivided into sub-GeV (visible energy < 1.33 GeV) events and multi-GeV (visible energy > 1.33 GeV) events. The zenith-angle distribution of the multi-GeV μ -like events is shown combined with that of the PC events. The final-state leptons in these events have good directional correlation with the parent neutrinos. The dotted histograms show the Monte Carlo expectation for neutrino events. If the produced flux of atmospheric neutrinos of a given flavour remains unchanged at the detector, the data should have similar distributions to the expectation. However, the zenith-angle distribution of the μ -like events shows a strong deviation from the expectation. On the other hand, the zenith-angle distribution of the e-like events is consistent with the expectation. This characteristic feature may be interpreted that muon neutrinos coming from the opposite side of the Earth's atmosphere, having travelled $\sim 10,000$ km, oscillate into other neutrinos and disappeared, while oscillations still do not take place for muon neutrinos coming from above the detector, having travelled from a few to a few tens km. Disappeared muon neutrinos may have oscillated into tau neutrinos because there is no indication of electron neutrino appearance. The atmospheric neutrinos corresponding to the events shown in Fig. 13.5 have $E=1\sim 10$ GeV. With L=10000 km, the hypothesis of neutrino oscillations suggests $\Delta m^2 \sim 10^{-3} - 10^{-4}$ eV². The solid histograms show the best-fit results of a two-neutrino oscillation analysis with the hypothesis of $\nu_{\mu} \leftrightarrow \nu_{\tau}$. For the allowed parameter region, see Fig. 13.6.

Also, a search for a ν_{τ} appearance signal by using the SK-I atmospheric neutrino data has been made by the Super-Kamiokande Collaboration [131], and no ν_{τ} appearance hypothesis is disfavored at 2.4 σ

Although the SK-I atmospheric neutrino observations gave compelling evidence for muon neutrino disappearance which is consistent with two-neutrino oscillation $\nu_{\mu} \leftrightarrow \nu_{\tau}$ [131], the question may be asked whether the observed muon neutrino disappearance is really due to neutrino oscillations. First, other exotic explanations such as neutrino decay [132] and quantum decoherence [133] cannot be completely ruled out from the zenith-angle distributions alone. To confirm neutrino oscillation, characteristic sinusoidal behavior of the conversion probability as a function of neutrino energy E for a fixed distance L in the case of long-baseline neutrino oscillation experiments, or as a function of L/E in the case of atmospheric neutrino experiments, should be observed. By selecting events with

high L/E resolution, evidence for the dip in the L/E distribution was observed at the right place expected from the interpretation of the SK-I data in terms of $\nu_{\mu} \leftrightarrow \nu_{\tau}$ oscillations [14], see Fig. 13.7. This dip cannot be explained by alternative hypotheses of neutrino decay and neutrino decoherence, and they are excluded at more than 3σ in comparison with the neutrino oscillation interpretation. For the constraints obtained from the L/E analysis, see Fig. 13.6.

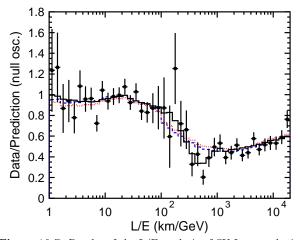

Figure 13.7: Results of the L/E analysis of SK-I atmospheric neutrino data. The points show the ratio of the data to the Monte Carlo prediction without oscillations, as a function of the reconstructed L/E. The error bars are statistical only. The solid line shows the best fit with 2-flavour $\nu_{\mu} \leftrightarrow \nu_{\tau}$ oscillations. The dashed and dotted lines show the best fit expectations for neutrino decay and neutrino decoherence hypotheses, respectively. (From Ref. 14.)

${\bf 13.5.2.} \ \ Results \ from \ accelerator \ experiments:$

The $\Delta m^2 \geq 2 \times 10^{-3} \ {\rm eV}^2$ region can be explored by accelerator-based long-baseline experiments with typically $E \sim 1$ GeV and $L \sim$ several hundred km. With a fixed baseline distance and a narrower, well understood neutrino spectrum, the value of $|\Delta m_{\rm A}^2|$ and, with higher statistics, also the mixing angle, are potentially better constrained in accelerator experiments than from atmospheric neutrino observations.

The K2K (KEK-to-Kamioka) long-baseline neutrino oscillation experiment [19] is the first accelerator-based experiment with a neutrino path length extending hundreds of kilometers. K2K aimed at confirmation of the neutrino oscillation in ν_{μ} disappearance in the $|\Delta m_{\rm A}^2| \geq 2 \times 10^{-3}~{\rm eV}^2$ region. A horn-focused wide-band muon neutrino beam having an average $L/E_{\nu} \sim 200~(L=250~{\rm km},$ $\langle E_{\nu} \rangle \sim 1.3~{\rm GeV}),$ was produced by 12-GeV protons from the KEK-PS and directed to the Super-Kamiokande detector. The spectrum and profile of the neutrino beam were measured by a near neutrino detector system located 300 m downstream from the production target.

The construction of the K2K neutrino beam line and the near detector began before Super-Kamiokande's discovery of atmospheric neutrino oscillations. K2K experiment started data-taking in 1999 and was completed in 2004. The total number of protons on target (POT) for physics analysis amounted to 0.92×10^{20} . The observed number of beam-originated FC events in the 22.5 kton fiducial volume of Super-Kamiokande was 112, compared with an expectation of $158.1^{+9.2}_{-8.6}$ events without oscillation. For 58 1-ring μ -like subset of the data, the neutrino energy was reconstructed from measured muon momentum and angle, assuming CC quasi-elastic kinematics. The measured energy spectrum showed the distortion expected from neutrino oscillations. The probability that the observations are due to a statistical fluctuation instead of neutrino oscillation is 0.0015% or 4.3 σ [19].

MINOS is the second long-baseline neutrino oscillation experiment with near and far detectors. Neutrinos are produced by the NuMI

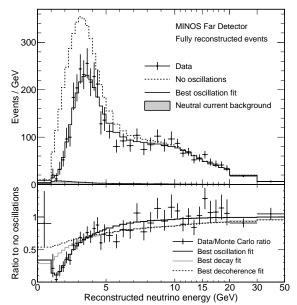

Figure 13.8: The top panel shows the energy spectra of fully reconstructed events in the MINOS far detector classified as CC interactions. The bottom panel shows the background subtracted ratios of data to the no-oscillation hypothesis. The best fit with the hypothesis of $\nu_{\mu} \rightarrow \nu_{\tau}$ oscillations as well as the best fit to alternative models (neutrino decay and decoherence) is also shown. This figure is taken from Ref. 130.

(Neutrinos at the Main Injector) facility using 120 GeV protons from the Fermilab Main Injector. The far detector is a 5.4 kton (total mass) iron-scintillator tracking calorimeter with toroidal magnetic field, located underground in the Soudan mine. The baseline distance is 735 km. The near detector is also an iron-scintillator tracking calorimeter with toroidal magnetic field, with a total mass of 0.98 kton. The neutrino beam is a horn-focused wide-band beam. Its energy spectrum can be varied by moving the target position relative to the first horn and changing the horn current.

MINOS started the neutrino-beam run in 2005. Earlier ν_{μ} disappearance results were reported in Ref. 20 with 1.27×10^{20} POT and in Ref. 21 with 3.36×10^{20} POT. The updated results corresponding to a total POT of 7.25×10^{20} have been published recently [130]. Most of the data were taken with a "low-energy" option for the spectrum of the neutrino beam (the flux was enhanced in the 1-5 GeV energy range, peaking at 3 GeV). In the far detector, a total of 1986 fully reconstructed CC events were produced by the NuMI beam, compared to the unoscillated expectation of 2451 events. Fig. 13.8 shows the observed energy spectra and the expected spectra with no oscillation. Fig. 13.6 shows the 68% and 90% CL allowed regions obtained from the $u_{\mu} \rightarrow
u_{\tau}$ oscillation analysis. The results are compared with the 90% CL allowed regions obtained from the earlier MINOS [21], SK-I zenith-angle dependence [129,79], and the SK-I L/E analysis [14]. The MINOS results constrain the oscillation parameters as $|\Delta m_{\rm A}^2| = (2.32^{+0.12}_{-0.08}) \times 10^{-3} \ {\rm eV^2}$ and $\sin^2 2\theta_{\rm A} > 0.90$ at 90% CL. The alternative models to explain the ν_{μ} disappearance, neutrino decay and quantum decoherence of neutrinos, are disfavored at the 7σ and 9σ , respectively, by the MINOS data (see Fig. 13.8).

In addition to ν_{μ} disappearance, MINOS first observed muon antineutrino disappearance [134] with the NUMI beam line optimized for $\bar{\nu}_{\mu}$ production. MINOS recently released $\bar{\nu}_{\mu}$ disappearance result corresponding to POT = 2.95×10^{20} [135]. With increased statistics, the best-fit oscillation parameters are $|\Delta\bar{m}_{\rm A}^2|=(2.62^{+0.31}_{-0.28}\pm0.09)\times10^{-3}~{\rm eV^2}$ and $\sin^22\bar{\theta}_{\rm A}=0.95^{+0.10}_{-0.11}\pm0.01,$ or $\sin^22\bar{\theta}_{\rm A}>0.75$ at 90% CL. These results are consistent with their neutrino counterparts.

The regions of neutrino parameter space favored or excluded by various neutrino oscillation experiments are shown in Fig. 13.9.

Although the atmospheric neutrino oscillations and accelerator long-baseline ν_{μ} disappearance data are fully consistent with $\nu_{\mu} \to \nu_{\tau}$

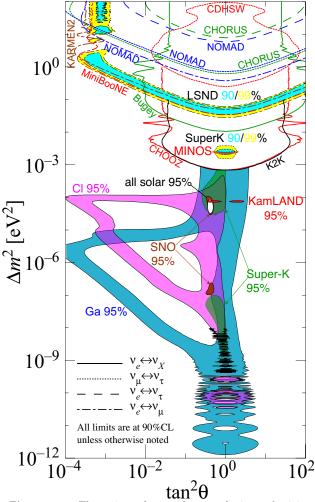

Figure 13.9: The regions of squared-mass splitting and mixing angle favored or excluded by various experiments based on two-flavor neutrino oscillation analyses. The figure was contributed by H. Murayama (University of California, Berkeley, and IPMU, University of Tokyo). References to the data used in the figure can be found at http://hitoshi.berkeley.edu/neutrino.

oscillations, appearance of ν_{τ} remained to be confirmed. For this purpose, a promising method is an accelerator long-baseline experiment using emulsion technique to identify short-lived τ leptons event-by-event. The only experiment of this kind is OPERA with a neutrino source at CERN and a detector at Gran Sasso with the baseline distance of 730 km. The detector is a combination of the "Emulsion Cloud Chamber" and magnetized spectrometer. The CNGS (CERN Neutrinos to Gran Sasso) neutrino beam with $\langle E_{\nu} \rangle = 17$ GeV is produced by high-energy protons from the CERN SPS. So far, OPERA reported observation of one ν_{τ} candidate in the hadronic decay channel of τ , corresponding to an exposure of 5.30 \times 10¹⁹ POT with a target mass of 1290 tons in 2008 and 2009 runs [60,61], with expectation of 1.65 signal events [61].

13.6. Measurements of θ_{13}

Reactor $\bar{\nu}_e$ disappearance experiments with $L \sim 1$ km, $\langle E \rangle \sim 3$ MeV are sensitive to $\sim E/L \sim 3 \times 10^{-3} \ {\rm eV^2} \sim |\Delta m_{\rm A}^2|$. At this baseline distance, the reactor $\bar{\nu}_e$ oscillations driven by Δm_{\odot}^2 are negligible. Therefore, as can be seen from Eq. (13.22) and Eq. (13.24), θ_{13} can be directly measured. A reactor neutrino oscillation experiment at the Chooz nuclear power station in France [58] was the first experiment of this kind. The detector was located in an underground laboratory with 300 mwe (meter water equivalent) rock overburden, at about 1 km from the neutrino source. It consisted of a central 5-ton target filled with 0.09% gadolinium loaded liquid scintillator,

surrounded by an intermediate 17-ton and outer 90-ton regions filled with undoped liquid scintillator. Reactor $\bar{\nu}_e$'s were detected via the reaction $\bar{\nu}_e + p \rightarrow e^+ + n$. Gd-doping was chosen to maximize the neutron capture efficiency. The Chooz experiment [58] found no evidence for $\bar{\nu}_e$ disappearance. The 90% CL upper limit for $|\Delta m_{\rm A}^2| = 2.0 \times 10^{-3} \ {\rm eV}^2$ is $\sin^2\!2\theta_{13} < 0.19$, and for the MINOS 2008 measurement [21] of $|\Delta m_{\rm A}^2| = 2.43 \times 10^{-3} \ {\rm eV}$ it is $\sin^2\!2\theta_{13} < 0.15$, both at 90% CL.

In the accelerator neutrino oscillation experiments with conventional neutrino beams, θ_{13} can be measured using $\nu_{\mu} \rightarrow \nu_{e}$ appearance. K2K was the first long-baseline experiment to search for ν_{e} appearance signal due to the $\nu_{\mu} \rightarrow \nu_{e}$ oscillations [136]. Based on the dominant term in the probability of $\nu_{\mu} \rightarrow \nu_{e}$ oscillations (see Eq. (13.23) and Eq. (13.24)),

$$P(\nu_{\mu} \to \nu_{e}) = \sin^{2} 2\theta_{13} \cdot \sin^{2} \theta_{23} \cdot \sin^{2}(1.27\Delta m_{A}^{2}L/E)$$
$$\sim \frac{1}{2} \sin^{2} 2\theta_{13} \sin^{2}(1.27\Delta m_{A}^{2}L/E) . \tag{13.75}$$

K2K set the 90% CL upper limit $\sin^2 2\theta_{13} < 0.26$.

By examining the expression for the probability of $\nu_{\mu} \rightarrow \nu_{e}$ oscillations in matter (given by Eq. (13.45) in which the sign of the $P_{\sin\delta}$ term is flipped), however, it is understood that subleading terms could have rather large effects and the unknown CP-violating phase δ causes uncertainties in determining the value of θ_{13} . Actually, from the measurement of $\nu_{\mu} \rightarrow \nu_{e}$ appearance, θ_{13} is given as a function of δ for a given sign of $\Delta m_{\rm A}^2$, or of $\Delta m_{32}^2 \cong \Delta m_{31}^2$. (Also, deviations from maximal θ_{23} mixing would cause a further uncertainty.) Therefore, a single experiment with a neutrino beam cannot determine the value of θ_{13} , although it is possible to establish a non-zero θ_{13} . In 2010, MINOS [137] set the limits for 2 $\sin^2\theta_{23} \sin^22\theta_{13}$ as a function of δ . At $\delta=0$, the 90% CL upper limit is 0.12 (0.20) for $\Delta m_{\rm A}^2>0$ ($\Delta m_{\rm A}^2<0$).

In 2011, experimental indications of $\nu_{\mu} \rightarrow \nu_{e}$ oscillations and a non-zero θ_{13} have been reported by the T2K [24] experiment. Also, MINOS [25] searched for $\nu_{\mu} \rightarrow \nu_{e}$ appearance and disfavored the $\theta_{13}=0$ hypothesis at the 89% CL.

The T2K experiment is the first off-axis long-baseline neutrino oscillation experiment. The baseline distance is 295 km between the J-PARC in Tokai, Japan and Super-Kamiokande. A narrow-band ν_{μ} beam produced by 30 GeV protons from the J-PARC Main Ring is directed 2.5° off-axis to SK. With this configuration, the ν_{μ} beam is tuned to the first oscillation maximum. With 1.43 \times 10 20 POT, the T2K [24] Collaboration observed six candidate ν_e events having all characteristics of being due to $\nu_{\mu} \rightarrow \nu_e$ oscillations, while the expectation for $\theta_{13}=0$ is 1.5 ± 0.3 events. The probability to observe six or more candidate events when 1.5 ± 0.3 events are predicted is 7×10^{-3} , implying a non-zero θ_{13} with statistical significance of 2.5σ . At $\delta=0$, $\sin^22\theta_{23}=1$ and $|\Delta m_A^2|=2.4\times10^{-3}$ eV², this result gives a best fit value of $\sin^22\theta_{13}=0.11$ (0.14) and a 90% CL interval of 0.03 (0.04) $<\sin^22\theta_{13}<0.28$ (0.34) for $\Delta m_A^2>0$ ($\Delta m_A^2<0$).

The MINOS Collaboration [25] also searched for the $\nu_{\mu} \rightarrow \nu_{e}$ appearance signal. Though dependent on the definition of the signal, typically 62 candidate events are observed with an exposure of 8.2×10^{20} POT, while the expectation for $\theta_{13}=0$ is $49.6\pm 7.0\pm 2.7$ events. At the 90% CL, the MINOS result implies that $2\,\sin^{2}\!2\theta_{13}$ $\sin^{2}\!\theta_{23}<0.12$ (0.20) for $\Delta m_{\rm A}^{2}>0$ ($\Delta m_{\rm A}^{2}<0$) and $\delta=0$, with a best fit value $2\,\sin^{2}\!\theta_{23}\,\sin^{2}\!2\theta_{13}=0.041^{+0.047}_{-0.031}$ (0.079 $^{+0.071}_{-0.053}$). The MINOS data disfavored the $\theta_{13}=0$ hypothesis at the 89% CL [25].

Recently, the three reactor neutrino experiments Double Chooz [59], Daya Bay [26], and RENO [27] reported their first results on reactor $\bar{\nu}_e$ disappearance. Daya Bay and RENO measured reactor $\bar{\nu}_e$ s with near and far detectors. The first results of Double Chooz was obtained with only a far detector, though this experiment is planning to have a near detector in 2012. The $\bar{\nu}_e$ detectors of all the three experiments have similar structures; an antineutrino detector consisting of three layers and an optically independent outer veto detector. The innermost layer of the antineutrino detector is filled with Gd-doped liquid scintillator (LS), which is surrounded by a " γ -catcher" layer filled with Gd-free LS, and outside the γ -catcher is a buffer layer filled with mineral oil.

An outer veto detector is filled with purified water (Daya Bay and RENO) or LS (Double Chooz).

The Daya Bay experiment [26] measured $\bar{\nu}_e$ s from the Daya Bay nuclear power complex (six 2.9 GW_{th} reactors) in China with six functionally identical detectors deployed in two near (470 m and 576 m of flux-weighted baselines) and one far (1648 m) underground halls. With live time of 55 days, the ratio of the observed to expected number of $\bar{\nu}_e$ s at the far hall is $R=0.940\pm0.011\pm0.004$ and the rate-only analysis yielded

$$\sin^2 2\theta_{13} = 0.092 \pm 0.016 \pm 0.005. \tag{13.76}$$

From this result, θ_{13} is non-zero with a significance of 5.2σ .

The RENO experiment [27] measured $\bar{\nu}_e$ s from six 2.8 GW_{th} reactors at Yonggwang Nuclear Power Plant in Korea with two identical detectors located at 294 m and 1383 m from the reactor array center. With 229 days of running time, the ratio of the observed to expected number of $\bar{\nu}_e$ s in the far detector is $R = 0.920 \pm 0.009 \pm 0.014$, and from a rate-only analysis the following result is obtained:

$$\sin^2 2\theta_{13} = 0.113 \pm 0.013 \pm 0.019 \tag{13.77}$$

This result excludes the no-oscillation hypothesis at the 4.9σ level.

The Double Chooz experiment [59] measured $\bar{\nu}_e$ s from two 4.25 GW_{th} reactors with a far detector at 1050 m from the two reactor cores. With 101 days of running, this experiment obtained $\sin^2 2\theta_{13} = 0.086 \pm 0.041 \pm 0.030$, or $0.017 < \sin^2 2\theta_{13} < 0.16$ at the 90% CL, by analyzing the rate and energy spectrum of prompt positrons using the reactor $\bar{\nu}_e$ spectrum of Ref. 36 and Ref. 34 and the Bugey4 rate measurement [138].

Turning to atmospheric and solar neutrino observations, Eq. (13.40) to Eq. (13.43) and Eq. (13.62) indicate that they are sensitive to θ_{13} through sub-leading effects. So far, the SK, SNO, and KamLAND Collaborations presented their own θ_{13} analyses by adding or updating their own data. In the atmospheric neutrino sector, the SK group analyzed its atmospheric neutrino data [79,139], and in the solar neutrino sector, SNO [117], SK [114], and KamLAND [128] analyzed the data from all solar neutrino experiments, with or without the KamLAND data, in terms of 3-neutrino oscillations. In addition, KamLAND [128] made a global analysis of all available neutrino data incorporating the Chooz, atmospheric and accelerator data. All these results are consistent with the recent results from accerelator [24,25] and reactor [59,26,27] experiments.

13.7. The three neutrino mixing

All existing compelling data on neutrino oscillations can be described assuming 3-flavour neutrino mixing in vacuum. This is the minimal neutrino mixing scheme which can account for the currently available data on the oscillations of the solar (ν_e) , atmospheric $(\nu_{\mu}$ and $\bar{\nu}_{\mu})$, reactor $(\bar{\nu}_e)$ and accelerator (ν_{μ}) neutrinos. The (left-handed) fields of the flavour neutrinos ν_e , ν_{μ} and ν_{τ} in the expression for the weak charged lepton current in the CC weak interaction Lagrangian, are linear combinations of the LH components of the fields of three massive neutrinos ν_i :

$$\mathcal{L}_{\text{CC}} = -\frac{g}{\sqrt{2}} \sum_{l=e,\mu,\tau} \overline{l_L}(x) \gamma_\alpha \nu_{lL}(x) W^{\alpha\dagger}(x) + h.c.,$$

$$\nu_{lL}(x) = \sum_{i=1}^3 U_{lj} \nu_{jL}(x), \qquad (13.78)$$

where U is the 3×3 unitary neutrino mixing matrix [17,18]. The mixing matrix U can be parameterized by 3 angles, and, depending on whether the massive neutrinos ν_j are Dirac or Majorana particles, by 1 or 3 CP violation phases [40,41]:

$$U = \begin{bmatrix} c_{12}c_{13} & s_{12}c_{13} & s_{13}e^{-i\delta} \\ -s_{12}c_{23} - c_{12}s_{23}s_{13}e^{i\delta} & c_{12}c_{23} - s_{12}s_{23}s_{13}e^{i\delta} & s_{23}c_{13} \\ s_{12}s_{23} - c_{12}c_{23}s_{13}e^{i\delta} & -c_{12}s_{23} - s_{12}c_{23}s_{13}e^{i\delta} & c_{23}c_{13} \end{bmatrix}$$

$$\times \operatorname{diag}(1, e^{i\frac{\alpha_{21}}{2}}, e^{i\frac{\alpha_{31}}{2}}) . \tag{13.79}$$

where $c_{ij} = \cos\theta_{ij}$, $s_{ij} = \sin\theta_{ij}$, the angles $\theta_{ij} = [0, \pi/2]$, $\delta = [0, 2\pi]$ is the Dirac CP violation phase and α_{21} , α_{31} are two Majorana CP violation phases. Thus, in the case of massive Dirac neutrinos, the neutrino mixing matrix U is similar, in what concerns the number of mixing angles and CP violation phases, to the CKM quark mixing matrix. The presence of two additional physical CP violation phases in U if ν_j are Majorana particles is a consequence of the special properties of the latter (see, e.g., Refs. [39,40]).

As we see, the fundamental parameters characterizing the 3-neutrino mixing are: i) the 3 angles θ_{12} , θ_{23} , θ_{13} , ii) depending on the nature of massive neutrinos ν_j - 1 Dirac (δ) , or 1 Dirac + 2 Majorana $(\delta, \alpha_{21}, \alpha_{31})$, CP violation phases, and iii) the 3 neutrino masses, m_1 , m_2 , m_3 . Thus, depending on whether the massive neutrinos are Dirac or Majorana particles, this makes 7 or 9 additional parameters in the minimally extended Standard Model of particle interactions with massive neutrinos.

The neutrino oscillation probabilities depend (Section 13.2), in general, on the neutrino energy, E, the source-detector distance L, on the elements of U and, for relativistic neutrinos used in all neutrino experiments performed so far, on $\Delta m_{ij}^2 \equiv (m_i^2 - m_j^2), i \neq j$. In the case of 3-neutrino mixing there are only two independent neutrino mass squared differences, say $\Delta m_{21}^2 \neq 0$ and $\Delta m_{31}^2 \neq 0$. The numbering of massive neutrinos ν_i is arbitrary. It proves convenient from the point of view of relating the mixing angles θ_{12} , θ_{23} and θ_{13} to observables, to identify $|\Delta m_{21}^2|$ with the smaller of the two neutrino mass squared differences, which, as it follows from the data, is responsible for the solar ν_e and, the observed by KamLAND, reactor $\bar{\nu}_e$ oscillations. We will number (just for convenience) the massive neutrinos in such a way that $m_1 < m_2$, so that $\Delta m_{21}^2 > 0$. With these choices made, there are two possibilities: either $m_1 < m_2 < m_3$, or $m_3 < m_1 < m_2$. Then the larger neutrino mass square difference $|\Delta m_{31}^2|$ or $|\Delta m_{32}^2|$, can be associated with the experimentally observed oscillations of the atmospheric ν_{μ} and $\bar{\nu}_{\mu}$ and accelerator ν_{μ} . The effects of Δm_{31}^2 or Δm_{32}^2 in the oscillations of solar ν_e , and of Δm_{21}^2 in the oscillations of atmospheric ν_{μ} and $\bar{\nu}_{\mu}$ and of accelerator ν_{μ} , are relatively small and subdominant as a consequence of the facts that i) L, E and L/Ein the experiments with solar ν_e and with atmospheric ν_μ and $\bar{\nu}_\mu$ or accelerator ν_{μ} , are very different, ii) the conditions of production and propagation (on the way to the detector) of the solar ν_e and of the atmospheric ν_{μ} and $\bar{\nu}_{\mu}$ or accelerator ν_{μ} , are very different, and iii) $|\Delta m_{21}^2|$ and $|\Delta m_{31}^2|$ ($|\Delta m_{32}^2|$) in the case of $m_1 < m_2 < m_3$ $(m_3 < m_1 < m_2)$, as it follows from the data, differ by approximately a factor of 30, $|\Delta m_{21}^2| \ll |\Delta m_{31(32)}^2|$, $|\Delta m_{21}^2| / |\Delta m_{31(32)}^2| \cong 0.03$. This implies that in both cases of $m_1 < m_2 < m_3$ and $m_3 < m_1 < m_2$ we have $\Delta m_{32}^2 \cong \Delta m_{31}^2$ with $|\Delta m_{31}^2 - \Delta m_{32}^2| = |\Delta m_{21}^2| \ll |\Delta m_{31,32}^2|$.

It follows from the results of the Chooz experiment with reactor $\bar{\nu}_e$ [58] and from the more recent data discussed in the preceding subsection that, in the convention we use, in which $0 < \Delta m_{21}^2 < |\Delta m_{31(32)}^2|$, the element $|U_{e3}| = \sin\theta_{13}$ of the neutrino mixing matrix U, as the results of the Daya Bay and RENO experiments show, is small. This makes it possible to identify the angles θ_{12} and θ_{23} as the neutrino mixing angles associated with the solar ν_e and the dominant atmospheric ν_μ (and $\bar{\nu}_\mu$) oscillations, respectively. The angles θ_{12} and θ_{23} are often called "solar" and "atmospheric" neutrino mixing angles, and are often denoted as $\theta_{12} = \theta_\odot$ and $\theta_{23} = \theta_A$ (or $\theta_{\rm atm}$) while Δm_{21}^2 and Δm_{31}^2 are often referred to as the "solar" and "atmospheric" neutrino mass squared differences and are often denoted as $\Delta m_{21}^2 \equiv \Delta m_\odot^2$, $\Delta m_{31}^2 \equiv \Delta m_A^2$ (or $\Delta m_{\rm atm}^2$).

The solar neutrino data tell us that $\Delta m^2_{21}\cos 2\theta_{12}>0.$ In the convention employed by us we have $\Delta m^2_{21}>0.$ Correspondingly, in this convention one must have $\cos 2\theta_{12}>0.$

Global analyses [140,141] of the existing neutrino oscillation data, including the T2K [24] and MINOS [25] (but not the Daya Bay [26] and RENO [27]) results, allowed us to determine the parameters which drive the solar neutrino and the dominant atmospheric neutrino oscillations, $\Delta m_{\odot}^2 = \Delta m_{21}^2$, θ_{12} , and $|\Delta m_{\rm A}^2| = |\Delta m_{31}^2| \cong |\Delta m_{32}^2|$, θ_{23} , with a relatively good precision, and to establish that the angle $\theta_{13} \neq 0$ at $\gtrsim 99.73\%$ CL. The Daya Bay and RENO experiments provided a rather precise determination of the angle θ_{13} . Analyses of

the global neutrino oscillation data, in which the Daya Bay and RENO results on θ_{13} are also included, are lacking at present. Therefore we present in Table 13.7 the best fit values and the 99.73% CL allowed ranges of Δm^2_{21} , $\sin^2\theta_{12}$, $|\Delta m^2_{31(32)}|$, $\sin^2\theta_{23}$ and $\sin^2\theta_{13}$, found in Ref. 140 as well as the PDG average [142] of the results of the three recent reactor experiments [26,27,59]. Since the PDG average of $\sin^2 \theta_{13}$ is very close to that obtained in the global analysis in Ref. 140, and since the other oscillation parameter ranges are almost uncorrelated from θ_{13} , we do not expect that the inclusion of the Daya Bay and RENO data will change significantly the results (neither the central values nor the errors) for Δm_{21}^2 , $\sin^2 \theta_{12}$, $|\Delta m_{31(32)}^2|$ and $\sin^2 \theta_{23}$ obtained in Ref. 140. Obviously, the uncertainty in the value of $\sin^2\theta_{13}$ will shrink considerably. We note also that the results from Ref. 140 quoted in Table 13.7 are derived by marginalizing over $\operatorname{sgn}(\Delta m_{31}^2) = \pm 1$ and over $\cos \delta = \pm 1$ and that the values (the values in brackets) of $\sin^2 \theta_{12}$ and $\sin^2 \theta_{13}$ are obtained in Ref. 140 using the reactor $\bar{\nu}_e$ fluxes from Ref. 35 (from Ref. 34).

Table 13.7: The best-fit values and 3σ allowed ranges of the 3-neutrino oscillation parameters, derived from a global fit of the current neutrino oscillation data, including the T2K and MINOS (but not the Daya Bay and RENO) results (from [140]). The PDG average of the results of the three recent reactor experiments [26,27,59] is given in the last line [142]. The values (values in brackets) of $\sin^2\theta_{12}$ and $\sin^2\theta_{13}$ are obtained using the "old" [35] ("new" [34]) reactor $\bar{\nu}_e$ fluxes in the analysis.

| Parameter | best-fit $(\pm 1\sigma)$ | 3σ |
|---------------------------------------------------|-------------------------------------|-------------------------------------|
| $\Delta m_{\odot}^2 \ [10^{-5} \ {\rm eV}^{\ 2}]$ | $7.58^{+0.22}_{-0.26}$ | 6.99 - 8.18 |
| $ \Delta m_A^2 [10^{-3} \text{ eV }^2]$ | $2.35_{-0.09}^{+0.12}$ | 2.06 - 2.67 |
| $\sin^2 \theta_{12}$ | $0.306 \ (0.312)^{+0.018}_{-0.015}$ | $0.259 \ (0.265) - 0.359 \ (0.364)$ |
| $\sin^2\theta_{23}$ | $0.42^{+0.08}_{-0.03}$ | 0.34 - 0.64 |
| $\sin^2 \theta_{13}$ [140] | $0.021 \ (0.025)^{+0.007}_{-0.008}$ | $0.001 \ (0.005) - 0.044 \ (0.050)$ |
| $\sin^2 \theta_{13}$ [142] | 0.0251 ± 0.0034 | 0.015 - 0.036 |

A combined analysis of the data on θ_{13} from the T2K, MINOS, Double Chooz, Daya Bay and RENO experiments was performed in Ref. 145. The authors find that $\theta_{13} \neq 0$ at 7.7σ :

$$\sin^2 2\theta_{13} = 0.096 \pm 0.013 \ (\pm 0.040) \ \text{at} \ 1\sigma \ (3\sigma)$$
 (13.80)

In this analysis the positive or negative sign of $\Delta m_{\rm A}^2$ was used as input and the values of $\sin^2 2\theta_{23}$ and $|\Delta m_{\rm A}^2|$ were varied imposing Gaussian priors based on the results of the atmospheric neutrino [139] and MINOS [130] experiments. The value of $\sin^2 2\theta_{13}$ thus obtained showed a statistically insignificant dependence on the Dirac phase δ .

It follows from the results given in Table 13.7 that $\theta_{23} \cong \pi/4$, $\theta_{12} \cong \pi/5.4$ and that $\theta_{13} \cong \pi/20$. Correspondingly, the pattern of neutrino mixing is drastically different from the pattern of quark mixing.

Note also that Δm^2_{21} , $\sin^2\theta_{12}$, $|\Delta m^2_{31(32)}|$, $\sin^2\theta_{23}$ and $\sin^2\theta_{13}$ are determined from the data with a 1σ uncertainty (= 1/6 of the 3σ range) of approximately 2.6%, 5.4%, 4.3%, 12% and absolute error 0.42×10^{-2} , respectively.

The existing SK atmospheric neutrino, K2K and MINOS data do not allow to determine the sign of $\Delta m_{31(32)}^2$. Maximal solar neutrino mixing, *i.e.*, $\theta_{12}=\pi/4$, is ruled out at more than 6σ by the data. Correspondingly, one has $\cos 2\theta_{12} \geq 0.27$ (at 99.73% CL).

At present no experimental information on the Dirac and Majorana CP violation phases in the neutrino mixing matrix is available. Thus, the status of CP symmetry in the lepton sector is unknown. With $\theta_{13} \neq 0$, the Dirac phase δ can generate CP violation effects in neutrino oscillations [40,52,53]. The magnitude of CP violation in $\nu_l \rightarrow \nu_{l'}$ and $\bar{\nu}_l \rightarrow \bar{\nu}_{l'}$ oscillations, $l \neq l' = e, \mu, \tau$, is determined, as we have seen, by the rephasing invariant J_{CP} (see Eq. (13.19)), which

in the "standard" parametrisation of the neutrino mixing matrix (Eq. (13.79)) has the form:

$$J_{CP} \equiv \operatorname{Im} \left(U_{\mu 3} \, U_{e3}^* \, U_{e2} \, U_{\mu 2}^* \right) = \frac{1}{8} \, \cos \theta_{13} \sin 2\theta_{12} \, \sin 2\theta_{23} \, \sin 2\theta_{13} \, \sin \delta \,.$$

$$(13.81)$$

Thus, given the fact that $\sin 2\theta_{12}$, $\sin 2\theta_{23}$ and $\sin 2\theta_{13}$ have been determined experimentally with a relatively good precision, the size of CP violation effects in neutrino oscillations depends essentially only on the magnitude of the currently unknown value of the Dirac phase δ . The current data implies $|J_{CP}| \lesssim 0.045$, where we have used the 3σ ranges of $\sin^2\theta_{12}$, $\sin^2\theta_{23}$ and $\sin^2\theta_{13}$ given in Table 13.7 and Eq. (13.76), respectively.

As we have indicated, the existing data do not allow one to determine the sign of $\Delta m_{\rm A}^2=\Delta m_{31(2)}^2.$ In the case of 3-neutrino mixing, the two possible signs of $\Delta m_{31(2)}^2$ correspond to two types of neutrino mass spectrum. In the widely used conventions of numbering the neutrinos with definite mass in the two cases, the two spectra read:

- i) spectrum with normal ordering:

$$\begin{split} & m_1 < m_2 < m_3, \, \Delta m_{\rm A}^2 = \Delta m_{31}^2 > 0, \\ & \Delta m_{\odot}^2 = \Delta m_{21}^2 > 0, \, m_{2(3)} = (m_1^2 + \Delta m_{21(31)}^2)^{\frac{1}{2}}; \end{split}$$

- ii) spectrum with inverted ordering (IO):

$$m_3 < m_1 < m_2, \, \Delta m_{\rm A}^2 = \Delta m_{32}^2 < 0, \, \Delta m_{\odot}^2 \equiv \Delta m_{21}^2 > 0,$$

 $m_2 = (m_3^2 + \Delta m_{23}^2)^{\frac{1}{2}}, \, m_1 = (m_3^2 + \Delta m_{23}^2 - \Delta m_{21}^2)^{\frac{1}{2}}.$

Depending on the values of the lightest neutrino mass [143], $\min(m_j)$, the neutrino mass spectrum can also be:

- Normal Hierarchical (NH):

$$m_1 \ll m_2 < m_3, \ m_2 \cong (\Delta m_{\odot}^2)^{\frac{1}{2}} \cong 0.0086 \text{ eV},$$

 $m_3 \cong |\Delta m_{\Delta}^2|^{\frac{1}{2}} \cong 0.048 \text{ eV}; \text{ or}$

- Inverted Hierarchical (IH):

$$m_3 \ll m_1 < m_2$$
, with $m_{1,2} \cong |\Delta m_{\rm A}^2|^{\frac{1}{2}} \cong 0.048$ eV; or – Quasi-Degenerate (QD):

$$m_1 \cong m_2 \cong m_3 \cong m_0, \ m_j^2 \gg |\Delta m_A^2|, \ m_0 \gtrsim 0.10 \text{ eV}.$$

All three types of spectrum are compatible with the existing constraints on the absolute scale of neutrino masses m_j . Information about the latter can be obtained, e.g., by measuring the spectrum of electrons near the end point in ${}^3{\rm H}$ β -decay experiments [146–149] and from cosmological and astrophysical data. The most stringent upper bounds on the $\bar{\nu}_e$ mass were obtained in the Troitzk [147,148] experiment:

$$m_{\bar{\nu}_e} < 2.05 \text{ eV}$$
 at 95% CL. (13.82)

We have $m_{\bar{\nu}e} \cong m_{1,2,3}$ in the case of QD spectrum. The KATRIN experiment [149] is planned to reach sensitivity of $m_{\bar{\nu}e} \sim 0.20$ eV, *i.e.*, it will probe the region of the QD spectrum.

The Cosmic Microwave Background (CMB) data of the WMAP experiment, combined with supernovae data and data on galaxy clustering can be used to obtain an upper limit on the sum of neutrinos masses (see review on Cosmological Parameters [150] and e.g., Ref. 151). Depending on the model complexity and the input data used one obtains [151]: $\sum_j m_j \lesssim (0.3-1.3)$ eV, 95% CL.

It follows from these data that neutrino masses are much smaller than the masses of charged leptons and quarks. If we take as an indicative upper limit $m_j \lesssim 0.5\,$ eV, we have $m_j/m_{l,q} \lesssim 10^{-6},$ $l=e,\mu,\tau,~q=d,s,b,u,c,t.$ It is natural to suppose that the remarkable smallness of neutrino masses is related to the existence of a new fundamental mass scale in particle physics, and thus to new physics beyond that predicted by the Standard Model.

13.7.1. The see-saw mechanism and the baryon asymmetry of the Universe:

A natural explanation of the smallness of neutrino masses is provided by the (type I) see-saw mechanism of neutrino mass generation [3]. An integral part of this rather simple mechanism [152] are the RH neutrinos ν_{lR} (RH neutrino fields $\nu_{lR}(x)$). The latter are assumed to possess a Majorana mass term as well as Yukawa type coupling $\mathcal{L}_{\rm Y}(x)$ with the Standard Model lepton and Higgs doublets, $\psi_{lL}(x)$ and $\Phi(x)$, respectively, $(\psi_{lL}(x))^T=(\nu_{lL}^T(x)\ l_L^T(x)),$ $l=e,\mu,\tau,(\Phi(x))^T=(\Phi^{(0)}\ \Phi^{(-)}).$ In the basis in which the Majorana mass matrix of RH neutrinos is diagonal, we have:

$$\mathcal{L}_{Y,M}(x) = \left(\lambda_{il} \, \overline{N_{iR}}(x) \, \Phi^{\dagger}(x) \, \psi_{lL}(x) + \text{h.c.}\right) - \frac{1}{2} \, M_i \, \overline{N_i}(x) \, N_i(x) \,, \tag{13.83}$$

where λ_{il} is the matrix of neutrino Yukawa couplings and N_i $(N_i(x))$ is the heavy RH Majorana neutrino (field) possessing a mass $M_i > 0$. When the electroweak symmetry is broken spontaneously, the neutrino Yukawa coupling generates a Dirac mass term: $m_{il}^D \overline{N_{iR}}(x) \nu_{lL}(x) + \text{h.c.}$, with $m^D = v\lambda$, v = 174 GeV being the Higgs doublet v.e.v. In the case when the elements of m^D are much smaller than $M_k, |m_{il}^D| \ll M_k, i, k = 1, 2, 3, l = e, \mu, \tau$, the interplay between the Dirac mass term and the mass term of the heavy (RH) Majorana neutrinos N_i generates an effective Majorana mass (term) for the LH flavour neutrinos [3]: $m_{l'l}^{LL} \cong -(m^D)_{l'j}^T M_j^{-1} m_{jl}^D$. In grand unified theories, m^D is typically of the order of the charged fermion masses. In SO(10) theories, for instance, m^D coincides with the up-quark mass matrix. Taking indicatively $m^{LL}\sim 0.1$ eV, $m^D\sim 100$ GeV, one finds $M \sim 10^{14}$ GeV, which is close to the scale of unification of the electroweak and strong interactions, $M_{GUT} \cong 2 \times 10^{16}$ GeV. In GUT theories with RH neutrinos one finds that indeed the heavy Majorana neutrinos N_j naturally obtain masses which are by few to several orders of magnitude smaller than M_{GUT} . Thus, the enormous disparity between the neutrino and charged fermion masses is explained in this approach by the huge difference between effectively the electroweak symmetry breaking scale and M_{GUT} .

An additional attractive feature of the see-saw scenario is that the generation and smallness of neutrino masses is related via the leptogenesis mechanism [2] to the generation of the baryon asymmetry of the Universe. The Yukawa coupling in Eq. (13.83), in general, is not CP conserving. Due to this CP-nonconserving coupling the heavy Majorana neutrinos undergo, e.g., the decays $N_j \to l^+ + \Phi^{(-)}, \ N_j \to l^- + \Phi^{(+)}, \ \text{which have different rates:}$ $\Gamma(N_j \to l^+ + \Phi^{(-)}) \neq \Gamma(N_j \to l^- + \Phi^{(+)}).$ When these decays occur in the Early Universe at temperatures somewhat below the mass of, say, N_1 , so that the latter are out of equilibrium with the rest of the particles present at that epoch, CP violating asymmetries in the individual lepton charges L_l , and in the total lepton charge L, of the Universe are generated. These lepton asymmetries are converted into a baryon asymmetry by (B-L) conserving, but (B+L) violating, sphaleron processes, which exist in the Standard Model and are effective at temperatures $T \sim (100-10^{12})$ GeV. If the heavy neutrinos N_i have hierarchical spectrum, $M_1 \ll M_2 \ll M_3$, the observed baryon asymmetry can be reproduced provided the mass of the lightest one satisfies $M_1 \gtrsim 10^9$ GeV [153]. Thus, in this scenario, the neutrino masses and mixing and the baryon asymmetry have the same origin - the neutrino Yukawa couplings and the existence of (at least two) heavy Majorana neutrinos. Moreover, quantitative studies based on recent advances in leptogenesis theory [154] have shown that the Dirac and/or Majorana phases in the neutrino mixing matrix U can provide the CP violation, necessary in leptogenesis for the generation of the observed baryon asymmetry of the Universe [155]. This implies, in particular, that if the CP symmetry is established not to hold in the lepton sector due to U, at least some fraction (if not all) of the observed baryon asymmetry might be due to the Dirac and/or Majorana CP violation present in the neutrino mixing.

13.7.2. The nature of massive neutrinos:

The experiments studying flavour neutrino oscillations cannot provide information on the nature - Dirac or Majorana, of massive neutrinos [40,54]. Establishing whether the neutrinos with definite mass ν_i are Dirac fermions possessing distinct antiparticles, or Majorana fermions, i.e. spin 1/2 particles that are identical with their antiparticles, is of fundamental importance for understanding the origin of ν -masses and mixing and the underlying symmetries of particle interactions (see e.g., Ref. 66). The neutrinos with definite mass ν_i will be Dirac fermions if the particle interactions conserve some additive lepton number, e.g., the total lepton charge $L = L_e + L_{\mu} + L_{\tau}$. If no lepton charge is conserved, ν_i will be Majorana fermions (see e.g., Ref. 39). The massive neutrinos are predicted to be of Majorana nature by the see-saw mechanism of neutrino mass generation [3]. The observed patterns of neutrino mixing and of neutrino mass squared differences can be related to Majorana massive neutrinos and the existence of an approximate symmetry in the lepton sector corresponding, e.g., to the conservation of the lepton charge $L' = L_e - L_{\mu} - L_{\tau}$ [156]. Determining the nature of massive neutrinos ν_i is one of the fundamental and most challenging problems in the future studies of neutrino mixing.

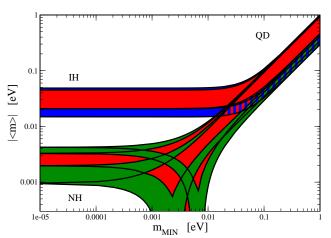

Figure 13.10: The effective Majorana mass |<m>| (including a 2σ uncertainty), as a function of $\min(m_j)$ for $\sin^2\theta_{13}=0.0236\pm0.0042$ [26] and $\delta=0$. The figure is obtained using also the best fit values and 1σ errors of Δm_{21}^2 , $\sin^2\theta_{12}$, and $|\Delta m_{31}^2|\cong |\Delta m_{32}^2|$ from Ref. 140 (given in Table 13.7). For $\sin^2\theta_{12}$ the results found with the "old" reactor $\bar{\nu}_e$ fluxes [35] were employed. The phases $\alpha_{21,31}$ are varied in the interval $[0,\pi]$. The predictions for the NH, IH and QD spectra are indicated. The red regions correspond to at least one of the phases $\alpha_{21,31}$ and $(\alpha_{31}-\alpha_{21})$ having a CP violating value, while the blue and green areas correspond to $\alpha_{21,31}$ possessing CP conserving values. (Update by S. Pascoli of a figure from the last article quoted in Ref. 160.)

The Majorana nature of massive neutrinos ν_j manifests itself in the existence of processes in which the total lepton charge L changes by two units: $K^+ \to \pi^- + \mu^+ + \mu^+$, $\mu^- + (A,Z) \to \mu^+ + (A,Z-2)$, etc. Extensive studies have shown that the only feasible experiments having the potential of establishing that the massive neutrinos are Majorana particles are at present the experiments searching for $(\beta\beta)_{0\nu}$ -decay: $(A,Z) \to (A,Z+2) + e^- + e^-$ (see e.g., Ref. 157). The observation of $(\beta\beta)_{0\nu}$ -decay and the measurement of the corresponding half-life with sufficient accuracy, would not only be a proof that the total lepton charge is not conserved, but might also provide unique information on the i) type of neutrino mass spectrum (see, e.g., Ref. 158), ii) Majorana phases in U [144,159] and iii) the absolute scale of neutrino masses (for details see Ref. 157 to Ref. 160 and references quoted therein).

Under the assumptions of $3-\nu$ mixing, of massive neutrinos ν_j being Majorana particles, and of $(\beta\beta)_{0\nu}$ -decay generated only by the (V-A) charged current weak interaction via the exchange of the

three Majorana neutrinos ν_j having masses $m_j \lesssim$ few MeV, the $(\beta\beta)_{0\nu}$ -decay amplitude has the form (see, e.g., Ref. 39 and Ref. 157): $A(\beta\beta)_{0\nu} \cong \langle m \rangle M$, where M is the corresponding nuclear matrix element which does not depend on the neutrino mixing parameters, and

$$|\langle m \rangle| = \left| m_1 U_{e1}^2 + m_2 U_{e2}^2 + m_3 U_{e3}^2 \right|$$

$$= \left| \left(m_1 c_{12}^2 + m_2 s_{12}^2 e^{i\alpha_{21}} \right) c_{13}^2 + m_3 s_{13}^2 e^{i(\alpha_{31} - 2\delta)} \right|, (13.84)$$

is the effective Majorana mass in $(\beta\beta)_{0\nu}$ -decay. In the case of CP-invariance one has [42], $\eta_{21} \equiv e^{i\alpha_{21}} = \pm 1$, $\eta_{31} \equiv e^{i\alpha_{31}} = \pm 1$, $e^{-i2\delta} = 1$. The three neutrino masses $m_{1,2,3}$ can be expressed in terms of the two measured Δm_{jk}^2 and, e.g., $\min(m_j)$. Thus, given the neutrino oscillation parameters Δm_{21}^2 , $\sin^2\theta_{12}$, Δm_{31}^2 and $\sin^2\theta_{13}$, |< m>| is a function of the lightest neutrino mass $\min(m_j)$, the Majorana (and Dirac) CP violation phases in U and of the type of neutrino mass spectrum. In the case of NH, IH and QD spectrum we have (see, e.g., Ref. 144 and Ref. 160):

$$|\!<\!m\!>\!|\cong \left|\sqrt{\Delta m_{21}^2}s_{12}^2c_{13}^2+\sqrt{\Delta m_{31}^2}s_{13}^2e^{i(\alpha_{31}-\alpha_{21}-2\delta)}\right|\,,\quad {\rm NH}\,, \eqno(13.85)$$

$$|\langle m \rangle| \cong \tilde{m} \left(1 - \sin^2 2\theta_{12} \sin^2 \frac{\alpha_{21}}{2}\right)^{\frac{1}{2}}$$
, IH (IO) and QD, (13.86)

where $\tilde{m} \equiv \sqrt{\Delta m_{23}^2 + m_3^2}$ and $\tilde{m} \equiv m_0$ for IH (IO) and QD spectrum, respectively. In Eq. (13.86) we have exploited the fact that $\sin^2\theta_{13} \ll \cos 2\theta_{12}$. The CP conserving values of the Majorana phases $(\alpha_{31} - \alpha_{21})$ and α_{21} determine the intervals of possible values of |< m>|, corresponding to the different types of neutrino mass spectrum. Using the 3σ ranges of the allowed values of the neutrino oscillation parameters from Table 13.7 and Eq. (13.76) one finds that: i) 2.3×10^{-4} eV $\lesssim |< m>| \lesssim 5.0 \times 10^{-3}$ eV in the case of NH spectrum; ii) $\sqrt{\Delta m_{23}^2 \cos 2\theta_{12}} \lesssim |< m>| \lesssim \sqrt{\Delta m_{23}^2}$, or 1.3×10^{-2} eV $\lesssim |< m>| \lesssim 5.2 \times 10^{-2}$ eV in the case of IH spectrum; iii) $m_0 \cos 2\theta_{12} \lesssim |< m>| \lesssim m_0$, or 2.8×10^{-2} eV $\lesssim |< m>| \lesssim m_0$ eV, $m_0 \gtrsim 0.10$ eV, in the case of QD spectrum. The difference in the ranges of |< m>| in the cases of NH, IH and QD spectrum opens up the possibility to get information about the type of neutrino mass spectrum from a measurement of |< m>| [158]. The predicted $(\beta\beta)_{0\nu}$ -decay effective Majorana mass |< m>| as a function of the lightest neutrino mass $\min(m_j)$ is shown in Fig. 13.10.

13.8. Outlook

After the spectacular experimental progress made in the studies of neutrino oscillations, further understanding of the pattern of neutrino masses and neutrino mixing, of their origins and of the status of CP symmetry in the lepton sector requires an extensive and challenging program of research. The main goals of such a research program, outlined in the 2010 PDG edition of the Review of Particle Physics, included:

- Determining the nature Dirac or Majorana, of massive neutrinos ν_j. This is of fundamental importance for making progress in our understanding of the origin of neutrino masses and mixing and of the symmetries governing the lepton sector of particle interactions.
- Determination of the sign of $\Delta m_{\rm A}^2~(\Delta m_{31}^2)$ and of the type of neutrino mass spectrum.
- Determining or obtaining significant constraints on the absolute scale of neutrino masses.
- Measurement of, or improving by at least a factor of (5 10) the existing upper limit on, the small neutrino mixing angle θ_{13} . Together with the Dirac CP-violating phase, the angle θ_{13} determines the magnitude of CP-violation effects in neutrino oscillations.
- \bullet Determining the status of CP symmetry in the lepton sector.
- High precision measurement of Δm_{21}^2 , θ_{12} , and $|\Delta m_{31}^2|$, θ_{23} .

• Understanding at a fundamental level the mechanism giving rise to neutrino masses and mixing and to L_l-non-conservation. This includes understanding the origin of the patterns of ν-mixing and ν-masses suggested by the data. Are the observed patterns of ν-mixing and of Δm²_{21,31} related to the existence of a new fundamental symmetry of particle interactions? Is there any relation between quark mixing and neutrino mixing, e.g., does the relation θ₁₂ + θ_c=π/4, where θ_c is the Cabibbo angle, hold? What is the physical origin of CP violation phases in the neutrino mixing matrix U? Is there any relation (correlation) between the (values of) CP violation phases and mixing angles in U? Progress in the theory of neutrino mixing might also lead to a better understanding of the mechanism of generation of baryon asymmetry of the Universe.

The successful realization of this research program, which would be a formidable task and would require many years, already began during the last two years with the results of the T2K and MINOS experiments on the value of θ_{13} , of the global analyses of the neutrino oscillation data, which showed that $\theta_{13} \neq 0$ at 3σ , and with the subsequent rather precise measurements of the value of $\sin^2 2\theta_{13}$ in the Daya Bay and RENO experiments. Averaging the results of the three recent reactor experiments with the standard PDG method, one obtains $\sin^2 2\theta_{13} = 0.098 \pm 0.013$ [142]. These results on θ_{13} have far reaching implications. The measured relatively large value of θ_{13} opens up the possibilities, in particular,

- i) for searching for CP violation effects in neutrino oscillation experiments with high intensity accelerator neutrino beams, like T2K, NO ν A, etc. NO ν A [63], an off-axis ν_e appearance experiment using the NuMI beam, is under construction and expected to be complete in 2014. The sensitivities of T2K and NO ν A on CP violation in neutrino oscillations are discussed in, e.g., Ref. 162.
- ii) for determining the sign of Δm_{32}^2 , and thus the type of neutrino mass spectrum in the long baseline neutrino oscillation experiments at accelerators, in the experiments studying the oscillations of atmospheric neutrinos (see, e.g., Ref. 82), as well as in experiments with reactor antineutrinos [161]. A value of $\sin\theta_{13}\gtrsim 0.09$ is a necessary condition for a successful "flavoured" leptogenesis with hierarchical heavy Majorana neutrinos when the CP violation required for the generation of the matter-antimatter asymmetry of the Universe is provided entirely by the Dirac CP violating phase in the neutrino mixing matrix [155].

With the measurement of θ_{13} , the first steps on the long "road" leading to a comprehensive understanding of the patterns of neutrino masses and mixing, of their origin and implications, were made.

14. QUARK MODEL

Revised August 2011 by C. Amsler (University of Zürich), T. DeGrand (University of Colorado, Boulder), and B. Krusche (University of Basel).

14.1. Quantum numbers of the quarks

Quantum chromodynamics (QCD) is the theory of the strong interactions. QCD is a quantum field theory and its constituents are a set of fermions, the quarks, and gauge bosons, the gluons. Strongly interacting particles, the hadrons, are bound states of quark and gluon fields. As gluons carry no intrinsic quantum numbers beyond color charge, and because color is believed to be permanently confined, most of the quantum numbers of strongly interacting particles are given by the quantum numbers of their constituent quarks and antiquarks. The description of hadronic properties which strongly emphasizes the role of the minimum-quark-content part of the wave function of a hadron is generically called the quark model. It exists on many levels: from the simple, almost dynamics-free picture of strongly interacting particles as bound states of quarks and antiquarks, to more detailed descriptions of dynamics, either through models or directly from QCD itself. The different sections of this review survey the many approaches to the spectroscopy of strongly interacting particles which fall under the umbrella of the quark model.

Quarks are strongly interacting fermions with spin 1/2 and, by convention, positive parity. Antiquarks have negative parity. Quarks have the additive baryon number 1/3, antiquarks -1/3. Table 14.1 gives the other additive quantum numbers (flavors) for the three generations of quarks. They are related to the charge Q (in units of the elementary charge e) through the generalized Gell-Mann-Nishijima formula

$$Q = I_z + \frac{B + S + C + B + T}{2} , \qquad (14.1)$$

where \mathcal{B} is the baryon number. The convention is that the flavor of a quark (I_z, S, C, B, or T) has the same sign as its charge Q. With this convention, any flavor carried by a charged meson has the same sign as its charge, e.g., the strangeness of the K^+ is +1, the bottomness of the B^+ is +1, and the charm and strangeness of the D_s^- are each -1. Antiquarks have the opposite flavor signs.

14.2. Mesons

Mesons have baryon number $\mathcal{B}=0$. In the quark model, they are $q\overline{q}'$ bound states of quarks q and antiquarks \overline{q}' (the flavors of q and q' may be different). If the orbital angular momentum of the $q\overline{q}'$ state is ℓ , then the parity P is $(-1)^{\ell+1}$. The meson spin J is given by the usual relation $|\ell-s| \leq J \leq |\ell+s|$, where s is 0 (antiparallel quark spins) or 1 (parallel quark spins). The charge conjugation, or C-parity $C=(-1)^{\ell+s}$, is defined only for the $q\overline{q}$ states made of quarks and their own antiquarks. The C-parity can be generalized to the G-parity $G=(-1)^{I+\ell+s}$ for mesons made of quarks and their own antiquarks (isospin $I_z=0$), and for the charged $u\overline{d}$ and $d\overline{u}$ states (isospin I=1).

Table 14.1: Additive quantum numbers of the quarks.

| | d | u | s | c | b | t |
|--------------------------------|----------------|----------------|----------------|----------------|----------------|----------------|
| Q – electric charge | $-\frac{1}{3}$ | $+\frac{2}{3}$ | $-\frac{1}{3}$ | $+\frac{2}{3}$ | $-\frac{1}{3}$ | $+\frac{2}{3}$ |
| I – isospin | $\frac{1}{2}$ | $\frac{1}{2}$ | 0 | 0 | 0 | 0 |
| I_z – isospin z -component | $-\frac{1}{2}$ | $+\frac{1}{2}$ | 0 | 0 | 0 | 0 |
| S – strangeness | 0 | 0 | -1 | 0 | 0 | 0 |
| C – charm | 0 | 0 | 0 | +1 | 0 | 0 |
| B – bottomness | 0 | 0 | 0 | 0 | -1 | 0 |
| T – topness | 0 | 0 | 0 | 0 | 0 | +1 |

The mesons are classified in J^{PC} multiplets. The $\ell=0$ states are the pseudoscalars (0^{-+}) and the vectors (1^{--}) . The orbital excitations $\ell=1$ are the scalars (0^{++}) , the axial vectors (1^{++}) and (1^{+-}) , and the tensors (2^{++}) . Assignments for many of the known mesons are given in Tables 14.2 and 14.3. Radial excitations are denoted by the principal quantum number n. The very short lifetime of the t quark makes it likely that bound-state hadrons containing t quarks and/or antiquarks do not exist.

States in the natural spin-parity series $P=(-1)^J$ must, according to the above, have s=1 and hence, CP=+1. Thus, mesons with natural spin-parity and CP=-1 (0⁺⁻, 1⁻⁺, 2⁺⁻, 3⁻⁺, etc.) are forbidden in the $q\bar{q}'$ model. The $J^{PC}=0^{--}$ state is forbidden as well. Mesons with such exotic quantum numbers may exist, but would lie outside the $q\bar{q}'$ model (see section below on exotic mesons).

Following SU(3), the nine possible $q\bar{q}'$ combinations containing the light $u,\ d,$ and s quarks are grouped into an octet and a singlet of light quark mesons:

$$\mathbf{3} \otimes \mathbf{\overline{3}} = \mathbf{8} \oplus \mathbf{1} \ . \tag{14.2}$$

A fourth quark such as charm c can be included by extending SU(3) to SU(4). However, SU(4) is badly broken owing to the much heavier c quark. Nevertheless, in an SU(4) classification, the sixteen mesons are grouped into a 15-plet and a singlet:

$$\mathbf{4} \otimes \overline{\mathbf{4}} = \mathbf{15} \oplus \mathbf{1} \ . \tag{14.3}$$

The weight diagrams for the ground-state pseudoscalar (0^{-+}) and vector (1^{--}) mesons are depicted in Fig. 14.1. The light quark mesons are members of nonets building the middle plane in Fig. 14.1(a) and (b).

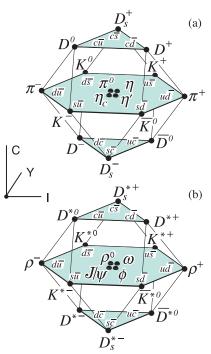

Figure 14.1: SU(4) weight diagram showing the 16-plets for the pseudoscalar (a) and vector mesons (b) made of the u, d, s, and c quarks as a function of isospin I, charm C, and hypercharge $\mathsf{Y} = \mathsf{S} + \mathcal{B} - \frac{\mathsf{C}}{3}$. The nonets of light mesons occupy the central planes to which the $c\bar{c}$ states have been added.

Isoscalar states with the same J^{PC} will mix, but mixing between the two light quark isoscalar mesons, and the much heavier charmonium or bottomonium states, are generally assumed to be negligible. In the

Table 14.2: Suggested $q\overline{q}$ quark-model assignments for some of the observed light mesons. Mesons in bold face are included in the Meson Summary Table. The wave functions f and f' are given in the text. The singlet-octet mixing angles from the quadratic and linear mass formulae are also given for the well established nonets. The classification of the 0^{++} mesons is tentative and the mixing angle uncertain due to large uncertainties in some of the masses. Also, the $f_0(1710)$ and $f_0(1370)$ are expected to mix with the $f_0(1500)$. The latter is not in this table as it is hard to accommodate in the scalar nonet. The light scalars $a_0(980)$, $f_0(980)$, and $f_0(500)$ are often considered as meson-meson resonances or four-quark states, and are therefore not included in the table. See the "Note on Scalar Mesons" in the Meson Listings for details and alternative schemes.

[†] The masses of these states are considerably smaller than most theoretical predictions. They have also been considered as four-quark states (See the "Note on Non- $q\bar{q}$ Mesons" at the end of the Meson Listings). The open flavor states in the 1⁺⁺ and 1⁺⁺ rows are mixtures of the 1^{+±} states.

following, we shall use the generic names a for the I=1, K for the I=1/2, and f and f' for the I=0 members of the light quark nonets. Thus, the physical isoscalars are mixtures of the SU(3) wave function ψ_8 and ψ_1 :

$$f' = \psi_8 \cos \theta - \psi_1 \sin \theta , \qquad (14.4)$$

$$f = \psi_8 \sin \theta + \psi_1 \cos \theta \,\,\,\,(14.5)$$

where θ is the nonet mixing angle and

$$\psi_8 = \frac{1}{\sqrt{6}} (u\bar{u} + d\bar{d} - 2s\bar{s}) , \qquad (14.6)$$

$$\psi_1 = \frac{1}{\sqrt{3}} (u\bar{u} + d\bar{d} + s\bar{s})$$
 (14.7)

These mixing relations are often rewritten to exhibit the $u\bar{u}+d\bar{d}$ and $s\bar{s}$ components which decouple for the "ideal" mixing angle θ_i , such that $\tan\theta_i=1/\sqrt{2}$ (or $\theta_i{=}35.3^\circ$). Defining $\alpha=\theta+54.7^\circ$, one obtains the physical isoscalar in the flavor basis

$$f' = \frac{1}{\sqrt{2}} (u\bar{u} + d\bar{d}) \cos \alpha - s\bar{s} \sin \alpha , \qquad (14.8)$$

and its orthogonal partner f (replace α by $\alpha - 90^{\circ}$). Thus for ideal mixing ($\alpha_i = 90^{\circ}$), the f' becomes pure $s\bar{s}$ and the f pure $u\bar{u} + d\bar{d}$. The mixing angle θ can be derived from the mass relation

$$\tan \theta = \frac{4m_K - m_a - 3m_{f'}}{2\sqrt{2}(m_a - m_K)} , \qquad (14.9)$$

which also determines its sign or, alternatively, from

$$\tan^2 \theta = \frac{4m_K - m_a - 3m_{f'}}{-4m_K + m_a + 3m_f} \,. \tag{14.10}$$

Eliminating θ from these equations leads to the sum rule [1]

$$(m_f + m_{f'})(4m_K - m_a) - 3m_f m_{f'} = 8m_K^2 - 8m_K m_a + 3m_a^2. \eqno(14.11)$$

This relation is verified for the ground-state vector mesons. We identify the $\phi(1020)$ with the f' and the $\omega(783)$ with the f. Thus

$$\phi(1020) = \psi_8 \cos \theta_V - \psi_1 \sin \theta_V , \qquad (14.12)$$

$$\omega(782) = \psi_8 \sin \theta_V + \psi_1 \cos \theta_V , \qquad (14.13)$$

with the vector mixing angle $\theta_V=35^\circ$ from Eq. (14.9), very close to ideal mixing. Thus $\phi(1020)$ is nearly pure $s\bar{s}$. For ideal mixing, Eq. (14.9) and Eq. (14.10) lead to the relations

$$m_K = \frac{m_f + m_{f'}}{2} , \quad m_a = m_f , \qquad (14.14)$$

which are satisfied for the vector mesons.

The situation for the pseudoscalar and scalar mesons is not so clear cut, either theoretically or experimentally. For the pseudoscalars, the mixing angle is small. This can be understood qualitatively via gluon-line counting of the mixing process. The size of the mixing process between the nonstrange and strange mass bases scales as α_s^2 , not α_s^3 , because of two rather than three gluon exchange as it does for the vector mesons. It may also be that the lightest isoscalar pseudoscalars mix more strongly with excited states or with states of substantial non- $\bar{q}q$ content, as will be discussed below.

A variety of analysis methods lead to similar results: First, for these states, Eq. (14.11) is satisfied only approximately. Then Eq. (14.9) and Eq. (14.10) lead to somewhat different values for the mixing angle. Identifying the η with the f' one gets

$$\eta = \psi_8 \cos \theta_P - \psi_1 \sin \theta_P , \qquad (14.15)$$

$$\eta' = \psi_8 \sin \theta_P + \psi_1 \cos \theta_P \ . \tag{14.16}$$

Following chiral perturbation theory, the meson masses in the mass formulae (Eq. (14.9) and Eq. (14.10)) might be replaced by their squares. Table 14.2 lists the mixing angle $\theta_{\rm lin}$ from Eq. (14.10) and the corresponding $\theta_{\rm quad}$ obtained by replacing the meson masses by their squares throughout.

The pseudoscalar mixing angle θ_P can also be measured by comparing the partial widths for radiative J/ψ decay into a vector and a pseudoscalar [2], radiative $\phi(1020)$ decay into η and η' [3], or $\bar{p}p$ annihilation at rest into a pair of vector and pseudoscalar or into two pseudoscalars [4,5]. One obtains a mixing angle between -10° and -20° . More recently, a lattice QCD simulation, Ref. 6, has successfully reproduced the masses of the η and η' , and as a byproduct find a mixing angle $\theta_{lin} = -14.1(2.8)^\circ$ We return to this point in Sec. 14.6.

The nonet mixing angles can be measured in $\gamma\gamma$ collisions, e.g., for the 0^{-+} , 0^{++} , and 2^{++} nonets. In the quark model, the amplitude for the coupling of neutral mesons to two photons is proportional to $\sum_i Q_i^2$, where Q_i is the charge of the *i*-th quark. The 2γ partial width of an isoscalar meson with mass m is then given in terms of the mixing angle α by

$$\Gamma_{2\gamma} = C(5\cos\alpha - \sqrt{2}\sin\alpha)^2 m^3 , \qquad (14.17)$$

for f' and f ($\alpha \to \alpha - 90^\circ$). The coupling C may depend on the meson mass. It is often assumed to be a constant in the nonet. For the isovector a, one then finds $\Gamma_{2\gamma}=9$ C m^3 . Thus the members of an ideally mixed nonet couple to 2γ with partial widths in the ratios f:f':a=25:2:9. For tensor mesons, one finds from the ratios of the measured 2γ partial widths for the $f_2(1270)$ and $f'_2(1525)$ mesons a mixing angle α_T of $(81\pm 1)^\circ$, or $\theta_T=(27\pm 1)^\circ$, in accord with the linear mass formula. For the pseudoscalars, one finds from the ratios of partial widths $\Gamma(\eta'\to 2\gamma)/\Gamma(\eta\to 2\gamma)$ a mixing angle $\theta_P=(-18\pm 2)^\circ$, while the ratio $\Gamma(\eta'\to 2\gamma)/\Gamma(\pi^0\to 2\gamma)$ leads to ~ -24 °. SU(3) breaking effects for pseudoscalars are discussed in Ref. 7.

Table 14.4: SU(3) couplings γ^2 for quarkonium decays as a function of nonet mixing angle α , up to a common multiplicative factor C ($\phi \equiv 54.7^{\circ} + \theta_P$).

| Isospin | Decay channel | γ^2 |
|---------------|-----------------|-------------------------------------------------------------------------------------------|

The partial width for the decay of a scalar or a tensor meson into a pair of pseudoscalar mesons is model-dependent. Following Ref. 8,

$$\Gamma = C \times \gamma^2 \times |F(q)|^2 \times q \ . \tag{14.18}$$

C is a nonet constant, q the momentum of the decay products, F(q) a form factor, and γ^2 the SU(3) coupling. The model-dependent form factor may be written as

$$|F(q)|^2 = q^{2\ell} \times \exp(-\frac{q^2}{8\beta^2}),$$
 (14.19)

where ℓ is the relative angular momentum between the decay products. The decay of a $q\bar{q}$ meson into a pair of mesons involves the creation of a $q\bar{q}$ pair from the vacuum, and SU(3) symmetry assumes that the

matrix elements for the creation of $s\bar{s}$, $u\bar{u}$, and $d\bar{d}$ pairs are equal. The couplings γ^2 are given in Table 14.4, and their dependence upon the mixing angle α is shown in Fig. 14.2 for isoscalar decays. The generalization to unequal $s\bar{s}$, $u\bar{u}$, and $d\bar{d}$ couplings is given in Ref. 8. An excellent fit to the tensor meson decay widths is obtained assuming SU(3) symmetry, with $\beta \simeq 0.5$ GeV/c, $\theta_V \simeq 26$ ° and $\theta_P \simeq -17$ ° [8].

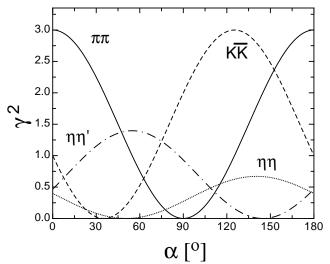

Figure 14.2: SU(3) couplings as a function of mixing angle α for isoscalar decays, up to a common multiplicative factor C and for $\theta_P = -17.3^{\circ}$.

14.3. Exotic mesons

The existence of a light nonet composed of four quarks with masses below 1 GeV was suggested a long time ago [9]. Coupling two triplets of light quarks u, d, and s, one obtains nine states, of which the six symmetric (uu, dd, ss, ud+du, us+su, ds+sd) form the six dimensional representation $\mathbf{6}$, while the three antisymmetric (ud-du, us-su, ds-sd) form the three dimensional representation $\overline{\mathbf{3}}$ of SU(3):

$$\mathbf{3} \otimes \mathbf{3} = \mathbf{6} \oplus \mathbf{\bar{3}} \ . \tag{14.20}$$

Combining with spin and color and requiring antisymmetry, one finds that the most deeply bound diquark (and hence the lightest) is the one in the $\overline{\bf 3}$ and spin singlet state. The combination of the diquark with an antidiquark in the $\bf 3$ representation then gives a light nonet of four-quark scalar states. Letting the number of strange quarks determine the mass splitting, one obtains a mass inverted spectrum with a light isosinglet $(ud\bar{u}d\bar{d})$, a medium heavy isodoublet $(e.g., ud\bar{s}d)$ and a heavy isotriplet $(e.g., ds\bar{u}\bar{s})$ + isosinglet $(e.g., us\bar{u}\bar{s})$. It is then tempting to identify the lightest state with the $f_0(500)$, and the heaviest states with the $a_0(980)$, and $f_0(980)$. Then the meson with strangeness $\kappa(800)$ would lie in between.

QCD predicts the existence of extra isoscalar mesons. In the pure gauge theory, they contain only gluons, and are called the glueballs. The ground state glueball is predicted by lattice gauge theories to be 0^{++} , the first excited state 2^{++} . Errors on the mass predictions are large. From Ref. 11 one obtains 1750 (50) (80) MeV for the mass of the lightest 0^{++} glueball from quenched QCD. As an example for the glueball mass spectrum, we show in Fig. 14.3 a recent calculation from Ref. 10. A mass of 1710 MeV is predicted for the ground state, also with an error of about 100 MeV. Earlier work by other groups produced masses at 1650 MeV [12] and 1550 MeV [13] (see also [14]). The first excited state has a mass of about 2.4 GeV, and the lightest glueball with exotic quantum numbers (2^{+-}) has a mass of about 4 GeV

These calculations are made in the so-called "quenched approximation" which neglects $q\bar{q}$ loops. However, both glue and $q\bar{q}$ states will couple to singlet scalar mesons. Therefore glueballs will mix

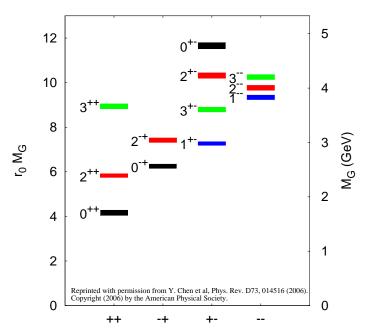

Figure 14.3: Predicted glueball mass spectrum from the lattice, in quenched approximation, (from Ref. 10).

with nearby $q\bar{q}$ states of the same quantum numbers. For example, the two isoscalar 0^{++} mesons around 1500 MeV will mix with the pure ground state glueball to generate the observed physical states $f_0(1370)$, $f_0(1500)$, and $f_0(1710)$ [8,15]. Lattice calculations are only beginning to include these effects. We return to a discussion of this point in Sec. 14.6.

The existence of three singlet scalar mesons around 1.5 GeV suggests additional degrees of freedom such as glue, since only two mesons are predicted in this mass range. The $f_0(1500)$ [8,15] or, alternatively, the $f_0(1710)$ [12], have been proposed as candidates for the scalar glueball, both states having considerable mixing also with the $f_0(1370)$. Other mixing schemes, in particular with the $f_0(500)$ and the $f_0(980)$, have also been proposed (more details can be found in the "Note on Scalar Mesons" in the Meson Listings and in Ref. 16).

Mesons made of $q\bar{q}$ pairs bound by excited gluons g, the hybrid states $q\bar{q}g$, are also predicted. They should lie in the 1.9 GeV mass region, according to gluon flux tube models [17]. Lattice QCD also predicts the lightest hybrid, an exotic 1^{-+} , at a mass of 1.8 to 1.9 GeV [18]. However, the bag model predicts four nonets, among them an exotic 1^{-+} around or above 1.4 GeV [19,20]. There are so far two candidates for exotic states with quantum numbers 1^{-+} , the $\pi_1(1400)$ and $\pi_1(1600)$, which could be hybrids or four-quark states (see the "Note on Non- $q\bar{q}$ Mesons" in the 2006 issue of this Review [21] and in Ref. 16).

14.4. Baryons: qqq states

Baryons are fermions with baryon number $\mathcal{B}=1,\ i.e.,$ in the most general case, they are composed of three quarks plus any number of quark - antiquark pairs. So far all established baryons are 3-quark (qqq) configurations. The color part of their state functions is an SU(3) singlet, a completely antisymmetric state of the three colors. Since the quarks are fermions, the state function must be antisymmetric under interchange of any two equal-mass quarks (up and down quarks in the limit of isospin symmetry). Thus it can be written as

$$|qqq\rangle_A = |\operatorname{color}\rangle_A \times |\operatorname{space}, \operatorname{spin}, \operatorname{flavor}\rangle_S,$$
 (14.21)

where the subscripts S and A indicate symmetry or antisymmetry under interchange of any two equal-mass quarks. Note the contrast with the state function for the three nucleons in $^3\mathrm{H}$ or $^3\mathrm{He}$:

$$|NNN\rangle_A = |\operatorname{space}, \operatorname{spin}, \operatorname{isospin}\rangle_A$$
. (14.22)

This difference has major implications for internal structure, magnetic moments, etc. (For a nice discussion, see Ref. 22.)

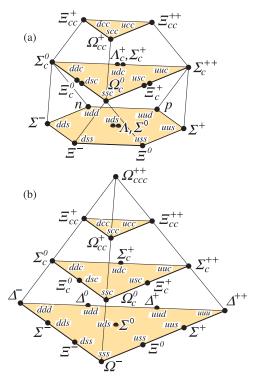

Figure 14.4: SU(4) multiplets of baryons made of u, d, s, and c quarks. (a) The 20-plet with an SU(3) octet. (b) The 20-plet with an SU(3) decuplet.

The "ordinary" baryons are made up of u, d, and s quarks. The three flavors imply an approximate flavor $\mathrm{SU}(3)$, which requires that baryons made of these quarks belong to the multiplets on the right side of

$$\mathbf{3} \otimes \mathbf{3} \otimes \mathbf{3} = \mathbf{10}_S \oplus \mathbf{8}_M \oplus \mathbf{8}_M \oplus \mathbf{1}_A \tag{14.23}$$

(see Sec. 42, on "SU(n) Multiplets and Young Diagrams"). Here the subscripts indicate symmetric, mixed-symmetry, or antisymmetric states under interchange of any two quarks. The 1 is a uds state (Λ_1), and the octet contains a similar state (Λ_8). If these have the same spin and parity, they can mix. The mechanism is the same as for the mesons (see above). In the ground state multiplet, the SU(3) flavor singlet Λ_1 is forbidden by Fermi statistics. Section 41, on "SU(3) Isoscalar Factors and Representation Matrices," shows how relative decay rates in, say, $\mathbf{10} \to \mathbf{8} \otimes \mathbf{8}$ decays may be calculated.

The addition of the c quark to the light quarks extends the flavor symmetry to SU(4). However, due to the large mass of the c quark, this symmetry is much more strongly broken than the SU(3) of the three light quarks. Figures 14.4(a) and 14.4(b) show the SU(4) baryon multiplets that have as their bottom levels an SU(3) octet, such as the octet that includes the nucleon, or an SU(3) decuplet, such as the decuplet that includes the $\Delta(1232)$. All particles in a given SU(4) multiplet have the same spin and parity. The charmed baryons are discussed in more detail in the "Note on Charmed Baryons" in the Particle Listings. The addition of a b quark extends the flavor symmetry to SU(5); the existence of baryons with t-quarks is very unlikely due to the short lifetime of the top.

Table 14.5: N and Δ states in the N=0,1,2 harmonic oscillator bands. L^P denotes angular momentum and parity, S the three-quark spin and 'sym'=A,S,M the symmetry of the spatial wave function. Only dominant components indicated. Assignments in the N=2 band are partly tentative.

For the "ordinary" baryons (no c or b quark), flavor and spin may be combined in an approximate flavor-spin SU(6), in which the six basic states are $d \uparrow$, $d \downarrow$, \cdots , $s \downarrow$ (\uparrow , \downarrow = spin up, down). Then the baryons belong to the multiplets on the right side of

$$\mathbf{6} \otimes \mathbf{6} \otimes \mathbf{6} = \mathbf{56}_S \oplus \mathbf{70}_M \oplus \mathbf{70}_M \oplus \mathbf{20}_A . \tag{14.24}$$

These SU(6) multiplets decompose into flavor SU(3) multiplets as follows:

$$\mathbf{56} = {}^{4}\mathbf{10} \oplus {}^{2}\mathbf{8} \tag{14.25a}$$

$$70 = {}^{2}10 \oplus {}^{4}8 \oplus {}^{2}8 \oplus {}^{2}1 \tag{14.25b}$$

$$20 = {}^{2}8 \oplus {}^{4}1 , \qquad (14.25c)$$

where the superscript (2S+1) gives the net spin S of the quarks for each particle in the SU(3) multiplet. The $J^P=1/2^+$ octet containing the nucleon and the $J^P=3/2^+$ decuplet containing the $\Delta(1232)$ together make up the "ground-state" 56-plet, in which the orbital angular momenta between the quark pairs are zero (so that the spatial part of the state function is trivially symmetric). The $\bf 70$ and $\bf 20$ require some excitation of the spatial part of the state function in order to make the overall state function symmetric. States with nonzero orbital angular momenta are classified in ${\rm SU}(6)\otimes {\rm O}(3)$ supermultiplets.

It is useful to classify the baryons into bands that have the same number N of quanta of excitation. Each band consists of a number of supermultiplets, specified by (D,L_N^P) , where D is the dimensionality of the SU(6) representation, L is the total quark orbital angular momentum, and P is the total parity. Supermultiplets contained in bands up to N = 12 are given in Ref. 24. The N = 0 band, which contains the nucleon and $\Delta(1232)$, consists only of the $(56,0_0^+)$ supermultiplet. The N = 1 band consists only of the $(70,1_1^-)$ multiplet and contains the negative-parity baryons with masses below about 1.9 GeV. The N = 2 band contains five supermultiplets: $(56,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(70,0_2^+),\,(7$

The wave functions of the non-strange baryons in the harmonic oscillator basis are often labeled by $|X^{2S+1}L_\pi J^P\rangle$, where S,L,J,P are as above, X=N or Δ , and $\pi=S,M$ or A denotes the symmetry of the spatial wave function. The possible model states for the bands with N=0,1,2 are given in Table 14.5. The assignment of experimentally observed states is only complete and well established up to the N=1 band. Some more tentative assignments for higher multiplets are suggested in Ref. 25.

In Table 14.6, quark-model assignments are given for many of the established baryons whose $\mathrm{SU}(6)\otimes\mathrm{O}(3)$ compositions are relatively unmixed. One must, however, keep in mind that apart from the mixing of the Λ singlet and octet states, states with same J^P but different L,S combinations can also mix. In the quark model with one-gluon exchange motivated interactions, the size of the mixing is determined by the relative strength of the tensor term with respect to the contact term (see below). The mixing is more important for the decay patterns of the states than for their positions. An example are the lowest lying $(70,1_1^-)$ states with $J^P\!=\!1/2^-$ and $3/2^-$. The physical states are:

$$|S_{11}(1535)\rangle = \cos(\Theta_S)|N^2P_M1/2^-\rangle - \sin(\Theta_S)|N^4P_M1/2^-\rangle$$
 (14.26)

$$|D_{13}(1520)\rangle = \cos(\Theta_D)|N^2 P_M 3/2^-\rangle - \sin(\Theta)_D|N^4 P_M 3/2^-\rangle$$
 (14.27)

and the orthogonal combinations for $S_{11}(1650)$ and $D_{13}(1700)$. The mixing is large for the $J^P = 1/2^-$ states ($\Theta_S \approx -32^o$), but small for the $J^P = 3/2^-$ states ($\Theta_D \approx +6^o$) [26,31].

All baryons of the ground state multiplets are known. Many of their properties, in particular their masses, are in good agreement even with the most basic versions of the quark model, including harmonic (or linear) confinement and a spin-spin interaction, which is responsible for the octet - decuplet mass shifts. A consistent description of the ground-state electroweak properties, however, requires refined relativistic constituent quark models.

Table 14.6: Quark-model assignments for some of the known baryons in terms of a flavor-spin SU(6) basis. Only the dominant representation is listed. Assignments for several states, especially for the $\Lambda(1810)$, $\Lambda(2350)$, $\Xi(1820)$, and $\Xi(2030)$, are merely educated guesses. † recent suggestions for assignments and re-assignments from ref. [28]. For assignments of the charmed baryons, see the "Note on Charmed Baryons" in the Particle Listings.

The situation for the excited states is much less clear. The assignment of some experimentally observed states with strange quarks to model configurations is only tentative and in many cases candidates are completely missing. Recently, Melde, Plessas and Sengl [28] have calculated baryon properties in relativistic constituent quark models, using one-gluon exchange and Goldstone-boson exchange for the modeling of the hyperfine interactions (see Sec. 14.5 on Dynamics). Both types of models give qualitatively comparable results, and underestimate in general experimentally observed decay widths. Nevertheless, in particular on the basis of the observed decay patterns, the authors have assigned some additional states with strangeness to the SU(3) multiplets and suggest re-assignments for a few others. Among the new assignments are states with weak experimental evidence (two or three star ratings) and partly without firm spin/parity assignments, so that further experimental efforts are necessary before final conclusions can be drawn. We have added their suggestions in Table 14.6.

In the non-strange sector there are two main problems which are illustrated in Fig. 14.5, where the experimentally observed excitation spectrum of the nucleon (N and Δ resonances) is compared to the results of a typical quark model calculation [27]. The lowest states from the N=2 band, the P₁₁(1440), and the P₃₃(1600), appear lower than the negative parity states from the N=1 band (see Table 14.5) and much lower than predicted by most models. Also negative parity Δ states from the N=3 band (S₃₁(1900), D₃₃(1940), and D₃₅(1930)) are too low in energy. Part of the problem could be experimental. Among the negative parity Δ states, only the D₃₅ has three stars and

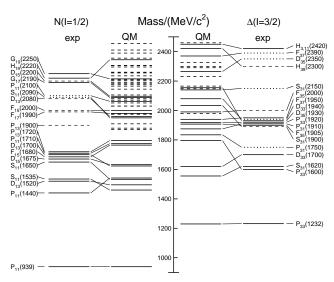

Figure 14.5: Excitation spectrum of the nucleon. Compared are the positions of the excited states identified in experiment, to those predicted by a relativized quark model calculation. Left hand side: isospin I=1/2 N-states, right hand side: isospin I=3/2 Δ -states. Experimental: (columns labeled 'exp'), three-and four-star states are indicated by full lines (two-star dashed lines, one-star dotted lines). At the very left and right of the figure, the spectroscopic notation of these states is given. Quark model [27]: (columns labeled 'QM'), all states for the N=1,2 bands, low-lying states for the N=3,4,5 bands. Full lines: at least tentative assignment to observed states, dashed lines: so far no observed counterparts. Many of the assignments between predicted and observed states are highly tentative.

the uncertainty in the position of the $\mathrm{P}_{33}(1600)$ is large (1550 - 1700 MeV).

Furthermore, many more states are predicted than observed. This has been known for a long time as the 'missing resonance' problem [26]. Up to an excitation energy of 2.4 GeV, about 45 Nstates are predicted, but only 12 are established (four- or three-star; see Note on N and Δ Resonances for the rating of the status of resonances) and 7 are tentative (two- or one-star). Even for the N=2 band, up to now only half of the predicted states have been observed. The most recent partial wave analysis of elastic pion scattering and charge exchange data by Arndt and collaborators [29] has made the situation even worse. They found no evidence for almost half of the states listed in this review (and included in Fig. 14.5). Such analyses are of course biased against resonances which couple only weakly to the $N\pi$ channel. Quark model predictions for the couplings to other hadronic channels and to photons are given in Ref. 27. A large experimental effort is ongoing at several electron accelerators to study the baryon resonance spectrum with real and virtual photon-induced meson production reactions. This includes the search for as-yet-unobserved states, as well as detailed studies of the properties of the low lying states (decay patterns, electromagnetic couplings, magnetic moments, etc.) (see Ref. 30 for recent reviews). This experimental effort has currently entered its final phase with the measurement of single and double polarization observables for many different meson production channels, so that a much better understanding of the experimental spectrum can be expected for the near future.

In quark models, the number of excited states is determined by the effective degrees of freedom, while their ordering and decay properties are related to the residual quark - quark interaction. An overview of quark models for baryons is given in Ref. 31, a recent discussion of baryon spectroscopy is given in Ref. 25. The effective degrees of freedom in the standard nonrelativistic quark model are three equivalent valence quarks with one-gluon exchange-motivated, flavor-independent color-magnetic interactions. A different class of models uses interactions which give rise to a quark - diquark clustering

of the baryons (for a review see Ref. 32). If there is a tightly bound diquark, only two degrees of freedom are available at low energies, and thus fewer states are predicted. Furthermore, selection rules in the decay pattern may arise from the quantum numbers of the diquark. More states are predicted by collective models of the baryon like the algebraic approach in Ref. 33. In this approach, the quantum numbers of the valence quarks are distributed over a Y-shaped string-like configuration, and additional states arise e.g., from vibrations of the strings. More states are also predicted in the framework of flux-tube models (see Ref. 34), which are motivated by lattice QCD. In addition to the quark degrees of freedom, flux-tubes responsible for the confinement of the quarks are considered as degrees of freedom. These models include hybrid baryons containing explicit excitations of the gluon fields. However, since all half integral J^P quantum numbers are possible for ordinary baryons, such 'exotics' will be very hard to identify, and probably always mix with ordinary states. So far, the experimentally observed number of states is still far lower even than predicted by the quark-diquark models.

Recently, the influence of chiral symmetry on the excitation spectrum of the nucleon has been hotly debated from a somewhat new perspective. Chiral symmetry, the fundamental symmetry of QCD, is strongly broken for the low lying states, resulting in large mass differences of parity partners like the $J^P=1/2^+$ P₁₁(938) ground state and the $J^P=1/2^-$ S₁₁(1535) excitation. However, at higher excitation energies there is some evidence for parity doublets and even some very tentative suggestions for full chiral multiplets of N^* and Δ resonances. An effective restoration of chiral symmetry at high excitation energies due to a decoupling from the quark condensate of the vacuum has been discussed (see Ref. 35 for recent reviews) as a possible cause. In this case, the mass generating mechanisms for low and high lying states would be essentially different. As a further consequence, the parity doublets would decouple from pions, so that experimental bias would be worse. However, parity doublets might also arise from the spin-orbital dynamics of the 3-quark system. Presently, the status of data does not allow final conclusions.

The most recent developments on the theory side are the first unquenched lattice calculations for the excitation spectrum discussed in Sec. 14.6. The results are basically consistent with the level counting of $\mathrm{SU}(6)\otimes\mathrm{O}(3)$ in the standard non-relativistic quark model and show no indication for quark-diquark structures or parity doubling. Consequently, there is as yet no indication from lattice that the mis-match between the excitation spectrum predicted by the standard quark model and experimental observations is due to inappropriate degrees of freedom in the quark model.

14.5. Dynamics

Quantum chromodynamics (QCD) is well-established as the theory for the strong interactions. As such, one of the goals of QCD is to predict the spectrum of strongly-interacting particles. To date, the only first-principles calculations of spectroscopy from QCD use lattice methods. These are the subject of Sec. 14.6. These calculations are difficult and unwieldy, and many interesting questions do not have a good lattice-based method of solution. Therefore, it is natural to build models, whose ingredients are abstracted from QCD, or from the low-energy limit of QCD (such as chiral Lagrangians) or from the data itself. The words "quark model" are a shorthand for such phenomenological models. Many specific quark models exist, but most contain a similar basic set of dynamical ingredients. These include:

- i) A confining interaction, which is generally spin-independent (e.g., harmonic oscillator or linear confinement);
- ii) Different types of spin-dependent interactions:
 - a) commonly used is a color-magnetic flavor-independent interaction modeled after the effects of gluon exchange in QCD (see e.g., Ref. 36). For example, in the S-wave states, there is a spin-spin hyperfine interaction of the form

$$H_{HF} = -\alpha_S M \sum_{i>j} (\overrightarrow{\sigma} \lambda_a)_i (\overrightarrow{\sigma} \lambda_a)_j , \qquad (14.28)$$

where M is a constant with units of energy, λ_a ($a = 1, \dots, 8$,) is the set of SU(3) unitary spin matrices, defined in Sec. 41,

on "SU(3) Isoscalar Factors and Representation Matrices," and the sum runs over constituent quarks or antiquarks. Spin-orbit interactions, although allowed, seem to be small in general, but a tensor term is responsible for the mixing of states with the same J^P but different L,S combinations.

b) other approaches include flavor-dependent short-range quark forces from instanton effects (see e.g., Ref. 37). This interaction acts only on scalar, isoscalar pairs of quarks in a relative S-wave state:

$$\langle q^2; S, L, T | W | q^2; S, L, T \rangle = -4g \delta_{S,0} \delta_{L,0} \delta_{L,0} \mathcal{W}$$
 (14.29)

where W is the radial matrix element of the contact interaction. c) a rather different and controversially discussed approach is

c) a rather different and controversially discussed approach is based on flavor-dependent spin-spin forces arising from one-boson exchange. The interaction term is of the form:

$$H_{HF} \propto \sum_{i < j} V(\overrightarrow{r}_{ij}) \lambda_i^F \cdot \lambda_j^F \overrightarrow{\sigma}_i \cdot \overrightarrow{\sigma}_j$$
 (14.30)

where the λ_i^F are in flavor space (see e.g., Ref. 38).

- iii) A strange quark mass somewhat larger than the up and down quark masses, in order to split the SU(3) multiplets;
- iv) In the case of spin-spin interactions (iia,c), a flavor-symmetric interaction for mixing $q\overline{q}$ configurations of different flavors (e.g., $u\overline{u} \leftrightarrow d\overline{d} \leftrightarrow s\overline{s}$), in isoscalar channels, so as to reproduce e.g., the η η' and ω ϕ mesons.

These ingredients provide the basic mechanisms that determine the hadron spectrum in the standard quark model.

14.6. Lattice Calculations of Hadronic Spectroscopy

Lattice calculations are a major source of information about QCD masses and matrix elements. The necessary theoretical background is given in Sec. 17 of this *Review*. Here we confine ourselves to some general comments and illustrations of lattice calculations for spectroscopy.

In general, the cleanest lattice results come from computations of processes in which there is only one particle in the simulation volume. These quantities include masses of hadrons, simple decay constants, like pseudoscalar meson decay constants, and semileptonic form factors (such as the ones appropriate to $B \to Dl\nu$, $Kl\nu$, $\pi l\nu$). The cleanest predictions for masses are for states which have narrow decay widths and are far below any thresholds to open channels, since the effects of final state interactions are not yet under complete control on the lattice. As a simple corollary, the lightest state in a channel is easier to study than the heavier ones. "Difficult" states for the quark model (such as exotics) are also difficult for the lattice because of the lack of simple operators which couple well to them.

Good-quality modern lattice calculations will present multi-part error budgets with their predictions. A small part of the uncertainty is statistical, from sample size. Typically, the quoted statistical uncertainty includes uncertainty from a fit: it is rare that a simulation computes one global quantity which is the desired observable. Simulations which include virtual quark-antiquark pairs (also known as "dynamical quarks" or "sea quarks") are often done at up and down quark mass values heavier than the experimental ones, and it is then necessary to extrapolate in these quark masses. Simulations can work at the physical values of the heavier quarks' masses. They are always done at nonzero lattice spacing, and so it is necessary to extrapolate to zero lattice spacing. Some theoretical input is needed to do this. Much of the uncertainty in these extrapolations is systematic, from the choice of fitting function. Other systematics include the effect of finite simulation volume, the number of flavors of dynamical quarks actually simulated, and technical issues with how these dynamical quarks are included. The particular choice of a fiducial mass (to normalize other predictions) is not standardized; there are many possible choices, each with its own set of strengths and weaknesses, and determining it usually requires a second lattice simulation from that used to calculate the quantity under consideration.

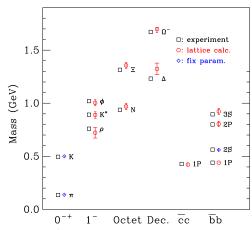

Figure 14.6: A recent calculation of spectroscopy with dynamical u, d, and s quarks. The pion and kaon fix the light quark masses. Only the mass splittings relative to the 1S states in the heavy quark sectors are shown. The Υ 2S-1S splitting sets the overall energy scale.

A systematic error of major historical interest is the "quenched approximation," in which dynamical quarks are simply left out of the simulation. This was done because the addition of these virtual pairs presented an expensive computational problem. No generally-accepted methodology has ever allowed one to correct for quenching effects, short of redoing all calculations with dynamical quarks. Recent advances in algorithms and computer hardware have rendered it obsolete.

With these brief remarks, we turn to examples. The field of lattice QCD simulations is vast, and so it is not possible to give a comprehensive review of them in a small space. The history of lattice QCD simulations is a story of thirty years of incremental improvements in physical understanding, algorithm development, and ever faster computers, which have combined to bring the field to a present state where it is possible to carry out very high quality calculations. We present a few representative illustrations, to show the current state of the art.

By far, the major part of all lattice spectroscopy is concerned with that of the light hadrons, and so we illustrate results from two groups. First, a recent calculation of spectroscopy with dynamical $u,\ d,$ and s quarks is shown in Fig. 14.6. The pion and kaon masses are used to set the light quark masses. The Υ 2S-1S splitting is used to set the lattice spacing or equivalently, the overall energy scale in the lattice calculation. This is an updated figure from Ref. 39, using results from Ref. 41 and Ref. 42 (D. Toussaint, private communication).

These results come from simulations using dynamical up and down quarks which are heavier than their physical values. As a result, the error bars on all the particles which decay strongly and are above their decay thresholds (the vector mesons and the Δ , for example) do not include the effect of coupling to the decay channels.

A more recent result by Ref. 40 goes farther, in that its simulations include the coupling of resonances to open channels in their analysis. Their plot of light hadron spectroscopy is shown in Fig. 14.7.

Flavor singlet mesons are at the frontier of lattice QCD calculations, because one must include the effects of "annihilation graphs," for the valence q and \bar{q} . Recently, the RBC and UKQCD collaborations, Ref. 6, have reported a calculation of the η and η' mesons, finding masses of 573(6) and 947(142) MeV, respectively. The singlet-octet mixing angle (in the conventions of Table 14.2) is $\theta_{lin}=-14.1(2.8)^{\circ}$.

The spectroscopy of mesons containing heavy quarks has become a truly high-precision endeavor. These simulations use Non-Relativistic QCD (NRQCD) or Heavy Quark Effective Theory (HQET), systematic expansions of the QCD Lagrangian in powers of the heavy quark velocity, or the heavy quark mass. Terms in the Lagrangian have obvious quark model analogs, but are derived directly from QCD. For example, the heavy quark potential is a derived quantity, extracted from simulations. Fig. 14.8 shows the mass spectrum for mesons containing at least one heavy (b or c) quark from Ref. 42 and Ref. 43.

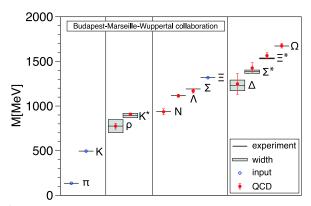

Figure 14.7: Light hadron spectroscopy from Ref. 40.

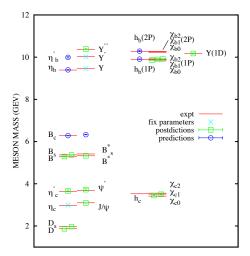

Figure 14.8: Spectroscopy for mesonic systems containing one or more heavy quarks (adapted from Ref. 42 and Ref. 43). Particles whose masses are used to fix lattice parameters are shown with crosses; the authors distinguish between "predictions" and "postdictions" of their calculation. Lines represent experiment.

The calculations uses a discretization of nonrelativistic QCD for bottom quarks with charm and lighter quarks being handled with an improved relativistic action. Three flavors of light dynamical quarks are included.

Finally, Fig. 14.9 shows recent lattice calculations of singly and double charmed baryons. Here we are at the forefront of theory and experiment.

Recall that lattice calculations take operators which are interpolating fields with quantum numbers appropriate to the desired states, compute correlation functions of these operators, and fit the correlation functions to functional forms parameterized by a set of masses and matrix elements. As we move away from hadrons which can be created by the simplest quark model operators (appropriate to the lightest meson and baryon multiplets) we encounter a host of new problems: either no good interpolating fields, or too many possible interpolating fields, and many states with the same quantum numbers. Techniques for dealing with these interrelated problems vary from collaboration to collaboration, but all share common features: typically, correlation functions from many different interpolating fields are used, and the signal is extracted in what amounts to a variational calculation using the chosen operator basis. In addition to mass spectra, wave function information can be garnered from the form of the best variational wave function. Of course, the same problems which are present in the spectroscopy of the lightest hadrons (the need to extrapolate to infinite volume, physical values of the light quark masses, and zero lattice spacing) are also present. We briefly touch on three different kinds of hadrons: excited states of baryons, glueballs,

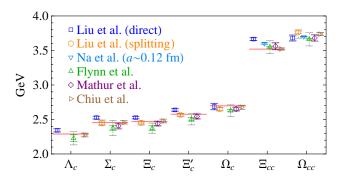

Figure 14.9: Lattice predictions for masses of charmed baryons. Data are Liu, et al., Ref. 44; Na et al., Ref. 45; Flynn et al., Ref. 46; Mathur et al., Ref. 47; and Chiu et al., Ref. 48. The first two references use full QCD; the latter three are quenched. Two mass extractions are taken from Ref. 44; the lighter (orange) circular points come from a calculation of mass splittings while the darker (blue) square points are from a direct mass extrapolation. Lines are from experiment.

and hybrid mesons. The quality of the data is not as good as for the ground states, and so the results continue to evolve.

Ref. 49 is a good recent review of excited baryon spectroscopy. The interesting physics questions to be addressed are precisely those enumerated in the last section. An example of a recent calculation, due to Ref. 50 is shown in Fig. 14.10. Notice that the pion is not yet at its physical value. The lightest positive parity state is the nucleon, and the Roper resonance has not yet appeared as a light state.

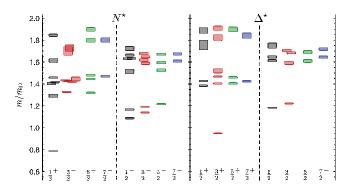

Figure 14.10: Spin-identified spectrum of nucleons and deltas, from lattices where $m_{\pi}=396$ MeV, in units of the calculated Ω mass, from Ref. 50. The colors just correspond to the different J assignments: grey for J=1/2, red for J=3/2, green for 5/2, blue for J=7/2.

Exotic mesons share the difficulties of ordinary excited states, and some recent calculations actually include both kinds of states in their combined fits. Ref. 51 provides a good summary of the theoretical and experimental situation regarding mesons with exotic quantum numbers, including a compilation of lattice data. The lightest exotics, the h_0, η_1 , and h_2 , have long been targets of lattice studies. Recently, the authors of Ref. 52 have presented new results for isoscalar and isovector meson spectroscopy, which observe the three states around 2 GeV. Again, the light quark masses in the simulations are higher than in nature; the pion is at 396 MeV.

Finally, glueballs. In Fig. 14.3 we showed a figure from Ref. 10 showing a lattice prediction for the glueball mass spectrum in quenched approximation. A true QCD prediction of the glueball spectrum requires dynamical light quarks and (because glueball operators are intrinsically noisy) high statistics. Only recently have the first useful such calculations appeared. Fig. 14.11 shows results from Ref. 53, done with dynamical $u,\ d$ and s quarks at two lattice spacings, 0.123 and 0.092 fm, along with comparisons to the quenched lattice calculation of Ref. 11 and to experimental isosinglet mesons.

The dynamical simulation is, of course, not the last word on this subject, but it shows that the effects of quenching seem to be small.

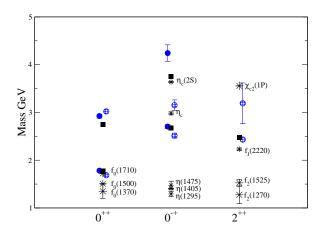

Figure 14.11: Lattice QCD predictions for glueball masses. The open and closed circles are the larger and smaller lattice spacing data of the full QCD calculation of glueball masses of Ref. 53. Squares are the quenched data for glueball masses of Ref. 11. The bursts labeled by particle names are experimental states with the appropriate quantum numbers.

15. GRAND UNIFIED THEORIES

Revised October 2011 by S. Raby (Ohio State University).

15.1. Grand Unification

15.1.1. Standard Model: An Introduction:

In spite of all the successes of the Standard Model [SM] it is unlikely to be the final theory. It leaves many unanswered questions. Why the local gauge interactions $SU(3)_C \times SU(2)_L \times U(1)_V$ and why 3 families of quarks and leptons? Moreover why does one family consist of the states $[Q, u^c, d^c; L, e^c]$ transforming as $[(3, 2, 1/3), (\bar{3}, 1, -4/3),$ $(\bar{3},1,2/3); (1,2,-1), (1,1,2)], \text{ where } Q=(u,d) \text{ and } L=(\nu,e) \text{ are }$ $SU(2)_L$ doublets and u^c , d^c , e^c are charge conjugate $SU(2)_L$ singlet fields with the $U(1)_Y$ quantum numbers given? [We use the convention that electric charge $Q_{EM} = T_{3L} + Y/2$ and all fields are left handed Weyl spinors.] Note the SM gauge interactions of quarks and leptons are completely fixed by their gauge charges. Thus if we understood the origin of this charge quantization, we would also understand why there are no fractionally charged hadrons. Finally, what is the origin of quark and lepton masses or the apparent hierarchy of family masses and quark and leptonic mixing angles? Perhaps if we understood this, we would also know the origin of CP violation, the solution to the strong CP problem, the origin of the cosmological matter - antimatter asymmetry. In addition, it lacks an explanation for the observed dark matter and dark energy of the universe.

The SM has 19 arbitrary parameters; their values are chosen to fit the data. Three arbitrary gauge couplings: g_3 , g, g' (where g, g' are the $SU(2)_L$, $U(1)_Y$ couplings, respectively) or equivalently $\alpha_s = (g_3^2/4\pi)$, $\alpha_{EM} = (e^2/4\pi)$ ($e = g \sin\theta_W$) and $\sin^2\theta_W = (g')^2/(g^2+(g')^2)$. In addition there are 13 parameters associated with the 9 charged fermion masses and the four mixing angles in the CKM matrix. The remaining 3 parameters are v, λ [the Higgs VEV and quartic coupling] (or equivalently M_Z , m_h^0) and the QCD θ parameter. In addition, data from neutrino oscillation experiments provide convincing evidence for neutrino masses. With 3 light Majorana neutrinos there are at least 9 additional parameters in the neutrino sector; 3 masses and 6 mixing angles and phases. In summary, the SM has too many arbitrary parameters and leaves open too many unresolved questions to be considered complete. These are the problems which grand unified theories hope to address.

15.1.2. Charge Quantization:

In the Standard Model, quarks and leptons are on an equal footing; both fundamental particles without substructure. It is now clear that they may be two faces of the same coin; unified, for example, by extending QCD (or $SU(3)_C$) to include leptons as the fourth color, $SU(4)_C$ [1]. The complete Pati-Salam gauge group is $SU(4)_C \times SU(2)_L \times SU(2)_R$ with the states of one family $[(Q,L),(Q^c,L^c)]$ transforming as $[(4,2,1),(\bar{4},1,\bar{2})]$ where $Q^c = (d^c,u^c),\ L^c = (e^c,\nu^c)$ are doublets under $SU(2)_R$. Electric charge is now given by the relation $Q_{EM} = T_{3L} + T_{3R} + 1/2(B-L)$ and $SU(4)_C$ contains the subgroup $SU(3)_C \times (B-L)$ where B(L) is baryon (lepton) number. Note ν^c has no SM quantum numbers and is thus completely "sterile". It is introduced to complete the $SU(2)_R$ lepton doublet. This additional state is desirable when considering neutrino masses.

Although quarks and leptons are unified with the states of one family forming two irreducible representations of the gauge group; there are still 3 independent gauge couplings (two if one also imposes parity, i.e. $L \leftrightarrow R$ symmetry). As a result the three low energy gauge couplings are still independent arbitrary parameters. This difficulty is resolved by embedding the SM gauge group into the simple unified gauge group, Georgi-Glashow SU(5), with one universal gauge coupling α_G defined at the grand unification scale M_G [2]. Quarks and leptons still sit in two irreducible representations, as before, with a $\mathbf{10} = [Q, u^c, e^c]$ and $\mathbf{\bar{5}} = [d^c, L]$. Nevertheless, the three low energy gauge couplings are now determined in terms of two independent parameters: α_G and M_G . Hence there is one prediction.

In order to break the electroweak symmetry at the weak scale and give mass to quarks and leptons, Higgs doublets are needed which can sit in either a ${\bf 5_H}$ or ${\bf \bar 5_H}$. The additional 3 states are color triplet Higgs scalars. The couplings of these color triplets violate baryon and

lepton number and nucleons decay via the exchange of a single color triplet Higgs scalar. Hence in order not to violently disagree with the non-observation of nucleon decay, their mass must be greater than $\sim 10^{11}$ GeV [3]. Moreover, in supersymmetric GUTs, in order to cancel anomalies as well as give mass to both up and down quarks, both Higgs multiplets $\mathbf{5_{H}}$, $\mathbf{\bar{5}_{H}}$ are required. As we shall discuss later, nucleon decay now constrains the color triplet Higgs states in a SUSY GUT to have mass significantly greater than M_G .

Complete unification is possible with the symmetry group SO(10)with one universal gauge coupling α_G and one family of quarks and leptons sitting in the 16 dimensional spinor representation $16 = [10 + \overline{5} + 1]$ [4]. The SU(5) singlet 1 is identified with ν^c . In Table 1 we present the states of one family of quarks and leptons, as they appear in the 16. It is an amazing and perhaps even profound fact that all the states of a single family of quarks and leptons can be represented digitally as a set of 5 zeros and/or ones or equivalently as the tensor product of 5 "spin" 1/2 states with $\pm = |\pm \frac{1}{2}>$ and with the condition that we have an even number of |+> spins. The first three "spins" correspond to $SU(3)_C$ color quantum numbers, while the last two are $SU(2)_L$ weak quantum numbers. In fact an $SU(3)_C$ rotation just raises one color index and lowers another, thereby changing colors $\{r,\ b,\ y\}$. Similarly an $SU(2)_L$ rotation raises one weak index and lowers another, thereby flipping the weak isospin from up to down or vice versa. In this representation weak hypercharge Y is given by the simple relation $Y = -2/3(\sum \text{ color spins}) + (\sum \text{ weak spins})$. SU(5)rotations [in particular, the ones NOT in $SU(3)_C \times SU(2)_L \times U(1)_Y$] then raise (or lower) a color index, while at the same time lowering (or raising) a weak index. It is easy to see that such rotations can mix the states $\{Q, u^c, e^c\}$ and $\{d^c, L\}$ among themselves and ν^c is a singlet. The new SO(10) rotations [not in SU(5)] are then given by either raising or lowering any two spins. For example, by raising the two weak indices ν^c rotates into e^c , etc.

Table 15.1: The quantum numbers of the ${\bf 16}$ dimensional representation of SO(10).

| State | Y | Color | Weak |
|----------------------|------|-------|------|
| $ u^c $ | 0 | | |
| e^c | 2 | | ++ |
| u_r | 1/3 | + | -+ |
| d_r | 1/3 | + | +- |
| $oldsymbol{u}_b$ | 1/3 | - + - | -+ |
| d_b | 1/3 | -+- | +- |
| $oldsymbol{u}_y$ | 1/3 | + | -+ |
| d_y | 1/3 | + | +- |
| $oldsymbol{u}_r^c$ | -4/3 | - + + | |
| \boldsymbol{u}_b^c | -4/3 | + - + | |
| $oldsymbol{u}_y^c$ | -4/3 | + + - | |
| d_r^c | 2/3 | -++ | ++ |
| $oldsymbol{d}_b^c$ | 2/3 | + - + | ++ |
| $oldsymbol{d}_y^c$ | 2/3 | + + - | ++ |
| ν | -1 | +++ | -+ |
| e | -1 | +++ | +- |

SO(10) has two inequivalent maximal breaking patterns. $SO(10) \rightarrow SU(5) \times U(1)_X$ and $SO(10) \rightarrow SU(4)_C \times SU(2)_L \times SU(2)_R$. In the first case we obtain Georgi-Glashow SU(5) if Q_{EM} is given in terms of SU(5) generators alone or so-called flipped SU(5) [5] if Q_{EM} is partly in $U(1)_X$. In the latter case we have the Pati-Salam symmetry. If SO(10) breaks directly to the SM at M_G , then we retain the prediction for gauge coupling unification. However more possibilities for breaking (hence more breaking scales and more parameters) are available in SO(10). Nevertheless with one breaking pattern $SO(10) \rightarrow SU(5) \rightarrow$ SM, where the last breaking scale is M_G , the predictions from gauge coupling unification are preserved. The Higgs multiplets in

minimal SO(10) are contained in the fundamental $\mathbf{10_H} = [\mathbf{5_H}, \ \mathbf{\bar{5}_H}]$ representation. Note, only in SO(10) does the gauge symmetry distinguish quark and lepton multiplets from Higgs multiplets.

Finally, larger symmetry groups have been considered. For example, E(6) has a fundamental representation ${\bf 27}$ which under SO(10) transforms as a $[{\bf 16+10+1}]$. The breaking pattern $E(6) \to SU(3)_C \times SU(3)_L \times SU(3)_R$ is also possible. With the additional permutation symmetry Z(3) interchanging the three SU(3)s we obtain so-called "trinification" [6] with a universal gauge coupling. The latter breaking pattern has been used in phenomenological analyses of the heterotic string [7]. However, in larger symmetry groups, such as E(6), SU(6), etc., there are now many more states which have not been observed and must be removed from the effective low energy theory. In particular, three families of ${\bf 27}$ s in E(6) contain three Higgs type multiplets transforming as ${\bf 10}$ s of SO(10). This makes these larger symmetry groups unattractive starting points for model building.

15.1.3. String Theory and Orbifold GUTs:

Orbifold compactification of the heterotic string [8-10], and recent field theoretic constructions known as orbifold GUTs [11], contain grand unified symmetries realized in 5 and 6 dimensions. However, upon compactifying all but four of these extra dimensions, only the MSSM is recovered as a symmetry of the effective four dimensional field theory. These theories can retain many of the nice features of four dimensional SUSY GUTs, such as charge quantization, gauge coupling unification and sometimes even Yukawa unification; while at the same time resolving some of the difficulties of 4d GUTs, in particular problems with unwieldy Higgs sectors necessary for spontaneously breaking the GUT symmetry, and problems with doublet-triplet Higgs splitting or rapid proton decay. We will comment further on the corrections to the four dimensional GUT picture due to orbifold GUTs in the following sections. Finally, recent progress has been made in finding MSSM-like theories in the string landscape. This success is made possible by incorporating SUSY GUTs at an intermediate step in the construction. For a brief discussion, see Sec. 15.1.

${\bf 15.1.4.} \quad \textit{Gauge coupling unification}:$

The biggest paradox of grand unification is to understand how it is possible to have a universal gauge coupling g_G in a grand unified theory [GUT] and yet have three unequal gauge couplings at the weak scale with $g_3 > g > g'$. The solution is given in terms of the concept of an effective field theory [EFT] [18]. The GUT symmetry is spontaneously broken at the scale M_G and all particles not in the SM obtain mass of order M_G . When calculating Green's functions with external energies $E \gg M_G$, we can neglect the mass of all particles in the loop and hence all particles contribute to the renormalization group running of the universal gauge coupling. However, for $E \ll M_G$ one can consider an effective field theory

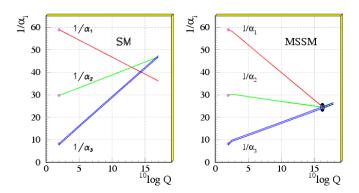

Figure 15.1: Gauge coupling unification in non-SUSY GUTs on the left vs. SUSY GUTs on the right using the LEP data as of 1991. Note, the difference in the running for SUSY is the inclusion of supersymmetric partners of standard model particles at scales of order a TeV (Fig. taken from Ref. 24). Given the present accurate measurements of the three low energy couplings, in particular $\alpha_s(M_Z)$, GUT scale threshold corrections are now needed to precisely fit the low energy data. The dark blob in the plot on the right represents these model dependent corrections.

including only the states with mass $< E \ll M_G$. The gauge symmetry of the EFT is $SU(3)_C \times SU(2)_L \times U(1)_Y$ and the three gauge couplings renormalize independently. The states of the EFT include only those of the SM; 12 gauge bosons, 3 families of quarks and leptons and one or more Higgs doublets. At M_G the two effective theories [the GUT itself is most likely the EFT of a more fundamental theory defined at a higher scale] must give identical results; hence we have the boundary conditions $g_3 = g_2 = g_1 \equiv g_G$ where at any scale $\mu < M_G$ we have $g_2 \equiv g$ and $g_1 = \sqrt{5/3} \ g'$. Then using two low energy couplings, such as $\alpha_s(M_Z)$, $\alpha_{EM}(M_Z)$, the two independent parameters α_G , M_G can be fixed. The third gauge coupling, $\sin^2\theta_W$ in this case, is then predicted. This was the procedure up until about 1991 [19,20]. Subsequently, the uncertainties in $\sin^2\theta_W$ were reduced ten fold. Since then, $\alpha_{EM}(M_Z)$, $\sin^2\theta_W$ have been used as input to predict α_G , M_G and $\alpha_s(M_Z)$ [21].

We emphasize that the above boundary condition is only valid when using one loop renormalization group [RG] running. With precision electroweak data, however, it is necessary to use two loop RG running. Hence one must include one loop threshold corrections to gauge coupling boundary conditions at both the weak and GUT scales. In this case it is always possible to define the GUT scale as the point where $\alpha_1(M_G) = \alpha_2(M_G) \equiv \tilde{\alpha}_G$ and $\alpha_3(M_G) = \tilde{\alpha}_G (1 + \epsilon_3)$. The threshold correction ϵ_3 is a logarithmic function of all states with mass of order M_G and $\tilde{\alpha}_G = \alpha_G + \Delta$ where α_G is the GUT coupling constant above M_G and Δ is a one loop threshold correction. Note, the popular code "SOFTSUSY" [22] has defined the GUT scale in just this way. The value of ϵ_3 can be read off from the output data. To the extent that gauge coupling unification is perturbative, the GUT threshold corrections are small and calculable. This presumes that the GUT scale is sufficiently below the Planck scale or any other strong coupling extension of the GUT, such as a strongly coupled string theory.

Supersymmetric grand unified theories [SUSY GUTs] are an extension of non-SUSY GUTs [23]. The key difference between SUSY GUTs and non-SUSY GUTs is the low energy effective theory. The low energy effective field theory in a SUSY GUT is assumed to satisfy N=1 supersymmetry down to scales of order the weak scale in addition to the SM gauge symmetry. Hence the spectrum includes all the SM states plus their supersymmetric partners. It also includes one pair (or more) of Higgs doublets; one to give mass to up-type quarks and the other to down-type quarks and charged leptons. Two doublets with opposite hypercharge Y are also needed to cancel fermionic triangle anomalies. Finally, it is important to recognize that a low energy SUSY breaking scale (the scale at which the SUSY partners of SM particles obtain mass) is necessary to solve the gauge hierarchy problem.

Also, in recent years there has been a great deal of progress in constructing three and four family models in Type IIA string theory with intersecting D6 branes [12]. Although these models can incorporate SU(5) or a Pati-Salam symmetry group in four dimensions, they typically have problems with gauge coupling unification. In the former case this is due to charged exotics which affect the RG running, while in the latter case the $SU(4)\times SU(2)_L\times SU(2)_R$ symmetry never unifies. Local models, however, with D-branes at singularities have had some more success in obtaining gauge coupling unification [13]. heterotic string theory models also exist whose low energy effective 4d field theory is a SUSY GUT [14]. These models have all the virtues and problems of 4d GUTs. Finally, many heterotic string models have been constructed with the standard model gauge symmetry in 4d and no intermediate GUT symmetry in less than 10d. Some minimal 3 family supersymmetric models have been constructed [15,16]. These theories may retain some of the symmetry relations of GUTs, however the unification scale would typically be the string scale, of order 5×10^{17} GeV, which is inconsistent with low energy data. A way out of this problem was discovered in the context of the strongly coupled heterotic string, defined in an effective 11 dimensions [17]. In this case the 4d Planck scale (which controls the value of the string scale) now unifies with the GUT scale.

Simple non-SUSY SU(5) is ruled out; initially by the increased accuracy in the measurement of $\sin^2 \theta_W$ and by early bounds on the proton lifetime (see below) [20]. However, by now LEP data [21] has conclusively shown that SUSY GUTs is the new standard model; by which we mean the theory used to guide the search for new physics beyond the present SM (see Fig. Fig. 15.1). SUSY extensions of the SM have the property that their effects decouple as the effective SUSY breaking scale is increased. Any theory beyond the SM must have this property simply because the SM works so well. However, the SUSY breaking scale cannot be increased with impunity, since this would reintroduce a gauge hierarchy problem. Unfortunately there is no clear-cut answer to the question, when is the SUSY breaking scale too high. A conservative bound would suggest that the third generation quarks and leptons must be lighter than about 1 TeV, in order that the one loop corrections to the Higgs mass from Yukawa interactions remains of order the Higgs mass bound itself.

At present gauge coupling unification within SUSY GUTs works extremely well. Exact unification at M_G , with two loop renormalization group running from M_G to M_Z , and one loop threshold corrections at the weak scale, fits to within 3 σ of the present precise low energy data. A small threshold correction at M_G ($\epsilon_3\sim$ - 3% to - 4%) is sufficient to fit the low energy data precisely [25,26,27]. 2 This may be compared to non-SUSY GUTs where the fit misses by \sim 12 σ and a precise fit requires new weak scale states in incomplete GUT multiplets or multiple GUT breaking scales. 3

Following the analysis of Ref. 27 let us try to understand the need for the GUT threshold correction and its order of magnitude. The renormalization group equations relate the low energy gauge coupling constants $\alpha_i(M_Z)$, i=1,2,3 to the value of the unification scale Λ_U and the GUT coupling α_U by the expression

$$\frac{1}{\alpha_i(M_Z)} = \frac{1}{\alpha_U} + \frac{b_i}{2\pi} \log\left(\frac{\Lambda_U}{M_Z}\right) + \delta_i \tag{15.1}$$

where Λ_U is the GUT scale evaluated at one loop and the threshold corrections, δ_i , are given by $\delta_i = \delta_i^{(2)} + \delta_i^{(l)} + \delta_i^{(g)}$ with $\delta_i^{(2)}$ representing two loop running effects, $\delta_i^{(l)}$ the light threshold corrections at the SUSY breaking scale and $\delta_i^{(g)} = \delta_i^{(h)} + \delta_i^{(b)}$ representing GUT scale threshold corrections. Note, in this analysis, the two loop RG running is treated on the same footing as weak and GUT scale threshold corrections. One then obtains the prediction

$$(\alpha_3(M_Z) - \alpha_3^{LO}(M_Z))/\alpha_3^{LO}(M_Z) = -\alpha_3^{LO}(M_Z) \delta_s$$
 (15.2)

where $\alpha_3^{LO}(M_Z)$ is the leading order one loop RG result and $\delta_s = \frac{1}{7}(5\delta_1 - 12\delta_2 + 7\delta_3)$ is the net threshold correction. [A similar formula applies at the GUT scale with the GUT threshold correction, ϵ_3 , given by $\epsilon_3 = -\tilde{\alpha}_G \ \delta_s^{(g)}$.] Given the experimental inputs [31,32]:

$$\begin{split} \alpha_{em}^{-1}(M_Z) &= 127.916 \pm 0.015 \\ \sin^2\!\theta_W(M_Z) &= 0.23116 \pm 0.00013 \\ \alpha_3(M_Z) &= 0.1184 \pm 0.0007 \end{split} \tag{15.3}$$

and taking into account the light threshold corrections, assuming an ensemble of 10 SUSY spectra [27](corresponding to the Snowmass benchmark points), we have

$$\alpha_3^{LO}(M_Z) \approx 0.118 \tag{15.4}$$

and

$$\begin{split} \delta_s^{(2)} &\approx -0.82 \\ \delta_s^{(l)} &\approx -0.50 + \frac{19}{28\pi} \log \frac{M_{SUSY}}{M_Z}. \end{split}$$

For $M_{SUSY}=1$ TeV, we have $\delta_s^{(2)}+\delta_s^{(l)}\approx-0.80$. Since the one loop result $\alpha_3^{LO}(M_Z)$ is very close to the experimental value, we need $\delta_s\approx0$ or equivalently, $\delta_s^{(g)}\approx0.80$. This corresponds, at the GUT scale, to $\epsilon_3\approx-3\%$. Note, this result depends implicitly on the assumption of universal soft SUSY breaking masses at the GUT scale, which directly affect the spectrum of SUSY particles at the weak scale. For example, if gaugino masses were not unified at M_G and, in particular, gluinos were lighter than winos at the weak scale, then it is possible that, due to weak scale threshold corrections, a much smaller or even slightly positive threshold correction at the GUT scale would be consistent with gauge coupling unification [34].

In four dimensional SUSY GUTs, the threshold correction ϵ_3 receives a positive contribution from Higgs doublets and triplets.⁴ Thus a larger, negative contribution must come from the GUT breaking sector of the theory. This is certainly possible in specific SO(10) [35] or SU(5) [36] models, but it is clearly a significant constraint on the 4d GUT sector of the theory. In five or six dimensional orbifold GUTs, on the other hand, the "GUT scale" threshold correction comes from the Kaluza-Klein modes between the compactification scale, M_c , and the effective cutoff scale M_* .⁵ Thus, in orbifold GUTs, gauge coupling unification at two loops is only consistent with the low energy data with a fixed value for M_c and M_* .6 Typically, one finds $M_c < M_G = 3 \times 10^{16}$ GeV, where M_G is the 4d GUT scale. Since the grand unified gauge bosons, responsible for nucleon decay, get mass at the compactification scale, the result $M_c < M_G$ for orbifold GUTs has significant consequences for nucleon decay.

A few final comments are in order. We do not consider the scenario of split supersymmetry [39] in this review. In this scenario squarks and sleptons have mass at a scale $\tilde{m}\gg M_Z$, while gauginos and Higgsinos have mass of order the weak scale. Gauge coupling unification occurs at a scale of order 10^{16} GeV, provided that the scale \tilde{m} lies in the range 10^3-10^{11} GeV [40]. A serious complaint concerning the split SUSY scenario is that it does not provide a solution to the gauge hierarchy problem. Moreover, it is only consistent with grand unification if it also postulates an "intermediate" scale, \tilde{m} , for scalar masses. In addition, it is in conflict with $b-\tau$ Yukawa unification, unless $\tan\beta$ is fine-tuned to be close to 1 [40]. 7

⁵ In string theory, the cutoff scale is the string scale.

² This result implicitly assumes universal GUT boundary conditions for soft SUSY breaking parameters at M_G . In the simplest case we have a universal gaugino mass $M_{1/2}$, a universal mass for squarks and sleptons m_{16} and a universal Higgs mass m_{10} , as motivated by SO(10). In some cases, threshold corrections to gauge coupling unification can be exchanged for threshold corrections to soft SUSY parameters. See for example, Ref. 28 and references therein.

 $^{^3}$ Non-SUSY GUTs with a more complicated breaking pattern can still fit the data. For example, non-SUSY $SO(10) \rightarrow SU(4)_C \times SU(2)_L \times SU(2)_R \rightarrow SM$ with the second breaking scale of order an intermediate scale, determined by light neutrino masses using the see-saw mechanism, can fit the low energy data for gauge couplings [29] and at the same time survive nucleon decay bounds [30], discussed in the following section.

 $^{^4}$ Note, the Higgs contribution is given by $\epsilon_3 = \frac{3\tilde{\alpha}_G}{5\pi}\log|\frac{\tilde{M}_t}{M_G}|$ where \tilde{M}_t is the effective color triplet Higgs mass (setting the scale for dimension 5 baryon and lepton number violating operators) and $\gamma = \lambda_b/\lambda_t$ at M_G . Since \tilde{M}_t is necessarily greater than M_G , the Higgs contribution to ϵ_3 is positive.

 $^{^6}$ It is interesting to note that a ratio $M_*/M_c \sim 100$, needed for gauge coupling unification to work in orbifold GUTs is typically the maximum value for this ratio consistent with perturbativity [37]. In addition, in orbifold GUTs brane-localized gauge kinetic terms may destroy the successes of gauge coupling unification. However, for values of $M_*/M_c = M_*\pi R \gg 1$ the unified bulk gauge kinetic terms can dominate over the brane-localized terms [38].

 $^{^7~}b-\tau$ Yukawa unification only works for $\tilde{m}<10^4$ for $\tan\beta\geq 1.5.$ This is because the effective theory between the gaugino mass scale and \tilde{m} includes only one Higgs doublet, as in the standard model. In this case, the large top quark Yukawa coupling tends to increase the ratio λ_b/λ_τ as one runs down in energy below \tilde{m} . This is opposite to what happens in MSSM where the large top quark Yukawa coupling decreases the ratio λ_b/λ_τ [41].

We have also neglected to discuss non-supersymmetric GUTs in four dimensions which still survive once one allows for several scales of GUT symmetry breaking [29]. Finally, it has been shown that non-supersymmetric GUTs in warped 5 dimensional orbifolds can be consistent with gauge coupling unification, assuming that the right-handed top quark and the Higgs doublets are composite-like objects with a compositeness scale of order a TeV [42]. However perturbative unification seems to fail.

15.1.5. Nucleon Decay:

Baryon number is necessarily violated in any GUT [43]. In SU(5), nucleons decay via the exchange of gauge bosons with GUT scale masses, resulting in dimension 6 baryon number violating operators suppressed by $(1/M_G^2)$. The nucleon lifetime is calculable and given by $\tau_N \propto M_G^4/(\alpha_G^2 m_p^5)$. The dominant decay mode of the proton (and the baryon violating decay mode of the neutron), via gauge exchange, is $p \to e^+ \pi^0$ $(n \to e^+ \pi^-)$. In any simple gauge symmetry, with one universal GUT coupling and scale (α_G, M_G) , the nucleon lifetime from gauge exchange is calculable. Hence, the GUT scale may be directly observed via the extremely rare decay of the nucleon. Experimental searches for nucleon decay began with the Kolar Gold Mine, Homestake, Soudan, NUSEX, Frejus, HPW, and IMB detectors [19]. The present experimental bounds come from Super-Kamiokande and Soudan II. We discuss these results shortly. Non-SUSY GUTs are also ruled out by the non-observation of nucleon decay [20]. In SUSY GUTs, the GUT scale is of order 3×10^{16} GeV, as compared to the GUT scale in non-SUSY GUTs which is of order 10^{15} GeV. Hence the dimension 6 baryon violating operators are significantly suppressed in SUSY GUTs [23] with $\tau_p \sim 10^{34-38}$ yrs.

However, in SUSY GUTs there are additional sources for baryon number violation – dimension 4 and 5 operators [44]. Although our notation does not change, when discussing SUSY GUTs all fields are implicitly chiral superfields and the operators considered are the so-called F terms which contain two fermionic components and the rest scalars or products of scalars. Within the context of SU(5) the dimension 4 and 5 operators have the form $(\mathbf{10}\ \mathbf{5}\ \mathbf{\bar{5}}) \supset (u^c\ d^c\ d^c) + (Q\ L\ d^c) + (e^c\ L\ L)$ and $(\mathbf{10}\ \mathbf{10}\ \mathbf{10}\ \mathbf{\bar{5}}) \supset (Q\ Q\ Q\ L) + (u^c\ u^c\ d^c\ e^c) + B$ and L conserving terms, respectively. The dimension 4 operators are renormalizable with dimensionless couplings; similar to Yukawa couplings. On the other hand, the dimension 5 operators have a dimensionful coupling of order $(1/M_G)$.

The dimension 4 operators violate baryon number or lepton number, respectively, but not both. The nucleon lifetime is extremely short if both types of dimension 4 operators are present in the low energy theory. However both types can be eliminated by requiring R parity. In SU(5) the Higgs doublets reside in a $\mathbf{5_H}$, $\mathbf{\bar{5}_H}$ and R parity distinguishes the $\mathbf{\bar{5}}$ (quarks and leptons) from $\mathbf{\bar{5}_H}$ (Higgs). R parity [45](or its cousin, family reflection symmetry (or matter parity) (see Dimopoulos and Georgi [23] and DRW [46]) takes $F \to -F$, $H \to H$ with $F = \{\mathbf{10}, \, \mathbf{\bar{5}}\}$, $H = \{\mathbf{\bar{5}_H}, \, \mathbf{5_H}\}$. This forbids the dimension 4 operator $(\mathbf{10} \, \mathbf{\bar{5}} \, \mathbf{\bar{5}})$, but allows the Yukawa couplings of the form $(\mathbf{10} \, \mathbf{\bar{5}} \, \mathbf{\bar{5}_H})$ and $(\mathbf{10} \, \mathbf{10} \, \mathbf{5_H})$. It also forbids the dimension 3, lepton number violating, operator $(\mathbf{\bar{5}} \, \mathbf{5_H}) \supset (L \, H_u)$ with a coefficient with dimensions of mass which, like the μ parameter, could be of order the weak scale and the dimension 5, baryon number violating, operator $(\mathbf{10} \, \mathbf{10} \, \mathbf{\bar{5}_H}) \supset (Q \, Q \, H_d) + \cdots$.

Note, in the MSSM it is possible to retain R parity violating operators at low energy as long as they violate either baryon number or lepton number only but not both. Such schemes are natural if one assumes a low energy symmetry, such as lepton number, baryon number, baryon triality [47] or proton hexality [48]. However these symmetries cannot be embedded in a GUT. Thus, in a SUSY GUT, only R parity can prevent all the dimension three and four baryon and lepton number violating operators. This does not mean to say that R parity is guaranteed to be satisfied in any GUT. For example the authors of Refs. [51,52] use constrained matter content to selectively generate safe effective R parity violating operators in a GUT. For a review on R parity violating interactions, see [53]. In Ref. [52], the authors show how to obtain the effective R parity violating operator $O^{ijk} = (\bar{5}^j \cdot \bar{5}^k)_{1\bar{5}} \cdot (10^i \cdot \Sigma)_{1\bar{5}}$ where Σ is an SU(5) adjoint field and the subscripts $\overline{15}$, 15 indicate that the product of fields in parentheses

have been projected into these SU(5) directions. As a consequence the operator O^{ijk} is symmetric under interchange of the two $\bar{\bf 5}$ states, $O^{ijk} = O^{ikj}$, and out of ${\bf 10} \ \bar{\bf 5} \ \bar{\bf 5}$ only the lepton number/R parity violating operator $QL\bar{D}$ survives.

Note also, R parity distinguishes Higgs multiplets from ordinary families. In SU(5), Higgs and quark/lepton multiplets have identical quantum numbers; while in E(6), Higgs and families are unified within the fundamental **27** representation. Only in SO(10) are Higgs and ordinary families distinguished by their gauge quantum numbers. Moreover the Z(4) center of SO(10) distinguishes **10**s from **16**s and can be associated with R parity [49].

Dimension 5 baryon number violating operators may be forbidden at tree level by symmetries in SU(5), etc. These symmetries are typically broken however by the VEVs responsible for the color triplet Higgs masses. Consequently these dimension 5 operators are generically generated via color triplet Higgsino exchange. Hence, the color triplet partners of Higgs doublets must necessarily obtain mass of order the GUT scale. [It is also important to note that Planck or string scale physics may independently generate dimension 5 operators, even without a GUT. These contributions must be suppressed by some underlying symmetry; for example, the same flavor symmetry which may be responsible for hierarchical fermion Yukawa matrices.]

The dominant decay modes from dimension 5 operators are $p \to K^+ \bar{\nu} \ (n \to K^0 \bar{\nu})$. This is due to a simple symmetry argument; the operators $(Q_i \ Q_j \ Q_k \ L_l)$, $(u_i^c \ u_j^c \ d_k^c \ e_l^c)$ (where i, j, k, l = 1, 2, 3 are family indices and color and weak indices are implicit) must be invariant under $SU(3)_C$ and $SU(2)_L$. As a result their color and weak doublet indices must be anti-symmetrized. However since these operators are given by bosonic superfields, they must be totally symmetric under interchange of all indices. Thus the first operator vanishes for i=j=k and the second vanishes for i=j. Hence a second or third generation member must exist in the final state [46].

Recent Super-Kamiokande bounds on the proton lifetime severely constrain these dimension 6 and 5 operators with (172.8 kt-yr) of data they find $\tau_{(p \to e^+ \pi^0)} > 1.0 \times 10^{34} \ {\rm yrs}, \ \tau_{(p \to K^+ \bar{\nu})} > 3.3 \times 10^{33} \ {\rm yrs}$ and $\tau_{(n \to e^+ \pi^-)} > 2 \times 10^{33} \ {\rm yrs}$ at (90% CL) [54]. These constraints are now sufficient to rule out minimal SUSY SU(5) [55]. 8 Non-minimal Higgs sectors in SU(5) or SO(10) theories still survive [26,36]. The upper bound on the proton lifetime from these theories are approximately a factor of 10 above the experimental bounds. They are also being pushed to their theoretical limits. Hence if SUSY GUTs are correct, then nucleon decay must be seen soon.

Is there a way out of this conclusion? Orbifold GUTs and string theories, see Sec. 15.1, contain grand unified symmetries realized in higher dimensions. In the process of compactification and GUT symmetry breaking, color triplet Higgs states are removed (projected out of the massless sector of the theory). In addition, the same projections typically rearrange the quark and lepton states so that the massless states which survive emanate from different GUT multiplets. In these models, proton decay due to dimension 5 operators can be severely suppressed or eliminated completely. However, proton decay due to dimension 6 operators may be enhanced, since the gauge bosons mediating proton decay obtain mass at the compactification scale, M_c , which is typically less than the 4d GUT scale (see the discussion at the end of Sec. 15.1), or suppressed, if the states of one family come from different irreducible representations. Which effect dominates is a model dependent issue. In some complete 5d orbifold
