POLARIZATION IN B DECAYS

Revised February 2012 by A. V. Gritsan (Johns Hopkins University) and J. G. Smith (University of Colorado at Boulder).

We review the notation used in polarization measurements in particle production and decay, with a particular emphasis on the B decays and the CP-violating observables in polarization measurements. We look at several examples of vector-vector and vector-tensor B meson decays, while more details about the theory and experimental results in B decays can be found in a separate mini-review [1] in this Review.

Figure 1 illustrates angular observables in an example of the sequential process $ab \to X \to P_1P_2 \to (p_{11}p_{12})(p_{21}p_{22})$ [2]. The angular distributions are of particular interest because they are sensitive to spin correlations and reveal properties of particles and their interactions, such as quantum numbers and couplings. In the case of a spin-zero particle X, such as Bmeson or a Higgs boson, there are no spin correlations in the production mechanism and the decay chain is to be analyzed. The angular distribution of decay products can be expressed as a function of three helicity angles which describe the alignment of the particles in the decay chain. The analyzer of the Bdaughter polarization is normally chosen for two-body decays, as the direction of the daughters in the center-of-mass of the parent $(e.g., \rho \to 2\pi)$ [3], and for three-body decays as the normal to the decay plane (e.g., $\omega \to 3\pi$) [4]. An equivalent set of transversity angles is sometimes used in polarization analyses [5]. The differential decay width depends on complex amplitudes $A_{\lambda_1\lambda_2}$, corresponding to the X-daughter helicity states λ_i .

In the case of a spin-zero B-meson decay, its daughter helicities are constrained to $\lambda_1=\lambda_2=\lambda$. Therefore we simplify amplitude notation as A_λ . Moreover, most B-decay polarization analyses are limited to the case when the spin of one of the B-meson daughters is 1. In that case, there are only three independent amplitudes corresponding to $\lambda=0$ or ± 1 [6], where the last two can be expressed in terms of parity-even and parity-odd amplitudes $A_{\parallel,\perp}=(A_{+1}\pm A_{-1})/\sqrt{2}$. The overall decay amplitude involves three complex terms proportional to the above amplitudes and the Wigner d functions of helicity angles. The exact angular dependence would depend on the quantum numbers of the B-meson daughters and of their decay products, and can be found in the literature [6,7]. The

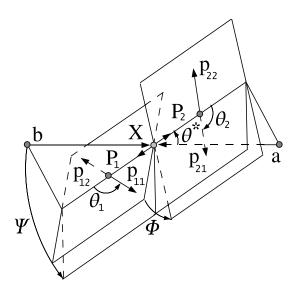

Figure 1: Definition of the production and helicity angles in the sequential process $ab \to X \to P_1P_2 \to (p_{11}p_{12})(p_{21}p_{22})$. The three helicity angles include θ_1 and θ_2 , defined in the rest frame of the two daughters P_1 and P_2 , and Φ , defined in the X frame as the angle between the two decay planes. The two production angles θ^* and Ψ are defined in the X frame, where Ψ is the angle between the production plane and the average of the two decay planes.

differential decay rate would involve six real quantities α_i , including interference terms,

$$\frac{d\Gamma}{\Gamma d\cos\theta_1 d\cos\theta_2 d\Phi} = \sum_i \alpha_i f_i (\cos\theta_1, \cos\theta_2, \Phi), \quad (1)$$

where each $f_i(\cos \theta_1, \cos \theta_2, \Phi)$ has unique angular dependence specific to particle quantum numbers, and the α_i parameters are defined as:

$$\alpha_1 = \frac{|A_0|^2}{\sum |A_1|^2} = f_L \,, \tag{2}$$

$$\alpha_2 = \frac{|A_{\parallel}|^2 + |A_{\perp}|^2}{\sum |A_{\lambda}|^2} = (1 - f_L), \qquad (3)$$

$$\alpha_3 = \frac{|A_{\parallel}|^2 - |A_{\perp}|^2}{\sum |A_{\lambda}|^2} = (1 - f_L - 2f_{\perp}), \tag{4}$$

$$\alpha_4 = \frac{\Im m(A_{\perp}A_{\parallel}^*)}{\Sigma |A_{\lambda}|^2} = \sqrt{f_{\perp}(1 - f_L - f_{\perp})} \sin(\phi_{\perp} - \phi_{\parallel}), \quad (5)$$

$$\alpha_5 = \frac{\Re e(A_{\parallel} A_0^*)}{\Sigma |A_{\lambda}|^2} = \sqrt{f_L \left(1 - f_L - f_{\perp}\right)} \cos(\phi_{\parallel}), \qquad (6)$$

$$\alpha_6 = \frac{\Im m(A_\perp A_0^*)}{\Sigma |A_\lambda|^2} = \sqrt{f_\perp f_L} \sin(\phi_\perp), \qquad (7)$$

where the amplitudes have been expressed with the help of polarization parameters f_L , f_\perp , ϕ_\parallel , and ϕ_\perp defined in Table 1. Note that the terms proportional to $\Re e(A_\perp A_\parallel^*)$, $\Im m(A_\parallel A_0^*)$, and $\Re e(A_\perp A_0^*)$ are absent in Eqs. (2-7). However, these terms may appear for some three-body decays of a B-meson daughter, see Ref. 7.

Table 1: Rate, polarization, and CP-asymmetry parameters defined for the B-meson decays to mesons with non-zero spin. Numerical examples are shown for the $B^0 \to \varphi K^*(892)^0$ decay. The first six parameters are defined under the assumption of no CP violation in decay, while they are averaged between the \overline{B} and B parameters in general. The last six parameters involve differences between the \overline{B} and B meson decay parameters. The phase convention δ_0 is chosen with respect to a single A_{00} amplitude from a reference B decay mode, which is $B^0 \to \varphi K_0^*(1430)^0$ for numerical results.

| parameter | definition | average |
|--------------------------|---------------------------------------------------------------|--------------------------------|
| \mathcal{B} | $\Gamma/\Gamma_{\rm total}$ | $(9.8 \pm 0.6) \times 10^{-6}$ |
| f_L | $ A_0 ^2/\Sigma A_\lambda ^2$ | 0.480 ± 0.030 |
| f_{\perp} | $ A_{\perp} ^2/\Sigma A_{\lambda} ^2$ | 0.24 ± 0.05 |
| $\phi_{\parallel}-\pi$ | $arg(A_{\parallel}/A_0) - \pi$ | -0.74 ± 0.13 |
| $\phi_{\perp} - \pi$ | $arg(A_{\perp}/A_0) - \pi$ | -0.75 ± 0.13 |
| $\delta_0 - \pi$ | $\arg(A_{00}/A_0) - \pi$ | -0.32 ± 0.17 |
| A_{CP} | $(\bar{\Gamma} - \Gamma)/(\bar{\Gamma} + \Gamma)$ | $+0.01 \pm 0.05$ |
| A_{CP}^0 | $(\bar{f_L}-f_L)/(\bar{f_L}+f_L)$ | $+0.04\pm0.06$ |
| A_{CP}^{\perp} | $(\bar{f}_{\perp} - f_{\perp})/(\bar{f}_{\perp} + f_{\perp})$ | -0.11 ± 0.12 |
| $\Delta\phi_{\parallel}$ | $(ar{\phi_{\parallel}} - \phi_{\parallel})/2$ | $+0.11 \pm 0.22$ |
| $\Delta\phi_{\perp}$ | $(\bar{\phi_{\perp}} - \phi_{\perp} - \pi)/2$ | $+0.08 \pm 0.22$ |
| $\Delta \delta_0$ | $(\bar{\delta_0} - \delta_0)/2$ | $+0.27 \pm 0.16$ |

Overall, six real parameters describe three complex amplitudes A_0 , A_{\parallel} , and A_{\perp} . These could be chosen to be the four polarization parameters f_L , f_{\perp} , ϕ_{\parallel} , and ϕ_{\perp} , one overall size normalization, such as decay rate Γ , or branching fraction \mathcal{B} , and one overall phase δ_0 . The phase convention is arbitrary for an isolated B decay mode. However, for several B decays, the relative phase could produce meaningful and observable effects through interference with other B decays with the same final states, such as for $B \to VK_J^*$ with $J=0,1,2,3,4,\ldots$ The phase could be referenced to the single $B \to VK_0^*$ amplitude A_{00} in such a case, as shown in Table 1. Here V stands for any spin-one vector meson.

Moreover, CP violation can be tested in the angular distribution of the decay as the difference between the B and \overline{B} . Each of the six real parameters describing the three complex amplitudes would have a counterpart CP-asymmetry term, corresponding to three direct-CP asymmetries in three amplitudes, and three CP-violating phase differences, equivalent to the phase measurements from the mixing-induced CP asymmetries in the time evolution of B-decays [1]. In Table 1 and Ref. 8, these are chosen to be the direct-CP asymmetries in the overall decay rate \mathcal{A}_{CP} , in the f_L fraction \mathcal{A}_{CP}^0 , and in the f_\perp fraction \mathcal{A}_{CP}^1 , and three weak phase differences:

$$\Delta \phi_{\parallel} = \frac{1}{2} \arg(\bar{A}_{\parallel} A_0 / A_{\parallel} \bar{A}_0),$$
 (8)

$$\Delta \phi_{\perp} = \frac{1}{2} \arg(\bar{A}_{\perp} A_0 / A_{\perp} \bar{A}_0) - \frac{\pi}{2}, \qquad (9)$$

 B^0

$$\Delta \delta_0 = \frac{1}{2} \arg(\bar{A}_{00} A_0 / A_{00} \bar{A}_0). \tag{10}$$

The $\frac{\pi}{2}$ term in Eq. (9) reflects the fact that A_{\perp} and \bar{A}_{\perp} differ in phase by π if CP is conserved. The two parameters $\Delta\phi_{\parallel}$ and $\Delta\phi_{\perp}$ are equivalent to triple-product asymmetries constructed from the vectors describing the decay angular distribution [9]. The CP-violating phase difference in the reference decay mode [8] is, in the Wolfenstein CKM quark-mixing phase convention,

$$\Delta\phi_{00} = \frac{1}{2}\arg(A_{00}/\bar{A}_{00}). \tag{11}$$

This can be measured only together with the mixing-induced phase difference for some of the neutral *B*-meson decays similar to other mixing-induced *CP* asymmetry measurements [1].

It may not always be possible to have a phase-reference decay mode which would define δ_0 and $\Delta\delta_0$ parameters. In that case, it may be possible to define the phase difference directly similarly to Eq. (11):

$$\Delta \phi_0 = \frac{1}{2} \arg(A_0/\bar{A}_0) \,.$$
 (12)

One can measure the angles of the CKM unitarity triangle, assuming Standard Model contributions to the $\Delta\phi_0$ and B-mixing phases. Examples include measurements of $\beta=\phi_1$ with $B\to J/\psi K^*$ and $\alpha=\phi_2$ with $B\to\rho\rho$.

Most of the B decays that arise from tree-level $b \rightarrow c$ transitions have the amplitude hierarchy $|A_0| > |A_+| > |A_-|$ which is expected from analyses based on quark-helicity conservation [10]. The larger the mass of the vector-meson daughters, the weaker the inequality. The B meson decays to heavy vector particles with charm, such as $B \to J/\psi K^*$, $\psi(2S)K^*$, $\chi_{c1}K^*$, $D^*\rho$, D^*K^* , D^*D^* , and $D^*D^*_s$, show a substantial fraction of the amplitudes corresponding to transverse polarization of the vector mesons $(A_{\pm 1})$, in agreement with the factorization prediction. The detailed amplitude analysis of the $B \to J/\psi K^*$ decays has been performed by the BABAR [11], Belle [12], CDF [13], CLEO [14], and D0 [15] collaborations. Most analyses are performed under the assumption of the absence of direct CP violation. The parameter values are given in the particle listing of this Review. The difference between the strong phases ϕ_{\parallel} and ϕ_{\perp} deviates significantly from zero. The recent measurements [11,12] of CP-violating terms similar to those in $B \to \varphi K^*$ [8] shown in Table 1 are consistent with zero.

In addition, the mixing-induced CP-violating asymmetry is measured in the $B^0 \to J/\psi K^{*0}$ decay [1,11,12] where angular analysis allows one to separate CP-eigenstate amplitudes. This allows one to resolve the sign ambiguity of the $\cos 2\beta$ ($\cos 2\phi_1$) term that appears in the time-dependent angular distribution due to interference of parity-even and parity-odd terms. This analysis relies on the knowledge of discrete ambiguities in the strong phases ϕ_{\parallel} and ϕ_{\perp} , as discussed below. The BABAR experiment used a method based on the dependence on the $K\pi$ invariant mass of the interference between the S- and P-waves to resolve the discrete ambiguity in the determination of the

strong phases $(\phi_{\parallel}, \phi_{\perp})$ in $B \to J/\psi K^*$ decays [11]. The result is in agreement with the amplitude hierarchy expectation [10]. The CDF [16], D0 [17], and LHCb [18] experiments have studied the $B_s^0 \to J/\psi \varphi$ decay and provided the lifetime, polarization, and phase measurements.

The amplitude hierarchy $|A_0| \gg |A_+| \gg |A_-|$ was expected in B decays to light vector particles in both penguin transitions [19,20] and tree-level transitions [10]. There is confirmation by the BABAR and Belle experiments of predominantly longitudinal polarization in the tree-level $b \to u$ transition, such as $B^0 \to \rho^+ \rho^-$ [21], $B^+ \to \rho^0 \rho^+$ [22], and $B^+ \to \omega \rho^+$ [23]; this is consistent with the analysis of the quark helicity conservation [10]. Because the longitudinal amplitude dominates the decay, a detailed amplitude analysis is not possible with current B samples, and limits on the transverse amplitude fraction are obtained. The fraction of transverse polarization is large in decays to heavier mesons such as $B^0 \to a_1(1260)^+ a_1(1260)^-$ [24]. Only limits have been set for $B^0 \to \omega \rho^0, \omega \omega$ [23]; there is some evidence for $B^0 \to \rho^0 \rho^0$ [25] decays. The small values for these branching fractions indicates that $b \to d$ penguin pollution is small in the charmless, strangeless vector-vector B decays.

The interest in the polarization and CP-asymmetry measurements in penguin transition, such as $b \rightarrow s$ decays $B \to \varphi K^*, \ \rho K^*, \ \omega K^*, \ {\rm or} \ B^0_s \to \varphi \varphi, \ {\rm and} \ b \to d \ {\rm decay}$ $B \to K^*K^*$, is motivated by their potential sensitivity to physics beyond the Standard Model. The decay amplitudes for $B \to \varphi K^*$ have been measured by the BABAR and Belle experiments [8,26,27]. The fractions of longitudinal polarization are $f_L = 0.50 \pm 0.05$ for the $B^+ \rightarrow \varphi K^{*+}$ decay and $f_L = 0.48 \pm 0.03$ for the $B^0 \to \varphi K^{*0}$ decay. These indicate significant departure from the naive expectation of predominant longitudinal polarization, suggesting other contributions to the decay amplitude, previously neglected, either within the Standard Model, such as penguin annihilation [28] or QCD rescattering [29], or from physics beyond the Standard Model [30]. The complete set of twelve amplitude parameters measured in the $B^0 \to \varphi K^{*0}$ decay is given in Table 1. Several other parameters could be constructed from the above twelve parameters, as suggested in Ref. 31.

The discrete ambiguity in the phase $(\phi_{\parallel}, \phi_{\perp}, \Delta\phi_{\parallel}, \Delta\phi_{\perp})$ measurements has been resolved by BABAR in favor of $|A_{+}| \gg |A_{-}|$ through interference between the S- and P-waves of $K\pi$. The search for vector-tensor and vector-axial vector $B \to \varphi K_{J}^{(*)}$ decays with J=1,2,3,4 revealed a large fraction of longitudinal polarization in the decay $B \to \varphi K_{2}^{*}(1430)$ with $f_{L}=0.90_{-0.07}^{+0.06}$ [8,32], but large contribution of transverse amplitude in $B \to \varphi K_{1}(1270)$ with $f_{L}=0.46_{-0.15}^{+0.13}$ [33].

Like $B \to \varphi K^*$, the decays $B \to \rho K^*$ and $B \to \omega K^*$ may be sensitive to New Physics. Measurements of the longitudinal polarization fraction in $B^+ \to \rho^0 K^{*0}$, $B^+ \to \rho^+ K^{*0}$ [34] and in both vector-vector and vector-tensor final states of $B \to \omega K_J^*$ [23] reveal a large fraction of transverse polarization, indicating an anomaly similar to $B \to \varphi K^*$ except for a different

pattern in vector-tensor final states. A large transverse polarization is also observed in the $B^0_s \to \varphi \varphi$ decays by CDF [37] and $B^0_s \to K^{*0} \bar{K}^{*0}$ decays by LHCb [36]. At the same time, first measurement of the polarization in the $b \to d$ penguin decays $B \to K^* \bar{K}^*$ indicates a large fraction of longitudinal polarization [35]. The polarization pattern in penguin-dominated B-meson decays is not fully understood [28,29,30].

The three-body semileptonic B-meson decays, such as $B \to V\ell_1\ell_2$, share many features with the two-body $B \to VV$ decays. Their differential decay width can be parameterized with the two helicity angles defined in the V and $(\ell_1\ell_2)$ frames and with the azimuthal angle, as defined in Fig. 1. However, since the $(\ell_1\ell_2)$ pair does not come from an on-shell particle, the angular distribution is unique to each point in the dilepton mass $m_{\ell\ell}$ spectrum. The polarization measurements as a function of $m_{\ell\ell}$ provide complementary information on physics beyond the Standard Model, as discussed for $B \to K^*\ell^+\ell^-$ decay in Ref. 38. The current data in this mode has been analyzed by the BABAR, Belle, and CDF experiments [39].

The examples of the angular distributions and observables in $B \to K^* \ell^+ \ell^-$ are discussed in Ref. 38. Typically two angular observables have been measured in this decay in certain ranges of the dilepton mass $m_{\ell\ell}$ [39]. One parameter is the fraction of longitudinal polarization F_L , which is determined by the K^* angular distribution and is similar to f_L defined for exclusive two-body decays. The other parameter is the forward-backward asymmetry of the lepton pair A_{FB} , which is the asymmetry of the decay rate with positive and negative values of $\cos \theta_1$.

In summary, there has been considerable recent interest in the polarization measurements of B-meson decays because they reveal both weak- and strong-interaction dynamics [28–30,40]. New measurements will further elucidate the pattern of spin alignment measurements in rare B decays, and further test the Standard Model and strong interaction dynamics, including the non-factorizable contributions to the B-decay amplitudes.

POLARIZATION IN BO DECAY

In decays involving two vector mesons, one can distinguish among the states in which meson polarizations are both longitudinal (L) or both are transverse and parallel (||) or perpendicular (\perp) to each other with the parameters Γ_L/Γ , Γ_\perp/Γ , and the relative phases ϕ_\parallel and ϕ_\perp . See the definitions in the note on "Polarization in B Decays" review in the $B^{\,0}$

$B^0-\overline{B}^0$ MIXING

Updated April 2012 by O. Schneider (Ecole Polytechnique Fédérale de Lausanne).

There are two neutral $B^0-\overline{B}^0$ meson systems, $B^0_d-\overline{B}^0_d$ and $B^0_s-\overline{B}^0_s$ (generically denoted $B^0_q-\overline{B}^0_q$, q=s,d), which exhibit particle-antiparticle mixing [1]. This mixing phenomenon is described in Ref. 2. In the following, we adopt the notation introduced in Ref. 2, and assume CPT conservation throughout. In each system, the light (L) and heavy (H) mass eigenstates,

$$|B_{\rm L,H}\rangle = p|B_q^0\rangle \pm q|\overline{B}_q^0\rangle,$$
 (1)

have a mass difference $\Delta m_q = m_{\rm H} - m_{\rm L} > 0$, and a total decay width difference $\Delta \Gamma_q = \Gamma_{\rm L} - \Gamma_{\rm H}$. In the absence of CP violation in the mixing, |q/p| = 1, these differences are given by $\Delta m_q = 2|M_{12}|$ and $|\Delta \Gamma_q| = 2|\Gamma_{12}|$, where M_{12} and Γ_{12} are the

off-diagonal elements of the mass and decay matrices [2]. The evolution of a pure $|B_q^0\rangle$ or $|\overline{B}_q^0\rangle$ state at t=0 is given by

$$|B_q^0(t)\rangle = g_+(t) |B_q^0\rangle + \frac{q}{p} g_-(t) |\overline{B}_q^0\rangle \,, \tag{2}$$

$$|\overline{B}_{q}^{0}(t)\rangle = g_{+}(t)|\overline{B}_{q}^{0}\rangle + \frac{p}{a}g_{-}(t)|B_{q}^{0}\rangle, \qquad (3)$$

which means that the flavor states remain unchanged (+) or oscillate into each other (-) with time-dependent probabilities proportional to

$$|g_{\pm}(t)|^2 = \frac{e^{-\Gamma_q t}}{2} \left[\cosh\left(\frac{\Delta\Gamma_q}{2}t\right) \pm \cos(\Delta m_q t) \right],$$
 (4)

where $\Gamma_q = (\Gamma_{\rm H} + \Gamma_{\rm L})/2$. In the absence of CP violation, the time-integrated mixing probability $\int |g_-(t)|^2 dt/(\int |g_-(t)|^2 dt + \int |g_+(t)|^2 dt)$ is given by

$$\chi_q = \frac{x_q^2 + y_q^2}{2(x_q^2 + 1)}, \quad \text{where} \quad x_q = \frac{\Delta m_q}{\Gamma_q}, \quad y_q = \frac{\Delta \Gamma_q}{2\Gamma_q}.$$
 (5)

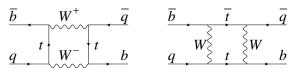

Figure 1: Dominant box diagrams for the $B_q^0 \to \overline{B}_q^0$ transitions (q = d or s). Similar diagrams exist where one or both t quarks are replaced with c or u quarks.

Standard Model predictions and phenomenology

In the Standard Model, the transitions $B_q^0 \to \overline{B}_q^0$ and $\overline{B}_q^0 \to B_q^0$ are due to the weak interaction. They are described, at the lowest order, by box diagrams involving two W bosons and two up-type quarks (see Fig. 1), as is the case for $K^0 - \overline{K}^0$ mixing. However, the long range interactions arising from intermediate virtual states are negligible for the neutral B meson systems, because the large B mass is off the region of hadronic resonances. The calculation of the dispersive and absorptive parts of the box diagrams yields the following predictions for the off-diagonal element of the mass and decay matrices [3],

$$\begin{split} M_{12} &= -\frac{G_F^2 m_W^2 \eta_B m_{B_q} B_{B_q} f_{B_q}^2}{12 \pi^2} \, S_0(m_t^2 / m_W^2) \, (V_{tq}^* V_{tb})^2 \,, \qquad (6) \\ \Gamma_{12} &= \frac{G_F^2 m_b^2 \eta_B' m_{B_q} B_{B_q} f_{B_q}^2}{8 \pi} \\ &\quad \times \left[(V_{tq}^* V_{tb})^2 + V_{tq}^* V_{tb} V_{cq}^* V_{cb} \, \mathcal{O} \left(\frac{m_c^2}{m_b^2} \right) \right. \\ &\quad \left. + (V_{cq}^* V_{cb})^2 \, \mathcal{O} \left(\frac{m_c^4}{m_b^4} \right) \right] \,, \end{split}$$

where G_F is the Fermi constant, m_W the W boson mass, and m_i the mass of quark i; m_{B_q} , f_{B_q} and B_{B_q} are the B_q^0 mass, weak decay constant and bag parameter, respectively. The known function $S_0(x_t)$ can be approximated very well by $0.784 \, x_t^{0.76} \, [4]$, and V_{ij} are the elements of the CKM matrix [5].

The QCD corrections η_B and η_B' are of order unity. The only non-negligible contributions to M_{12} are from box diagrams involving two top quarks. The phases of M_{12} and Γ_{12} satisfy

$$\phi_M - \phi_\Gamma = \pi + \mathcal{O}\left(\frac{m_c^2}{m_b^2}\right), \tag{8}$$

implying that the mass eigenstates have mass and width differences of opposite signs. This means that, like in the $K^0 - \overline{K}{}^0$ system, the heavy state is expected to have a smaller decay width than that of the light state: $\Gamma_{\rm H} < \Gamma_{\rm L}$. Hence, $\Delta \Gamma = \Gamma_{\rm L} - \Gamma_{\rm H}$ is expected to be positive in the Standard Model.

Furthermore, the quantity

$$\left| \frac{\Gamma_{12}}{M_{12}} \right| \simeq \frac{3\pi}{2} \frac{m_b^2}{m_W^2} \frac{1}{S_0(m_t^2/m_W^2)} \sim \mathcal{O}\left(\frac{m_b^2}{m_t^2}\right)$$
 (9)

is small, and a power expansion of $|q/p|^2$ yields

$$\left|\frac{q}{p}\right|^2 = 1 + \left|\frac{\Gamma_{12}}{M_{12}}\right| \sin(\phi_M - \phi_\Gamma) + \mathcal{O}\left(\left|\frac{\Gamma_{12}}{M_{12}}\right|^2\right). \tag{10}$$

Therefore, considering both Eqs. (8) and (9), the CP-violating parameter

$$1 - \left| \frac{q}{p} \right|^2 \simeq \operatorname{Im} \left(\frac{\Gamma_{12}}{M_{12}} \right) \tag{11}$$

is expected to be very small: $\sim \mathcal{O}(10^{-3})$ for the $B_d^0 - \overline{B}_d^0$ system and $\lesssim \mathcal{O}(10^{-4})$ for the $B_s^0 - \overline{B}_s^0$ system [6].

In the approximation of negligible CP violation in mixing, the ratio $\Delta\Gamma_q/\Delta m_q$ is equal to the small quantity $|\Gamma_{12}/M_{12}|$ of Eq. (9); it is hence independent of CKM matrix elements, *i.e.*, the same for the $B_d^0-\overline{B}_d^0$ and $B_s^0-\overline{B}_s^0$ systems. Calculations [7] yield $\sim 5\times 10^{-3}$ with a $\sim 20\%$ uncertainty. Given the published experimental knowledge [8] on the mixing parameter x_q

$$\begin{cases} x_d = 0.770 \pm 0.008 & (B_d^0 - \overline{B}_d^0 \text{ system}) \\ x_s = 26.49 \pm 0.29 & (B_o^0 - \overline{B}_o^0 \text{ system}) \end{cases} , \tag{12}$$

the Standard Model thus predicts that $\Delta\Gamma_d/\Gamma_d$ is very small (below 1%), but $\Delta\Gamma_s/\Gamma_s$ considerably larger (\sim 10%). These width differences are caused by the existence of final states to which both the B_q^0 and \overline{B}_q^0 mesons can decay. Such decays involve $b \to c\overline{c}q$ quark-level transitions, which are Cabibbosuppressed if q=d and Cabibbo-allowed if q=s.

A complete set of Standard Model predictions for all mixing parameters in both the $B_d^0 - \overline{B}_d^0$ and $B_s^0 - \overline{B}_s^0$ systems can be found in Ref. 7.

$\label{lem:experimental} Experimental \ issues \ and \ methods \ for \ oscillation \ analyses$

Time-integrated measurements of B^0 – \overline{B}^0 mixing were published for the first time in 1987 by UA1 [9] and ARGUS [10], and since then by many other experiments. These measurements are typically based on counting same-sign and opposite-sign lepton pairs from the semileptonic decay of the produced $b\overline{b}$ pairs. Such analyses cannot easily separate the contributions from the different b-hadron species, therefore, the clean environment of $\Upsilon(4S)$ machines (where only B_d^0 and charged B_u mesons are produced) is in principle best suited to measure χ_d .

However, better sensitivity is obtained from time-dependent analyses aiming at the direct measurement of the oscillation frequencies Δm_d and Δm_s , from the proper time distributions of B_d^0 or B_s^0 candidates identified through their decay in (mostly) flavor-specific modes, and suitably tagged as mixed or unmixed. This is particularly true for the $B_s^0 - \overline{B}_s^0$ system, where the large value of x_s implies maximal mixing, i.e., $\chi_s \simeq 1/2$. In such analyses, the B_d^0 or B_s^0 mesons are either fully reconstructed, partially reconstructed from a charm meson, selected from a lepton with the characteristics of a $b \to \ell^-$ decay, or selected from a reconstructed displaced vertex. At high-energy colliders (LEP, SLC, Tevatron, LHC), the proper time $t = \frac{m_B}{L}$ is measured from the distance L between the production vertex and the B decay vertex, and from an estimate of the Bmomentum p. At asymmetric B factories (KEKB, PEP-II), producing $e^+e^- \to \Upsilon(4S) \to B_d^0 \overline{B}_d^0$ events with a boost $\beta \gamma$ (=0.425, 0.55), the proper time difference between the two B candidates is estimated as $\Delta t \simeq \frac{\Delta z}{\beta \gamma c}$, where Δz is the spatial separation between the two B decay vertices along the boost direction. In all cases, the good resolution needed on the vertex positions is obtained with silicon detectors.

The average statistical significance \mathcal{S} of a B_d^0 or B_s^0 oscillation signal can be approximated as [11]

$$S \approx \sqrt{N/2} f_{\text{sig}} (1 - 2\eta) e^{-(\Delta m \sigma_t)^2/2}, \qquad (13)$$

where N is the number of selected and tagged candidates, $f_{\rm sig}$ is the fraction of signal in that sample, η is the total mistag probability, and σ_t is the resolution on proper time (or proper time difference). The quantity \mathcal{S} decreases very quickly as Δm increases; this dependence is controlled by σ_t , which is therefore a critical parameter for Δm_s analyses. At high-energy colliders, the proper time resolution $\sigma_t \sim \frac{m_B}{\langle p \rangle} \sigma_L \oplus t \frac{\sigma_p}{p}$ includes a constant contribution due to the decay length resolution σ_L (typically 0.04–0.3 ps), and a term due to the relative momentum resolution σ_p/p (typically 10–20% for partially reconstructed decays), which increases with proper time. At B factories, the boost of the B mesons is estimated from the known beam energies, and the term due to the spatial resolution dominates (typically 1–1.5 ps because of the much smaller B boost).

In order to tag a B candidate as mixed or unmixed, it is necessary to determine its flavor both in the initial state and in the final state. The initial and final state mistag probabilities, η_i and η_f , degrade \mathcal{S} by a total factor $(1-2\eta)=(1-2\eta_i)(1-2\eta_f)$. In lepton-based analyses, the final state is tagged by the charge of the lepton from $b \to \ell^-$ decays; the largest contribution to η_f is then due to $\overline{b} \to \overline{c} \to \ell^-$ decays. Alternatively, the charge of a reconstructed charm meson $(D^{*-}$ from B_d^0 or D_s^- from B_s^0), or that of a kaon hypothesized to come from a $b \to c \to s$ decay [12], can be used. For fully-inclusive analyses based on topological vertexing, final-state tagging techniques include jetcharge [13] and charge-dipole [14,15] methods. At high-energy colliders, the methods to tag the initial state (i.e., the state at production), can be divided into two groups: the ones that tag

R

the initial charge of the \overline{b} quark contained in the B candidate itself (same-side tag), and the ones that tag the initial charge of the other b quark produced in the event (opposite-side tag). On the same side, the sign of a charged pion or kaon from the primary vertex is correlated with the production state of the B_d^0 or B_s^0 if that particle is a decay product of a B^{**} state or the first in the fragmentation chain [16,17]. Jet- and vertexcharge techniques work on both sides and on the opposite side, respectively. Finally, the charge of a lepton from $b \to \ell^-$ or of a kaon from $b \to c \to s$ can be used as opposite side tags, keeping in mind that their performance is degraded due to integrated mixing. At SLC, the beam polarization produced a sizeable forward-backward asymmetry in the $Z \to b\overline{b}$ decays, and provided another very interesting and effective initial state tag based on the polar angle of the B candidate [14]. Initial state tags have also been combined to reach $\eta_i \sim 26\%$ at LEP [17,18], or even 22% at SLD [14] with full efficiency. In the case $\eta_f = 0$, this corresponds to an effective tagging efficiency $Q = \epsilon D^2 = \epsilon (1 - 2\eta)^2$, where ϵ is the tagging efficiency, in the range 23 - 31%. The equivalent figure achieved by CDF during Tevatron Run I was $\sim 3.5\%$ [19], reflecting the fact that tagging is more difficult at hadron colliders. The current CDF and DØ analyses of Tevatron Run II data reach $\epsilon D^2 = (1.8 \pm 0.1)\%$ [20] and $(2.5 \pm 0.2)\%$ [21] for opposite-side tagging, while same-side kaon tagging (for B_s^0 analyses) is contributing an additional 3.7-4.8% at CDF [20], and pushes the combined performance to $(4.7 \pm 0.5)\%$ at DØ [22]. LHCb, operating in the forward region at the LHC where the environment is different in terms of track multiplicity and b-hadron production kinematics, has reported $\epsilon D^2 = (2.10 \pm 0.25)\%$ [23] for opposite-side tagging and $(1.3 \pm 0.4)\%$ [24] for same-side kaon tagging.

At B factories, the flavor of a B_d^0 meson at production cannot be determined, since the two neutral B mesons produced in a $\Upsilon(4S)$ decay evolve in a coherent P-wave state where they keep opposite flavors at any time. However, as soon as one of them decays, the other follows a time-evolution given by Eqs. (2) or (3), where t is replaced with Δt (which will take negative values half of the time). Hence, the "initial state" tag of a B can be taken as the final-state tag of the other B. Effective tagging efficiencies Q of 30% are achieved by BaBar and Belle [25], using different techniques including $b \to \ell^-$ and $b \to c \to s$ tags. It is worth noting that, in this case, mixing of the other B (i.e., the coherent mixing occurring before the first B decay) does not contribute to the mistag probability.

In the absence of experimental observation of a decaywidth difference, oscillation analyses typically neglected $\Delta\Gamma$ in Eq. (4), and described the data with the physics functions $\Gamma e^{-\Gamma t} (1 \pm \cos(\Delta m t))/2$ (high-energy colliders) or $\Gamma e^{-\Gamma |\Delta t|} (1 \pm \cos(\Delta m \Delta t))/4$ (asymmetric $\Upsilon(4S)$ machines). As can be seen from Eq. (4), a non-zero value of $\Delta\Gamma$ would effectively reduce the oscillation amplitude with a small time-dependent factor that would be very difficult to distinguish from time resolution effects. Measurements of Δm are usually extracted from the data using a maximum likelihood fit.

Δm_d and $\Delta \Gamma_d$ measurements

Many $B_d^0 - \overline{B}_d^0$ oscillations analyses have been published [26] by the ALEPH [27], DELPHI [15,28], L3 [29], OPAL [30,31] BaBar [32], Belle [33], CDF [16], DØ [21], and LHCb [34] collaborations. Although a variety of different techniques have been used, the individual Δm_d results obtained at high-energy colliders have remarkably similar precision. Their average is compatible with the recent and more precise measurements from asymmetric B factories. The systematic uncertainties are not negligible; they are often dominated by sample composition, mistag probability, or b-hadron lifetime contributions. Before being combined, the measurements are adjusted on the basis of a common set of input values, including the b-hadron lifetimes and fractions published in this Review. Some measurements are statistically correlated. Systematic correlations arise both from common physics sources (fragmentation fractions, lifetimes, branching ratios of b hadrons), and from purely experimental or algorithmic effects (efficiency, resolution, tagging, background description). Combining all published measurements [15,16,21,27-34] and accounting for all identified correlations yields $\Delta m_d = 0.507 \pm 0.003 \text{(stat)} \pm 0.003 \text{(syst)} \text{ ps}^{-1}$ [8], a result dominated by the B factories.

On the other hand, ARGUS and CLEO have published time-integrated measurements [35–37], which average to $\chi_d=0.182\pm0.015$. Following Ref. 37, the width difference $\Delta\Gamma_d$ could in principle be extracted from the measured value of Γ_d and the above averages for Δm_d and χ_d (see Eq. (5)), provided that $\Delta\Gamma_d$ has a negligible impact on the Δm_d measurements. However, direct time-dependent studies published by DELPHI [15], BaBar [38] and Belle [39] provide stronger constraints, which can be combined to yield [8]

$$sign(Re\lambda_{CP})\Delta\Gamma_{d}/\Gamma_{d} = 0.015 \pm 0.018$$
,

where $sign(Re\lambda_{CP}) = +1$ is expected in the Standard Model.

Assuming $\Delta\Gamma_d=0$ and no CP violation in mixing, and using the measured B_d^0 lifetime of 1.519 ± 0.007 ps, the Δm_d and χ_d results are combined to yield the world average

$$\Delta m_d = 0.507 \pm 0.004 \text{ ps}^{-1}$$
 (14)

or, equivalently,

$$\chi_d = 0.1862 \pm 0.0023 \,. \tag{15}$$

This Δm_d value provides an estimate of $2|M_{12}|$, and can be used with Eq. (6) to extract $|V_{td}|$ within the Standard Model [40]. The main experimental uncertainties on the result come from m_t and Δm_d , but are completely negligible with respect to the uncertainty due to the hadronic matrix element $f_{B_d}\sqrt{B_{B_d}} = 211 \pm 12$ MeV obtained from lattice QCD calculations [41].

Δm_s and $\Delta \Gamma_s$ measurements

After many years of intense search at LEP and SLC, $B_s^0 - \overline{B}_s^0$ oscillations were first observed in 2006 by CDF using 1 fb⁻¹ of Tevatron Run II data [20]. A year later DØ reported an independent preliminary evidence using 2.4 fb⁻¹ of data [46]. Recently LHCb obtained the most precise results

using 0.036 fb⁻¹ [34] and 0.34 fb⁻¹ [24] of data collected at the LHC in 2010 and 2011, respectively. While the average of the published measurements of Δm_s [20,34] is

$$\Delta m_s = 17.69 \pm 0.08 \text{ ps}^{-1},$$
 (16)

including also the preliminary LHCb measurement [24] and taking systematic correlations into account yields

$$\Delta m_s = 17.719 \pm 0.036(\text{stat}) \pm 0.023(\text{syst}) \text{ ps}^{-1}$$
. (17)

The information on $|V_{ts}|$ obtained in the framework of the Standard Model is hampered by the hadronic uncertainty, as in the B_d^0 case. However, several uncertainties cancel in the frequency ratio

$$\frac{\Delta m_s}{\Delta m_d} = \frac{m_{B_s}}{m_{B_d}} \xi^2 \left| \frac{V_{ts}}{V_{td}} \right|^2 \,, \tag{18}$$

where $\xi = (f_{B_s}\sqrt{B_{B_s}})/(f_{B_d}\sqrt{B_{B_d}}) = 1.237 \pm 0.032$ is an SU(3) flavor-symmetry breaking factor obtained from lattice QCD calculations [41]. Using the measurements of Eqs. (14) and (16), one can extract

$$\left| \frac{V_{td}}{V_{ts}} \right| = 0.2111 \pm 0.0010 \text{(exp)} \pm 0.0055 \text{(lattice)},$$
 (19)

in good agreement with (but much more precise than) the value obtained from the ratio of the $b \to d\gamma$ and $b \to s\gamma$ transition rates observed at the B factories [40].

The CKM matrix can be constrained using experimental results on observables such as Δm_d , Δm_s , $|V_{ub}/V_{cb}|$, ϵ_K , and $\sin(2\beta)$ together with theoretical inputs and unitarity conditions [40,47,48]. The constraint from our knowledge on the ratio $\Delta m_s/\Delta m_d$ is more effective in limiting the position of the apex of the CKM unitarity triangle than the one obtained from the Δm_d measurements alone, due to the reduced hadronic uncertainty in Eq. (18). We also note that the measured value of Δm_s is consistent with the Standard Model prediction obtained from CKM fits where no experimental information on Δm_s is used, e.g., $19.0 \pm 1.5 \text{ ps}^{-1}$ [47] or $18.1^{+2.2}_{-2.1} \text{ ps}^{-1}$ [48].

Information on $\Delta\Gamma_s$ can be obtained from the study of the proper time distribution of untagged B_s^0 samples [49]. In the case of an inclusive B_s^0 selection [50], or a semileptonic (or flavor-specific) B_s^0 decay selection [18,51], both the shortand long-lived components are present, and the proper time distribution is a superposition of two exponentials with decay constants $\Gamma_{L,H} = \Gamma_s \pm \Delta \Gamma_s/2$. In principle, this provides sensitivity to both Γ_s and $(\Delta \Gamma_s/\Gamma_s)^2$. Ignoring $\Delta \Gamma_s$ and fitting for a single exponential leads to an estimate of Γ_s with a relative bias proportional to $(\Delta \Gamma_s/\Gamma_s)^2$. An alternative approach, which is directly sensitive to first order in $\Delta\Gamma_s/\Gamma_s$, is to determine the effective lifetime of untagged B_s^0 candidates decaying to (fairly pure) CP eigenstates; measurements exist for $B_s^0 \to D_s^{(*)+} D_s^{(*)-}$ [52], $B_s^0 \to K^+ K^-$ [53], and $B_s^0 \to J/\psi f_0(980)$ [54]. The extraction of $1/\Gamma_s$ and $\Delta\Gamma_s$ from such measurements, discussed in detail in Ref. [55], requires additional information in the form of theoretical assumptions

or external inputs on weak phases and hadronic parameters. In what follows, only the effective lifetimes from the decays to the pure CP eigenstates K^+K^- and $J/\psi f_0(980)$ will be used, under the assumption that these decays are dominated by a single weak phase.

The best sensitivity to $1/\Gamma_s$ and $\Delta\Gamma_s$ is achieved by the recent time-dependent measurements of the $B_s^0 \to J/\psi \phi$ decay rates performed at CDF [56,57], DØ [58] and LHCb [59,60], where the CP-even and CP-odd amplitudes are separated statistically through a full angular analysis. In particular LHCb obtained the first observation of a non-zero value of $\Delta\Gamma_s$ [60]. These studies use both untagged and tagged B_s^0 candidates and are optimized for the measurement of the CP-violating phase ϕ_s , defined as the weak phase difference between the $B_s^0 - \overline{B}_s^0$ mixing amplitude and the $b \to c\overline{c}s$ decay amplitude. The Standard Model prediction for ϕ_s , if Penguin pollution is neglected, is equal to $-2\beta_s = -2\arg(-(V_{ts}V_{th}^*)/(V_{cs}V_{ch}^*)) =$ $-0.0363^{\,+0.0016}_{\,-0.0015}$ [48]. With a Gaussian constraint on ϕ_s to this Standard Model expectation, a combination [8] of the published $B_s^0 \to J/\psi \phi$ analyses [56,58,59] and of the lifetime measurements with flavor-specific [18,51] and pure CP [53,54] final states yields

$$\Delta\Gamma_s = +0.100 \pm 0.013 \text{ ps}^{-1}$$
 and $1/\Gamma_s = 1.497 \pm 0.015 \text{ ps}$, (20)

or, equivalently,

$$1/\Gamma_{\rm L} = 1.393 \pm 0.019 \ {\rm ps}$$
 and $1/\Gamma_{\rm H} = 1.618 \pm 0.024 \ {\rm ps} \, ,$ (21)

in good agreement with the Standard Model prediction $\Delta\Gamma_s = 0.087 \pm 0.021~{\rm ps}^{-1}$ [7].

The positive sign of $\Delta\Gamma_s$ is due to the constraint applied on ϕ_s . In absence of such constraint, there would be two mirror solutions related by the transformation $(\Delta\Gamma_s,\phi_s)\to (-\Delta\Gamma_s,\pi-\phi_s)$. Recently the LHCb collaboration analyzed the $B^0_s\to J/\psi K^+K^-$ decay, considering that the K^+K^- system can be in a P-wave or S-wave state, and measured the dependence of the strong phase difference between the P-wave and S-wave amplitudes as a function of the K^+K^- invariant mass [61]. This allowed, for the first time, the unambiguous determination of the sign of $\Delta\Gamma_s$, which was found to be positive at the 4.7 σ level.

Independent estimates of $\Delta\Gamma_s/\Gamma_s$ obtained from measurements of the $B_s^0 \to D_s^{(*)+} D_s^{(*)-}$ branching fractions [52,62] are no longer included in the average, since they are based on the questionable [7] assumption that these decays account for all CP-even final states.

Average b-hadron mixing probability and b-hadron production fractions at high energy

Mixing measurements can significantly improve our knowledge on the fractions f_u , f_d , f_s , and f_{baryon} , defined as the fractions of B_u , B_d^0 , B_s^0 , and b-baryons in an unbiased sample of weakly decaying b hadrons produced in high-energy collisions.

R

Indeed, time-integrated mixing analyses using lepton pairs from $b\bar{b}$ events at high energy measure the quantity

$$\overline{\chi} = f_d' \chi_d + f_s' \chi_s \,, \tag{22}$$

where f'_d and f'_s are the fractions of B^0_d and B^0_s hadrons in a sample of semileptonic b-hadron decays. Assuming that all b hadrons have the same semileptonic decay width implies $f'_q = f_q/(\Gamma_q \tau_b)$ (q = s, d), where τ_b is the average b-hadron lifetime. Hence $\overline{\chi}$ measurements performed at LEP [63] and Tevatron [64,65,66], together with the χ_d average of Eq. (15) and the very good approximation $\chi_s = 1/2$ (in fact $\chi_s = 0.499292 \pm 0.000016$ from Eqs. (5), (16) and (20)), provide constraints on the fractions f_d and f_s . In what follows, we use the preliminary $\overline{\chi}$ result from CDF [65] instead of the published one [64]. Averages based on published data only can be found in the full listings of this Review.

The LEP experiments have measured $\mathcal{B}(\bar{b} \to B_s^0) \times \mathcal{B}(B_s^0 \to B_s^0)$ $D_s^-\ell^+\nu_\ell X)$ [67], $\mathcal{B}(b\to\Lambda_b^0)\times\mathcal{B}(\Lambda_b^0\to\Lambda_c^+\ell^-\overline{\nu}_\ell X)$ [68], and $\mathcal{B}(b \to \Xi_b^-) \times \mathcal{B}(\Xi_b^- \to \Xi^- \ell^- \overline{\nu}_\ell X)$ [69] from partially reconstructed final states including a lepton, f_{baryon} from protons identified in b events [70], and the production rate of charged b hadrons [71]. The b-hadron fraction ratios measured at CDF are based on double semileptonic $K^*\mu\mu$ and $\phi\mu\mu$ final states [72] and lepton-charm final states [73]; in addition CDF and DØ have both measured strange b-baryon production [74]. On the other hand, fraction ratios have been studied by LHCb using fully reconstructed hadronic B_s^0 and B_d^0 decays [75], as well as semileptonic decays [76]. Both CDF and LHCb observe that the ratio $f_{\Lambda_i^0}/(f_u+f_d)$ decreases with the transverse momentum of the lepton+charm system, indicating that the b-hadron fractions are not the same in different environments. We therefore provide sets of fractions separately for LEP and Tevatron (and no complete set for LHCb, where strange bbaryon production has not been measured yet). A combination of all the available information under the constraints $f_u = f_d$, $f_u + f_d + f_s + f_{\text{baryon}} = 1$, and Eq. (22), yields the averages shown in Table 1.

Table 1: $\overline{\chi}$ and b-hadron fractions (see text).

| | in Z decays [8] | at Tevatron [8] | at LHCb [76] |
|-------------------|---------------------|-------------------|---------------------------|
| $\overline{\chi}$ | 0.1259 ± 0.0042 | 0.127 ± 0.008 | |
| $f_u = f_d$ | 0.403 ± 0.009 | 0.330 ± 0.030 | |
| f_s | 0.103 ± 0.009 | 0.103 ± 0.012 | |
| $f_{ m baryon}$ | 0.090 ± 0.015 | 0.236 ± 0.067 | |

$CP\mbox{-}violation\ studies$

Evidence for CP violation in $B_q^0 - \overline{B}_q^0$ mixing has been searched for, both with flavor-specific and inclusive B_q^0 decays, in samples where the initial flavor state is tagged, usually with a lepton from the other b-hadron in the event. In the

case of semileptonic (or other flavor-specific) decays, where the final-state tag is also available, the following asymmetry [2]

$$\mathcal{A}_{\mathrm{SL}}^{q} = \frac{N(\overline{B}_{q}^{0}(t) \to \ell^{+}\nu_{\ell}X) - N(B_{q}^{0}(t) \to \ell^{-}\overline{\nu}_{\ell}X)}{N(\overline{B}_{q}^{0}(t) \to \ell^{+}\nu_{\ell}X) + N(B_{q}^{0}(t) \to \ell^{-}\overline{\nu}_{\ell}X)} \simeq 1 - |q/p|_{q}^{2}$$

$$\tag{23}$$

has been measured either in time-integrated analyses at CLEO [37,77], CDF [78] and DØ [79], or in time-dependent analyses at LEP [31,80], BaBar [38,81], Belle [82] and DØ [83]. In the inclusive case, also investigated at LEP [80,84], no final-state tag is used, and the asymmetry [85]

$$\frac{N(B_q^0(t) \to \text{all}) - N(\overline{B}_q^0(t) \to \text{all})}{N(B_q^0(t) \to \text{all}) + N(\overline{B}_q^0(t) \to \text{all})}$$

$$\simeq \mathcal{A}_{\text{SL}}^q \left[\frac{x_q}{2} \sin(\Delta m_q t) - \sin^2\left(\frac{\Delta m_q t}{2}\right) \right] \tag{24}$$

must be measured as a function of the proper time to extract information on ${\cal CP}$ violation.

The DØ collaboration measures a like-sign dimuon charge asymmetry in semileptonic b decays that deviates by $3.9\,\sigma$ from the Standard Model prediction [79]. In all other cases, asymmetries compatible with zero (and the Standard Model) have been found, with a precision limited by the available statistics. Most of the analyses at high energy don't disentangle the B^0_d and B^0_s contributions, and either quote a mean asymmetry or a measurement of $\mathcal{A}^d_{\rm SL}$ assuming $\mathcal{A}^s_{\rm SL}=0$: we no longer include these in the average. An exception is the latest dimuon DØ analysis [79], which separates the two contributions by exploiting their dependence on the muon impact parameter cut. The resulting measurements of $\mathcal{A}^d_{\rm SL}$ and $\mathcal{A}^s_{\rm SL}$ are then both compatible with the Standard Model. They are also correlated. We therefore perform a two-dimensional average of all published measurements [37,38,77,79,81–83] and obtain [8]

$$\mathcal{A}_{SL}^d = -0.0033 \pm 0.0033$$
, or $|q/p|_d = 1.0017 \pm 0.0017$, (25)

$$\mathcal{A}_{SL}^{s} = -0.0105 \pm 0.0064$$
, or $|q/p|_{s} = 1.0052 \pm 0.0032$, (26)

with a correlation coefficient of -0.57 between $\mathcal{A}_{\mathrm{SL}}^d$ and $\mathcal{A}_{\mathrm{SL}}^s$. These results show no evidence of CP violation and don't constrain yet the Standard Model.

CP violation induced by $B_s^0 - \overline{B}_s^0$ mixing in $b \to c\bar{c}s$ decays has been a field of very active study in the past couple of years. In addition to the previously mentioned $B_s^0 \to J/\psi \phi$ studies, the recently observed CP-odd decay mode $B_s^0 \to J/\psi f_0(980)$, $f_0(980) \to \pi^+\pi^-$ has also been analyzed by LHCb to measure ϕ_s , without the need for an angular analysis [86]. A two-dimensional fit [8] of all published analyses [56,58,59,86] in the $(\phi_s, \Delta\Gamma_s)$ plane, shown on Fig. 2, yields $\phi_s = -0.14^{+0.16}_{-0.11}$. This is consistent with the Standard Model expectation, although with a large uncertainty. The fit is then repeated, but using the external constraint provided by the measured semileptonic asymmetry of Eq. (26), which depends on $\Delta\Gamma_s$ and on the mixing phase difference $\phi_M - \phi_\Gamma - \pi = \arg(-M_{12}/\Gamma_{12})$ of Eq. (8). Since New Physics is expected to affect $\arg(-M_{12}/\Gamma_{12})$

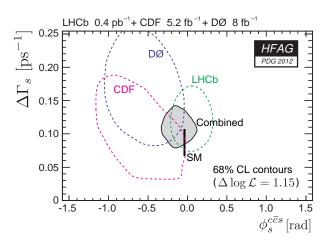

Figure 2: 68% CL contours in the $(\phi_s, \Delta\Gamma_s)$ plane, showing the measurements from CDF [56], DØ [58] and LHCb [59,86], with their combination [8]. The unphysical mirror solution with $\Delta\Gamma_s < 0$ [61] is not shown. The thin rectangle represents the Standard Model predictions of ϕ_s [48] and $\Delta\Gamma_s$ [7].

and ϕ_s in the same way, the constraint is implemented under the assumption that a new phase in B_s^0 mixing would not change the difference $\arg(-M_{12}/\Gamma_{12}) - \phi_s$ from its Standard Model value [7]. The result is [8]

$$\phi_s = -0.17^{+0.14}_{-0.11}, \tag{27}$$

still not showing any sign of CP violation or New Physics. The precision on this average will soon improve significantly. Indeed it does not include yet the preliminary updates of CDF [57] and LHCb [60], nor a new preliminary LHCb measurement using $B_s^0 \to J/\psi \pi^+ \pi^-$ decays [87]. The LHCb preliminary combined value is $\phi_s = -0.002 \pm 0.083 ({\rm stat}) \pm 0.027 ({\rm syst})$ [60].

Summary

 $B^0-\overline{B}^0$ mixing has been and still is a field of intense study. While relatively little experimental progress was achieved in the B_d^0 sector during the past years, impressive new B_s^0 results became available from CDF, DØ and LHCb. The mass difference in the $B_s^0 - \overline{B}_s^0$ system is now known to a relative precision which is significantly better than that in the B_d^0 \overline{B}_d^0 system. The non-zero decay width difference in the $B_s^0 - \overline{B}_s^0$ system is now firmly established, with a relative difference of $(15 \pm 2)\%$. Its sign has been determined: the heavy state of the $B_s^0 - \overline{B}_s^0$ system lives longer than the light state. In contrast, the relative decay width difference in the $B_d^0 - \overline{B}_d^0$ system, $(1.5 \pm 1.8)\%$, is still consistent with zero. CP violation in mixing has not been observed yet, with precisions on the semileptonic asymmetries below 1%. A quantum step has been achieved in the measurement of the mixing-induced phase ϕ_s in B_s^0 decays proceeding through the $b \to c\bar{c}s$ transition, with a Gaussian uncertainty reaching the 0.1 radian level. Despite these significant improvements, all observations remain consistent with the Standard Model expectations.

However, the measurements where New Physics might show up are still statistically limited. More results are expected in the future, especially from LHCb in the B_s^0 sector, with promising prospects for the investigation of the CP-violating phase $\arg(-M_{12}/\Gamma_{12})$ and an expected uncertainty on ϕ_s of ~ 0.05 radian by the time of the next edition of this *Review*.

Mixing studies have clearly reached the stage of precision measurements, where much effort is needed, both on the experimental and theoretical sides, in particular to further reduce the hadronic uncertainties of lattice QCD calculations. In the long term, a stringent check of the consistency of the B_d^0 and B_s^0 mixing amplitudes (magnitudes and phases) with all other measured flavor-physics observables will be possible within the Standard Model, leading to very tight limits on (or otherwise a long-awaited surprize about) New Physics.

B⁰-B⁰ MIXING PARAMETERS

For a discussion of $B^0-\overline{B}^0$ mixing see the note on " $B^0-\overline{B}^0$ Mixing" in the B^0 Particle Listings above.

 χ_d is a measure of the time-integrated $B^0 extstyle - \overline{B}{}^0$ mixing probability that a produced $B^0(\overline{B}^0)$ decays as a $\overline{B}^0(B^0)$. Mixing violates $\Delta B \neq 2$ rule.

$$\chi_d = \frac{x_d^2}{2(1+x_d^2)}$$

$$x_d = \frac{\Delta m_{B^0}}{\Gamma_{B^0}} = (m_{B^0_H} - m_{B^0_L}) \ \tau_{B^0} \ ,$$

where H, L stand for heavy and light states of two B^0 CP eigenstates and $\tau_{B^0}=\frac{1}{0.5(\Gamma_{B^0_H}+\Gamma_{B^0_L})}$.

This B^0 - \overline{B}^0 mixing parameter is the probability (integrated over time) that a produced B^0 (or \overline{B}^0) decays as a \overline{B}^0 (or B^0), e.g. for inclusive lepton decays $\chi_d = \Gamma(B^0 \to \ell^- X \text{ (via } \overline{B}^0))/\Gamma(B^0 \to \ell^\pm X)$

$$\chi_d = \Gamma(B^0 \to \ell^- X \text{ (via } \overline{B}^0)) / \Gamma(B^0 \to \ell^{\pm} X)$$

$$= \Gamma(\overline{B}^0 \to \ell^+ X \text{ (via } B^0)) / \Gamma(\overline{B}^0 \to \ell^{\pm} X)$$

 $\begin{array}{l} \chi_{\overline{G}} = \Gamma(\overline{B}^0 \to \ell^+ X \text{ (via } B^0))/\Gamma(\overline{B}^0 \to \ell^\pm X) \\ \text{Where experiments have measured the parameter } r = \chi/(1-\chi), \text{ we have converted to} \end{array}$ χ . Mixing violates the $\Delta B \neq 2$ rule.

Note that the measurement of χ at energies higher than the $\varUpsilon(4S)$ have not separated χ_d from χ_S where the subscripts indicate $B^0(\overline{b}d)$ or $B_S^0(\overline{b}s)$. They are listed in the $B^{\pm}/B^0/B_S^0/b$ -baryon ADMIXTURE section.

The experiments at $\Upsilon(4S)$ make an assumption about the $B^0\overline{B}{}^0$ fraction and about the ratio of the B^\pm and B^0 semileptonic branching ratios (usually that it equals one).

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account correlations between the measurements, includes χ_d calculated from Δm_{B^0} and au_{B^0} .

¹BEHRENS 00B uses high-momentum lepton tags and partially reconstructed \overline{B}^0 \rightarrow $D^{*+}\pi^-$, ρ^- decays to determine the flavor of the B meson.

 2 ALBRECHT 94 reports $\it r$ =0.194 \pm 0.062 \pm 0.054. We convert to $\it \chi$ for comparison. Uses tagged events (lepton + pion from D^*).

 3 BARTELT 93 analysis performed using tagged events (lepton+pion from D^*). Using dilepton events they obtain 0.157 \pm 0.016 $^+_{-}0.028$

⁴ ALBRECHT 92L is a combined measurement employing several lepton-based techniques. It uses all previous ARGUS data in addition to new data and therefore supersedes ALBRECHT 87i. A value of $r=20.6\pm7.0\%$ is directly measured. The value can be used to measure $x=\Delta M/\Gamma=0.72\pm0.15$ for the B_d meson. Assumes $f_{+-}/f_0=1.0\pm0.05$ and uses $\tau_{B^{\pm}}/\tau_{B^0} = (0.95 \pm 0.14) (f_{+-}/f_0)$

5 Uses D^{*+} K^{\pm} correlations. 6 Uses $(D^{*+}\ell^{-})$ K^{\pm} correlations.

 $^{7}\,\mathrm{These}$ experiments see a combination of B_{S} and B_{d} mesons.

⁸ ALBRECHT 871 is inclusive measurement with like-sign dileptons, with tagged *B* decays plus leptons, and one fully reconstructed event. Measures r=0.21 \pm 0.08. We convert to χ for comparison. Superseded by ALBRECHT 92L.

 9 BEAN 87B measured $r < \,$ 0.24; we converted to χ

 10 Same-sign dilepton events. Limit assumes semileptonic BR for ${\it B}^{+}$ and ${\it B}^{\,0}$ equal. If $B^0/B^{\pm^{\circ}}$ ratio <0.58, no limit exists. The limit was corrected in BEAN 87B from r < 0.30 to r < 0.37. We converted this limit to χ

$\Delta m_{B^0} = m_{B^0_H} - m_{B^0_L}$

 $\Delta m_{B^0}^{-}$ is a measure of 2π times the $B^0 {\ensuremath{-}} \overline B^0$ oscillation frequency in time-dependent mixing experiments.

The second "OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/.The averaging/rescaling procedure takes into account correlations between the mea-

The first "OUR EVALUATION", also provided by the HFAG, includes Δm_d calculated from χ_d measured at $\Upsilon(4S)$.

CP VIOLATION PARAMETERS

$\operatorname{Re}(\epsilon_{B^0})/(1+|\epsilon_{B^0}|^2)$

CP impurity in B_d^0 system. It is obtained from either $a_{\ell\ell}$, the charge asymmetry in like-sign dilepton events or a_{cp} , the time-dependent asymmetry of inclusive B^0 and $\overline{B}^{\,0}$ decays.

The second "OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account correlations between the measurements. It assumes there is no CP violation in B_S mixing.

The first "OUR EVALUATION", also provided by the HFAG, uses the measurements from B-factories only.

⁴ Measured using inclusive dilepton events from B^0 decay.

B^{\pm}/B^{0} ADMIXTURE

B DECAY MODES

The branching fraction measurements are for an admixture of B mesons at the $\Upsilon(4S)$. The values quoted assume that $B(\varUpsilon(4S) \to B\overline{B}) = 100\%$.

For inclusive branching fractions, e.g., $B \to D^\pm$ anything, the treatment of multiple D's in the final state must be defined. One possibility would be to count the number of events with one-or-more D's and divide by the total number of B's. Another possibility would be to count the total number of D's and divide by the total number of B's, which is the definition of average multiplicity. The two definitions are identical if only one D is allowed in the final state. Even though the "one-or-more" definition seems sensible, for practical reasons inclusive branching fractions are almost always measured using the multiplicity definition. For heavy final state particles, authors call their results inclusive branching fractions while for light particles some authors call their results multiplicities. In the B sections, we list all results as inclusive branching fractions, adopting a multiplicity definition. This means that inclusive branching fractions can exceed 100% and that inclusive partial widths can exceed total widths, just as inclusive cross sections can exceed total cross sections.

 $\overline{{\it B}}$ modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing.

- 1 URQUIJO 07 report a measurement of (10.07 \pm 0.18 \pm 0.21)% for the partial branching fraction of $B\to e\nu_e X_c$ decay with electron energy above 0.6 GeV. We converted the result to $B\to e\nu_e X$ branching fraction.
- 2 The measurements are obtained for charged and neutral B mesons partial rates of semileptonic decay to electrons with momentum above 0.6 GeV/c in the B rest frame. The best precision on the ratio is achieved for a momentum threshold of 1.0 GeV: B($B^+
 ightarrow$ $e^+ \nu_e X$) / B($B^0 \rightarrow e^+ \nu_e X$) = 1.074 ± 0.041 ± 0.026.
- 3 Uses charge and angular correlations in $\varUpsilon(4S)$ events with a high-momentum lepton and
- All BRECHT 93H analysis performed using tagged semileptonic decays of the B. This technique is almost model independent for the lepton branching ratio.
- ⁵ The measurements are obtained for charged and neutral B mesons partial rates of semileptonic decay to electrons with momentum above 0.6 GeV/c in the B rest frame, and their ratio of B(B⁺ $\rightarrow e^+ \nu_e X)/B(B^0 \rightarrow e^+ \nu_e X) = 1.08 \pm 0.05 \pm 0.02$.
- 6 The semileptonic branching ratio, $|V_{cb}|$ and other heavy-quark parameters are determined from a simultaneous fit to moments of the hadronic-mass and lepton-energy dis-
- 7 Uses the high-momentum lepton tag method and requires the electron energy above 0.6
- 8 Uses the high-momentum lepton tag method. They also report $|V_{C\,D}|=0.0423$ \pm $0.0007(exp) \pm 0.0020(theo.)$
- 9 Uses the high-momentum lepton tag method. ABE 02Y also reports $|V_{C\,D}|=0.0408\pm0.0010(\exp)\pm0.0025(theo.)$. The second error is due to uncertainties of theoretical
- 10 BARISH 96B analysis performed using tagged semileptonic decays of the B. This technique is almost model independent for the lepton branching ratio.

- 11 YA NA GISAWA 91 also measures an average semileptonic branching ratio at the $\varUpsilon(5S)$ of 9.6–10.5% depending on assumptions about the relative production of different ${\cal B}$ meson species
- 12 ALBRECHT 90H uses the model of ALTARELLI 82 to correct over all lepton momenta. 0.099 \pm 0.006 is obtained using ISGUR 89B
- 13 Using data above p(e)=2.4 GeV, WACHS 89 determine $\sigma(B\to e\nu {\rm up})/\sigma(B\to e\nu {\rm charm})<0.065$ at 90% CL.
- ¹⁴ Ratio $\sigma(b \rightarrow e \nu up)/\sigma(b \rightarrow e \nu charm) < 0.055$ at CL = 90%

$\Gamma(\ell^+ \nu_\ell \, charm)/\Gamma_{total}$ "OUR EVALUATION" is an average using rescaled values of the data listed below.

The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account correlations between the measurements.

0.1051±0.0013 OUR EVALUATION 0.1058±0.0015 OUR AVERAGE ¹ AUBERT $0.1064 \pm 0.0017 \pm 0.0006$ 10A BABR $e^+e^-

- 1 Obtained from the partial rate $\Delta B = (0.572 \pm 0.041 \pm 0.065) \times 10^{-3}$ for the electron momentum interval of 2.0-2.6 GeV/c based on BLNP method.
- 2 Determined from the partial rate $\Delta \vec{B} = (4.41 \pm 0.42 \pm 0.42) \times 10^{-4}$ measured for electron energy > 2 GeV and hadronic mass squared < 3.5 GeV², and calculated acceptance 0.174 in that region. The V_{ub} is measured as $(4.41\pm0.30^{+0.65}_{-0.47}\pm0.28)\times10^{-3}$.
- 3 Uses electrons in the momentum interval 1.9–2.6 GeV/c in the center-of-mass frame. The V_{ub} is found to be (5.08 \pm 0.47 $^+_{-0.48}$) \times 10 $^{-3}$.
- 4 BORNHEIM 02 uses the observed yield of leptons from semileptonic B decays in the end-point momentum interval 2.2–2.6 GeV/c with recent CLEO-2 data on $B\to X_S\gamma$. The V_{ub} is found to be (4.08 \pm 0.34 \pm 0.53) imes 10 $^{-3}$.
- 5 Uses a multivariate analysis method and requires lepton momentum in the B rest frame, $\mathbf{p}_l^{*B} > 1.0 \text{ GeV/c}.$
- $^6\,{\rm Me}_{\rm asures}$ several partial branching fractions in different phase space regions. The most precise result is obtained in the region for hadronic mass ${\rm M}_X < 1.55~{\rm GeV/c^2}$, and is $\Delta {\rm B} = (1.18 \pm 0.09 \pm 0.07) \times 10^{-3}$. The corresponding $|V_{ub}|$ from the BLNP method $\Delta B = (1.10 \pm 0.39 \pm 0.37) \times 10^{-3}$, where the last uncertainty comes from the theoretical prediction of the partial rate in the given phase-space region.
- ⁷ Used BaBar measurement of Semileptonic branching fraction B($B \to X \ell \nu_{\ell}$) = (10.87 \pm 0.18 ± 0.30)% to convert the ratio of rates to branching fraction.
- $^{8}\,\mathrm{The\;third\;error\;includes\;the\;systematics\;and\;theoretical\;errors\;summed\;in\;quadrature.}$

| <4.0 | 90 | CHEN | 84 | CLEO | Direct e at $\Upsilon(4S)$ |
| < 5.5 | 90 | KLOPEEN | 83B | CUSB | Direct e at $\Upsilon(4S)$ |

- $^{
 m 1}$ The third error includes the systematics and theoretical errors summed in quadrature.
- ²ALBRECHT 94c find $\Gamma(b \rightarrow c)/\Gamma(b \rightarrow all) = 0.99 \pm 0.02 \pm 0.04$.
- 3 BARTELT 93B (CLEO II) measures an excess of 107 \pm 15 \pm 11 leptons in the lepton momentum interval 2.3–2.6 GeV/c which is attributed to $b\to~u\ell\nu_\ell$. This corresponds to a model-dependent partial branching ratio $\Delta B_{u\,b}$ between $(1.15\pm0.16\pm0.15)\times10^{-4}$, as evaluated using the KS model (KOERNER 88), and (1.54 \pm 0.22 \pm 0.20) imes 10^{-4} using the ACCMM model (ARTUSO 93). The corresponding values of $|V_{UB}|/|V_{CB}|$ are 0.056 \pm 0.006 and 0.076 \pm 0.008, respectively. ⁴ ALBRECHT 91c result supersedes ALBRECHT 90. Two events are fully reconstructed
- providing evidence for the $b \to u$ transition. Using the model of ALTARELLI 82, they obtain $|V_{ub}/V_{cb}| = 0.11 \pm 0.012$ from 77 leptons in the 2.3–2.6 GeV momentum range.

- 5 ALBRECHT 90 observes 41 \pm 10 excess e and μ (lepton) events in the momentum interval $\rho=2.3-2.6$ GeV signaling the presence of the $b \to u$ transition. The events correspond to a model-dependent measurement of $\left|V_{U\,D}/V_{C\,D}\right|=0.10\pm0.01$.
- 6 FULTON 90 observe 76 \pm 20 excess e and μ (lepton) events in the momentum interval p=2.4–2.6 GeV signaling the presence of the $b\to u$ transition. The average branching ratio, $(1.8\,\pm\,0.4\,\pm\,0.3)\,\times\,10^{-4}$, corresponds to a model-dependent measurement of approximately $|V_{ub}/V_{cb}|=0.1$ using B(b $\rightarrow c\ell\nu$) = 10.2 \pm 0.2 \pm 0.7%.
- 7 The quoted possible limits range from 0.018 to 0.04 for the ratio, depending on which model or momentum range is chosen. We select the most conservative limit they have calculated. This corresponds to a limit on $|v_{u\,b}|/|v_{c\,b}|<0.20$. While the endpoint technique employed is more robust than their previous results in CHEN 84, these results do not provide a numerical improvement in the limit.

0.27 ± 0.06 $^{+0.08}_{-0.06}$ 510 6 CSORNA 85 CLEO Repl. by BORTOLETTO 87

 1 GIBBONS 97B reports B($B\to D^*(2010)^+$ anything) = 0.239 \pm 0.015 \pm 0.014 \pm 0.009 using CLEO measured D and D^* branching fractions. We rescale to our PDG 96 values of D and D^* branching ratios. Our first error is their experiment's error and our second error is the systematic error from using our best value.

²ALBRECHT 96D reports $B(B\to D^*(2010)^+$ anything) 0.196 ± 0.019 using CLEO measured $B(D^*(2010)^+\to D^0\pi^+)=0.681\pm0.01\pm0.013,\ B(D^0\to K^-\pi^+)=0.0401\pm0.0014,\ B(D^0\to K^-\pi^+\pi^+\pi^-)=0.081\pm0.005$., We rescale to our PDG 96 values of D and D^* branching ratios. Our first error is their experiment's error and our second error is the systematic error from using our best value.

second error is the systematic error from using our best value. ³ BORTOLETTO 92 reports B($B \to D^*(2010)^+$ anything) = 0.25 \pm 0.03 \pm 0.04 using MARKII B($D^*(2010)^+ \to D^0\pi^+$) = 0.57 \pm 0.06 and B($D^0 \to K^-\pi^+$) = 0.042 \pm 0.008. We rescale to our PDG 96 values of D and D^* branching ratios. Our first error is their experiment's error and our second error is the systematic error from using our best value.

4 ALBRECHT 91H reports 0.348 \pm 0.060 \pm 0.035 from a measurement of [$\Gamma(B \to D^*(2010)^\pm \text{anything})/\Gamma_{\text{total}}$] \times [$B(D^*(2010)^+ \to D^0\pi^+)$] assuming $B(D^*(2010)^+ \to D^0\pi^+)$ = 0.55 \pm 0.04, which we rescale to our best value $B(D^*(2010)^+ \to D^0\pi^+)$ = (67.7 \pm 0.5) \times 10⁻². Our first error is their experiment's error and our second error is the systematic error from using our best value. Uses the PDG 90 $B(D^0 \to K^-\pi^+)$ = 0.0371 \pm 0.0025.

 5 BORTOLETTO 87 uses old MARK III (BALTRUSAITIS 86E) branching ratios B($D^0\to K^-\pi^+)=0.056\pm0.004\pm0.003$ and also assumes B($D^*(2010)^+\to D^0\pi^+)=0.60^{+0.08}_{-0.15}$. The product branching ratio for B($B\to D^*(2010)^+)$ B($D^*(2010)^+\to D^0\pi^+)$ is $0.13\pm0.02\pm0.012$. Superseded by BORTOLETTO 92.

 6 V-A momentum spectrum used to extrapolate below p=1 GeV. We correct the value assuming B($D^0\to K^-\pi^+)=0.042\pm0.006$ and B($D^{*+}\to D^0\pi^+)=0.6\pm0.08$. The product branching fraction is B($B\to D^{*+}X$)·B($D^{*+}\to \pi^+D^0$)·B($D^0\to K^-\pi^+$) = (68 \pm 15 \pm 9) \times 10 $^{-4}$.

 1 ABE 02L uses PDG 01 values for ${\rm B}(J/\psi(1{\rm S})\to~\ell^+\,\ell^-)$ and ${\rm B}(\chi_{c1,c2}\to~J/\psi(1{\rm S})\,\gamma).$

 3 BALEST 95B assume PDG 1994 values. $J/\psi(1S)$ mesons are reconstructed in the e^+e^- and $\mu^+\mu^-$ modes. The $B\to\chi_{c1}(1P){\rm X}$ branching ratio contains $\chi_{c1}(1P)$ mesons directly from B decays and also from feeddown through $\psi(2{\rm S})\to\chi_{c1}(1P)\gamma.$ Using the measured inclusive rates, BALEST 95B corrects for the feeddown and finds the $B\to\chi_{c1}(1P)$ (direct) X branching ratio.

 1 ALBRECHT 931 value is not independent of the sum of $B\to K^+$ anything and $B\to K^-$ anything ALBRECHT 94c values.

² Assuming $\Upsilon(4S) \to B\overline{B}$, a total of $3.38 \pm 0.34 \pm 0.68$ kaons per $\Upsilon(4S)$ decay is found (the second error is systematic). In the context of the standard B-decay model, this leads to a value for (b-quark $\to c$ -quark)/(b-quark \to all) of $1.09 \pm 0.33 \pm 0.13$.

 3 GIANNINI 82 at CESR-CUSB observed $1.58\pm0.35~K^0$ per hadronic event much higher than 0.82 ± 0.10 below threshold. Consistent with predominant $b\to cX$ decay.

 $^{^2}$ CHEN 01 reports 0.00383 \pm 0.00031 \pm 0.00040 from a measurement of $[\Gamma(B\to\chi_{c1}(1P)(\text{direct})\ \text{anything})/\Gamma_{\text{total}}]\times [B(\chi_{c1}(1P)\to \gamma J/\psi(1S))]$ assuming $B(\chi_{c1}(1P)\to \gamma J/\psi(1S))]=0.273 \pm 0.016,$ which we rescale to our best value $B(\chi_{c1}(1P)\to \gamma J/\psi(1S))=(34.4\pm 1.5)\times 10^{-2}.$ Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

²CHEN 01 reports $(9.8\pm4.8\pm1.5)\times10^{-4}$ from a measurement of $[\Gamma(B\to\chi_{C2}(1P)\text{ anything})/\Gamma_{\text{total}}]\times[B(\chi_{C2}(1P)\to\gamma J/\psi(1S))]$ assuming $B(\chi_{C2}(1P)\to\gamma J/\psi(1S))=0.135\pm0.011$, which we rescale to our best value $B(\chi_{C2}(1P)\to\gamma J/\psi(1S))=(19.5\pm0.8)\times10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the T(4S).

In decays involving two vector mesons, one can distinguish among the states in which meson polarizations are both longitudinal (£) or both are transverse and parallel (\parallel) or perpendicular (\perp) to each other with the parameters $\Gamma_L/\Gamma,\,\Gamma_\perp/\Gamma,$ and the relative phases ϕ_\parallel and $\phi_\perp.$ See the definitions in the note on "Polarization in B Decays" review in the B^0 Particle Listings.

 $^{^{1}}$ Results with different \mathbf{q}^{2} cuts are also reported.

ISOSPIN ASYMMETRY

 Δ_{0-} is defined as

$$\frac{\Gamma(B^0 \to f_d) - \Gamma(B^+ \to f_u)}{\Gamma(B^0 \to f) + \Gamma(B^+ \to f)}$$

the isospin asymmetry of inclusive neutral and charged B decay.

$\Delta_{0-}(B(B \rightarrow X_s \gamma))$

$B^{\pm}/B^{0}/B_{s}^{0}/b$ -baryon ADMIXTURE

$B^{\pm}/B^{0}/B_{s}^{0}/b$ -baryon ADMIXTURE MEAN LIFE

Each measurement of the B mean life is an average over an admixture of various bottom mesons and baryons which decay weakly. Different techniques emphasize different admixtures of produced particles, which could result in a different B mean life.

"OUR EVALUATION" is an average using rescaled values of the The average and rescaling were performed by data listed below. the Heavy Flavor Averaging Group (HFAG) and are described at $http://www.slac.stanford.edu/xorg/hfag/. \ \ The \ averaging/rescaling \ pro-prosphere and the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of t$ cedure takes into account correlations between the measurements and asymmetric lifetime errors, but ignores the small differences due to dif-

 $^{^{}m 30}$ Data analyzed using both the jet charge and the charge of secondary vertex in the opposite hemisphere

 $^{^2}$ Measured using inclusive $J/\psi(1{\rm S}) \to ~\mu^+\,\mu^-$ vertex.

³ ACCIARRI 98 uses inclusively reconstructed secondary vertex and lepton impact param-

eter.

4 ACKERSTAFF 97F uses inclusively reconstructed secondary vertices.

⁵ BUSKULIC 96F analyzed using 3D impact parameter.

⁶ ABE,K 95B uses an inclusive topological technique.

⁷ABREU 94L uses charged particle impact parameters. Their result from inclusively reconstructed secondary vertices is superseded by ABREU 96E.

 $^{^8}$ ACTON 93L and ADRIA NI 93K analyzed using lepton (e and μ) impact parameter at Z. ⁹BUSKULIC 930 analyzed using dipole method.

¹⁰ Combines ABREU 96E secondary vertex result with ABREU 94L impact parameter result.

 $^{^{11}}$ From proper time distribution of $b
ightarrow \ J/\psi(1{\cal S})$ anything.

 $^{^{12}}$ ABE 93J analyzed using $J/\psi(1S)
ightarrow \mu\mu$ vertices.

 $^{^{13}}$ ABREU 93D data analyzed using $D/D^*\ell$ anything event vertices.

 $^{^{\}rm 14}\,{\sf ABREU}$ 93G data analyzed using charged and neutral vertices.

 $^{^{15}}$ ACTON 93c analysed using $D/D*\ell$ anything event vertices.

¹⁶ ABREU 92 is combined result of muon and hadron impact parameter analyses. Hadron tracks gave $(12.7 \pm 0.4 \pm 1.2) \times 10^{-13}$ s for an admixture of B species weighted by production fraction and mean charge multiplicity, while muon tracks gave (13.0 \pm 1.0 \pm 0.8) imes $10^{-13}\,\mathrm{s}$ for an admixture weighted by production fraction and semileptonic branching

¹⁷ ACTON 92 is combined result of muon and electron impact parameter analyses.

 $^{^{18}\,\}mathrm{BUSKULIC}$ 92F uses the lepton impact parameter distribution for data from the 1991

 $^{^{19}}$ BUSKULIC 92G use $J/\psi(1S)$ tags to measure the average b lifetime. This is comparable to other methods only if the $J/\psi(1S)$ branching fractions of the different b-flavored

hadrons are in the same ratio. 20 Using $Z \to e^+ X$ or $\mu^+ X$, ADEVA 91H determined the average lifetime for an admixture of B hadrons from the impact parameter distribution of the lepton. 21 Using $Z \to J/\psi(1S) X$, $J/\psi(1S) \to \ell^+ \ell^-$, ALEXANDER 91G determined the average

lifetime for an admixture of B hadrons from the decay point of the $J/\psi(1S)$

²² Using $Z \to e X$ or μX , DECA MP 91c determines the average lifetime for an admixture of ${\it B}$ hadrons from the signed impact parameter distribution of the lepton.

²³ HAGEMANN 90 uses electrons and muons in an impact parameter analysis.

²⁴ LYONS 90 combine the results of the B lifetime measurements of ONG 89, BRAUN-SCHWEIG 89B, KLEM 88, and ASH 87, and JADE data by private communication. They use statistical techniques which include variation of the error with the mean life, and possible correlations between the systematic errors. This result is not independent of the measured results used in our average.

 $^{^{25}}$ We have combined an overall scale error of 15% in quadrature with the systematic error of \pm 0.7 to obtain \pm 2.1 systematic error.

 $^{^{}m 26}$ Statistical and systematic errors were combined by BROM 87

b PRODUCTION FRACTIONS AND DECAY MODES

The branching fraction measurements are for an admixture of B mesons and baryons at energies above the $\varUpsilon(4S)$. Only the highest energy results (LHC, LEP, Tevatron, $Sp\,\overline{p}S$) are used in the branching fraction averages. In the following, we assume that the production fractions are the same at the LHC, LEP, and at the Tevatron.

For inclusive branching fractions, e.g., $B
ightarrow D^{\pm}$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

The modes below are listed for a \overline{b} initial state. b modes are their charge conjugates. Reactions indicate the weak decay vertex and do not include mixing.

Scale factor / Mode Fraction (Γ_i/Γ) Confidence level

PRODUCTION FRACTIONS

The production fractions for weakly decaying b-hadrons at high energy have been calculated from the best values of mean lives, mixing parameters, and branching fractions in this edition by the Heavy Flavor Averaging Group (HFAG) as described in the note " B^0 – \overline{B}^0 Mixing" in the B^0 Particle Listings. The production fractions in b-hadronic Z decay or $p\overline{p}$ collisions at the Tevatron are also listed at the end of the section. Values assume

$$\begin{array}{ll} \mathsf{B}(\overline{b} \to B^+) = \mathsf{B}(\overline{b} \to B^0) \\ \mathsf{B}(\overline{b} \to B^+) + \mathsf{B}(\overline{b} \to B^0) + \mathsf{B}(\overline{b} \to B^0) + \mathsf{B}(b \to b\text{-baryon}) = 100 \ \%. \end{array}$$

The correlation coefficients between production fractions are also re-

 $cor(B_c^0, b\text{-baryon}) = -0.277$ $cor(B_5^0, B^{\pm}=B^0) = -0.119$ cor(b-baryon, $B^{\pm}=B^{0})=-0.921$.

The notation for production fractions varies in the literature $(f_d,\ d_{B^0},$ $f(b \to \overline{B}{}^0)$, ${
m Br}(b \to \overline{B}{}^0))$. We use our own branching fraction notation here, $B(\overline{b} \rightarrow B^0)$.

Note these production fractions are b-hadronization fractions, not the conventional branching fractions of b-quark to a B-hadron, which may have considerable dependence on the initial and final state kinematic and production environment.

 $^{
m 43}$ Uses the combination of lepton transverse momentum spectrum and the correlation between the charge of the lepton and opposite jet charge. The first error is statistic and the second error is the total systematic error including the modeling.

44 The experimental systematic and model uncertainties are combined in quadrature.

45 ABBIENDI 00E result is determined by comparing the distribution of several kinematic

variables of leptonic events in a lifetime tagged $\ddot{Z} \to b \, \bar{b}$ sample using artificial neural network techniques. The first error is statistic; the second error is the total systematic

⁴⁶ ACCIARRI 00 result obtained from a combined fit of $R_b = \Gamma(Z \to b \, \overline{b})/\Gamma(Z \to \text{hadrons})$

and B($b \to \ell \nu X$), using double-tagging method. 47 ACCIARRI 96c result obtained by a fit to the single lepton spectrum

 49 ASBINED Standard Model value for R_B . 49 ASBINED 95D give systematic errors ± 0.0019 (model) and 0.0012 (R_c). We combine these in quadrature.

This value is from a global fit to the lepton p

these in quadrature. So BUSKULIC 946 uses e and μ events. This value is from a global fit to the lepton p and p_T (relative to jet) spectra which also determines the b and c production fractions, the fragmentation functions, and the forward-backward asymmetries. This branching ratio depends primarily on the ratio of dileptons to single leptons at high p_T . But the lower p_T portion of the lepton spectrum is included in the global fit to reduce the model dependence. The model dependence is ± 0.0026 and is included in the systematic error.

dependence. The incode dependence is ± 0.0020 and is incoded in ± 0.002 and ± 0.002 and ± 0.002 and ± 0.007 ± 0.007 . So patial 0.100 $\pm 0.007 \pm 0.007$.

 60 ABBIENDI 00E result is determined by comparing the distribution of several kinematic variables of leptonic events in a lifetime tagged $Z \to b \, \overline{b}$ sample using artificial neural network techniques. The first error is statistic; the second error is the total systematic

 63 ABREU 93c event count includes $\mu\mu$ events. Combining ee, $\mu\mu$, and e μ events, they

error. 61 ACCIARRI 96c result obtained by a fit to the single lepton spectrum.
