 χ_{b} is the average $B \text{-} \overline{B}$ mixing parameter at high-energy $\chi_{b} = f'_{d} \chi_{d} + f'_{S} \chi_{S}$ where f'_{d} and f'_{S} are the fractions of B^{0} and B^{0}_{S} hadrons in an unbiased sample of semileptonic b-hadron decays.

$B^{\pm}/B^{0}/B_{s}^{0}/b$ -baryon ADMIXTURE

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at $http://www.slac.stanford.edu/xorg/hfag/. \ \ The \ averaging/rescaling \ pro-prosphere and the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of t$ cedure takes into account correlations between the measurements

| 134 Uses the dimuon charge | as ym me | ry Averaged ove | rthe | mix of b | -flavored hadrons |

- 135 Measurement performed using events containing a dimuon or an e/μ pair.
- 136 The average B mixing parameter is determined simultaneously with b and c forwardbackward asymmetries in the fit.
- 137 The experimental systematic and model uncertainties are combined in quadrature.
- 138 ACCIARRI 99D uses maximum-likelihood fits to extract χ_b as well as the A^b_{FB} in Z
 ightharpoonup $b\,\overline{b}$ events containing prompt leptons.
- 139 This ABREU 941 result is from 5182ℓℓ and 279 Λℓ events. The systematic error includes 0.004 for model dependence.
- $^{140}\,\mathrm{BUSKULIC}$ 94G data analyzed using $e\,e,\,e\,\mu$, and $\mu\,\mu$ events.
- $^{141}\,\mathrm{BUSKULIC}$ 92B uses a jet charge technique combined with electrons and muons.
- $^{142}\,\mathrm{ABE}$ 91G measurement of χ is done with $e\,\mu$ and $e\,e$ events.
- $^{143}\mathrm{ALBAJAR}$ 91D measurement of χ is done with dimuons.
- 144 Uses di-muon events.
- 145 ALEXANDER 96 uses a maximum likelihood fit to simultaneously extract χ as well as the forward-backward asymmetries in $e^+e^- \rightarrow Z \rightarrow b\overline{b}$ and $c\overline{c}$.
- 146 UENO 96 extracted χ from the energy dependence of the forward-backward asymmetry.
- 147 ABREU 94F uses the average electric charge sum of the jets recoiling against a b-quark jet tagged by a high p_T muon. The result is for $\overline{\chi}=f_d\chi_d+0.9f_s\chi_s$
- 148 This ABREU 941 result combines $\ell\ell$, $\hbar\ell$, and jet-charge ℓ (ABREU 94F) analyses. It is for $\overline{\chi}=\mathit{f_d}\chi_d+0.96\mathit{f_S}\chi_S$
- 149 ALBAJAR 94 uses dimuon events. Not independent of ALBAJAR 91D.
- $^{150}\mathrm{ABREU}$ 93c data analyzed using ee, $e\mu$, and $\mu\mu$ events.
- 151 AKERS 93B analysis performed using dilepton events.
- $^{152}\mathrm{ACTON}$ 92c uses electrons and muons. Superseded by AKERS 93B.
- $^{153}_{154}$ ADEVA 92c uses electrons and muons.
- 154 DECAMP 91 done with opposite and like-sign dileptons. Superseded by BUSKULIC 92B.
- 155 ADEVA 90P measurement uses e.e, $\mu\mu$, and $e\mu$ events from 118k events at the ZSuperseded by ADEVA 92c.
- 156 These experiments are not in the average because the combination of B_{S} and B_{d} mesons which they see could differ from those at higher energy.
- 157 The WEIR 90 measurement supersedes the limit obtained in SCHAAD 85. The 90% CL are 0.06 and 0.38. 158 ALBAJAR 87c measured $\chi=(\overline{\cal B}^0\to {\cal B}^0\to \mu^+{\rm X})$ divided by the average production
- weighted semileptonic branching fraction for B hadrons at 546 and 630 GeV
- 159 Limit is average probability for hadron containing B quark to produce a positive lepton.

CP VIOLATION PARAMETERS in semileptonic b-hadron decays.

B-HADRON PRODUCTION FRACTIONS IN HADRONIC Z DECAY

The production fractions of b-hadrons in hadronic Z decays have been calculated using the best values of mean lives, mixing parameters and branching fractions in this edition by the Heavy Flavor Averaging Group (HFAG) (see http://www.slac.stanford.edu/xorg/hfag/).

The values reported below assume: $f(\overline{b} \rightarrow B^+) = f(\overline{b} \rightarrow B^0)$

$$f(\overline{b} \to B^+) = f(\overline{b} \to B^0)$$

$$f(\overline{b} \to B^+) + f(\overline{b} \to B^0) + f(\overline{b} \to B^0) + f(b \to b\text{-baryon}) = 1$$

The values are:
$$f(\overline{b} \to B^+) = f(\overline{b} \to B^0) = 0.403 \pm 0.009$$

 $f(\overline{b} \to B_s^0) = 0.103 \pm 0.009$

 $f(b \rightarrow b\text{-baryon}) = 0.090 \pm 0.015$ and their correlation coefficients are: $cor(B_S^0, b\text{-baryon}) = +0.036$

 $cor(B_{c}^{0}, B^{+}=B^{0}) = -0.522$

the note "The Z boson").

cor(b-baryon, $B^+ = B^0) = -0.871$ as obtained using a time-integrated mixing parameter $\overline{\chi}=0.1259\pm0.0042$ given by a fit to heavy quark quantities with asymmetries removed (see

B-HADRON PRODUCTION FRACTIONS IN pp COLLISIONS AT Tevatron

The production fractions for b-hadrons in $p\overline{p}$ collisions at the Tevatron have been calculated from the best values of mean lifetimes, mixing parameters, and branching fractions in this edition by the Heavy Flavor Averaging Group (HFAG) (see http://www.slac.stanford.edu/xorg/hfag/).

The values reported below assume:

$$\begin{array}{ll} f(\overline{b} \rightarrow B^{'+}) = f(\overline{b} \rightarrow B^0) \\ f(\overline{b} \rightarrow B^+) + f(\overline{b} \rightarrow B^0) + f(\overline{b} \rightarrow B^0_S) + f(b \rightarrow b\text{-baryon}) = 1 \end{array}$$

The values are: $f(\overline{b} \rightarrow B^+) = f(\overline{b} \rightarrow B^0) = 0.339 \pm 0.031$

 $f(\overline{b} \rightarrow B_s^0) = 0.111 \pm 0.014$

 $f(b \rightarrow b\text{-baryon}) = 0.212 \pm 0.069$ and their correlation coefficients are: $cor(B_S^0, b\text{-baryon}) = -0.581$

 $cor(B_0^0, B^+ = B^0) = +0.425$

cor(b-baryon, $B^+ = B^0) = -0.984$

as obtained with the Tevatron average of time-integrated mixing parameter

$B^{\pm}/B^{0}/B_{s}^{0}/b$ -baryon ADMIXTURE REFERENCES

V_{cb} and V_{ub} CKM Matrix Elements

OMITTED FROM SUMMARY TABLE

DETERMINATION OF V_{cb} AND V_{ub}

Updated February 2012 by R. Kowalewski (Univ. of Victoria, Canada) and T. Mannel (Univ. of Siegen, Germany)

INTRODUCTION

Precision determinations of $|V_{ub}|$ and $|V_{cb}|$ are central to testing the CKM sector of the Standard Model, and complement the measurements of CP asymmetries in B decays. The length of the side of the unitarity triangle opposite the well-measured angle β is proportional to the ratio $|V_{ub}|/|V_{cb}|$, making its determination a high priority of the heavy-flavor physics program.

The semileptonic transitions $b\to c\ell\overline{\nu}_\ell$ and $b\to u\ell\overline{\nu}_\ell$ provide two avenues for determining these CKM matrix elements, namely through inclusive and exclusive final states. The experimental and theoretical techniques underlying these two avenues are independent, providing a crucial cross-check on our understanding. Recent measurements and calculations are reflected in the values quoted in this article, which is an update on the previous review [1]. The leptonic decay $B^-\to \tau\overline{\nu}$ can also be used to extract $|V_{ub}|$, but we do not use this information at present since none of the current experimental measurements have a significance above 3.6σ .

The theory underlying the determination of $|V_{qb}|$ is mature, in particular for $|V_{cb}|$. Most of the theoretical approaches use the fact that the mass m_b of the b quark is large compared to the scale $\Lambda_{\rm QCD}$ that determines low-energy hadronic physics. The basis for precise calculations is a systematic expansion in powers of Λ/m_b , where $\Lambda \sim 500-700$ MeV is a hadronic scale of the order of $\Lambda_{\rm QCD}$, using effective-field-theory methods to separate non-perturbative from perturbative contributions. The expansion in Λ/m_b and α_s works well enough to enable a precision determination of $|V_{cb}|$ and $|V_{ub}|$ in semileptonic decays.

The large data samples available at the B factories enable analyses where one B meson from an $\Upsilon(4S)$ decay is fully reconstructed, allowing a recoiling semileptonic B decay to be studied with high purity. Improved knowledge of $\overline{B} \to X_c \ell \overline{\nu}_\ell$ decays allows partial rates for $\overline{B} \to X_u \ell \overline{\nu}_\ell$ transitions to be measured in regions previously considered inaccessible, increasing the acceptance for $\overline{B} \to X_u \ell \overline{\nu}_\ell$ transitions and reducing theoretical uncertainties.

Experimental measurements of the exclusive $\overline{B} \to \pi \ell \overline{\nu}_{\ell}$ decay are quite precise, and recent improvements in the theoretical calculation of the form factor normalization have enabled a determination of $|V_{ub}|$ from this decay with an uncertainty below 10%

Throughout this review the numerical results quoted are based on the methods of the Heavy Flavor Averaging Group [2].

V_{cb} and V_{ub} CKM Matrix Elements

DETERMINATION OF $|V_{cb}|$

Summary: The determination of $|V_{cb}|$ from $\overline{B} \to D^*\ell\overline{\nu}_{\ell}$ decays is currently at a relative precision of about 2%. The main limitation is the knowledge of the form factor near the maximum momentum transfer to the leptons. For the $\overline{B} \to D\ell\overline{\nu}_{\ell}$ channel experimental measurements have recently been substantially improved, allowing this channel to provide a meaningful cross-check on $\overline{B} \to D^*\ell\overline{\nu}_{\ell}$.

Determinations of $|V_{cb}|$ from inclusive decays are currently below 2% relative uncertainty. The limitations arise mainly from our ignorance of higher-order perturbative and non-perturbative corrections.

The values obtained from inclusive and exclusive determinations are marginally consistent with each other:

$$|V_{cb}| = (41.9 \pm 0.7) \times 10^{-3} \text{ (inclusive)}$$
 (1)

$$|V_{cb}| = (39.6 \pm 0.9) \times 10^{-3} \text{ (exclusive)}.$$
 (2)

An average of the above gives $|V_{cb}| = (40.9 \pm 0.6) \times 10^{-3}$, with $p(\chi^2) = 0.04$. Scaling the error by $\sqrt{\chi^2/1} = 2.0$ we quote

$$|V_{cb}| = (40.9 \pm 1.1) \times 10^{-3}$$
 (3)

$|V_{cb}|$ from exclusive decays

Exclusive determinations of $|V_{cb}|$ are based on a study of semileptonic B decays into the ground state charmed mesons D and D^* . The main uncertainties in this approach stem from our ignorance of the form factors describing the $B \to D$ and $B \to D^*$ transitions. However, in the limit of infinite bottom and charm quark masses only a single form factor appears, the Isgur-Wise function [3], which depends on the product of the four-velocities v and v' of the initial and final-state hadrons.

The extraction of $|V_{cb}|$ is based on the distribution of the variable $w \equiv v \cdot v'$, which corresponds to the energy of the final state $D^{(*)}$ meson in the rest frame of the decay. Heavy Quark Symmetry (HQS) [3,4] predicts the normalization of the rate at w = 1, the point of maximum momentum transfer to the leptons, and $|V_{cb}|$ is obtained from an extrapolation of the measured spectrum to w = 1. This extrapolation relies on a parametrization of the form factor, as explained below.

A precise determination requires corrections to the HQS prediction for the normalization as well as some information on the slope of the form factors near the point w=1, since the phase space vanishes there. The corrections to the HQS prediction due to finite quark masses are given in terms of the symmetry-breaking parameter

$$\frac{1}{\mu} = \frac{1}{m_c} - \frac{1}{m_b},$$

which is essentially $1/m_c$ for realistic quark masses. HQS ensures that those matrix elements that correspond to the currents that generate the HQS are normalized at w=1; as a result, some of the form factors either vanish or are normalized to unity at w=1. Due to Luke's Theorem [5] (which is an application of the Ademollo-Gatto theorem [6] to heavy

quarks), the leading correction to those form factors normalized due to HQS is quadratic in $1/\mu$, while for the form factors that vanish in the infinite mass limit the corrections are in general linear in $1/m_c$ and $1/m_b$. Thus we have, using the definitions as in Eq. (2.84) of Ref. [7]

$$h_i(1) = 1 + \mathcal{O}(1/\mu^2)$$
 for $i = +, V, A_1, A_3$,
 $h_i(1) = \mathcal{O}(1/m_c, 1/m_b)$ for $i = -, A_2$. (4)

In addition to these corrections, there are perturbatively calculable radiative corrections from QCD and QED, which will be discussed in the relevant sections. Both - radiative corrections as well as $1/m_{b,c}$ corrections - are considered in the framework of Heavy Quark Effective Theory (HQET) [8], which provides for a systematic expansion.

$$\overline{B} \to D^* \ell \overline{\nu}_{\ell}$$

The decay rate for $\overline{B} \to D^* \ell \overline{\nu}_{\ell}$ is given by

$$\frac{d\Gamma}{dw}(\overline{B} \to D^* \ell \overline{\nu}_{\ell}) = \frac{G_F^2}{48\pi^3} |V_{cb}|^2 m_{D^*}^3 (w^2 - 1)^{1/2} P(w) (\eta_{\rm em} \mathcal{F}(w))^2.$$
(5)

where P(w) is a phase space factor with $P(1) = 12(m_B - m_{D^*})^2$ and $\mathcal{F}(w)$ is dominated by the axial vector form factor h_{A_1} as $w \to 1$. Furthermore, $\eta_{\rm em} = 1.007$ accounts for the electroweak corrections to the four-fermion operator mediating the semileptonic decay [11]. In the infinite-mass limit, the HQS normalization gives $\mathcal{F}(1) = 1$.

The form factor $\mathcal{F}(w)$ must be parametrized to perform an extrapolation to the zero-recoil point. A frequently used one-parameter form motivated by analyticity and unitarity is [9,10]

$$\mathcal{F}(w) = \eta_{\mathcal{A}} \left[1 + \delta_{1/m^2} + \cdots \right]$$
$$\left[1 - 8\rho_{\mathcal{A}1}^2 z + (53\rho_{\mathcal{A}1}^2 - 15)z^2 - (231\rho_{\mathcal{A}1}^2 - 91)z^3 \right]$$
(6)

with $z=(\sqrt{w+1}-\sqrt{2})/(\sqrt{w+1}+\sqrt{2})$ originating from a conformal transformation. The parameter $\rho_{\rm A1}^2$ is the slope of the form factor at w=1. The factor $\eta_{\rm A}$ is the QCD short-distance radiative correction [12] to the form factor

$$\eta_{\rm A} = 0.960 \pm 0.007,\tag{7}$$

and δ_{1/m^2} comes from non-perturbative $1/m^2$ corrections.

Improved lattice simulations that include effects from finite quark masses are used to calculate the deviation of $\mathcal{F}(1)$ from unity. A recent calculation gives

$$\mathcal{F}(1) = 0.902 \pm 0.017,\tag{8}$$

where the factor $\eta_{\rm em}$ has been divided out from the value quoted in Ref. [13] and the errors have been added in quadrature. The leading uncertainties are due to heavy-quark discretization and chiral extrapolation errors.

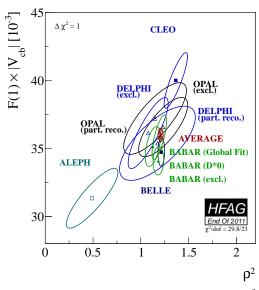

Figure 1: Measurements of $|V_{cb}|\mathcal{F}(1)$ vs. $\rho_{A_1}^2$ are shown as $\Delta \chi^2 = 1$ ellipses.

Non-lattice estimates based on sum rules for the form factor tend to yield lower values for $\mathcal{F}(1)$ [14,15,16]. Omitting the contributions from excited states, the sum rules indicate that $\mathcal{F}(1) < 0.93$. Including an estimate for the contribution of the excited states yields $\mathcal{F}(1) = 0.86 \pm 0.01 \pm 0.02$ [16]. where the second uncertainty originates from the estimate for the excited states.

Many experiments [17–25] have measured the differential rate as a function of w. Fig. 1 shows corresponding values of $\mathcal{F}(1) |V_{cb}|$ and $\rho_{A_1}^2$ (as defined in Ref. [10]) . These measurements are input to a four-dimensional fit [26] for $\mathcal{F}(1)|V_{cb}|$, $\rho_{A_1}^2$ and the form factor ratios $R_1 \propto A_2/A_1$ and $R_2 \propto V/A_1$. The leading sources of uncertainty on $\mathcal{F}(1) |V_{cb}|$ are due to detection efficiencies and $D^{(*)}$ decay branching fractions, while for $\rho_{A_1}^2$ the uncertainties in R_1 and R_2 still dominate. Recent BABAR measurements, one using $\overline{B}^0 \to D^{*0}\ell\overline{\nu}_\ell$ decays [23] and the other using a global fit to $\overline{B} \to D\ell\overline{\nu}_\ell X$ decays [24] are completely insensitive to uncertainties related to the reconstruction of the charged pion from $D^* \to D\pi$ decays; both measurements agree with the average given below.

The fit gives $\mathcal{F}(1) |V_{cb}| = (36.0 \pm 0.5) \times 10^{-3}$ with a *p*-value of 0.15. Along with the lattice value given above for $\mathcal{F}(1)$ this yields

$$|V_{cb}| = (39.6 \pm 0.6_{\text{exp}} \pm 0.8_{\text{theo}}) \times 10^{-3} \quad (\overline{B} \to D^* \ell \overline{\nu}_{\ell}, \text{ LQCD}).$$
(9)

The value of $\mathcal{F}(1)$ obtained from QCD sum rules results in a larger value for $|V_{cb}|$:

$$|V_{cb}| = (41.6 \pm 0.6_{\text{exp}} \pm 1.9_{\text{theo}}) \times 10^{-3} \quad (\overline{B} \to D^* \ell \overline{\nu}_{\ell}, \text{ SR}).$$
 (10)

$$\overline{B} \to D \ell \overline{
u}_{\ell}$$

The differential rate for $\overline{B} \to D\ell \overline{\nu}_{\ell}$ is given by

$$\frac{d\Gamma}{dw}(\overline{B} \to D\ell \overline{\nu}_{\ell}) = \frac{G_F^2}{48\pi^3} |V_{cb}|^2 (m_B + m_D)^2 m_D^3 (w^2 - 1)^{3/2} (\eta_{\rm em} \mathcal{G}(w))^2. \quad (11)$$

The form factor is

$$G(w) = h_{+}(w) - \frac{m_B - m_D}{m_B + m_D} h_{-}(w), \tag{12}$$

where h_+ is normalized to unity in the infinite-mass limit due to HQS and h_- vanishes in the heavy-mass limit. Thus

$$\mathcal{G}(1) = 1 + \mathcal{O}\left(\frac{m_B - m_D}{m_B + m_D} \frac{1}{m_c}\right) \tag{13}$$

and the corrections to the HQET predictions are parametrically larger than was the case for $\overline{B} \to D^* \ell \overline{\nu}_{\ell}$.

In order to get a more precise prediction for the form factor $\mathcal{G}(1)$ the heavy-quark expansion can be supplemented by additional assumptions. It has been argued in Ref. [27] that in a limit in which the kinetic energy μ_{π}^2 is equal to the chromomagnetic moment μ_G^2 (these quantities are discussed below in more detail) one may obtain the value

$$G(1) = 1.04 \pm 0.01_{\text{power}} \pm 0.01_{\text{pert}}.$$
 (14)

Lattice calculations including effects beyond the heavy mass limit have become available, and hence the fact that deviations from the HQET predictions are parametrically larger than in the case $\overline{B} \to D^* \ell \overline{\nu}_{\ell}$ is irrelevant. These unquenched calculations quote a value (preliminary, from 2005) [28]

$$\mathcal{G}(1) = 1.074 \pm 0.018 \pm 0.016.$$
 (15)

The measurements of $\overline{B} \to D\ell\overline{\nu}_{\ell}$ have improved substantially in the last few years. The new measurements [24,29] are consistent with previous measurements [17,30,31] but significantly more precise. The average of these inputs [26] gives $\mathcal{G}(1)|V_{cb}|=(42.6\pm0.7\pm1.4)\times10^{-3}$. Using the value given in Eq. (15) for $\mathcal{G}(1)$, accounting for the electroweak correction and conservatively adding the theory uncertainties linearly results in

$$|V_{cb}| = (39.4 \pm 1.4 \pm 1.3) \times 10^{-3} \quad (\overline{B} \to D\ell \overline{\nu}_{\ell}, \text{ LQCD}), (16)$$

where the first uncertainty is from experiment and the second from theory.

Using the non-lattice estimate from Eq. (14) one finds $|V_{cb}|=(40.7\pm1.5\pm0.8)\times10^{-3}$.

Measuring the differential rate at w=1 is more difficult in $\overline{B} \to D\ell\overline{\nu}_\ell$ decays than in $\overline{B} \to D^*\ell\overline{\nu}_\ell$ decays, since the rate is smaller and the background from mis-reconstructed $\overline{B} \to D^*\ell\overline{\nu}_\ell$ decays is significant; this is reflected in the larger experimental uncertainty. The B factories address these limitations by studying decays recoiling against fully reconstructed B mesons or doing a global fit to $\overline{B} \to X_c\ell\overline{\nu}_\ell$ decays. Theoretical input

V_{cb} and V_{ub} CKM Matrix Elements

on the shape of the w spectrum in $\overline{B} \to D\ell\overline{\nu}_{\ell}$ is valuable, as precise measurements of the total rate are easier; recent measurements [24,29] of $\mathcal{B}(\overline{B} \to D\ell\overline{\nu}_{\ell})$ have uncertainties of $\sim 5\%$.

The determinations from $\overline{B} \to D^* \ell \overline{\nu}_{\ell}$ and $\overline{B} \to D \ell \overline{\nu}_{\ell}$ decays are consistent, and their uncertainties are largely uncorrelated. Averaging these two lattice-based results gives

$$|V_{cb}| = (39.6 \pm 0.9) \times 10^{-3}$$
 (exclusive). (17)

Prospects for Lattice determinations of the $B \to D^{(*)}$ form factors

Lattice determinations of the $B \to D^{(*)}$ form factors naturally build in heavy-quark symmetries, so all uncertainties scale with the deviation of the form factor from unity [32,33]. In combination with unquenched calculations, i.e. calculations with realistic sea quarks, one obtains quite precise calculations of the form factors, now at the 2% level. The dominant uncertainties are due to the chiral extrapolation from the light quark masses used in the numerical lattice computation to realistic up and down quark masses, and to discretization errors. These sources of uncertainty will be reduced with larger lattice sizes and smaller lattice spacings.

A further ongoing development is the extension of these calculations to nonzero recoil. Such calculations are especially helpful for avoiding the $w \to 1$ extrapolation in $B \to D$.

Decays to Excited D Meson States

Above the ground state D and D^* mesons lie four positiveparity states with one unit of orbital angular momentum, generically denoted as D^{**} . In the heavy mass limit they form two spin symmetry doublets with $j_{\ell} = 1/2$ and $j_{\ell} = 3/2$, where j_{ℓ} is the total angular momentum of the light degrees of freedom. The doublet with $j_{\ell} = 3/2$ is expected to be narrow while the states with $j_{\ell} = 1/2$ should be broad, consistent with experimental measurements. Furthermore, one expects that in the heavy mass limit $\Gamma(B \to D^{**}(j_{\ell} = 3/2)\ell\bar{\nu}) \gg \Gamma(B \to D^{**}(j_{\ell} = 3/2)\ell\bar{\nu})$ $D^{**}(j_{\ell}=1/2)\ell\bar{\nu})$ [34,35,36]. Measurements indicate that this expectation may be violated, although the experimental situation is not clear. BELLE [37] and BABAR [38] report different results for the broad states and the experiments do not have the sensitivity to identify the spin-parity of these states. It has been suggested that decays to radially excited charm mesons may play a role in this puzzle [39]. If a violation is confirmed, it may indicate substantial mixing between the two spin symmetry doublets, which can occur due to terms of order $1/m_c$. However, the impact on the exclusive $|V_{cb}|$ determination is expected to be small, since the zero-recoil point is protected against corrections of order $1/m_c$ by Luke's theorem.

$|V_{cb}|$ from inclusive decays

At present the most precise determinations of $|V_{cb}|$ come from inclusive decays. The method is based on a measurement of the total semileptonic decay rate, together with the leptonic energy and the hadronic invariant mass spectra of inclusive semileptonic decays. The total decay rate can be calculated quite reliably in terms of non-perturbative parameters that can be extracted from the information contained in the spectra.

Inclusive semileptonic rate

The theoretical foundation for the calculation of the total semileptonic rate is the Operator Product Expansion (OPE) which yields the Heavy Quark Expansion (HQE), a systematic expansion in inverse powers of the b-quark mass [40,41]. The validity of the OPE is proven in the deep Euclidean region for the momenta (which is satisfied, e.g., in deep inelastic scattering), but its application to heavy-quark decays requires a continuation to time-like momenta $p_B^2 = M_B^2$, where possible contributions which are exponentially damped in the Euclidean region could become oscillatory. The validity of the OPE for inclusive decays is equivalent to the assumption of partonhadron duality, hereafter referred to simply as duality, and possible oscillatory contributions would be an indication of duality violation.

Duality-violating effects are hard to quantify. In practice, they would appear as unnaturally large coefficents of higher order terms in the 1/m expansion [42]. The description of ~ 60 measurements in terms of ~ 6 free parameters in global fits to $\overline{B} \to X_c \ell \overline{\nu}_\ell$ decays provides a non-trivial testing ground for the HQE predictions. Present fits include terms up to order $1/m_b^3$, the coefficients of which have sizes as expected a priori by theory and are in quantitative agreement with extractions from other observables. The consistency of the data with these OPE fits will be discussed later; no indication is found that terms of order $1/m_b^4$ or higher are large, and there is no evidence for duality violations in the data. Thus duality or, likewise, the validity of the OPE, is assumed in the analysis, and no further uncertainty is assigned to potential duality violations.

The OPE result for the total rate can be written schematically (the details of the expression can be found, e.g., in Ref. [43]) as

$$\Gamma = |V_{cb}|^2 \hat{\Gamma}_0 m_b^5(\mu) (1 + A_{\text{ew}}) \times \left[z_0^{(0)}(r) + \frac{\alpha_s(\mu)}{\pi} z_0^{(1)}(r) + \left(\frac{\alpha_s(\mu)}{\pi} \right)^2 z_0^{(2)}(r) + \cdots \right. \\ + \frac{\mu_{\pi}^2}{m_b^2} \left(z_2^{(0)}(r) + \frac{\alpha_s(\mu)}{\pi} z_2^{(1)}(r) + \cdots \right) \\ + \frac{\mu_G^2}{m_b^2} \left(y_2^{(0)}(r) + \frac{\alpha_s(\mu)}{\pi} y_2^{(1)}(r) + \cdots \right) \\ + \frac{\rho_{\text{DS}}^3}{m_b^3} \left(z_3^{(0)}(r) + \frac{\alpha_s(\mu)}{\pi} z_3^{(1)}(r) + \cdots \right) \\ + \frac{\rho_{\text{LS}}^3}{m_b^3} \left(y_3^{(0)}(r) + \frac{\alpha_s(\mu)}{\pi} y_3^{(1)}(r) + \cdots \right) \\ + z_4 \left(r, \frac{s_i}{m_b^4}, \frac{\alpha_s(\mu)}{\pi} \right) + \dots \right]$$

$$(18)$$

where $A_{\rm ew}$ denotes the electroweak corrections, r is the ratio m_c/m_b and the y_i and z_i are known functions which appear in the perturbative expansion of the different orders of the heavy mass expansion. A similar expansion can be set up for

moments of the distributions of charged-lepton energy, hadronic invariant mass and hadronic energy.

This expression is known up to order $1/m_b^5$, where the terms of order $1/m_b^n$ with n>2 have been computed only at tree level [44,45,46,47]. The leading term is the parton model, which is known completely to order α_s and α_s^2 [48–50], and the terms of order $\alpha_s^{n+1}\beta_0^n$ (where β_0 is the first coefficient of the QCD β function, $\beta_0 = (33 - 2n_f)/3$) have been included by the usual BLM procedure [43,51,52]. Furthermore, the corrections of order $\alpha_s\mu_\pi^2/m_b^2$ have been computed [53].

Starting at order $1/m_b^3$ contributions with an infrared sensitivity to the charm mass m_c appear [46,54,112]. At order $1/m_b^3$ this "intrinsic charm" contribution is a $\log(m_c)$ in the coefficient of the Darwin term ρ_D^3 . At higher orders, terms such as $1/m_b^3 \times 1/m_c^2$ and $\alpha_s(m_c)1/m_b^3 \times 1/m_c$ appear, which are comparable in size to the contributions of order $1/m_b^4$

The HQE parameters are given in terms of forward matrix elements; the parameters entering the expansion for orders up to $1/m_b^3$ are

$$\overline{\Lambda} = M_B - m_b ,$$

$$\mu_{\pi}^2 = -\langle B|\overline{b}(iD_{\perp})^2b|B\rangle ,$$

$$\mu_G^2 = \langle B|\overline{b}(iD_{\perp}^{\mu})(iD_{\perp}^{\nu})\sigma_{\mu\nu}b|B\rangle ,$$

$$\rho_D^3 = \langle B|\overline{b}(iD_{\perp\mu})(ivD)(iD_{\perp}^{\nu})b|B\rangle ,$$

$$\rho_{\rm LS}^3 = \langle B|\overline{b}(iD_{\perp}^{\mu})(ivD)(iD_{\perp}^{\nu})\sigma_{\mu\nu}b|B\rangle .$$
(19)

The hadronic parameters of the orders $1/m_b^4$ and $1/m_b^5$ can be found in Ref. [47] while the five hadronic parameters s_i of the order $1/m_b^4$ can be found in Ref. [45]; these have not yet been included in the fits. The non-perturbative matrix elements depend on the renormalization scale μ , on the chosen renormalization scheme and on the quark mass m_b , and may eventually be calculated in Lattice QCD. The rates and the spectra depend strongly on m_b (or equivalently on $\overline{\Lambda}$), which makes the discussion of renormalization issues mandatory.

Using the pole mass definition for the heavy quark masses, it is well known that the corresponding perturbative series of decay rates does not converge very well, making a precision determination of $|V_{cb}|$ in such a scheme impossible. The solution to this problem is to choose an appropriate "short-distance" mass definition. Frequently used mass definitions are the kinetic scheme [14], or the 1S scheme [56]. Both of these schemes have been applied to semileptonic $b \to c$ transitions, yielding comparable results and uncertainties.

The 1S scheme eliminates the b quark pole mass by relating it to the perturbative expression for the mass of the 1S state of the Υ system. The physical mass of the $\Upsilon(1S)$ contains non-perturbative contributions, which have been estimated in Ref. [57]. These non-perturbative contributions are small; nevertheless, the best determination of the b quark mass in the 1S scheme is obtained from sum rules for $e^+e^- \to b\bar{b}$ [58].

Alternatively one may use a short-distance mass definition such as the $\overline{\rm MS}$ mass $m_b^{\overline{\rm MS}}(m_b)$. However, it has been argued that the scale m_b is unnaturally high for B decays, while

for smaller scales $\mu \sim 1 \, \text{GeV} \, m_b^{\overline{\text{MS}}}(\mu)$ is under poor control. For this reason the so-called "kinetic mass" $m_b^{\text{kin}}(\mu)$, has been proposed. It is the mass entering the non-relativistic expression for the kinetic energy of a heavy quark, and is defined using heavy-quark sum rules [14].

The HQE parameters also depend on the renormalization scale and scheme. The matrix elements given in Eq. (19) are defined with the full QCD fields and states, which is the definition frequently used in the kinetic scheme. Sometimes slightly different parameters λ_1 and λ_2 are used, which are defined in the infinite mass limit. The relation between these parameters is

$$\overline{\Lambda}_{\text{HQET}} = \lim_{m_b \to \infty} \overline{\Lambda}, \quad -\lambda_1 = \lim_{m_b \to \infty} \mu_{\pi}^2,
\lambda_2 = \lim_{m_b \to \infty} \mu_G^2, \quad \rho_1 = \lim_{m_b \to \infty} \rho_D^3,
\rho_2 = \lim_{m_b \to \infty} \rho_{LS}^3.$$
(20)

Defining the kinetic energy and the chromomagnetic moment in the infinite-mass limit (as, e.g., in the 1S scheme) requires that $1/m_b$ corrections to the matrix elements defined in Eq. (19) be taken into account once one goes beyond order $1/m_b^2$. As a result, additional quantities $\mathcal{T}_1 \cdots \mathcal{T}_4$ appear at order $1/m_b^3$. However, these quantities are correlated such that the total number of non-perturbative parameters to order $1/m_b^3$ is the same as in the scheme where m_b is kept finite in the matrix elements which define the non-perturbative parameters. A detailed discussion of these issues can be found in Ref. [59].

In order to define the HQE parameters properly one must adopt a renormalization scheme, as was done for the heavy quark mass. Since all these parameters can again be determined by heavy-quark sum rules, one may adopt a scheme similar to the kinetic scheme for the quark mass. The HQE parameters in the kinetic scheme depend on powers of the renormalization scale μ , and the above relations are valid in the limit $\mu \to 0$, leaving only logarithms of μ .

Some of these parameters also appear in the relation for the heavy hadron masses. The quantity $\overline{\Lambda}$ is determined once a definition is specified for the quark mass. The parameter μ_G^2 can be extracted from the mass splitting in the lowest spin-symmetry doublet of heavy mesons [60]

$$\mu_G^2(\mu) = \frac{3}{4} C_G(\mu, m_b) (M_{B^*}^2 - M_B^2), \tag{21}$$

where $C_G(\mu, m_b)$ is a perturbatively-computable coefficient which depends on the scheme. In the kinetic scheme we have

$$\mu_G^2(1\text{GeV}) = 0.35_{-0.02}^{+0.03} \,\text{GeV}^2.$$
 (22)

Determination of HQE Parameters and $|V_{cb}|$

Several experiments have measured moments in $\overline{B} \to X_c \ell \overline{\nu}_\ell$ decays [61–69] as a function of the minimum lepton momentum. The measurements of the moments of the electron energy spectrum (0th-3rd) and of the squared hadronic mass spectrum (0th-2nd) have statistical uncertainties that are roughly equal

V_{cb} and V_{ub} CKM Matrix Elements

to their systematic uncertainties. They can be improved with more data and significant effort. The sets of moments measured by each experiment have strong correlations; the full statistical and systematic correlation matrices are required to allow these to be used in a global fit. Measurements of photon energy moments $(0^{\text{th}}-2^{\text{nd}})$ in $B \to X_s \gamma$ decays [70–74] as a function of the minimum accepted photon energy are still primarily statistics limited.

Global fits to the full set of moments [69,71,75–78] have been performed in the 1S and kinetic schemes. The semileptonic moments alone determine a linear combination of m_b and m_c very accurately but leave the orthogonal combination poorly determined [79]; additional input is required to allow a precise determination of m_b . This additional information can come from the radiative $B \to X_s \gamma$ moments, which provide complementary information on m_b and μ_π^2 , or from precise determinations of the charm quark mass [80,81]. The values obtained in the kinetic scheme fits [77] with these two constraints are consistent. Based on the charm quark mass constraint [80], $m_c^{\overline{\rm MS}}(3\,{\rm GeV}) = 0.998 \pm 0.029\,{\rm GeV}$,

$$|V_{cb}| = (41.88 \pm 0.44 \pm 0.59) \times 10^{-3}$$
 (23)

$$m_h^{\text{kin}} = 4.560 \pm 0.023 \,\text{GeV}$$
 (24)

$$\mu_{\pi}^{2}(\text{kin}) = 0.453 \pm 0.036 \,\text{GeV}^{2},$$
(25)

where the first error on $|V_{cb}|$ includes experimental and theoretical uncertainties and the second error is from the estimated accuracy of the HQE for the total semileptonic rate.

Theoretical uncertainties are estimated and included in performing the fits. The $\chi^2/{\rm dof}$ is substantially below unity in all fits, suggesting that the theoretical uncertainties may be overestimated. In any case, the low χ^2 shows no evidence for duality violations at a significant level. Similar values for the parameters are obtained when only experimental uncertainties are used in the fits. If the photon energy spectrum moments from $\overline{B} \to X_s \gamma$ are used in place of the constraint on the charm quark mass, the results change by only small amounts, e.g., $m_b^{\rm kin}$ increases to $4.574 \pm 0.032 \,{\rm GeV}$. The mass in the $\overline{\rm MS}$ scheme corresponding to Eq. (24) is $m_b^{\overline{\rm MS}} = 4.19 \pm 0.04 \,{\rm GeV}$, which can be compared with a recent value obtained using relativistic sum rules [82], $m_b^{\overline{\rm MS}} = 4.163 \pm 0.016 \,{\rm GeV}$, and provides a non-trivial cross-check.

A fit to the same moments in the 1S scheme gives [78]

$$|V_{cb}| = (41.96 \pm 0.45 \pm 0.07) \times 10^{-3}$$
 (26)

$$m_b^{1S} = 4.691 \pm 0.037 \,\text{GeV}$$
 (27)

$$\lambda_1(1S) = -0.362 \pm 0.067 \,\text{GeV}^2,$$
 (28)

where the last error on $|V_{cb}|$ is due to the uncertainties in the B meson lifetimes. This fit uses semileptonic and radiative moments and constrains the chromomagnetic operator using the mass difference between the D and D^* mesons. This independent fit gives consistent results for $|V_{cb}|$ and, after translation to a common renormalization scheme, for m_b and μ^2

The precision of the global fit results can be further improved. Some of the measurements, in particular of the $\overline{B} \to X_s \gamma$ photon energy spectrum, can be improved by using the full B-factory data sets. Improvements can be made in the theory by calculating higher order perturbative corrections to the coefficients of the HQE parameters, in particular the still missing $\alpha_s \mu_G^2$ corrections, which are presently only known for $B \to X_s \gamma$ [84]. The inclusion of still higher order moments may improve the sensitivity of the fits to higher order terms in the HQE.

Determination of $|V_{ub}|$

Summary: The determination of $|V_{ub}|$ is the focus of significant experimental and theoretical work. The determinations based on inclusive semileptonic decays using different calculational ansätze are consistent. The largest parametric uncertainty comes from the error on m_b . Significant progress has been made in determinations of $|V_{ub}|$ from $\overline{B} \to \pi \ell \overline{\nu}_\ell$ decays by using combined fits to theory and experimental data as a function of q^2 . Further improvements in the form factor normalization are needed to improve the precision.

The values obtained from inclusive and exclusive determinations are

$$|V_{ub}| = (4.41 \pm 0.15 + 0.15 + 0.15) \times 10^{-3}$$
 (inclusive), (29)

$$|V_{ub}| = (3.23 \pm 0.31) \times 10^{-3}$$
 (exclusive). (30)

The two determinations are independent, and the dominant uncertainties are on multiplicative factors. The inclusive and exclusive values are weighted by their relative errors and the uncertainties are treated as normally distributed. The resulting average has $p(\chi^2) = 0.01$, so we scale the error by $\sqrt{\chi^2/1} = 2.6$ to find

$$|V_{ub}| = (4.15 \pm 0.49) \times 10^{-3}.$$
 (31)

Given the poor consistency between the two determinations, this average should be treated with caution.

$|V_{ub}|$ from inclusive decays

The theoretical description of inclusive $\overline{B} \to X_u \ell \overline{\nu}_\ell$ decays is based on the Heavy Quark Expansion, as for $\overline{B} \to X_c \ell \overline{\nu}_\ell$ decays, and leads to a predicted total decay rate with uncertainties below 5% [85,86]. Unfortunately, the total decay rate is hard to measure due to the large background from CKMfavored $\overline{B} \to X_c \ell \overline{\nu}_{\ell}$ transitions. Technically, the calculation of the partial decay rate in regions of phase space where $\overline{B} \to X_c \ell \overline{\nu}_\ell$ decays are suppressed is different from what has been described above, since it requires the introduction of a non-perturbative distribution function, the "shape function" (SF) [87,88]. Due to this, the theoretical input for the extraction on V_{ub} from inclusive decays is more challenging. The shape function becomes important when the light-cone momentum component $P_{+} \equiv E_{X} - |P_{X}|$ is not large compared to Λ_{QCD} . This additional difficulty can be addressed in two complementary ways. The leading shape function can either be measured in the radiative decay $\overline{B} \to X_s \gamma$, or be modeled with

constraints on the 0th-2nd moments, and the results applied to the calculation of the $\overline{B} \to X_u \ell \overline{\nu}_\ell$ partial decay rate [89–91]; in such an approach the largest challenges are for the theory. Alternatively, measurements of $\overline{B} \to X_u \ell \overline{\nu}_\ell$ partial decay rates can be extended further into the $\overline{B} \to X_c \ell \overline{\nu}_\ell$ -allowed region, enabling a simplified theoretical (pure HQE) treatment [92] but requiring precise experimental knowledge of the $\overline{B} \to X_c \ell \overline{\nu}_\ell$ background.

The shape function is a universal property of B mesons at leading order. It has been recognized for many years [87,88] that the leading SF can be measured in $\overline{B} \to X_s \gamma$ decays. However, sub-leading shape functions [93-98] arise at each order in $1/m_b$, and differ in semileptonic and radiative B decays. The form of the SFs cannot be calculated from first principles. Prescriptions that relate directly the partial rates for $\overline{B} \to X_s \gamma$ and $\overline{B} \to X_u \ell \overline{\nu}_{\ell}$ decays and thereby avoid any parameterization of the leading SF are available [99–102]; uncertainties due to sub-leading SFs remain in these approaches. Existing measurements have tended to use parameterizations of the leading SF that respect constraints on the zeroth, first and second moments. At leading order the first and second moments are equal to $\overline{\Lambda} = M_B - m_b$ and μ_{π}^2 , respectively. The relations between SF moments and the non-perturbative parameters of the HQE are known to second order in α_s [103]. As a result, measurements of HQE parameters from global fits to $\overline{B} \to X_c \ell \overline{\nu}_\ell$ and $\overline{B} \to X_s \gamma$ moments can be used to constrain the SF moments, as well as provide accurate values of m_b and other parameters for use in determining $|V_{ub}|$. The possibility of measuring these HQE parameters directly from moments in $\overline{B} \to X_u \ell \overline{\nu}_\ell$ decays has been explored [104], but the experimental precision achievable there is not competitive with other approaches.

A recent development is to use appropriate basis functions to approximate the shape function, thereby also including the known short-distance contributions as well as the renormalization properties of the SF [105], in order to allow a global fit of all inclusive B meson decay data.

The calculations that are used for the fits performed by HFAG are documented in Refs. [89] (BLNP), [106] (GGOU), [107] (DGE) and [92] (BLL).

The calculations start from the triple diffential rate using the variables

$$P_l = M_B - 2E_l, \quad P_- = E_X + |\vec{P}_X|, \quad P_+ = E_X - |\vec{P}_X| \quad (32)$$

for which the differential rate becomes

$$\frac{d^{3}\Gamma}{dP_{+}dP_{-}dP_{l}} = \frac{G_{F}^{2}|V_{ub}|^{2}}{16\pi^{2}}(M_{B} - P_{+})$$

$$\left\{ (P_{-} - P_{l})(M_{B} - P_{-} + P_{l} - P_{+})\mathcal{F}_{1} + (M_{B} - P_{-})(P_{-} - P_{+})\mathcal{F}_{2} + (P_{-} - P_{l})(P_{l} - P_{+})\mathcal{F}_{3} \right\}.$$
(33)

The "structure functions" \mathcal{F}_i can be calculated using factorization theorems that have been proven to subleading order in the $1/m_b$ expansion.

The BLNP [89] calculation uses these factorization theorems to write the \mathcal{F}_i in terms of perturbatively calculable hard coefficients H and jet functions J, which are convolved with the (soft) light-cone distribution functions S, the shape functions of the B meson. The BLNP calculation has been updated to include the full $\mathcal{O}(\alpha_S^2)$ contributions [108].

The leading order term in the $1/m_b$ expansion of the \mathcal{F}_i contains a single non-perturbative function and is calculated to subleading order in α_s , while at subleading order in the $1/m_b$ expansion there are several independent non-perturbative functions which have been calculated only at tree level in the α_s expansion.

To extract the non-perturbative input one can study the photon energy spectrum in $B \to X_s \gamma$ [91]. This spectrum is known at a similar accuracy as the P_+ spectrum in $B \to X_u \ell \overline{\nu}_\ell$. Going to subleading order in the $1/m_b$ expansion requires the modeling of subleading SFs, a large variety of which were studied in Ref. [89].

A distinct approach (GGOU) [106] uses a hard, Wilsonian cut-off that matches the definition of the kinetic mass. The non-perturbative input is similar to what is used in BLNP, but the shape functions are defined differently. In particular, they are defined at finite m_b and depend on the light-cone component k_+ of the b quark momentum and on the momentum transfer q^2 to the leptons. These functions include sub-leading effects to all orders; as a result they are non-universal, with one shape function corresponding to each structure function in Eq. (33). Their k_+ moments can be computed in the OPE and related to observables and to the shape functions defined in Ref. [89].

Going to subleading order in α_s requires the definition of a renormalization scheme for the HQE parameters and for the SF. It has been noted that the relation between the moments of the SF and the forward matrix elements of local operators is plagued by ultraviolet problems which require additional renormalization. A possible scheme for improving this behavior has been suggested in Refs. [89,91], which introduce a particular definition of the quark mass (the so-called shape function scheme) based on the first moment of the measured spectrum. Likewise, the HQE parameters can be defined from measured moments of spectra, corresponding to moments of the SF.

One can also attempt to calculate the SF by using additional assumptions. One possible approach (DGE) is the so-called "dressed gluon exponentiation" [107], where the perturbative result is continued into the infrared regime using the renormalon structure obtained in the large β_0 limit, where β_0 has been defined following Eq. (18).

While attempts to quantify the SF are important, the impact of uncertainties in the SF is significantly reduced in some recent measurements that cover a larger portion of the $\overline{B} \to X_u \ell \overline{\nu}_\ell$ phase space. Several measurements using a combination of cuts on the leptonic momentum transfer q^2 and the hadronic invariant mass m_X as suggested in Ref. [109] have been made. Measurements of the electron spectrum in

V_{cb} and V_{ub} CKM Matrix Elements

 $\overline{B} \to X_u \ell \overline{\nu}_\ell$ decays have been made down to momenta of 1.9 GeV or even lower, where SF uncertainties are not dominant. Of course, determining $\overline{B} \to X_u \ell \overline{\nu}_\ell$ partial rates in charm-dominated regions can bring in a strong dependence on the modeling of the $\overline{B} \to X_u \ell \overline{\nu}_\ell$ spectrum, which is problematic. The measurements quoted below have used a variety of functional forms to parameterize the leading SF; in no case does this lead to more than a 2% uncertainty on $|V_{ub}|$.

Weak Annihilation [110,111,106] (WA) can in principle contribute significantly in the restricted region (at high q^2) accepted by measurements of $\overline{B} \to X_u \ell \overline{\nu}_\ell$ decays. An estimate [92] based on leptonic D_s decays [111,112] leads to a $\sim 2\%$ uncertainty on the total $\overline{B} \to X_u \ell \overline{\nu}_\ell$ rate from the $\Upsilon(4S)$. The differential spectrum from WA decays is not well known, but they are expected to contribute predominantly at high q^2 . More recent investigations of WA [112,113,114] confirm that WA is a small effect, but may become a significant source of uncertainty for $|V_{ub}|$ measurements that only accept a small fraction, f_u , of the full $\overline{B} \to X_u \ell \overline{\nu}_\ell$ phase space. Modeldependent limits on WA were determined in Ref. [115], where the CLEO data were fitted to combinations of WA models and a spectator $\overline{B} \to X_u \ell \overline{\nu}_{\ell}$ component and background. More direct experimental constraints [116] on WA have recently been made by comparing the $\overline{B} \to X_u \ell \overline{\nu}_\ell$ decay rates of charged and neutral B mesons. However, these constraints are not sensitive to the isoscalar contribution to WA. The sensitivity of $|V_{ub}|$ determinations to WA can also be reduced by removing the region at high q^2 in those measurements where q^2 is determined.

Measurements

We summarize the measurements used in the determination of $|V_{ub}|$ below. Given the improved precision and more rigorous theoretical interpretation of the recent measurements, earlier determinations [117–120] will not be further considered in this review.

Inclusive electron momentum measurements [121–123] reconstruct a single charged electron to determine a partial decay rate for $\overline{B} \to X_u \ell \overline{\nu}_{\ell}$ near the kinematic endpoint. This results in a high $\mathcal{O}(50\%)$ selection efficiency and only modest sensitivity to the modeling of detector response. The decay rate can be cleanly extracted for $E_e > 2.3 \,\text{GeV}$, but this is deep in the SF region, where theoretical uncertainties are large. Measurements down to 2.0 or 1.9 GeV exist, but have low (< 1/10) signal-to-background (S/B) ratio, making the control of the $\overline{B} \to X_c \ell \overline{\nu}_{\ell}$ background a crucial point. In these analyses the inclusive electron momentum spectrum from $B\overline{B}$ events is determined by subtracting the $e^+e^- \rightarrow q\bar{q}$ continuum background using data samples collected just below $B\overline{B}$ threshold. The continuum-subtracted spectrum is fitted to a combination of a model $\overline{B} \to X_u \ell \overline{\nu}_{\ell}$ spectrum and several components $(D\ell\overline{\nu}_{\ell}, D^*\ell\overline{\nu}_{\ell}, ...)$ of the $\overline{B} \to X_c\ell\overline{\nu}_{\ell}$ background. The resulting $|V_{ub}|$ values for various E_e cuts are given in Table 1. The leading uncertainty at the lower lepton momentum cuts comes from the $\overline{B} \to X_c \ell \overline{\nu}_{\ell}$ background. Prospects for

reducing further the lepton momentum cut are improving in light of better knowledge of the semileptonic decays to higher mass $X_c\ell\overline{\nu}$ states [124,37]. The determination of $|V_{ub}|$ from these measurements is discussed below.

An untagged "neutrino reconstruction" measurement [125] from BABAR uses a combination [126] of a high-energy electron with a measurement of the missing momentum vector. This allows a much higher S/B ~ 0.7 at the same E_e cut and a $\mathcal{O}(5\%)$ selection efficiency, but at the cost of a smaller accepted phase space for $\overline{B} \to X_u \ell \overline{\nu}_\ell$ decays and uncertainties associated with the determination of the missing momentum. A control sample of $\Upsilon(4S) \to B\overline{B}$ decays where one B is reconstructed as $\overline{B} \to D^0(X) e \overline{\nu}$ with $D^0 \to K^- \pi^+$ is used to reduce uncertainties from detector and background modeling. The corresponding values for $|V_{ub}|$ are given in Table 1.

The large samples accumulated at the B factories allow studies in which one B meson is fully reconstructed and the recoiling B decays semileptonically [127–130]. ments can fully reconstruct a "tag" B candidate in about 0.5%(0.3%) of $B^+B^ (B^0\overline{B}^0)$ events. An electron or muon with center-of-mass momentum above 1.0 GeV is required amongst the charged tracks not assigned to the tag B and the remaining particles are assigned to the X_u system. The full set of kinematic properties $(E_{\ell}, m_X, q^2, etc.)$ are available for studying the semileptonically decaying B, making possible selections that accept up to 70% of the full $\overline{B} \to X_u \ell \overline{\nu}_\ell$ rate. Despite requirements (e.g. on the square of the missing mass) aimed at rejecting events with additional missing particles, undetected or mis-measured particles from $\overline{B} \to X_c \ell \overline{\nu}_\ell$ decay (e.g., K_L^0 and additional neutrinos) remain an important source of uncertainty. Measurements with the largest kinematic acceptance (i.e. $E_{\ell} > 1 \, \mathrm{GeV}$) lead to the smallest theoretical and overall uncertainties on $|V_{ub}|$.

BABAR [127] and BELLE [128,129] have measured partial rates with cuts on m_X , m_X and q^2 , and P_+ based on large samples of $B\overline{B}$ events. Correlations amongst these related partial rates are taken into account in the average given in Table 1. In each case the experimental systematics have significant contributions from the modeling of $\overline{B} \to X_u \ell \overline{\nu}_\ell$ and $\overline{B} \to X_c \ell \overline{\nu}_\ell$ decays and from the detector response to charged particles, photons and neutral hadrons.

Determination of $|V_{ub}|$

The determination of $|V_{ub}|$ from the measured partial rates requires input from theory. The BLNP, GGOU and DGE calculations described previously are used to determine $|V_{ub}|$ from all measured partial $\overline{B} \to X_u \ell \overline{\nu}_\ell$ rates; the values [26] are given in Table 1. The m_b input values used are derived from the fitted value in equation Eq. (24): $m_b^{SF} = 4.588 \pm 0.025$ GeV for BLNP, $m_b^{\rm kin} = 4.560 \pm 0.023$ GeV for GGOU, and $m_b^{\overline{MS}} = 4.194 \pm 0.043$ GeV for DGE. The larger uncertainties on m_b^{SF} and $m_b^{\overline{MS}}$ reflect the effect of scheme translations, which are done at fixed-order in α_s .

As an illustration of the relative sizes of the uncertainties entering $|V_{ub}|$ we give the error breakdown for the GGOU average: statistical—2.0%; experimental—1.7%; $\overline{B} \to X_c \ell \overline{\nu}_\ell$ modeling—1.3%; $\overline{B} \to X_u \ell \overline{\nu}_\ell$ modeling—1.9%; HQE parameters —1.9%; higher-order corrections—1.4%; q^2 modeling—1.3%; Weak Annihilation— $^{+0}_{-1.9}$ %; SF form—0.2%. The uncertainty on m_b dominates the uncertainty on $|V_{ub}|$ from HQE parameters, but no longer dominates the overall uncertainty.

The correlations amongst the multiple BABAR recoil-based measurements [127] are fully accounted for in the average. The statistical correlations amongst the other measurements used in the average are tiny (due to small overlaps among signal events and large differences in S/B ratios) and have been ignored. Correlated systematic and theoretical errors are taken into account, both within an experiment and between experiments.

Table 1: $|V_{ub}|$ (in units of 10^{-5}) from inclusive $\overline{B} \to X_u \ell \overline{\nu}_\ell$ measurements. The first uncertainty on $|V_{ub}|$ is experimental, while the second includes both theoretical and HQE parameter uncertainties. The values are listed in order of increasing f_u (0.19 to 0.90); those below the horizontal bar are based on recoil methods.

The theoretical calculations produce very similar results for $|V_{ub}|$; the standard deviation of the theory predictions for the endpoint rate is 4.6%, for the m_X - q^2 rate is 2.2%, and for the $E_e > 1$ GeV rate is 0.8%. The $|V_{ub}|$ values do not show a marked trend versus the kinematic acceptance, f_u , for $\overline{B} \to X_u \ell \overline{\nu}_\ell$ decays. The p-values of the averages are in the range 30-50%, indicating that the ratios of calculated partial widths in the different phase space regions are in good agreement with ratios of measured partial branching fractions.

A recent calculation [108] at NNLO accuracy of the leading term in the partial rate for kinematically restrictive cuts (e.g. near the electron endpoint energy) shows a surprisingly large change from the NLO calculation used in the BLNP method, increasing $|V_{ub}|$ by up to $\sim 8\%$ for some measurements. These updated calculations are not reflected in the BLNP values shown in Table 1. In the GGOU and the DGE approaches the inclusion of the dominant $\alpha_s^2\beta_0$ contributions do not suggest large α_s^2 corrections in these methods.

All calculations yield compatible $|V_{ub}|$ values and similar error estimates. We take the arithmetic mean of the values and errors to find

$$|V_{ub}| = (4.41 \pm 0.15_{\text{exp}} ^{+0.15}_{-0.17 \text{ th}}) \times 10^{-3}$$
 (inclusive). (34)

As was the case with $|V_{cb}|$, it is hard to assign an uncertainty to $|V_{ub}|$ for possible duality violations. However, theoretical arguments suggest that duality should hold even better in $b \to u\ell \overline{\nu}_\ell$ than in $b \to c\ell \overline{\nu}_\ell$ [42]. In any case, unless duality violations are much larger in $\overline{B} \to X_u\ell \overline{\nu}_\ell$ decays than in $\overline{B} \to X_c\ell \overline{\nu}_\ell$ decays, the precision of the $|V_{ub}|$ determination is not yet at the level where duality violations are likely to be significant.

Hadronization uncertainties also impact the $|V_{ub}|$ determination. The theoretical expressions are valid at the parton level and do not incorporate any resonant structure (e.g. $\overline{B} \to \pi \ell \overline{\nu}_{\ell}$); this must be added "by hand" to the simulated $\overline{B} \to X_u \ell \overline{\nu}_{\ell}$ event samples, since the detailed final state multiplicity and structure impacts the estimates of experimental acceptance and efficiency. The experiments have adopted procedures to input resonant structure while preserving the appropriate behavior in the kinematic variables averaged over the sample. The resulting uncertainties have been estimated to be $\sim 1\text{-}2\%$ on $|V_{ub}|$.

A separate class of analyses follows the strategy discussed in Refs. [99–102], where integrals of differential distributions in $\overline{B} \to X_u \ell \overline{\nu}_\ell$ decays are compared with corresponding integrals in $\overline{B} \to X_s \gamma$ decays to extract $|V_{ub}|$, thereby eliminating the need to model the leading shape function. A study [132] using the measured BABAR electron spectrum in $\overline{B} \to X_u \ell \overline{\nu}_\ell$ decays provides $|V_{ub}|$ determinations using all available "SF-free" calculations; the resulting $|V_{ub}|$ values have total uncertainties of $\sim 12\%$ and are compatible with the average quoted above.

The BLL [109] calculation can be used for measurements [128,130,131] with cuts on m_X and q^2 . Using the same HQE parameter input as above yields a $|V_{ub}|$ value of $(4.62 \pm 0.20 \pm 0.29) \times 10^{-3}$, which is about 7% higher than the values obtained from the calculations used in Table 1 for these measurements.

Status and outlook

At present, as indicated by the average given above, the uncertainty on $|V_{ub}|$ from inclusive decays is at the 5% level. Are these uncertainties justified? The uncertainty on m_b was discussed in detail above. The uncertainties quoted in the calculations due to matching scales, higher order corrections, etc., are at the few percent level on $|V_{ub}|$. While these uncertainties are inherently difficult to quantify, the calculations take different approaches yet produce similar estimates. Experimental uncertainties have been assessed independently by BaBar and Belle. An important common source of uncertainty comes from modelling the $\overline{B} \to X_u \ell \overline{\nu}_\ell$ decays. Better measurements of these exclusive decays would be helpful in this regard, as would improved knowledge of the main $\overline{B} \to X_c \ell \overline{\nu}_\ell$ decays.

V_{cb} and V_{ub} CKM Matrix Elements

$|V_{ub}|$ from exclusive decays

Exclusive charmless semileptonic decays offer a complementary means of determining $|V_{ub}|$. For the experiments, the specification of the final state provides better background rejection, but the lower branching fraction reflects itself in lower yields compared with inclusive decays. For theory, the calculation of the form factors for $\overline{B} \to X_u \ell \overline{\nu}_\ell$ decays is challenging, but brings in a different set of uncertainties from those encountered in inclusive decays. In this review we focus on $\overline{B} \to \pi \ell \overline{\nu}_\ell$, as it is the most promising mode for both experiment and theory, and recent improvements have been made in both areas. Measurements of other exclusive states can be found in Refs. [135–140,154].

 $\overline{B} \to \pi \ell \overline{\nu}_{\ell}$ form factor calculations The relevant form factors for the decay $\overline{B} \to \pi \ell \overline{\nu}_{\ell}$ are usually defined as

$$\langle \pi(p_{\pi})|V^{\mu}|B(p_B)\rangle = \tag{35}$$

$$f_{+}(q^2)\left[p_B^{\mu}+p_\pi^{\mu}-\frac{m_B^2-m_\pi^2}{q^2}q^{\mu}\right]+f_0(q^2)\frac{m_B^2-m_\pi^2}{q^2}q^{\mu}$$

in terms of which the rate becomes (in the limit $m_{\ell} \to 0$)

$$\frac{d\Gamma}{da^2} = \frac{G_F^2 |V_{ub}|^2}{24\pi^3} |p_{\pi}|^3 |f_+(q^2)|^2, \tag{36}$$

where p_{π} is the momentum of pion in the B meson rest frame.

Currently available non-perturbative methods for the calculation of the form factors include lattice QCD (LQCD) and light-cone sum rules (LCSR). The two methods are complementary in phase space, since the lattice calculation is restricted to the kinematical range of high momentum transfer q^2 to the leptons, to avoid large discretization errors, while light-cone sum rules provide information near $q^2 = 0$. Interpolations between these two regions can be constrained by unitarity and analyticity.

Unquenched simulations, for which quark loop effects in the QCD vacuum are fully incorporated, have become quite common, and the first results based on these simulations for the $\overline{B} \to \pi \ell \overline{\nu}_{\ell}$ form factors have been obtained by the Fermilab/MILC collaboration [141] and the HPQCD collaboration [142]. The two calculations differ in the way the b quark is simulated, with HPQCD using nonrelativistic QCD and Fermilab/MILC the so-called Fermilab heavy-quark method; they agree within the quoted errors.

In order to obtain the partially-integrated differential rate, the BK parameterization [143]

$$f_{+}(q^{2}) = \frac{c_{B}(1 - \alpha_{B})}{(1 - \tilde{q}^{2})(1 - \alpha_{B}\tilde{q}^{2})},$$
(37)

$$f_0(q^2) = \frac{c_B(1 - \alpha_B)}{(1 - \tilde{q}^2/\beta_B)},\tag{38}$$

with $\tilde{q}^2 \equiv q^2/m_{B^*}^2$ has been used frequently to extrapolate to small values of q^2 . It includes the leading pole contribution from B^* , and higher poles are modeled by a single pole. The heavy-quark scaling is satisfied if the parameters c_B , α_B and β_B scale appropriately. However, the BK parameterization should

be used with some caution, since it is not consistent with SCET [144]. More recently, analyticity and unitarity bounds have been employed to constrain the form factors. Making use of the heavy-quark limit, stringent constraints on the shape of the form factor can be derived [144], and the conformal mapping of the kinematical variables onto the complex unit disc yields a rapidly converging series in this variable. The use of lattice data in combination with a data point at small q^2 from SCET or sum rules provides a stringent constraint on the shape of the form factor [145]. The form factor parametrization given in Ref. [145] has been applied to the extraction of $|V_{ub}|$ from $B \to \pi \ell \bar{\nu}_{\ell}$ using lattice data in Ref. [141].

Much work remains to be done, since the current combined statistical plus systematic errors in the lattice results are still at the $\sim 10\%$ level on $|V_{ub}|$ and need to be reduced. Reduction of errors to the ~ 5 -6% level for $|V_{ub}|$ will be feasible within the next few years, with the inclusion of numerical data at lighter pion masses and finer lattice spacings, as well as possibly two-loop or nonperturbative matching between lattice and continuum heavy-to-light current operators.

Another established non-perturbative approach to obtain the form factors is through Light-Cone QCD Sum Rules (LCSR), where the heavy mass limit has been discussed from the point of view of SCET in Ref. [147]. The sum-rule approach provides an approximation for the product $f_B f_+(q^2)$, valid in the region $0 < q^2 < \sim 12 \text{ GeV}^2$. The determination of $f_+(q^2)$ itself requires knowledge of the decay constant f_B , which usually is obtained by replacing f_B by its two-point QCD (SVZ) sum rule [148] in terms of perturbative and condensate contributions. The advantage of this procedure is the approximate cancellation of various theoretical uncertainties in the ratio $(f_B f_+)/(f_B)$. The LCSR for $f_B f_+$ is based on the lightcone OPE of the relevant vacuum-to-pion correlation function, calculated in full QCD at finite b-quark mass. The resulting expressions actually comprise a triple expansion: in the twist tof the operators near the light-cone, in α_s , and in the deviation of the pion distribution amplitudes from their asymptotic form, which is fixed from conformal symmetry.

There are multiple sources of uncertainties in the LCSR calculation, which are discussed in Refs. [149,150]. Currently, a total uncertainty slightly larger than 10% on $|V_{ub}|$ is extracted from a LCSR calculation of

$$\Delta\zeta(0, q_{max}^2) = \frac{G_F^2}{24\pi^3} \int_0^{q_{max}^2} dq^2 \, p_\pi^3 |f_+(q^2)|^2$$

$$= \frac{1}{|V_{ub}|^2 \tau_{B_0}} \int_0^{q_{max}^2} dq^2 \, \frac{d\mathcal{B}(B \to \pi \ell \nu)}{dq^2} \qquad (39)$$

which turn out to be [151]

$$\Delta \zeta(0, 12 \,\text{GeV}^2) = 4.59^{+1.00}_{-0.85} \,\text{ps}^{-1}.$$
 (40)

It is interesting to note that the results from the LQCD and LCSR are consistent with each other when either the

BK parameterization or parametrizations based on conformal mappings [145,146] are used to relate them. This increases confidence in the theoretical predictions for the rate of $\overline{B} \to \pi \ell \overline{\nu}_{\ell}$. This is complementary to the lattice results at large values of q^2 , and the results from LCSR smoothly extrapolate the lattice data to small values of q^2 .

An alternative determination of $|V_{ub}|$ has been proposed by several authors [152,153] based on a model-independent relation between rare decays such as $\overline{B} \to K^* \ell^+ \ell^-$ and $\overline{B} \to \rho \ell \overline{\nu}_\ell$. However, it requires a precise measurement of the $\overline{B} \to K^* \ell^+ \ell^-$ decay, which is a task for ultra-high-rate experiments.

$\overline{B} \to \pi \ell \overline{\nu}_{\ell}$ measurements

The $\overline{B} \to \pi \ell \overline{\nu}_\ell$ measurements fall into two broad classes: untagged, in which case the reconstruction of the missing momentum of the event serves as an estimator for the unseen neutrino, and tagged, in which the second B meson in the event is fully reconstructed in either a hadronic or semileptonic decay mode. The tagged measurements have high and uniform acceptance, S/B as high as 10, but low statistics. The untagged measurements have somewhat higher background levels (S/B < 1) and make slightly more restrictive kinematic cuts, but have adequate statistics to measure the q^2 dependence of the form factor.

Table 2: Total and partial branching fractions for $\overline{B}{}^0 \to \pi^+ \ell^- \overline{\nu}_\ell$, scaled to a common set of external inputs. The uncertainties are from statistics and systematics. Measurements of $\mathcal{B}(B^- \to \pi^0 \ell^- \overline{\nu}_\ell)$ have been multiplied by a factor $2\tau_{B^0}/\tau_{B^+}$ to obtain the values below.

CLEO has analyzed $\overline{B} \to \pi \ell \overline{\nu}_{\ell}$ and $\overline{B} \to \rho \ell \overline{\nu}_{\ell}$ using an untagged analysis [139]. Similar analyses have been done at BABAR [140,154] and BELLE [155]. The leading systematic uncertainties in the untagged $\overline{B} \to \pi \ell \overline{\nu}_{\ell}$ analyses are associated with modeling the missing momentum reconstruction, with backgrounds from $\overline{B} \to X_u \ell \overline{\nu}_{\ell}$ decays and $e^+e^- \to q\overline{q}$ continuum events, and with varying the form factor for the $\overline{B} \to \rho \ell \overline{\nu}_{\ell}$ decay. The values obtained for the full and partial

branching fractions [26] are listed in Table 2 above the horizontal line. These BABAR and BELLE measurements provide the differential $\overline{B} \to \pi \ell \overline{\nu}_{\ell}$ rate versus q^2 , shown in Fig. 2, which is used in the determination of $|V_{ub}|$ discussed below.

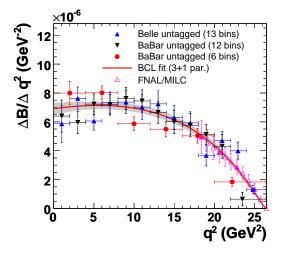

Figure 2: The untagged measurements of the differential $\overline{B} \to \pi \ell \overline{\nu}_{\ell}$ branching fraction versus q^2 that are used together with lattice calculations in the determination of $|V_{ub}|$.

Analyses [156,158] based on reconstructing a B in the $\overline{D}^{(*)}\ell^+\nu_\ell$ decay mode and looking for a $\overline{B}\to\pi\ell\overline{\nu}_\ell$ or $\overline{B}\to\rho\ell\overline{\nu}_\ell$ decay amongst the remaining particles in the event make use of the fact that the B and \overline{B} are back-to-back in the $\Upsilon(4S)$ frame to construct a discriminant variable that provides a signal-to-noise ratio above unity for all q^2 bins. A related technique was discussed in Ref. [161]. BABAR [158] and BELLE [157] have also used their samples of B mesons reconstructed in hadronic decay modes to measure exclusive charmless semileptonic decays giving very clean but low-yield samples. The resulting full and partial branching fractions are given in Table 2. The averages take account of correlations and common systematic uncertainties, and have $p(\chi^2) > 0.5$ in each case.

 $|V_{ub}|$ can be obtained from the average $\overline{B} \to \pi \ell \overline{\nu}_{\ell}$ branching fraction and the measured q^2 spectrum. Using the average [26] of partial branching fractions in the $q^2 < 12 \,\text{GeV}^2$ region, $(0.81 \pm 0.02 \pm 0.03) \times 10^{-4}$, along with an LCSR calculation of the theoretical rate [151] gives

$$|V_{ub}| = (3.40 \pm 0.07_{\text{exp}}^{+0.37}_{-0.32 \text{ theo}}) \times 10^{-3} \text{ (LCSR}, q^2 < 12 \text{ GeV}^2).$$
(41)

Fits to the measured q^2 spectrum using a theoretically motivated parameterization (e.g. "BCL" from Ref. [146]) remove most of the model dependence from theoretical uncertainties in the shape of the spectrum. Recent determinations [26,141] of $|V_{ub}|$ from $\overline{B} \to \pi \ell \overline{\nu}_{\ell}$ decays have used simultaneous fits (see

V_{cb} and V_{ub} CKM Matrix Elements

also Refs. [162]) to the experimental partial rate and lattice points versus q^2 . A fit [26] to the untagged measurements incorporates the full statistical and systematic uncertainties in the measured spectrum and uses four lattice points in the region $q^2 > 16 \, \text{GeV}^2$, taking into account their correlations. The fit, shown in Fig. 2, has $p(\chi^2) = 2.2\%$. If the tagged measurements, which are less consistent in the $q^2 < 8 \, \text{GeV}^2$ region, are included, the fit gives $p(\chi^2) < 0.01\%$. We quote the result from the untagged measurements and add the difference (0.09×10^{-3}) between the $|V_{ub}|$ values from the two fits as an additional uncertainty to find

$$|V_{ub}| = (3.23 \pm 0.31) \times 10^{-3}$$
 (exclusive). (42)

The largest contributions to the uncertainty come from lattice systematic and statistical errors, which will be further improved in the future.

Conclusion

The study of semileptonic B meson decays continues to be an active area for both theory and experiment. Substantial progress has been made in the application of HQE calculations to inclusive decays, where fits to moments of $\overline{B} \to X_c \ell \overline{\nu}_\ell$ decays provide precise values for $|V_{cb}|$ and, in conjunction with $B \to X_s \gamma$ decays or input on m_c , provide precise and consistent values for m_b . The values from the inclusive and exclusive $|V_{cb}|$ determinations are in reasonable agreement.

Continued improvements in measurements of inclusive $\overline{B} \to X_u \ell \overline{\nu}_\ell$ decays, along with additional theoretical studies of higher order contributions and improved knowledge of m_b , have strengthened our determination of $|V_{ub}|$. Further progress in this area is possible, but will require better theoretical control over higher order terms, and improved experimental knowledge of the $\overline{B} \to X_c \ell \overline{\nu}_\ell$ background.

Progress in both $b \to u$ and $b \to c$ exclusive channels depends crucially on progress in lattice calculations. Here the prospects are good, since unquenched calculations are now available for the semileptonic form factors discussed here, as well as for other hadronic weak matrix elements needed to obtain the elements and phase of the CKM matrix [163,164]. Projections for future uncertainties from lattice calculations can be found in Ref. [165].

The measurements of the $\overline{B} \to \pi \ell \overline{\nu}_{\ell}$ branching fraction have uncertainties below 4%, and the measured q^2 dependence is reasonably precise. Reducing the theoretical uncertainties to a comparable level will require significant effort, but is clearly vital.

The difference between the values for $|V_{ub}|$ obtained from inclusive and exclusive decays has persisted for many years, despite significant improvements in both theory and experiment for both methods. How to reconcile these results remains an intriguing puzzle.

Both $|V_{cb}|$ and $|V_{ub}|$ are indispensable inputs into unitarity triangle fits. In particular, knowing $|V_{ub}|$ with good precision allows a test of CKM unitarity in the most direct way, by

comparing the length of the $|V_{ub}|$ side of the unitarity triangle with the measurement of $\sin(2\beta)$. This comparison of a "tree" process $(b \to u)$ with a "loop-induced" process $(B^0 - \overline{B}^0)$ mixing) provides sensitivity to possible contributions from new physics. While the effort required to further improve our knowledge of these CKM matrix elements is large, it is well motivated.

Vcb MEASUREMENTS

For the discussion of $V_{\mathcal{C}\mathcal{D}}$ measurements, which is not repeated here, see the review on "Determination of $|V_{CD}|$ and $|V_{UD}|$."

The CKM matrix element $|V_{cb}|$ can be determined by studying the rate of the semileptonic decay $B o D^{(*)} \ell
u$ as a function of the recoil kinematics of $D^{(*)}$ mesons. Taking advantage of theoretical constraints on the normalization and a linear ω dependence of the form factors $(F(\omega),~G(\omega))$ provided by Heavy Quark Effective Theory (HQET), the $|V_{cb}| \times F(\omega)$ and $ho^2~(a^2)$ can be simultaneously extracted from data, where ω is the scalar product of the two-meson four velocities, F(1) is the form factor at zero recoil $(\omega=1)$ and ρ^2 is the slope, sometimes denoted as a^2 . Using the theoretical input of F(1), a value of $\left|V_{CD}\right|$ can be obtained.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account correlations between the measurements

$\left|V_{cb}\right|\times F(1) \; (\text{from} \; B^0 \to \; D^{*-}\ell^+\nu)$

TECN COMMENT DOCUMENT ID

0.03590 \pm 0.00045 OUR EVALUATION with ρ^2 =1.207 \pm 0.026 and a correlation 0.32. The fitted χ^2 is 29.7 for 23 degrees of freedom.

0.0360 ±0.0009 OUR AVERAGE Error includes scale factor of 1.5. See the ideogram

¹ Uses fully reconstructed $D^{*-}\ell^+\nu$ events $(\ell=e \text{ or } \mu)$.

² Obtained from a global fit to $B \to D^{(*)}\ell\nu_\ell$ events, with reconstructed $D^0\ell$ and $D^+\ell$ final states and $ho^2=1.22\pm0.02\pm0.07$.

 3 Measured using the dependence of $B^- o D^{*0} e^- \overline{
u}_e$ decay differential rate and the form factor description by CAPRINI 98 with $ho^2=1.16\pm0.06\pm0.08$.

 4 Measurement using fully reconstructed D^* sample with a $\rho^2=1.32\pm0.15\pm0.33$. 5 Average of the $B^0\to \ D^*(2010)^-\ell^+\nu$ and $B^+\to \ \overline{D}^*(2007))\,\ell^+\nu$ modes with $\rho^2=1.61\pm0.09\pm0.21$ and $f_{+-}=0.521\pm0.012$.

 6 ABREU 01H measured using about 5000 partial reconstructed D^* sample with a $ho^2 = 1.34 \pm 0.14 ^{+~0.24}_{-~0.22}$

 7 ABBIENDI 00Q: measured using both inclusively and exclusively reconstructed $D^{*\pm}$ samples with a ρ^2 =1.21 \pm 0.12 \pm 0.20. The statistical and systematic correlations between $|V_{cb}| \times F(1)$ and ρ^2 are 0.90 and 0.54 respectively.

 8 BUSKULIC 97: measured using exclusively reconstructed $D^{*\pm}$ with a a^2 =0.31 \pm 0.17 \pm

 $_{0}$ 0.08. The statistical correlation is 0.92. $_{0}^{9}$ Measured using fully reconstructed D^{\ast} sample and a simultaneous fit to the Caprini-Lellouch-Neubert form factor parameters: $\rho^2=1.191\pm0.048\pm0.028$, $R_1(1)=1.429\pm0.061\pm0.044$, and $R_2(1)=0.827\pm0.038\pm0.022$.

10 Measurement using fully reconstructed D^* sample with a $\rho^2=1.29\pm0.03\pm0.27.$ 11 Combines with previous partial reconstructed D^* measurement with a $\rho^2=1.39\pm0.10\pm0.10$

10.35. The Measured using exclusive $B^0 \to D^*(892)^- e^+ \nu$ decays with $\rho^2 = 1.35 \pm 0.17 \pm 0.19$ and a correlation of 0.91. The SBRIERE 02 result is based on the same analysis and data sample reported in ADAM 03.

 14 ABREU 96P: measured using both inclusively and exclusively reconstructed $\mathit{D}^{*\pm}$ samples.

 15 BARISH 95: measured using both exclusive reconstructed $B^0 o D^{*-} \ell^+
u$ and $B^+ o$ $D^{*0}\ell^+\nu$ samples. They report their experiment's uncertainties $\pm 0.0019 \pm 0.0018 \pm 0.0008$, where the first error is statistical, the second is systematic, and the third is the uncertainty in the lifetimes. We combine the last two in quadrature.

$|V_{cb}| \times G(1) \text{ (from } B \rightarrow D^- \ell^+ \nu)$

DOCUMENT ID TECN COMMENT **0.04264 \pm 0.00153 OUR EVALUATION** with ρ^2 =1.186 \pm 0.054 and a correlation 0.83.

 16 Obtained from a fit to the combined $B o \, \overline{D} \ell^+
u_\ell$ sample in which a hadronic decay of

the second B meson is fully reconstructed and $\rho^2=1.20\pm0.09\pm0.04.$ 17 Obtained from a global fit to $B\to~D^{(*)}\ell\,\nu_\ell$ events, with reconstructed $D^0\,\ell$ and $D^+\,\ell$ final states and $ho^2=1.20\pm0.04\pm0.07$.

18 Using the missing energy and momentum to extract kinematic information about the undetected neutrino in the $B^0 \rightarrow D^- \ell^+ \nu$ decay.

¹⁹BARTELT 99: measured using both exclusive reconstructed $B^0 \to D^- \ell^+ \nu$ and $B^+ \to D^- \ell^+ \nu$ $D^0\ell^+
u$ samples.

 20 BUSKULIC 97: measured using exclusively reconstructed D^{\pm} with a $a^2 = -0.05 \pm 0.53 \pm 0.00$

0.38. The statistical correlation is 0.99. 21 ATHANAS 97: measured using both exclusive reconstructed $B^0 \to D^- \ell^+ \nu$ and $B^+ \to D^+ \ell^+ \nu$ $D^0\ell^+\nu$ samples with a ρ^2 =0.59 \pm 0.22 \pm 0.12 \pm 0.59. They report their experiment's uncertainties $\pm 0.0044 \pm 0.0048 ^{+0.0053}_{-0.0012}$, where the first error is statistical, the second is systematic, and the third is the uncertainty due to the form factor model variations. We combine the last two in quadrature.

Vub MEASUREMENTS

For the discussion of V_{ub} measurements, which is not repeated here, see the review on "Determination of $|V_{CD}|$ and $|V_{UD}|$."

The CKM matrix element $|V_{UD}|$ can be determined by studying the rate of the charmless semileptonic decay $b \to u \ell \nu$. The relevant branching ratio measurements based on exclusive and inclusive decays can be found in the B Listings, and are not repeated here.

¹ AFFOLDER 01F uses the reconstructed B meson through semileptonic decay channels. The fraction of light B mesons that are produced at L=1 B^{**} states is measured to be 0.28 + 0.06 + 0.03.

 2 BARATE 98L uses fully reconstructed B mesons to search for B^{**} production in the $B\,\pi^\pm$ system. In the framework of heavy quark symmetry (HQS), they also measured the mass of B_2^* to be $5739^{+1}_{-11}^{+1}^{-4}_{-4}$ MeV/c² and the relative production rate of B(b \rightarrow B_2^* \rightarrow $B^{(*)}_{-1}^{+1}\pi)B(b$ \rightarrow $B_{u,d}^{+})=(31\pm9^{+6}_{-5})\%$.

 3 Using $m_{B\,\pi} - m_B = 424 \pm 4 \pm 10$ MeV.

 4 ACCIARRI 99N uses inclusive reconstructed B mesons to search for B^{**} production in the $B^{(*)}\pi^\pm$ system. In the framework of HQET, they measured the mass of B_1^* and B_2^* to be $5670\pm10\pm13$ MeV and $5768\pm5\pm6$ with the $B(b\to B^{**})=(32\pm3\pm6)\times10^{-2}$. They also reported the evidence for the existence of an excited B-meson state or mixture of states in the region 5.9–6.0 GeV.

BO MEAN LIFE

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors.

First "OUR EVALUATION" is an average of 1 / [0.5 ($\Gamma_{B^0_{sL}} + \Gamma_{B^0_{sH}}$)]. The Second "OUR EVALUATION" is the average of $B_s \xrightarrow{} D_s X$ data

 1 Measured using decays $B_{s}^{\,0} \rightarrow K^{+}K^{-}$.

- ² Uses the time-dependent angular analysis of $B_s^0 \to J/\psi \phi$ decays and assuming *CP*-violating angle $\beta_s(B^0 \to J/\psi \phi) = 0.02$.
- 3 Obtained from $\Delta\Gamma_s$ and Γ_s fit with a correlation of 0.6.
- 4 Measured using the time-dependent angular analysis of $B_{\,\rm S}^{\,0} \to \, J/\psi\,\phi$ decays.
- ⁵ Uses $\phi \phi$ correlations from $B_S^0 \to D_S^{(*)+} D_S^{(*)-}$.

$\Delta \Gamma_{B_c^0}/\Gamma_{B_c^0}$

 $\Gamma_{B^0_s}$ and $\Delta\Gamma_{B^0_s}$ are the decay rate average and difference between two B^0_s CP eigenstates (light — heavy).

"OUR EVALUATION" is an average of all available B_S flavor-specific lifetime measurements with the $\Delta\Gamma_{B_2^0}/\Gamma_S$ analyses performed by the Heavy

Flavor Averaging Group (HFAG) as described in our "Review on B- \overline{B} Mixing" in the B^0 Section of these Listings.

B_s^0

- 1 Measured using the time-dependent angular analysis of $B_{\,S}^{\,0} \rightarrow \,\, J/\psi\,\phi$ decays.
- 2 Uses the time-dependent angular analysis of B $^0_{\rm S} \rightarrow ~J/\psi \, \phi$ decays and assuming CPviolating angle $\beta_{\rm S}(B^0 \to J/\psi \phi) = 0.02$.
- $^3\,\mbox{The error includes}$ both statistical and systematic uncertainties.
- 4 Measured using fully reconstructed $B_{S}\,\rightarrow\,J/\psi\,\phi$ decays.
- Measured the angular and lifetime parameters for the time-dependent angular untagged decays $B_d^0 \to J/\psi \, K^{*0}$ and $B_s^0 \to J/\psi \, \phi$.
- 6 Measured using the time-dependent angular analysis of $B_S^0
 ightarrow J/\psi\,\phi$ decays and assuming *CP*-violating phase $\phi_s=0.$ 7 Obtaines 90% CL interval $-0.06 < \Delta\Gamma_s < 0.30.$
- $^8\,\mathrm{ABAZOV}$ 07 reports 0.17 \pm 0.09 \pm 0.02 with $\mathit{CP}\text{-violating phase}$ $\phi_{_S}$ as a free parameter.
- 9 Combines D^0 measurements of time-dependent angular distributions in $B^0_s
 ightarrow J/\psi \phi$ and charge asymmetry in semileptonic decays. There is a 4-fold ambiguity in the solution.

$\Delta\Gamma_s^{CP} / \Gamma_s$

 Γ_s and $\Delta\Gamma_s^{CP}$ are the decay rate average and difference between even, $\Gamma_s^{CP-even}$, and odd, Γ_s^{CP-odd} , CP eigenstates.

BO DECAY MODES

These branching fractions all scale with B($\overline{b} \to B_c^0$).

The branching fraction B(B $_S^0 \to D_S^- \ell^+ \nu_\ell$ anything) is not a pure measurement since the measured product branching fraction $B(\overline{b} \to B_s^0) \times$ $\mathsf{B}(B_s^0\to\ D_s^-\ell^+\nu_\ell \mathrm{anything}) \ \mathrm{was} \ \mathrm{used} \ \mathrm{to} \ \mathrm{determine} \ \mathsf{B}(\overline{b}\to\ B_s^0), \ \mathrm{as}$ described in the note on " $B^0-\overline{B}^0$ Mixing"

For inclusive branching fractions, e.g., $B\to D^\pm$ anything, the values usually are multiplicities, not branching fractions. They can be greater

CONSTRAINED FIT INFORMATION

An overall fit to 8 branching ratios uses 11 measurements and one constraint to determine 6 parameters. The overall fit has a $\chi^2 =$ 1.5 for 6 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv$ $\Gamma_i/\Gamma_{
m total}$. The fit constrains the x_i whose labels appear in this array to sum to

| 0.93±0.25 OUR AVE | RAGE | | | | |
| $0.91 \pm 0.18 \pm 0.41$ | | | 07 | BELL | $e^+ e^- \rightarrow \Upsilon(4S)$ |
| $0.81 \pm 0.24 \pm 0.22$ | 90 | ² BUSKULIC | 96E | ALEP | $e^+ e^- \rightarrow Z$ |
| $1.56 \pm 0.58 \pm 0.44$ | 147 | ³ ACTON | 92N | OPAL | $e^+ e^- \rightarrow Z$ |

 1 The extraction of this result takes into account the correlation between the measurements of B($\varUpsilon(5S)\to \ D_5X)$ and B($\varUpsilon(5S)\to \ D^0X).$

²BUSKULIC 96E separate $c\overline{c}$ and $b\overline{b}$ sources of D_s^+ mesons using a lifetime tag, subtract generic $\overline{b} \to W^+ \to D_S^+$ events, and obtain $B(\overline{b} \to B_S^0) \times B(B_S^0 \to D_S^-$ anything) = 0.088 ± 0.020 ± 0.020 assuming B($D_S \rightarrow \phi \pi$) = (3.5 ± 0.4) × 10⁻² and PDG 1934 values for the relative partial widths to other D_S channels. We evaluate using our current values B($\overline{b} \to B_S^0$) = 0.107 \pm 0.014 and B($D_S \to \phi \pi$) = 0.036 \pm 0.009. Our first error is their experiment's and our second error is that due to $B(\overline{b}\to B_s^0)$ and $B(D_s\to B_s^0)$ $\phi\pi$).

 3 ACTON 92N assume that excess of 147 \pm 48 D_s^0 events over that expected from B^0 , B^+ , and $c\,\overline{c}$ is all from B^0_S decay. The product branching fraction is measured to be $\mathsf{B}(\overline{b}\to \mathsf{B}_s^0)\mathsf{B}(\mathsf{B}_s^0\to \mathsf{D}_s^- \mathsf{anything})\times \mathsf{B}(\mathsf{D}_s^-\to \phi\pi^-) = (5.9\pm1.9\pm1.1)\times 10^{-3}.$ We evaluate using our current values B($\overline{b} \to B_s^0$) = 0.107 \pm 0.014 and B($D_s \to \phi \pi$) $= 0.036 \pm 0.009$. Our first error is their experiment's and our second error is that due to $B(\overline{b} \to B_s^0)$ and $B(D_s \to \phi \pi)$.

| $9.5 + 2.5 + 1.1 \\ -2.0 - 1.9$ | ¹ LEES | 12A | BABR | e^+e^- | |

 $^{1}\,\mathrm{The}$ measurement corresponds to a branching fraction where the lepton originates from bottom decay and is the average between the electron and muon branching fractions. LEES 12A uses the correlation of the production of ϕ mesons in association with a lepton in $e^+\,e^-$ data taken at center-of-mass energies between 10.54 and 11.2 GeV.

 $\Gamma(D_s^-\ell^+\nu_\ell \text{ anything})/\Gamma_{\text{total}}$

The values and averages in this section serve only to show what values result if one assumes our $\mathsf{B}(\overline{b} \to B_0^S)$. They cannot be thought of as measurements since the underlying product branching fractions were also used to determine $B(\overline{b} \to B_s^0)$ as described in the note on "Production and Decay of b-Flavored Hadrons."

 1 BUSKULIC 950 use $D_{_S}\ell$ correlations. The measured product branching ratio is B(\overline{b} ightarrow $B_S) imes {\sf B}(B_S o D_S^- \ell^+ \nu_\ell \, {\sf anything}) = (0.82 \pm 0.09 {+ 0.13 \atop - 0.14}) \% \, {\sf assuming} \, \, {\sf B}(D_S o \phi \pi)$ = $(3.5 \pm 0.4) \times 10^{-2}$ and PDG 1994 values for the relative partial widths to the six other D_S channels used in this analysis. Combined with results from $\varUpsilon(4S)$ experiments this can be used to extract B($\overline{b} \to B_S$) = (11.0 \pm 1.2 $^{+2.5}_{-2.6}$)%. We evaluate using our current values B($\overline{b} \to B_s^0$) = 0.107 \pm 0.014 and B($D_s \to \phi \pi$) = 0.036 \pm 0.009. Our first error is their experiment's and our second error is that due to B($\overline{b} \to B_c^0$) and

²ABREU 92M measured muons only and obtained product branching ratio B($Z \rightarrow b$ or $\overline{b}) \times \mathsf{B}(\overline{b} \to \ B_S) \times \mathsf{B}(B_S \to \ D_S \, \mu^+ \, \nu_\mu \, \mathsf{anything}) \times \mathsf{B}(D_S \to \ \phi \, \pi) = (18 \pm 8) \times 10^{-5}.$ We evaluate using our current values $B(\overline{b}\to B_s^0)=0.107\pm0.014$ and $B(D_s\to\phi\pi)=0.036\pm0.009$. Our first error is their experiment's and our second error is that due

to $B(\overline{b}\to B^0_s)$ and $B(D_s\to \phi\pi)$. We use $B(Z\to b\text{ or }\overline{b})=2B(Z\to b\overline{b})=$ $2 \times (0.2212 \pm 0.0019)$. 3 ACTON 92N is measured using $D_{_S}
ightarrow \phi \pi^+$ and $K^*(892)^0 \, K^+$ events. The product branching fraction measured is measured to be B($\overline{b} \to B_s^0$)B($B_s^0 \to D_s^- \ell^+ \nu_\ell$ anything)

 \times B $(D_c^- \to \phi \pi^-) = (3.9 \pm 1.1 \pm 0.8) \times 10^{-4}$. We evaluate using our current values $B(\overline{b} \to B_s^0) = 0.107 \pm 0.014$ and $B(D_S \to \phi \pi) = 0.036 \pm 0.009$. Our first error is their experiment's and our second error is that due to $B(\overline{b} \to B_s^0)$ and $B(D_s \to \phi \pi)$. 4 BUSKULIC 92E is measured using $D_S \to \phi \pi^+$ and $K^*(892)^0 K^+$ events. They use $2.7\pm0.7\%$ for the $\phi\pi^+$ branching fraction. The average product branching fraction is measured to be B($\overline{b}\to B_s^0$)B(B $_s^0\to D_s^-\ell^+\nu_\ell$ anything) =0.020 \pm 0.0055 $_-^0$ 0.006. We evaluate using our current values B($\overline{b}\to B_S^0$) = 0.107 \pm 0.014 and B($D_S\to\phi\pi$) = 0.036 \pm 0.009. Our first error is their experiment's and our second error is that due to $B(\overline{b} \to B_s^0)$ and $B(D_s \to \phi \pi)$. Superseded by BUSKULIC 95 o.

<sup>1</sup> AALTONEN 12C reports (f_S/f_d) (B(B_S^0 \rightarrow D_S^{*+}D_S^- + D_S^{*-}D_S^+) / B(B^0 \rightarrow D_S^{*+}D_S^-)
             (D^-D_s^+)) = 0.424 \pm 0.046 \pm 0.035. We multiply this result by our best value of
            B(B^0 \to D^-D_s^+) = (7.2 \pm 0.8) \times 10^{-3} and divide by our best value of f_s/f_d, where
            1/2\ f_{\rm S}/f_{\rm d}=0.131 \times 0.008. Our first quoted uncertainty is the combined experiment's uncertainty and our second is the systematic uncertainty from using out best values.
         <sup>2</sup>Uses \Upsilon(10860) \to B_S^* \overline{B}_S^* assuming B(\Upsilon(10860) \to B_S^{(*)} \overline{B}_S^{(*)}) = (19.3 ± 2.9)% and
            \Gamma(\Upsilon(10860) \to B_s^* \overline{B}_s^*) / \Gamma(\Upsilon(10860) \to B_s^{(*)} \overline{B}_s^{(*)}) = (90.1^{+3.8}_{-4.0})\%.
\Gamma(D_s^{*+}D_s^{*-})/\Gamma_{\text{total}}

| B ⁰ Particle Listings a | | | | |

 χ_S is a measure of the time-integrated $B_S^0 \overline{B}_S^0$ mixing probability that produced $B_S^0 (\overline{B}_S^0)$ decays as a $\overline{B}_S^0 (B_S^0)$. Mixing violates $\Delta B \neq 2$ rule.

$$\chi_s = \frac{x_s^2}{2(1+x_s^2)}$$

$$x_{s} = \frac{\Delta m_{B_{s}^{0}}}{\Gamma_{B_{s}^{0}}} = (m_{B_{sH}^{0}} - m_{B_{sL}^{0}}) \tau_{B_{s}^{0}},$$

where H, L stand for heavy and light states of two B_s^0 CP eigenstates and $\tau_{B_s^0} = \frac{1}{0.5(\Gamma_{B_s^0 H}^0 + \Gamma_{B_s^0 L}^0)}$.

$\Delta m_{B_s^0} = m_{B_{sH}^0} - m_{B_{sL}^0}$

's "sH"'sL $\Delta m_{B_s^0}$ is a measure of 2π times the B_s^0 - \overline{B}_s^0 oscillation frequency in time-dependent mixing experiments.

"OUR EVALUATION" is provided by the Heavy Flavor Averaging Group (HFAG) by taking into account correlations between measurements.

- ¹ Measured using $B_S^0 \rightarrow D_S^- \pi^+$ and $D_S^- \pi^+ \pi^- \pi^+$ decays.
- 2 Significance of oscillation signal is 5.4 $\sigma.$ Also reports $|V_{td}|/|V_{ts}|=0.2060$ \pm
- 3 A likelihood scan over the oscillation frequency, $\Delta m_{_S}$, gives a most probable value of 19 ps $^{-1}$ and a range of 17< $\Delta m_s <$ 21 (ps $^{-1}$) at 90% C.L. assuming Gaussian uncertainties. Also excludes $\Delta m_s < \!\! 14.8~\mathrm{ps}^{-1}$ at 95% C.L
- 4 Significance of oscillation signal is 0.2%. Also reported the value $\left|V_{\,td}\right|$ / $\left|V_{\,ts}\right|$ = $0.208 + 0.001 + 0.008 \\ -0.002 - 0.006$
- 5 Uses leptons emitted with large momentum transverse to a jet and improved techniques for vertexing and flavor-tagging.
- $^{6}\,\mathrm{Updates}$ of $\overset{\smile}{D}_{S}\text{-lepton}$ analysis.
- 7 Combined results from all Delphi analyses.
- $8\,\mbox{Events}$ with a high transverse momentum lepton were removed and an inclusively reconstructed vertex was required.
- and tertiary vertices originating from the $B \to D$ decay chain. The analysis excludes $\Delta m_S < 4.9 \, \mathrm{ps}^{-1}$ and $7.9 < \Delta m_S < 10.3 \, \mathrm{ps}^{-1}$.
- 10 Three analyses based on complementary event selections: (1) fully-reconstructed hadronic decays; (2) semileptonic decays with $D_{\rm S}$ exclusively reconstructed; (3) inclusive semileptonic decays
- $^{11}\,\mathrm{ABE}$ 02v uses exclusively reconstructed D_s^- mesons and excludes $\Delta m_s < \!\! 1.4\,\mathrm{ps}^{-1}$ and $2.4 < \, \Delta m_{\,S} <$ 5.3 ps $^{-1}\,$ at 95%CL.
- 12 Uses fully or partially reconstructed $D_{\rm S}\ell$ vertices and a mixing tag as a flavor tagging.
- 13 Replaced by ABDALLAH 04A. Uses $D_s^-\ell^+$, and $\phi\ell^+$ vertices, and a multi-variable discriminant as a flavor tagging.
- 14 Uses inclusive D_S vertices and fully reconstructed B_S decays and a multi-variable discriminant as a flavor tagging.
- 15 Uses $\ell ext{-}Q_{ ext{hem}}$ and $\ell ext{-}\ell ext{.}$
- 16 ABE 99D assumes $\tau_{B_{s}^{0}}=1.55\,\pm\,0.05$ ps and $\Delta\Gamma/\Delta \textit{m}=\,(5.6\,\pm\,2.6)\times10^{-3}.$
- $^{17} \mathrm{ABE}$ 99J uses ϕ $\ell\text{-}\ell$ correlation.
- 18 BARATE 99J uses combination of an inclusive lepton and D_s^- -based analyses.
- 19 BARATE 98c combines results from $D_s h$ - $\ell/Q_{
 m hem}$, $D_s h$ -K in the same side, $D_s \ell$ - $\ell/Q_{\mbox{\scriptsize hem}}$ and $D_S\,\ell ext{-}K$ in the same side.
- ²⁰ Uses ℓ-Q_{hem}
- 21 Uses ℓ - ℓ . 22 ADAM 97 combines results from $D_S\ell$ - $Q_{\rm hem}$, ℓ - $Q_{\rm hem}$, and ℓ - ℓ .
- 23 BUSKULIC 96M uses $D_{\scriptscriptstyle S}$ lepton correlations and lepton, kaon, and jet charge tags.
- 24 BUSKULIC 95J uses $\ell\text{-}Q_{\text{hem}}$. They find $\Delta m_S>5.6$ [> 6.1] for $\textit{f}_{\text{S}}{=}10\%$ [12%]. We interpolate to our central value $\textit{f}_{\text{S}}{=}10.5\%$.

$x_s = \Delta m_{B_s^0} / \Gamma_{B_s^0}$

This is derived by the Heavy Flavor Averaging Group (HFAG) from the results on $\Delta m_{B_0^0}$ and "OUR EVALUATION" of the B_0^0 mean lifetime.

CP VIOLATION PARAMETERS in B

$\operatorname{Re}(\epsilon_{B_s^0}) / (1 + |\epsilon_{B_s^0}|^2)$

CP impurity in B_s^0 system.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/scaling procedure takes into account correlation between the measurements. The value has been obtained from a 2D fit of the B_d and B_s asymmetries, which includes the B_s measurements listed below and the B factory average for the B_d .

⁴ ABAZOV $6.1 \pm 4.8 \pm 0.9$ 07A D0 Repl. by ABAZOV 10E 1 Uses the dimuon charge asymmetry with different impact parameters from which it reports $A_{SL}^s = (-18.1 \pm 10.6) \times 10^{-3}$.

 2 ABAZOV 10E reports a measurement of flavor-specific asymmetry in $B^0_{(s)}
ightarrow \mu^+ \, D^{*-}_{(s)} X$ decays with a decay-time analysis including initial-state flavor tagging, A $_{SL}^{s}$ =(-1.7 \pm $9.1^{+1.4}_{-1.5}) imes 10^{-3}$ which is approximately equal to 4 imes Re($\epsilon_{B^0_-}$) / (1 + $|\epsilon_{B^0_-}|^2$).

 3 ABAZOV 10H reports a measurement of like-sign dimuon charge asymmetry of $A_{SL}^b=(-9.57\pm2.51\pm1.46)\times10^{-3}$ in semileptonic b-hadron decays. Using the measurement sured production ratio of B_d^0 and B_s^0 , and the asymmetry of B_d^0 A_{SL}^0 =(-4.7 \pm 4.6) \times 10⁻³ measured from B-factories, they obtain the asymmetry for B_s^0 .

⁴ The first direct measurement of the time integrated flavor untagged charge asymmetry in semileptonic B_s^0 decays is reported as $2 \mathrm{xA}_{SL}^s (\mathrm{untagged}) = \mathrm{A}_{SL}^s = (2.45 \pm 1.93 \pm$ $0.35) \times 10^{-2}$.

CP Violation phase β_s

 $-2eta_s$ is the weak phase difference between B^0_s mixing amplitude and the B^0_s ightarrow $J/\psi\,\phi$ decay amplitude. The Standard Model value of β_{S} is $\arg(-\frac{V_{tS}V_{tb}^{*}}{V_{cS}V_{cb}^{*}})$.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at $http://www.slac.stanford.edu/xorg/hfag/. \ \ The \ averaging/scaling$ procedure takes into account correlation between the measurements.

 1 Reports $\phi_{\it S}=-$ 2 $\beta_{\it S}=-$ 0.44 \pm 0.44 \pm 0.02 that was measured using a time-dependent fit to $B_s^0 \rightarrow J/\psi f_0(980)$ decays.

 2 Reports $\phi_S=-2$ $eta_S=0.15\pm0.18\pm0.06$ that was measured using a time-dependent angular analysis of $B_s^0 \to J/\psi \phi$ decays.

 3 Reports 0.02 < ϕ_S < 0.52 or 1.08 < ϕ_S < 1.55 at 68% C.L. confidence regions in the two-dimensional space of ϕ_s and $\Delta\Gamma_{B^0_s}$ from $B^0_s \to J/\psi \phi$ decays.

⁴ The error includes both statistical and systematic uncertainties

 5 Measured using fully reconstructed $B_{S} \rightarrow J/\psi \phi$ decays.

⁶ Reports ϕ_s which equals to $-2\beta_s$.

 $^7\,\mathrm{Reports}$ 0.32 $<2\beta_\mathrm{S}<$ 2.82 at 68% C.L. and confidence regions in the two-dimensional space of $2\beta_s$ and $\Delta\Gamma$ from the first measurement of $B_s^0 \to J/\psi \phi$ decays using flavor tagging. The probability of a deviation from SM prediction as large as the level of observed data is 15%. 8 Reports $\phi_S=-2$ β_S and obtains 90% CL interval -0.03 < β_S < 0.60.

⁹The first direct measurement of the *CP*-violating mixing phase is reported from the time-dependent analysis of flavor untagged $B_s^0 \rightarrow J/\psi \phi$ decays.

 $^{
m 10}$ Combines D0 collaboration measurements of time-dependent angular distributions in $B^0_s o J/\psi \, \phi$ and charge asymmetry in semileptonic decays. There is a 4-fold ambiguity in the solution.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account correlations between the measurements.

DEVELOPMENTS IN HEAVY QUARKONIUM SPECTROSCOPY

Written May 2012 by S. Eidelman (Budker Inst. and Novosibirsk State Univ.), B.K. Heltsley (Cornell Univ.), J.J. Hernandez-Rey (Univ. Valencia—CSIC), S. Navas (Univ. Granada), and C. Patrignani (Univ. Genova, INFN).

A golden age for heavy quarkonium physics dawned a decade ago, initiated by the confluence of exciting advances in quantum chromodynamics (QCD) and an explosion of related experimental activity. The subsequent broad spectrum of breakthroughs, surprises, and continuing puzzles had not been anticipated. In that period, the BESII program concluded only

² ABE 98M observed 20.4 $^{+}_{-5.5}$ events in the $B_c^+ \to J/\psi(1s) \ell \nu_\ell$ with a significance of > 4.8 standard deviations. The mass value is estimated from $m(J/\psi(1S)\,\ell)$.

 $^{^3}$ ACKERSTAFF 980 observed 2 candidate events in the $B_C\to J/\psi(1S)\,\pi^+$ channel with an estimated background of 0.63 \pm 0.20 events.

Heavy Quarkonium Spectroscopy

to give birth to BESIII; the *B*-factories and CLEO-c flourished; quarkonium production and polarization measurements at HERA and the Tevatron matured; and heavy-ion collisions at RHIC opened a window on the deconfinement regime. For an extensive presentation of the status of heavy quarkonium physics, the reader is referred to several reviews [1–7], the last of which covers developments through the middle of 2010, and which supplies some tabular information and phrasing reproduced here (with kind permission, copyright 2011, Springer). This note focuses solely on experimental developments in heavy quarkonium spectroscopy, and in particular on those too recent to have been included in Ref. 7.

Table 1 lists properties of newly observed conventional heavy quarkonium states, where "newly" is interpreted to mean within the past decade. The h_c is the 1P_1 state of charmonium, singlet partner of the long-known χ_{cJ} triplet 3P_J . The $\eta_c(2S)$ is the first excited state of the pseudoscalar ground state $\eta_c(1S)$, lying just below the mass of its vector counterpart, $\psi(2S)$. The state originally dubbed Z(3930) is now regarded by many as the first observed 2P state of χ_{cJ} , the $\chi_{c2}(2P)$. The first B-meson seen that contains charm is the B_c^+ . The ground state of bottomonium is the $\eta_b(1S)$, recently confirmed with a second observation of more than 5σ significance. The $\Upsilon(1D)$ is the lowest-lying D-wave triplet of the $b\bar{b}$ system.

Table 1: New conventional states in the $c\bar{c}$, $b\bar{c}$, and $b\bar{b}$ regions, ordered by mass. Masses m and widths Γ represent the weighted averages from the listed sources. Quoted uncertainties reflect quadrature summation from individual experiments. In the Process column, the decay mode of the new state claimed is indicated in parentheses. Ellipses (...) indicate inclusively selected event topologies; i.e., additional particles not required by the Experiments to be present. A question mark (?) indicates an unmeasured value. For each Experiment a citation is given, as well as the statistical significance in number of standard deviations (#σ), or "(np)" for "not provided". The Year column gives the date of first measurement cited. The Status column indicates that the state has been observed by at most one (NC!-needs confirmation) or at least two independent experiments with significance of >5σ (OK). The state labelled $\chi_{c2}(2P)$ has previously been called Z(3930). See also the reviews in [1–7]. Adapted from [7] with kind permission, copyright (2011), Springer.

Both the $h_b(1P)$, the bottomonium counterpart of $h_c(1P)$, and the next excited state, $h_b(2P)$, were very recently observed by Belle [31], as described further below, in dipion transitions from either the $\Upsilon(5S)$ or $Y_b(10888)$. All fit into their respective spectroscopies roughly where expected. Their exact masses, production mechanisms, and decay modes provide guidance to their descriptions within QCD. The $h_b(nP)$ states still need experimental confirmation at the 5σ level, as does the $\chi_{bJ}(3P)$ triplet.

Correspondingly, the menagerie of new, heavy-quarkoniumlike unanticipated states* is shown in Table 2; notice that just a handful have been experimentally confirmed. None can unambiguously be assigned a place in the hierarchy of charmonia or bottomonia; neither do any have a universally accepted unconventional origin. The X(3872) occupies a unique niche among the unexplained states as both the first and the most intriguing. It is, by now, widely studied, yet its interpretation demands much more experimental attention. The Y(4260) and Y(4360)are vector states decaying to $\pi^+\pi^-J/\psi$ and $\pi^+\pi^-\psi(2S)$, respectively, yet, unlike most conventional vector charmonia, do not correspond to enhancements in the e^+e^- hadronic cross section. The three Z_c^+ and two Z_b^+ states, each decaying to a charged pion and conventional heavy quarkonium state, would be manifestly exotic, but remain unconfirmed. Final states of the type $\Upsilon(nS)\pi^+\pi^-$ from e^+e^- collisions acquired near the $\Upsilon(5S)$ have a lineshape differing somewhat from that of multi-hadronic events, which suggested a new state $Y_b(10888)$, distinct from $\Upsilon(5S)$, which could be analogous to Y(4260). The nature of $Y_b(10888)$, if it does mimic the behavior of the charmonium-region Y's, could help to explain the observed (and otherwise unexpected) high rate of dipion transitions to $\Upsilon(nS)$ and $h_b(nP)$ seen in the e^+e^- collisions near the $\Upsilon(5S)$. It could also provide insight into the Z_b^+ states, which appear to be intermediate resonances in the dipion transitions.

BABAR [71,59] has searched for the three Z_c^{\pm} states in the charmonium mass region seen by Belle, and failed to observe any significant signals. The approach taken in searching for $B \to Z^{\pm}K \to (c\bar{c})K\pi$, where $(c\bar{c})$ is $\psi(2S)$ or χ_{c1} , is to first fit the data for all reasonable $K\pi$ mass or angular structure, having demonstrated that the presence of one or more Z's cannot be accommodated by this procedure. After doing so, the finding is that some of what might be the Belle excess of events above Belle background gets absorbed into the $K\pi$ structure of the BABAR background. As shown in Table 2, where Belle observes signals of significances 5.0σ , 5.0σ , and 6.4σ for $Z_1(4050)^+$, $Z_2(4250)^+$, and $Z(4430)^+$, respectively, BABAR reports 1.1σ , 2.0σ , and 2.4σ effects, setting upper limits on product branching fractions that are not inconsistent with Belle's measured rates, leaving the situation unresolved.

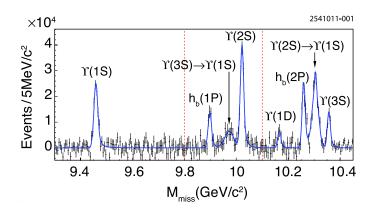

Figure 1: From Belle [31], the mass recoiling against $\pi^+\pi^-$ pairs, $M_{\rm miss}$, in e^+e^- collision data taken near the peak of the $\Upsilon(5S)$ (points with error bars). The smooth combinatoric and $K_S^0 \to \pi^+\pi^-$ background contributions have already been subtracted. The fit to the various labeled signal contributions overlaid (curve). Although $\eta_c(2S)$ measurements began to converge on a mass and width nearly a decade ago, refinements are still in progress. In particular, Belle [14] has revisited its analysis of $B \to K\eta_c(2S)$, $\eta_c(2S) \to KK\pi$ decays with more data and methods that account for interference between the above decay chain, an equivalent one with the $\eta_c(1S)$ instead, and one with no intermediate resonance. The net effect of this interference is far from trivial; it shifts the apparent mass by $\sim +10$ MeV and blows up the apparent width by a factor of six. The updated $\eta_c(2S)$ mass and width are in better accordance with other measurements than the previous treatment [13] not including interference. Complementing this measurement in B-decay, BABAR [15] updated their previous [16] $\eta_c(2S)$ mass and width measurements in two-photon production, where interference effects, judging from studies of $\eta_c(1S)$, appear to be small. In combination, precision on the $\eta_c(2S)$ mass has improved dramatically.

New results on η_b , h_b , and Z_b^+ mostly come from Belle, all from analyses of 121.4 fb⁻¹ of e^+e^- collision data collected near the peak of the $\Upsilon(5S)$ resonance. They also appear in the same types of decay chains: $\Upsilon(5S) \to \pi^- Z_b^+$, $Z_b^+ \to \pi^+ (b\bar{b})$, and, when the $b\bar{b}$ forms an $h_b(1P)$, frequently $h_b(1P) \to \gamma \eta_b$.

Previous unsuccessful searches for h_b focused on what was considered the most easily detected production mechanism, $\Upsilon(3S) \to \pi^0 h_b(1P)$. In early 2011 BABAR presented marginal evidence for this transition at the 3σ level, at a mass near that expected for zero hyperfine splitting.

^{*} For consistency with the literature, we preserve the use of X, Y, Z, and G, contrary to the practice of the PDG, which exclusively uses X for unidentified states.

Heavy Quarkonium Spectroscopy

Table 2: As in Table 1, but for new unconventional states in the $c\bar{c}$ and $b\bar{b}$ regions, ordered by mass. For X(3872), the values given are based only upon decays to $\pi^+\pi^-J/\psi$. X(3945) and Y(3940) have been subsumed under X(3915) due to compatible properties. The state known as Z(3930) appears as the $\chi_{c2}(2P)$ in Table 1. In some cases experiment still allows two J^{PC} values, in which case both appear. See also the reviews in [1-7]. Adapted from [7] with kind permission, copyright (2011), Springer.

The Belle h_b discovery analysis [31] selects hadronic events and looks for peaks in the mass recoiling against $\pi^+\pi^-$ pairs, the spectrum for which, after subtraction of smooth combinatoric and $K_S^0 \to \pi^+\pi^-$ backgrounds, appears in Fig. 1. Prominent and unmistakable $h_b(1P)$ and $h_b(2P)$ peaks are present. This search was directly inspired by a new CLEO result [77], which found the surprisingly copious transitions $\psi(4160) \rightarrow \pi^+\pi^-h_c(1P)$ and an indication that $Y(4260) \to \pi^+\pi^- h_c(1P)$ occurs at a comparable rate as the signature mode, $Y(4260) \to \pi^+\pi^- J/\psi$. The presence of $\Upsilon(nS)$ peaks in Fig. 1 at rates two orders of magnitude larger than expected for transitions requiring a heavy-quark spin-flip, along with separate studies with exclusive decays $\Upsilon(nS) \to \mu^+\mu^-$, allow precise calibration of the $\pi^+\pi^-$ recoil mass spectrum and very accurate measurements of $h_b(1P)$ and $h_b(2P)$ masses. Both corresponding hyperfine splittings are consistent with zero

within an uncertainty of about 1.5 MeV (lowered to ± 1.1 MeV for $h_b(1P)$ in Ref. 30). Belle soon noticed that, for events in the peaks of Fig. 1, there seemed to be two intermediate charged states nearby. For example, Fig. 2 shows a Dalitz plot for events restricted to the $\Upsilon(2S)$ region of $\pi^+\pi^-$ recoil mass. The two bands observed in the maximum of the two $M[\pi^{\pm}\Upsilon(2S)]^2$ values also appear for $\Upsilon(1S)$, $\Upsilon(3S)$, $h_b(1P)$, and $h_b(2P)$ samples, but do not appear in the respective $[b\bar{b}]$ sidebands. Belle fits all subsamples to resonant plus non-resonant amplitudes, allowing for interference (notably, between $\pi^- Z_b^+$ and $\pi^+ Z_b^-$), and finds consistent pairs of Z_h^+ masses for all bottomonium transitions, and comparable strengths of the two states. Angular analysis favors a $J^P = 1^+$ assignment for both Z_b^+ states, which must also have negative G-parity. Transitions through Z_h^+ to the $h_b(nP)$ saturate the observed $\pi^+\pi^-h_b(nP)$ cross sections. The two masses of Z_b^+ states are just a few MeV above the $B^*\bar{B}$

and $B^*\bar{B}^*$ thresholds, respectively. The Z_b^+ cannot be simple mesons because they are charged and have $b\bar{b}$ content.

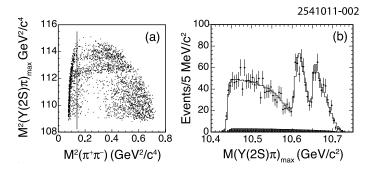

Figure 2: From Belle [74] e^+e^- collision data taken near the peak of the $\Upsilon(5S)$ for events with a $\pi^+\pi^-$ -missing mass consistent with a $\Upsilon(nS)2$, (a) the maximum of the two possible single π^\pm -missing-mass-squared combinations vs. the $\pi^+\pi^-$ -mass-squared; and (b) projection of the maximum of the two possible single π^\pm -missing-mass combinations (points with error bars) overlaid with a fit (curve). Events to the left of the vertical line in (a) are excluded from further analysis. The two horizontal stripes in (a) and two peaks in (b) correspond to the two Z_b^+ states. Adapted from [74] with kind permission, copyright (2011) The American Physical Society.

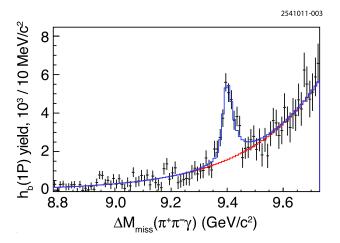

Figure 3: From Belle [30] e^+e^- collision data taken near the peak of the $\Upsilon(5S)$, the $h_b(1P)$ event yield vs. the mass recoiling against the $\pi^+\pi^-\gamma$ (corrected for misreconstructed $\pi^+\pi^-$), where the $h_b(1P)$ yield is obtained by fitting the mass recoiling against the $\pi^+\pi^-$ (points with error bars). The fit results (solid histograms) for signal plus background and background alone are superimposed. Adapted from [30] with kind permission, copyright (2011) The American Physical Society.

The third Belle result to flow from these data is confirmation of the $\eta_b(1S)$ and measurement of the $h_b(1P) \to \gamma \eta_b(1S)$ branching fraction, expected to be several tens of percent. To accomplish this, events with the $\pi^+\pi^-$ recoil mass in the $h_b(1P)$ mass window and a radiative photon candidate are selected, and the $\pi^+\pi^-\gamma$ recoil mass queried for correlation with non-zero $h_b(1P)$ population in the $\pi^+\pi^-$ missing mass spectrun, as shown in Fig. 3. A clear peak is observed, corresponding to the $\eta_b(1S)$. A fit is performed to extract the $\eta_b(1S)$ mass, and first measurements of its width and the branching fraction for $h_b(1P) \to \gamma \eta_b(1S)$ (the latter of which is $(49.8 \pm 6.8^{+10.9}_{-5.2})\%$). The mass determination has comparable uncertainty to and a larger central value (by 10 MeV, or 2.4σ) than the average of previous measurements, thereby reducing the new world average hyperfine splitting by nearly 5 MeV, as shown in Table 3.

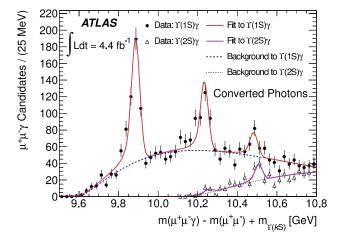

Figure 4: From ATLAS [35] pp collision data (points with error bars) taken at $\sqrt{s}=7$ TeV, the effective mass of $\chi_{bJ}(1P,2P,3P) \rightarrow \gamma \Upsilon(1S,2S)$ candidates in which $\Upsilon(1S,2S) \rightarrow \mu^+\mu^-$ and the photon is reconstructed as an e^+e^- conversion in the tracking system. Fits (smooth curves) show significant signals for each triplet (merged-J) on top of a smooth background. From [35] with kind permission, copyright (2012) The American Physical Society.

The $\chi_{bJ}(nP)$ states have recently been observed at the LHC by ATLAS [35] for n=1,2,3, although in each case the three J states are not distinguished from one another. Events are sought which have both a photon and an $\Upsilon(1S,2S) \to \mu^+\mu^-$ candidate which together form a mass in the χ_b region. Observation of all three J-merged peaks is seen at significance in excess of 6σ for both unconverted and converted photons. The mass plot for converted photons, which provide better mass resolution, is shown in Fig. 4. This marks the first observation of the $\chi_{bJ}(3P)$ triplet, quite near the expected mass.

Heavy Quarkonium Spectroscopy

Table 3: Measured $\eta_b(1S)$ masses and hyperfine splittings, by experiment and production mechanism.

| $m(\eta_b)$ | Δm_{hf} | Process | Ref. $(\chi^2/\text{d.o.f.})$ |
|---------------------------------------------------------|--------------------------------------------------------|------------------------------------------------------------------------|-------------------------------|
| $9394.2^{+4.8}_{-4.9}\pm 2.0$ | 4.0 | $\Upsilon(nS)2 \to \gamma \eta_b$ | BABAR [29] |
| $9388.9^{+3.1}_{-2.3}\pm 2.7$ $9391.8\pm 6.6\pm 2.0$ | $71.4^{+2.3}_{-3.1} \pm 2.7$ $68.5 \pm 6.6 \pm 2.0$ | $\Upsilon(nS)3 \to \gamma \eta_b$ $\Upsilon(nS)3 \to \gamma \eta_b$ | BABAR [27] CLEO [28] |
| 9391.0 ± 2.8 | 69.3 ± 2.9 | Above [7] | $Avg^a (0.6/2)$ |
| $9401.0 \pm 1.9^{+1.4}_{-2.4}$ 9395.8 ± 3.0 | $59.3 \pm 1.9_{-1.4}^{+2.4}$ 64.5 ± 3.0 | $h_b(1P) \to \gamma \eta_b$ All | Belle [30] $Avg^a (6.1/3)$ |

^a An inverse-square-error-weighted average of the individual measurements appearing above, for which all statistical and systematic errors were combined in quadrature without accounting for any possible correlations between them. The uncertainty on this average is inflated by the multiplicative factor S if $S^2 \equiv \chi^2/\text{d.o.f.} > 1$.

Charmonium, $\eta_c(1S)$

cc MESONS

THE CHARMONIUM SYSTEM

The level scheme of the $c\overline{c}$ states showing experimentally established states with solid lines. Singlet states are called η_c and h_c , triplet states ψ and χ_{cJ} , and unassigned charmonium-like states X. In parentheses it is sufficient to give the radial quantum number and the orbital angular momentum to specify the states with all their quantum numbers. Only observed hadronic transitions are shown; the single photon transitions $\psi(nS) \to \gamma \eta_c(mP)$, $\psi(nS) \to \gamma \chi_{cJ}(mP)$, and $\chi_{cJ}(1P) \to \gamma J/\psi$ are omitted for clarity.

 $\eta_c(1S)$

$$I^G(J^{PC}) = 0^+(0^{-+})$$

$\eta_c(1S)$ MASS

Supersedes ABE,K 02 and ABE 04G. 4 Using mass of $\psi(2S)=3686.00$ MeV. ⁵ From a simultaneous fit of five decay modes of the η_C . 6 MITCHELL 09 observes a significant asymmetry in the lineshapes of $\psi(2S) \to \gamma \eta_{\mathcal{C}}$ and $J/\psi \to \gamma \eta_{\mathcal{C}}$ transitions. If ignored, this asymmetry could lead to significant bias whenever the mass and width are measured in $\psi(2S)$ or J/ψ radiative decays. $^7\,\mathrm{Using}$ an η_{C} width of 13.2 MeV. ⁸ Weighted average of the $\psi(2S)$ and $J/\psi(1S)$ samples. ⁹ Not independent from the measurements reported by LEES 10.

 $^{10}\,\mathrm{From}$ the fit of the kaon momentum spectrum. Systematic errors not evaluated.

 $^{11}\,\mathrm{Superseded}$ by LEES 10.

CONSTRAINED FIT INFORMATION

An overall fit to the total width, 8 combinations of partial widths obtained from integrated cross section, and 14 branching ratios uses 73 measurements and one constraint to determine 11 parameters. The overall fit has a $\chi^2=$ 136.4 for 63 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

- 49 The quoted branching ratios use B($J/\psi(1S) \to \gamma \eta_{\rm C}(1S)) = 0.0127 \pm 0.0036$. Where relevant, the error in this branching ratio is treated as a common systematic in computing
- $^{\rm averages.}$ 50 ABLIKIM 06A reports [$\Gamma(\eta_C(1S) \to K^{*0} \overline{K}^{*0} \pi^+ \pi^-)/\Gamma_{\rm total}$] \times [B ($J/\psi(1S) \to \gamma\eta_C(1S)$)] = (1.91 ± 0.64 ± 0.48) × 10^{-4} which we divide by our best value B ($J/\psi(1S) \to \gamma\eta_C(1S)$)] = (1.91 ± 0.64 ± 0.48) × 10^{-4} which we divide by our best value B ($J/\psi(1S) \to \gamma\eta_C(1S)$) $\gamma \eta_{\rm C}(1S) = (1.7 \pm 0.4) \times 10^{-2}$. Our first error is their experiment's error and our second
- $\eta_{RC}(13)=(1.1\pm0.4)$ ATO . Our instantial states where Experiments early and our section error is the systematic error from using our best value. 51 Using B($B^+\to \eta_C$ K $^+$) = $(1.25\pm0.12^+0.10^-)$ $\times 10^{-3}$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^{-3}$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^{-3}$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^{-3}$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^{-3}$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^{-3}$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^{-3}$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^{-3}$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^{-3}$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^{-3}$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^{-3}$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^{-3}$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^{-3}$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^{-3}$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^{-3}$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^{-3}$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^{-3}$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^{-3}$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^{-3}$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^{-3}$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^{-3}$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^{-3}$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^{-3}$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^{-3}$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^{-3}$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^{-3}$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^{-3}$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^{-3}$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^{-3}$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^{-3}$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^{-3}$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^{-3}$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^-$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^-$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^-$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^-$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^-$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^-$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^-$ from FANG 03 and B($\eta_C\to 10^-$) $\times 10^-$ from FANG 04 $\times 10^-$ f $K\overline{K}\pi$) = $(5.5 \pm 1.7) \times 10^{-2}$.
- $^{52} \text{ABLIKIM 06A reports} \left[\Gamma \left(\eta_{\mathcal{C}}(1S) \rightarrow \ \phi 2(\pi^{+}\pi^{-}) \right) / \Gamma_{\text{total}} \right] \times \left[\text{B}(\textit{J}/\psi(1S) \rightarrow \ \gamma \eta_{\mathcal{C}}(1S)) \right]$ < 0.603 imes 10⁻⁴ which we divide by our best value B $(J/\psi(1S)
 ightarrow \gamma\eta_{\it C}(1S)) = 1.7 <math> imes$ 10^{-2}
- ⁵³We are assuming B($a_0(980) \rightarrow \eta \pi$) >0.5.
- ⁵⁴ ABLIKIM 04M reports $[\Gamma(\eta_C(1S) \rightarrow \eta_A) > 0.3.$ $\uparrow \eta_C(1270) f_2(1270))/\Gamma_{total}] \times [B(J/\psi(1S) \rightarrow \eta_C(1S))] = (1.3 \pm 0.3 \stackrel{+}{_{-}} 0.3) \times 10^{-4}$ which we divide by our best value $B(J/\psi(1S) \rightarrow \eta_C(1S))] = (1.3 \pm 0.3 \stackrel{+}{_{-}} 0.3) \times 10^{-4}$ $\gamma \eta_c(15)$) = $(1.7 \pm 0.4) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.
- 55 Determined from the ratio of $B(B^\pm\to K^\pm\eta_C)$ B($\eta_C\to K\overline{K}\pi)=(7.4\pm0.5\pm0.7)\times 10^{-5}$ reported in AUBERT,B 04B and B($B^\pm\to K^\pm\eta_C)=(8.7\pm1.5)\times 10^{-3}$ reported in AUBERT 06E. So Average from $K^+K^-\pi^0$ and $K^\pm K^0_S \pi^\mp$ decay channels.
- ⁵⁷ Estimated using B($\psi(2S) \rightarrow \gamma \eta_{C}(1S)$) = 0.0028 \pm 0.0006
- ⁵⁸We have multiplied the value of $\Gamma(K^+ K^- \pi^+ \pi^- \pi^0)/\Gamma(K^0_S K^\pm \pi^\mp)$ reported in DEL-
- AMO-SANCHEZ 11M by a factor 1/3 to obtain $\Gamma(K^+K^-\pi^+\pi^-\pi^0)/\Gamma(K\overline{K}\pi)$. Not independent from other measurements reported in DEL-A MO-SANCHEZ 11M. 59 ABLIKIM 06A reports $[\Gamma(\eta_c(1s) \to K^+K^-2(\pi^+\pi^-))/\Gamma_{\text{total}}] \times [B(J/\psi(1s) \to \gamma\eta_c(1s))] = (1.21\pm0.32\pm0.24)\times10^{-4}$ which we divide by our best value $B(J/\psi(1s) \to \gamma\eta_c(1s))$ $\gamma\eta_c(1S)=(1.7\pm0.4)\times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.
- 60 Normalized to the sum of B(η_{c} $\xrightarrow{}$ K^{\pm} K^{0}_{S} $\pi^{\mp}),$ B(η_{c} \rightarrow $\phi\phi),$ B(η_{c} \rightarrow ${\it K}^+ \, {\it K}^- \, \pi^+ \, \pi^-)$, and ${\it B}(\eta_{\it C} \rightarrow \, 2\pi^+ \, 2\pi^-)$.
- 61 ABLIKIM 06A reports $[\Gamma(\eta_C(1S) \to 3(\pi^+\pi^-))/\Gamma_{\text{total}}] \times [B(J/\psi(1S) \to \gamma\eta_C(1S))] = (2.59 \pm 0.32 \pm 0.47) \times 10^{-4}$ which we divide by our best value $B(J/\psi(1S) \to \gamma\eta_C(1S)) = (1.7 \pm 0.4) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.
- ⁶² WU 06 reports $[\Gamma(\eta_C(1S)
 ightarrow
 ho \overline{
 ho})/\Gamma_{ ext{total}}] \times [B(B^+
 ightarrow \eta_C K^+)] = (1.42 \pm 0.11 ^{+0.16}_{-0.20}) \times 10^{-10}$ 10^{-6} which we divide by our best value B($B^+ \to \eta_c \, K^+$) = $(9.6 \pm 1.2) \times 10^{-4}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.
- 63 WU 06 reports $\left[\Gamma(\eta_c(1S) \rightarrow \Lambda \overline{\Lambda})/\Gamma_{\text{total}}\right] \times \left[B(B^+ \rightarrow \eta_c K^+)\right] =$ $(0.95 + 0.25 + 0.08) \times 10^{-6}$ which we divide by our best value B($B^+ \rightarrow \eta_c K^+$) = $(9.6 \pm 1.2) \times 10^{-4}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.
- ⁶⁴ Not independent from other $\eta_C \to \Lambda \overline{\Lambda}$, $p\overline{p}$ branching ratios reported by WU 06.

- 1 Reanalysis of ZHOLENTZ 80 using new electron mass (COHEN 87) and radiative corrections (KURAEV 85). 2 Mass central value and systematic error recalculated by us according to Eq. (16) in ARMSTRONG 938, using the value for the $\psi(25)$ mass from AULCHENKO 03.
- ³ Superseded by ARTAMONOV 00.

Mode

 $^4\,{\rm From}$ a simultaneous fit to $e^+\,e^-$, $\mu^+\,\mu^-$ and hadronic channels assuming $\Gamma(e^+\,e^-)$ $=\Gamma(\mu^+\mu^-).$

 $^{94}\,\mathrm{AUBERT}$ 07AU reports $[\Gamma\big(J/\psi(1S)~\rightarrow~\pi^+\,\pi^-\,\pi^0\big)/\Gamma_{\mathsf{total}}]~\times~[\Gamma\big(\psi(2S)~\rightarrow~\pi^+\,\pi^-\,\pi^0)]$ $J/\psi(1S)\,\pi^+\,\pi^-\big)\times\Gamma\big(\psi(2S)\to\,e^+\,e^-\big)/\Gamma_{\mbox{total}}\big]=(18.6\pm1.2\pm1.1)\times10^{-3}\;\mbox{keV which}$ we divide by our best value $\Gamma(\psi(2S) \to J/\psi(1S) \pi^+ \pi^-) \times \Gamma(\psi(2S) \to e^+ e^-)$ $\Gamma_{total}=0.789\pm0.015$ keV. Our first error is their experiment's error and our second error is the systematic error from using our best value.

 95 From the ratio of $\Gamma(e^+\,e^-)$ B $(\pi^+\,\pi^-\,\pi^0)$ and $\Gamma(e^+\,e^-)$ B $(\mu^+\,\mu^-)$ (AUBERT 04).

 96 Mostly $\rho\pi$, see also $\rho\pi$ subsection. 97 From $J/\psi\to~\pi^+\pi^-\pi^0$ events directly.

 98 Obtained comparing the rates for $\pi^+\pi^-\pi^0$ and $\mu^+\mu^-$, using J/ψ events produced via $\psi(2S) \rightarrow \pi^{+} \pi^{-} J/\psi$ and with $B(J/\psi \rightarrow \mu^{+} \mu^{-}) = 5.88 \pm 0.10\%$.

BRANCHING RATIOS OF $\psi(2S)$ AND $\chi_{c0,1,2}$

Updated May 2012 by J.J. Hernández-Rey (IFIC, Valencia), S. Navas (University of Granada), and C. Patrignani (INFN, Genova)

Since 2002, the treatment of the branching ratios of the $\psi(2S)$ and $\chi_{c0,1,2}$ has undergone an important restructuring.

When measuring a branching ratio experimentally, it is not always possible to normalize the number of events observed in the corresponding decay mode to the total number of particles produced. Therefore, the experimenters sometimes report the number of observed decays with respect to another decay mode of the same or another particle in the relevant decay chain. This is actually equivalent to measuring combinations of branching fractions of several decay modes.

To extract the branching ratio of a given decay mode, the collaborations use some previously reported measurements of the required branching ratios. However, the values are frequently taken from the Review of Particle Physics (RPP), which in turn uses the branching ratio reported by the experiment in the following edition, giving rise either to correlations or to plain vicious circles Ref. 1, Ref. 2 as discussed in more detail in earlier editions of this mini-review.

The way to avoid these dependencies and correlations is to extract the branching ratios through a fit that uses the truly measured combinations of branching fractions and partial widths. This fit, in fact, should involve decays from the four concerned particles, $\psi(2S)$, χ_{c0} , χ_{c1} , and χ_{c2} , and occasionally some combinations of branching ratios of more than one of them. This is what is done since the 2002 edition [3].

The PDG policy is to quote the results of the collaborations in a manner as close as possible to what appears in their original publications. However, in order to avoid the problems mentioned above, we had in some cases to work out the values originally measured, using the number of events and detection efficiencies given by the collaborations, or rescaling back the published results. The information was sometimes spread over several articles, and some articles referred to papers still unpublished, which in turn contained the relevant numbers in footnotes.

Even though the experimental collaborations are entitled to extract whatever branching ratios they consider appropriate by using other published results, we would like to encourage them to also quote explicitly in their articles the actual quantities measured, so that they can be used directly in averages and fits of different experimental determinations.

To inform the reader how we computed some of the values used in this edition of RPP, we use footnotes to indicate the branching ratios actually given by the experiments and the quantities they use to derive them from the true combination of branching ratios actually measured.

None of the branching ratios of the $\chi_{c0,1,2}$ are measured independently of the $\psi(2S)$ radiative decays. We tried to identify those branching ratios which can be correlated in a non-trivial way, and although we cannot preclude the existence of other cases, we are confident that the most relevant correlations have already been removed. Nevertheless, correlations in the errors of different quantities measured by the same experiment have not been taken into account.

FIT INFORMATION

This is an overall fit to 4 total widths, 1 partial width, 25 combinations of partial widths, 7 branching ratios, and 77 combinations of branching ratios. Of the latter 57 involve decays of more than one particle.

The overall fit uses 223 measurements to determine 49 parameters and has a χ^2 of 312.2 for 174 degrees of freedom.

The relatively high χ^2 of the fit, 1.8 per d.o.f., can be traced back to a few specific discrepancies in the data. No rescaling of errors has been applied.

In the listing we provide the correlation coefficients $<\delta x_i \delta x_i>/(\delta x_i \cdot \delta x_i)$, in percent, from the fit to the corresponding parameter x_i .

CONSTRAINED FIT INFORMATION

A multiparticle fit to $\chi_{c1}(1P)$, $\chi_{c0}(1P)$, $\chi_{c2}(1P)$, and $\psi(2S)$ with 4 total widths, a partial width, 25 combinations of partial widths obtained from integrated cross section, and 84 branching ratios uses 223 measurements to determine 49 parameters. The overall fit has a $\chi^2=312.2$ for 174 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\left\langle \delta \rho_i \delta \rho_j \right\rangle / (\delta \rho_i \cdot \delta \rho_j)$, in percent, from the fit to parameters ρ_i , including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$.

27 ABLIKIM 05Q reports < 0.73 × 10⁻⁴ from a measurement of $[\Gamma(\chi_{C0}(1P) \rightarrow f_0(1500) f_0(1710))/\Gamma_{total}]$ × $[B(\psi(2S) \rightarrow \gamma\chi_{C0}(1P))]$ assuming $B(\psi(2S) \rightarrow \gamma\chi_{C0}(1P))$] = $(9.22\pm0.11\pm0.46)\times10^{-2}$, which we rescale to our best value $B(\psi(2S) \rightarrow \gamma\chi_{C0}(1P))$ = 9.68×10^{-2} . The f_0 mesons are identified via $f_0(1500) \rightarrow \pi^+\pi^-$ and $f_0(1710) \rightarrow K^+K^-$ decays. Both branching fractions for these f_0 decays are implicitly included in the quoted result.

 $[\]frac{1}{2}$ Recalculated by ANDREOTTI 05A, using the value of $\psi(2S)$ mass from AULCHENKO 03.

² Using mass of $\psi(2S)=3686.0$ MeV. ³ $J/\psi(1S)$ mass constrained to 3097 MeV.

of Very Mass constants to 307 MeV. A Mass value shifted by us by amount appropriate for $\psi(2s)$ mass = 3686 MeV and $J/\psi(1s)$ mass = 3097 MeV. From a simultaneous fit to radiative and hadronic decay channels.

CONSTRAINED FIT INFORMATION

A multiparticle fit to $\chi_{c1}(1P)$, $\chi_{c0}(1P)$, $\chi_{c2}(1P)$, and $\psi(2S)$ with 4 total widths, a partial width, 25 combinations of partial widths obtained from integrated cross section, and 84 branching ratios uses 223 measurements to determine 49 parameters. The overall fit has a $\chi^2=312.2$ for 174 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\left\langle \delta p_i \delta p_j \right\rangle / (\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$.

CONSTRAINED FIT INFORMATION

A multiparticle fit to $\chi_{c1}(1P),~\chi_{c0}(1P),~\chi_{c2}(1P),~$ and $\psi(2S)$ with 4 total widths, a partial width, 25 combinations of partial widths obtained from integrated cross section, and 84 branching ratios uses 223 measurements to determine 49 parameters. The overall fit has a $\chi^2=312.2$ for 174 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\left\langle \delta \rho_i \delta \rho_j \right\rangle / (\delta \rho_i \cdot \delta \rho_j)$, in percent, from the fit to parameters ρ_i , including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$.

 11 Calculated by us using B($J/\psi \to \ell^+\ell^-$) = 0.1187 \pm 0.0008. 12 All systematic errors added in quadrature.

13 The value for $\Gamma(\chi_{C2} \to \gamma \gamma)$ reported in ACCIARRI 99E is derived using B($\chi_{C2} \to \gamma \gamma$)/ $(15) \times B(J/\psi(15)) \to \ell^+\ell^-) = 0.0162 \pm 0.0014$.

¹⁴ The value for $\Gamma(\chi_{c2} \to \gamma \gamma)$ reported in ACKERSTAFF, K 98 is derived using B($\chi_{c2} \to \gamma J/\psi(1s)$) = 0.135 \pm 0.011 and B($J/\psi(1s) \to \ell^+\ell^-$) = 0.1203 \pm 0.0038.

15 The value for $\Gamma(\chi_{c2} \to \gamma \gamma)$ reported in DOMINICK 94 is derived using $B(\chi_{c2} \to \gamma J/\psi(1S)) = 0.135 \pm 0.011$, $B(J/\psi(1S) \to e^+e^-) = 0.0627 \pm 0.0020$, and $B(J/\psi(1S) \to \mu^+\mu^-) = 0.0597 \pm 0.0025$.

 16 The value for $\Gamma(\chi_{C2}\to \gamma\gamma)$ reported in BAUER 93 is derived using B($\chi_{C2}\to \gamma J/\psi(1S))=0.135\pm0.011,\ B(J/\psi(1S)\to e^+e^-)=0.0627\pm0.0020,\ and\ B(J/\psi(1S)\to \mu^+\mu^-)=0.0597\pm0.0025.$
