Hadronic modes with photons -

$\Gamma(\pi^+\pi^0\gamma(|NT))/\Gamma_{total}$

The $K^+ \to \pi^+ \pi^0 \gamma$ differential decay rate can be described in terms of T_{π^+} , the charged pion kinetic energy, and W^2 = (${\rm P}_K \, \cdot \, {\rm P}_\gamma$) (${\rm P}_{\pi^+} \, \cdot \, {\rm P}_\gamma$) / ($m_K \, m_{\pi^+}$)²; then we can write $d^2\Gamma(K^+ \to \pi^+ \pi^0 \gamma) / (dT_{\pi^+} dW^2) = d^2\Gamma(K^+ \to \pi^+ \pi^0 \gamma)_{IB}$ X_{M}^{2}) W⁴]. The IB differential and total branching ratios are expressed in terms of the non-radiative experimental width $\Gamma(K^+ \to \pi^+ \pi^0)$ by Low's theorem. Using PDG 10 B(K $^+$ \rightarrow $\pi^+\pi^0)$ = 0.2066 \pm 0.0008, one obtains respectively B(K $^+$ \rightarrow $\pi^+ \, \pi^0 \, \gamma)_{IB} \; ({\rm 55} \, < \, {\rm T}_{\pi^+} \; < \, {\rm 90 \; MeV}) = \, 2.55 \, \times \, 10^{-4} \; {\rm and} \; {\rm B}({\rm \textit{K}}^+ \rightarrow \; \pi^+ \, \pi^0 \, \gamma)_{IB} \; ({\rm 000} \, {\rm MeV}) = \, 2.55 \, \times \, 10^{-4} \; {\rm and} \; {\rm B}({\rm \textit{K}}^+ \rightarrow \; \pi^+ \, \pi^0 \, \gamma)_{IB} \; ({\rm 000} \, {\rm MeV}) = \, 2.55 \, \times \, 10^{-4} \; {\rm and} \; {\rm B}({\rm \textit{K}}^+ \rightarrow \; \pi^+ \, \pi^0 \, \gamma)_{IB} \; ({\rm 000} \, {\rm MeV}) = \, 2.55 \, \times \, 10^{-4} \; {\rm and} \; {\rm B}({\rm \textit{K}}^+ \rightarrow \; \pi^+ \, \pi^0 \, \gamma)_{IB} \; ({\rm 000} \, {\rm MeV}) = \, 2.55 \, \times \, 10^{-4} \; {\rm and} \; {\rm B}({\rm \textit{K}}^+ \rightarrow \; \pi^+ \, \pi^0 \, \gamma)_{IB} \; ({\rm 000} \, {\rm MeV}) = \, 2.55 \, \times \, 10^{-4} \; {\rm and} \; {\rm B}({\rm \textit{K}}^+ \rightarrow \; \pi^+ \, \pi^0 \, \gamma)_{IB} \; ({\rm 000} \, {\rm MeV}) = \, 2.55 \, \times \, 10^{-4} \; {\rm and} \; {\rm B}({\rm \textit{K}}^+ \rightarrow \; \pi^+ \, \pi^0 \, \gamma)_{IB} \; ({\rm 000} \, {\rm MeV}) = \, 2.55 \, \times \, 10^{-4} \; {\rm and} \; {\rm B}({\rm \textit{K}}^+ \rightarrow \; \pi^+ \, \pi^0 \, \gamma)_{IB} \; ({\rm 000} \, {\rm MeV}) = \, 2.55 \, \times \, 10^{-4} \; {\rm and} \; {\rm B}({\rm \textit{K}}^+ \rightarrow \; \pi^+ \, \pi^0 \, \gamma)_{IB} \; ({\rm 000} \, {\rm MeV}) = \, 2.55 \, \times \, 10^{-4} \; {\rm and} \; {\rm B}({\rm \textit{K}}^+ \rightarrow \; \pi^+ \, \pi^0 \, \gamma)_{IB} \; ({\rm 000} \, {\rm MeV}) = \, 2.55 \, \times \, 10^{-4} \; {\rm and} \; {\rm B}({\rm \textit{K}}^+ \rightarrow \; \pi^+ \, \pi^0 \, \gamma)_{IB} \; ({\rm 000} \, {\rm MeV}) = \, 2.55 \, \times \, 10^{-4} \; {\rm and} \; {\rm B}({\rm \textit{K}}^+ \rightarrow \; \pi^+ \, \pi^0 \, \gamma)_{IB} \; ({\rm 000} \, {\rm MeV}) = \, 2.55 \, \times \, 10^{-4} \; {\rm and} \; {\rm B}({\rm \textit{K}}^+ \rightarrow \; \pi^+ \, \pi^0 \, \gamma)_{IB} \; ({\rm 000} \, {\rm MeV}) = \, 2.55 \, \times \, 10^{-4} \; {\rm and} \; {\rm B}({\rm \textit{K}}^+ \rightarrow \; \pi^+ \, \pi^0 \, \gamma)_{IB} \; ({\rm 000} \, {\rm MeV}) = \, 2.55 \, \times \, 10^{-4} \; {\rm and} \; {\rm B}({\rm \textit{K}}^+ \rightarrow \; \pi^+ \, \pi^0 \, \gamma)_{IB} \; ({\rm 000} \, {\rm MeV}) = \, 2.55 \, \times \, 10^{-4} \, {\rm and} \; {\rm B}({\rm \textit{K}}^+ \rightarrow \; \pi^+ \, \pi^0 \, \gamma)_{IB} \; ({\rm 000} \, {\rm MeV}) = \, 2.55 \, \times \, 10^{-4} \, {\rm and} \; {\rm B}({\rm \textit{K}}^+ \rightarrow \; \pi^+ \, \pi^0 \, \gamma)_{IB} \; ({\rm 000} \, {\rm MeV}) = \, 2.55 \, \times \, 10^{-4} \, {\rm and} \; {\rm B}({\rm N}^+ \rightarrow \; \pi^+ \, \pi^0 \, \gamma)_{IB} \; ({\rm N}^+ \rightarrow \; \pi^+ \, \pi^0 \, \gamma)_{IB} \; ({\rm N}^+ \rightarrow \; \pi^+ \, \pi^0 \, \gamma)_{IB} \; ({\rm N}^+ \rightarrow \; \pi^+ \, \pi^0 \, \gamma)_{IB} \; ({\rm N}^+ \rightarrow \; \pi^+ \, \pi^0 \, \gamma)_{IB} \; ({\rm N}^+ \rightarrow \; \pi^+ \, \pi^0 \, \gamma)_{IB} \; ({\rm N}^+ \rightarrow \; \pi^+ \, \pi^0 \, \gamma)_{IB} \; ({\rm N}^+ \rightarrow \; \pi^+ \, \pi^0 \,$ < T_{_+} < 80 MeV)= 1.80×10^{-4} . Fitting respectively the piece proportional to W² and the piece proportional to W^4 , the interference contribution (INT), proportional to X_E , and the direct contribution (DE) proportional to $\mathsf{X}_E^2 + \mathsf{X}_M^2$ are extracted.

Direct emission (DE) part of $\Gamma(\pi^+\pi^0\gamma)/\Gamma_{\rm total}$, assuming that interference (INT) component is zero.

VALUE (units 10^{-6}) DO CUMENT ID TECN CHG COMMENT ⁵⁵ BATLEY 10A NA48 \pm T $_{\pi^+}$ 0-80 MeV $5.99 \pm 0.27 \pm 0.25$ 600k

⁴⁸BARMIN 91 quotes branching ratio $\Gamma(K \to e \pi^0 \nu \gamma)/\Gamma_{\rm all}$. The measured normalization is $[\Gamma(K \to e \pi^0 \nu) + \Gamma(K \to \pi^+ \pi^+ \pi^-)]$. For comparison with other experiments we used $\Gamma(K \rightarrow e \pi^0 \nu)/\Gamma_{\rm all} = 0.0482$ to calculate the values quoted here.

 $^{^{49}\}cos(heta_{e\gamma})$ between 0.6 and 0.9.

 $^{^{50}}$ First LJUNG 73 value is for $\cos(\theta_{e\gamma})$ <0.9, second value is for $\cos(\theta_{e\gamma})$ between 0.6 and 0.9 for comparison with ROMANO 71.

 $^{^{51}}$ Both ROMANO 71 values are for $\cos(\theta_{e\gamma})$ between 0.6 and 0.9. Second value is for comparison with second LJUNG 73 value. We use lowest E_{γ} cut for Summary Table value. See ROMANO 71 for \boldsymbol{E}_{γ} dependence.

 $^{^{54}}$ The cut on the photon energy implies W $^2>0.2.$ BATLEY 10A obtains the INT and DE fractional branchings with respect to IB from a simultaneous kinematical fit of INT and DE and then we use the PDG 10 value for B(K $^+\to~\pi^+\pi^0$) = 20.66 \pm 0.08 to determine the IB. The INT and DE correlation coefficients - 0.83. Assuming a constant electric amplitude, ${\rm X}_E$, this INT value implies ${\rm X}_E=-$ 24 \pm 6 GeV $^{-4}$.

Violates angular momentum conservation and gauge invariance. Current interest in this decay is as a search for non-commutative space-time effects as discussed in AR-TAMONOV 05 and for exotic physics such as a vacuum expectation value of a new vector field, non-local Superstring effects, or departures from Lorentz invariance, as discussed in ADLER 02B.

DALITZ PLOT PARAMETERS FOR $K \rightarrow 3\pi$ DECAYS

Revised 1999 by T.G. Trippe (LBNL).

The Dalitz plot distribution for $K^{\pm} \to \pi^{\pm}\pi^{\pm}\pi^{\mp}$, $K^{\pm} \to$ $\pi^0\pi^0\pi^\pm$, and $K_L^0\to\pi^+\pi^-\pi^0$ can be parameterized by a series expansion such as that introduced by Weinberg [1]. We use the form

$$\left| M \right|^2 \propto 1 + g \frac{(s_3 - s_0)}{m_{\pi^+}^2} + h \left[\frac{s_3 - s_0}{m_{\pi^+}^2} \right]^2$$

$$+ j \frac{(s_2 - s_1)}{m_{\pi^+}^2} + k \left[\frac{s_2 - s_1}{m_{\pi^+}^2} \right]^2$$

$$+ f \frac{(s_2 - s_1)}{m_{\pi^+}^2} \frac{(s_3 - s_0)}{m_{\pi^+}^2} + \cdots , \qquad (1)$$

where $m_{\pi^{+}}^{2}$ has been introduced to make the coefficients g, h, j, and k dimensionless, and

$$s_i = (P_K - P_i)^2 = (m_K - m_i)^2 - 2m_K T_i , i = 1, 2, 3,$$

 $s_0 = \frac{1}{3} \sum_i s_i = \frac{1}{3} (m_K^2 + m_1^2 + m_2^2 + m_3^2) .$

Here the P_i are four-vectors, m_i and T_i are the mass and kinetic energy of the i^{th} pion, and the index 3 is used for the odd pion.

The coefficient g is a measure of the slope in the variable s_3 (or T_3) of the Dalitz plot, while h and k measure the quadratic dependence on s_3 and $(s_2 - s_1)$, respectively. The coefficient j is related to the asymmetry of the plot and must be zero if CPinvariance holds. Note also that if CP is good, q, h, and k must be the same for $K^+ \to \pi^+ \pi^+ \pi^-$ as for $K^- \to \pi^- \pi^- \pi^+$.

Since different experiments use different forms for M, in order to compare the experiments we have converted to g, h, j, and k whatever coefficients have been measured. Where such conversions have been done, the measured coefficient a_u , a_t , a_u , or a_v is given in the comment at the right. For definitions of these coefficients, details of this conversion, and discussion of the data, see the April 1982 version of this note [2].

ENERGY DEPENDENCE OF K^{\pm} DALITZ PLOT

|matrix element|^2 = 1 + gu + hu^2 + kv^2
where
$$u=(s_3-s_0)$$
 / m_π^2 and $v=(s_2-s_1)$ / m_π^2

LINEAR COEFFICIENT g FOR $K^{\pm} \rightarrow \pi^{\pm}\pi^{+}\pi^{-}$

Some experiments use Dalitz variables x and y. In the comments we give $a_y=$ coefficient of y term. See note above on "Dalitz Plot Parameters for $K\to 3\pi$ Decays." For discussion of the conversion of a_v to g, see the earlier version of the same note in the Review published in Physics Letters 111B 70 (1982).

⁹⁷ BATLEY 07E includes data from BATLEY 06. Uses quadratic parametrization and value $g_+ + g_- = 2g$ from BATLEY 07B. This measurement neglects any possible charge asymmetries in higher order slope parameters \hbar or k.

LINEAR COEFFICIENT g FOR $K^\pm ightarrow \ \pi^\pm \pi^0 \pi^0$

Unless otherwise stated, all experiments include terms quadratic in (s_3-s_0) / $m_{\pi^\pm}^2$. See note above on "Dalitz Plot Parameters for $K\to 3\pi$ Decays."

See BATUSOV 98 for a discussion of the discrepancy between their result and others, especially BOLOTOV 86. At this time we have no way to resolve the discrepancy so

 $^{103}\,\mathrm{BATLEY}$ 07E includes data from BATLEY 06A. Uses quadratic parametrization and PDG 06 value $g=0.626\pm0.007$ to obtain $g_+-g_-=(2.2\pm2.1\pm0.7)\times10^{-4}$. Neglects any possible charge asymmetries in higher order slope parameters h or k.

104 Asymmetry obtained assuming that $g_+ + g_- = 2 \times 0.652$ (PDG 02) and that asymmetries in h and k are zero.

105 Linear and quadratic slopes from PDG 04 are used. Any possible charge asymmetries in higher order slope parameters h or k are neglected.

ALTERNATIVE PARAMETRIZATIONS OF $K^{\pm} \rightarrow \pi^{\pm}\pi^{0}\pi^{0}$ DALITZ PLOT

The following functional form for the matrix element suggested by $\pi\pi$ rescattering in $K^+\to \pi^+\,\pi^+\pi^-^{n}\to \pi^+\pi^0\,\pi^0$ is used for this fit (CABIBBO 04A, CABIBBO 05): Matrix element $= M_0 + M_1$ where $M_0 = 1 + (1/2)g_0 \ u + (1/2) \ h' \ u^2 + (1/2)k_0 \ v^2$ with $u = (s_3 - s_0)/(m_{\pi^+})^2$, $v=(s_2-s_1)/(m_{\pi^+})^2$ and where M_1 takes into account the non-analytic piece due to pi pi rescattering amplitudes a_0 and a_2 ; The parameters g_0 and h' are related to the parameters g and h of the matrix element squared given in the previous section by the approximations $g_0 \sim g^{PDG}$ and $h' \sim h^{PDG} - (\mathrm{g}/2)^2$ and $k_0 \sim k^{PDG}$.

In addition, we also consider the effective field theory framework of COLANGELO 06A and BISSEGGER 09 to extract \mathbf{g}_{BB} and \mathbf{h}_{BB}' .

$K_{\ell 3}^{\pm}$ AND $K_{\ell 3}^{0}$ FORM FACTORS

Updated March 2012 by T.G. Trippe (LBNL) and C.-J. Lin

Assuming that only the vector current contributes to $K \rightarrow$ $\pi\ell\nu$ decays, we write the matrix element as

$$M \propto f_{+}(t) \left[(P_K + P_{\pi})_{\mu} \overline{\ell} \gamma_{\mu} (1 + \gamma_5) \nu \right]$$

+ $f_{-}(t) \left[m_{\ell} \overline{\ell} (1 + \gamma_5) \nu \right] ,$ (1)

where P_K and P_{π} are the four-momenta of the K and π mesons, m_{ℓ} is the lepton mass, and f_{+} and f_{-} are dimensionless form factors which can depend only on $t = (P_K - P_\pi)^2$, the square of the four-momentum transfer to the leptons. If timereversal invariance holds, f_+ and f_- are relatively real. $K_{\mu3}$ experiments, discussed immediately below, measure f_{+} and f_{-} , while K_{e3} experiments, discussed further below, are sensitive only to f_+ because the small electron mass makes the f_- term

 $K_{\mu 3}$ Experiments. Analyses of $K_{\mu 3}$ data frequently assume a linear dependence of f_+ and f_- on t, *i.e.*,

$$f_{\pm}(t) = f_{\pm}(0) \left[1 + \lambda_{\pm}(t/m_{\pi^{+}}^{2}) \right] .$$
 (2)

Most $K_{\mu 3}$ data are adequately described by Eq. (2) for f_+ and a constant f_{-} (i.e., $\lambda_{-}=0$).

There are two equivalent parametrizations commonly used in these analyses:

(1) $\lambda_+, \xi(0)$ parametrization. Older analyses of $K_{\mu 3}$ data often introduce the ratio of the two form factors

$$\xi(t) = f_{-}(t)/f_{+}(t) . \tag{3}$$

 K^{\pm}

The $K_{\mu 3}$ decay distribution is then described by the two parameters λ_{+} and $\xi(0)$ (assuming time reversal invariance and $\lambda_{-}=0$).

(2) λ_+ , λ_0 parametrization. More recent $K_{\mu 3}$ analyses have parametrized in terms of the form factors f_+ and f_0 , which are associated with vector and scalar exchange, respectively, to the lepton pair. f_0 is related to f_+ and f_- by

$$f_0(t) = f_+(t) + \left[t/(m_K^2 - m_\pi^2) \right] f_-(t)$$
 (4)

Here $f_0(0)$ must equal $f_+(0)$ unless $f_-(t)$ diverges at t=0. The earlier assumption that f_+ is linear in t and f_- is constant leads to f_0 linear in t:

$$f_0(t) = f_0(0) \left[1 + \lambda_0 (t/m_{\pi^+}^2) \right]$$
 (5)

With the assumption that $f_0(0) = f_+(0)$, the two parametrizations, $(\lambda_+, \xi(0))$ and (λ_+, λ_0) are equivalent as long as correlation information is retained. (λ_+, λ_0) correlations tend to be less strong than $(\lambda_+, \xi(0))$ correlations.

Since the 2006 edition of the Review [4], we no longer quote results in the $(\lambda_+, \xi(0))$ parametrization. We have removed many older low statistics results from the Listings. See the 2004 version of this note [5] for these older results, and the 1982 version [6] for additional discussion of the $K_{\mu 3}^0$ parameters, correlations, and conversion between parametrizations.

Quadratic Parametrization. More recent high-statistics experiments have included a quadratic term in the expansion of $f_{+}(t)$,

$$f_{+}(t) = f_{+}(0) \left[1 + \lambda'_{+}(t/m_{\pi^{+}}^{2}) + \frac{\lambda''_{+}}{2}(t/m_{\pi^{+}}^{2})^{2} \right]$$
 (6)

If there is a non-vanishing quadratic term, then λ_+ of Eq. (2) represents the average slope, which is then different from λ'_+ . Our convention is to include the factor $\frac{1}{2}$ in the quadratic term, and to use m_{π^+} even for K^+_{e3} and $K^+_{\mu3}$ decays. We have converted other's parametrizations to match our conventions, as noted in the beginning of the " $K^\pm_{\ell3}$ and $K^0_{\ell3}$ Form Factors" sections of the Listings.

Pole Parametrization: The pole model describes the t-dependence of $f_+(t)$ and $f_0(t)$ in terms of the exchange of the lightest vector and scalar K^* mesons with masses M_v and M_s , respectively:

$$f_{+}(t) = f_{+}(0) \left[\frac{M_{v}^{2}}{M_{v}^{2} - t} \right] , \quad f_{0}(t) = f_{0}(0) \left[\frac{M_{s}^{2}}{M_{s}^{2} - t} \right] .$$
 (7)

Dispersive Parametrization [7,8]. This approach uses dispersive techniques and the known low-energy K- π phases to parametrize the vector and scalar form factors:

$$f_{+}(t) = f_{+}(0) \exp\left[\frac{t}{m_{\pi}^{2}}(\Lambda_{+} + H(t))\right];$$
 (8)

$$f_0(t) = f_+(0) \exp\left[\frac{t}{(m_K^2 - m_\pi^2)} (\ln[C] - G(t))\right],$$
 (9)

where Λ_+ is the slope of the vector form factor, and $\ln[C] = \ln[f_0(m_K^2 - m_\pi^2)]$ is the logarithm of the scalar form factor at

the Callan-Treiman point. The functions H(t) and G(t) are dispersive integrals.

 K_{e3} Experiments: Analysis of K_{e3} data is simpler than that of $K_{\mu3}$ because the second term of the matrix element assuming a pure vector current [Eq. (1) above] can be neglected. Here f_+ can be assumed to be linear in t, in which case the linear coefficient λ_+ of Eq. (2) is determined, or quadratic, in which case the linear coefficient λ_+' and quadratic coefficient λ_+'' of Eq. (6) are determined.

If we remove the assumption of a pure vector current, then the matrix element for the decay, in addition to the terms in Eq. (1), would contain

$$+2m_K f_S \overline{\ell}(1+\gamma_5)\nu$$

$$+(2f_T/m_K)(P_K)_{\lambda}(P_{\pi})_{\mu} \overline{\ell} \sigma_{\lambda\mu}(1+\gamma_5)\nu , \qquad (10)$$

where f_S is the scalar form factor, and f_T is the tensor form factor. In the case of the K_{e3} decays where the f_- term can be neglected, experiments have yielded limits on $|f_S/f_+|$ and $|f_T/f_+|$.

Fits for $K_{\ell 3}$ Form Factors. For K_{e3} data, we determine best values for the three parametrizations: linear (λ_+) , quadratic $(\lambda'_+, \lambda''_+)$ and pole (M_v) . For $K_{\mu 3}$ data, we determine best values for the three parametrizations: linear (λ_+, λ_0) , quadratic $(\lambda'_+, \lambda''_+, \lambda_0)$ and pole (M_v, M_s) . We then assume $\mu - e$ universality so that we can combine K_{e3} and $K_{\mu 3}$ data, and again determine best values for the three parametrizations: linear (λ_+, λ_0) , quadratic $(\lambda'_+, \lambda''_+, \lambda_0)$, and pole (M_v, M_s) . When there is more than one parameter, fits are done including input correlations. Simple averages suffice in the two K_{e3} cases where there is only one parameter: linear (λ_+) and pole (M_v) .

Both KTeV and KLOE see an improvement in the quality of their fits relative to linear fits when a quadratic term is introduced, as well as when the pole parametrization is used. The quadratic parametrization has the disadvantage that the quadratic parameter λ'_+ is highly correlated with the linear parameter λ'_+ , in the neighborhood of 95%, and that neither parameter is very well determined. The pole fit has the same number of parameters as the linear fit, but yields slightly better fit probabilities, so that it would be advisable for all experiments to include the pole parametrization as one of their choices [9].

The "Kaon Particle Listings" show the results with and without assuming μ -e universality. The "Meson Summary Tables" show all of the results assuming μ -e universality, but most results not assuming μ -e universality are given only in the Listings.

KA FORM FACTORS

In the form factor comments, the following symbols are used.

 f_{+} and f_{-} are form factors for the vector matrix element.

 $f_{\mathcal{S}}$ and $f_{\mathcal{T}}$ refer to the scalar and tensor term.

$$f_0 = f_+ + f_- t/(m_{K^+}^2 - m_{\pi^0}^2).$$

t= momentum transfer to the π .

 λ_+ and λ_0 are the linear expansion coefficients of f_+ and f_0

$$f_{+}(t) = f_{+}(0) (1 + \lambda_{+} t / m_{\pi^{+}}^{2})$$

For quadratic expansion

$$f_{+}(t) = f_{+}(0) \left(1 + \lambda'_{+} t / m_{\pi^{+}}^{2} + \frac{\lambda''_{+}}{2} t^{2} / m_{\pi^{+}}^{4}\right)$$

as used by KTeV. If there is a non-vanishing quadratic term, then λ_+ represents an average slope, which is then different from λ'_{+} .

NA48 and ISTRA quadratic expansion coefficients are converted with

$$\lambda''_{+} \stackrel{PDG}{=} 2 \left(\frac{m_{\pi^{+}}}{m_{\pi^{0}}} \right)^{4} \lambda'_{+} \stackrel{ISTRA}{=}$$

ISTRA linear expansion coefficients are converted with $\lambda_{+}^{~PDG}=(\frac{m_{\pi^{+}}}{m_{\pi^{0}}})^{2}~\lambda_{+}^{~ISTRA}$ and $\lambda_{0}^{~PDG}=(\frac{m_{\pi^{+}}}{m_{\pi^{0}}})^{2}~\lambda_{0}^{~ISTRA}$

$$f_{+}(t) = f_{+}(0) \left(\frac{M_{V}^{2}}{M_{V}^{2} - t} \right)$$

$$f_{0}(t) = f_{0}(0) \left(\frac{M_{S}^{5}}{M_{S}^{5} - t} \right)$$

where M_V and M_S are the vector and scalar pole masses

The following abbreviations are used:

 $\mathsf{DP} \,=\, \mathsf{Dalitz} \,\, \mathsf{plot} \,\, \mathsf{analysis}.$

 $PI = \pi$ spectrum analysis.

 $MU = \mu$ spectrum analysis.

 $\mathsf{POL} = \mu$ polarization analysis. BR = $K_{\mu 3}^{\pm}/K_{e3}^{\pm}$ branching ratio analysis.

E = positron or electron spectrum analysis.

 ${\sf RC} = {\sf radiative} \ {\sf corrections}.$

 λ_+ (LINEAR ENERGY DEPENDENCE OF f_+ IN K_{e3}^\pm DECAY)

These results are for a linear expansion only. See the next section for fits including a quadratic term. For radiative correction of the K_{e3}^\pm Dalitz plot, see GINSBERG 67, BECHERRAWY 70, CIRIGLIANO 02, CIRIGLIANO 04, and ANDRE 07. Results labeled OUR FIT are discussed in the review " K_{e3}^\pm and K_{e3}^0 Form Factors" above. For earlier, lower statistics results, see the 2004 edition of this review, Physics Letters ${\bf B592}$ 1 (2004).

K₄ FORM FACTORS

Based on the parametrizations of AMOROS 99, the $K^\pm_{\ell 4}$ form factors can

$$F_{s} = f_{s} + f'_{s} q^{2} + f''_{s} q^{4} + f'_{e} S_{e} / 4m_{\pi}^{2}$$

$$F_{p} = f_{p} + f'_{p} q^{2}$$

$$G_{p} = g_{p} + g'_{p} q^{2}$$

$$H_{p} = h_{p} + h'_{p} q^{2}$$

 $\begin{array}{c} H_p = h_p + h_p^{\prime} \ {\bf q}^2 \\ \text{where } {\bf q}^2 = ({\bf S}_\pi \ / \ 4m_\pi^2) - {\bf 1}, \ {\bf S}_\pi \ \text{is the invariant mass squared of the dipion, and } {\bf S}_e \ \text{is the invariant mass squared of the dilepton.} \end{array}$

 154 Vector form factor fitted with a linear function, V(x) = F_V (1 + $\lambda(1-{\rm x}))$, x = $2E_\gamma/m_K$. The fitted value of $\lambda=0.38\pm0.20\pm0.02$ with a correlation of -0.93 between (F_V+F_A) and λ .

 155 HEINTZE 79 quotes absolute value of $|F_A+F_V|\sin\theta_C$. We use $\sin\theta_C=V_{US}=0.2205.$ 156 HEARD 75 quotes absolute value of $|F_A+F_V|\sin\theta_C$. We use $\sin\theta_C=V_{US}=0.2205.$

 $\mathit{F_A} + \mathit{F_V},$ SUM OF AXIAL-VECTOR AND VECTOR FORM FACTOR FOR $\mathit{K} \rightarrow \mathit{e}\, \nu_\mathit{e}\, \gamma$

$F_A + F_V$, SUM OF AXIAL-VECTOR AND VECTOR FORM FACTOR FOR $K \to \mu \nu_\mu \gamma$

T-VIOLATION PARAMETER IN KO-KO MIXING

The asymmetry $A_T = \frac{\Gamma(\overline{K}^0 \to K^0) - \Gamma(K^0 \to \overline{K}^0)}{\Gamma(\overline{K}^0 \to K^0) + \Gamma(K^0 \to \overline{K}^0)}$ must vanish if

ASYMMETRY AT IN KO-KO MIXING

| VALUE (units 10 ⁻³) | EVTS | DO CUMENT ID | TECN |
|---------------------------------|------|----------------|------|
| 6.6±1.3±1.0 | 640k | 1 ANGELOPO 98E | CPLR |

 1 ANGELOPOULOS 98E measures the asymmetry $A_{T} = [\Gamma(\overline{K}_{1=0}^0 \to e^+ \pi^- \nu_{t=\tau}) - \Gamma(K_{0=0}^0 \to e^- \pi^+ \overline{\nu}_{t=\tau})]/[\Gamma(\overline{K}_{1=0}^0 \to e^+ \pi^- \nu_{t=\tau}) + \Gamma(K_{t=0}^0 \to e^- \pi^+ \overline{\nu}_{t=\tau})]$ as a function of the neutral-kaon eigentime τ . The initial strangeness of the neutral kaon is tagged by the charge of the accompanying charged kaon in the reactions $p\overline{p} \to K^- \pi^+ K^0$ and $p\overline{p} \to K^+ \pi^- \overline{K}^0$. The strangeness at the time of the decay is tagged by the lepton charge. The reported result is the average value of A_T over the interval $1\tau_S < \tau < 20\tau_S$. From this value of A_T ANGELOPOULOS 018, assuming CPT invariance in the $e\pi\nu$ decay amplitude, determine the T-violating as $\Delta S = \Delta S$ conserving parameter (for its definition, see Review below) $4\text{Re}(\epsilon) = (6.2 \pm 1.4 \pm 1.0) \times 10^{-3}$.

CPT INVARIANCE TESTS IN NEUTRAL KAON DECAY

Updated April 2012 by M. Antonelli (LNF-INFN, Frascati) and G. D'Ambrosio (INFN Sezione di Napoli).

CPT theorem is based on three assumptions: quantum field theory, locality, and Lorentz invariance, and thus it is a fundamental probe of our basic understanding of particle physics. Strangeness oscillation in $K^0-\overline{K}^0$ system, described by the equation

$$i\frac{d}{dt} \left[\frac{K^0}{\overline{K}^0} \right] = \left[M - i \Gamma/2 \right] \left[\frac{K^0}{\overline{K}^0} \right] \ ,$$

where M and Γ are hermitian matrices (see PDG review [1], references [2,3], and KLOE paper [4] for notations and previous literature), allows a very accurate test of CPT symmetry; indeed since CPT requires $M_{11}=M_{22}$ and $\Gamma_{11}=\Gamma_{22}$, the mass and width eigenstates, $K_{S,L}$, have a CPT-violating piece, δ , in addition to the usual CPT-conserving parameter ϵ :

$$K_{S,L} = \frac{1}{\sqrt{2\left(1 + \left|\epsilon_{S,L}\right|^{2}\right)}} \left[\left(1 + \epsilon_{S,L}\right) K^{0} + \left(1 - \epsilon_{S,L}\right) \overline{K}^{0} \right]$$

$$\epsilon_{S,L} = \frac{-i\Im(M_{12}) - \frac{1}{2}\Im(\Gamma_{12}) \mp \frac{1}{2} \left[M_{11} - M_{22} - \frac{i}{2} (\Gamma_{11} - \Gamma_{22}) \right]}{m_L - m_S + i(\Gamma_S - \Gamma_L)/2}$$

$$\equiv \epsilon \pm \delta. \tag{1}$$

Using the phase convention $\Im(\Gamma_{12})=0$, we determine the phase of ϵ to be $\varphi_{SW}\equiv\arctan\frac{2(m_L-m_S)}{\Gamma_S-\Gamma_L}$. Imposing unitarity to an arbitrary combination of K^0 and \overline{K}^0 wave functions, we obtain the Bell-Steinberger relation [5] connecting CP and

K^0

CPT violation in the mass matrix to CP and CPT violation in the decay; in fact, neglecting $\mathcal{O}(\epsilon)$ corrections to the coefficient of the CPT-violating parameter, δ , we can write [4]

$$\left[\frac{\Gamma_S + \Gamma_L}{\Gamma_S - \Gamma_L} + i \tan \phi_{\text{SW}}\right] \left[\frac{\Re(\epsilon)}{1 + |\epsilon|^2} - i\Im(\delta)\right] = \frac{1}{\Gamma_S - \Gamma_L} \sum_f A_L(f) A_S^*(f), \tag{2}$$

where $A_{L,S}(f) \equiv A(K_{L,S} \to f)$. We stress that this relation is phase-convention-independent. The advantage of the neutral kaon system is that only a few decay modes give significant contributions to the r.h.s. in Eq. (2); in fact, defining for the hadronic modes

$$\alpha_i \equiv \frac{1}{\Gamma_S} \langle \mathcal{A}_L(i) \mathcal{A}_S^*(i) \rangle = \eta_i \ \mathcal{B}(K_S \to i),$$

$$i = \pi^0 \pi^0, \pi^+ \pi^-(\gamma), 3\pi^0, \pi^0 \pi^+ \pi^-(\gamma),$$
 (3)

the recent data from CPLEAR, KLOE, KTeV, and NA48 have led to the following determinations (the analysis described in Ref. 4 has been updated by using the recent measurements of K_L branching ratios from KTeV [6,7], NA48 [8,9], and the results described in the CP violation in K_L decays minireview)

$$\begin{split} \alpha_{\pi^+\pi^-} &= \left((1.112 \pm 0.010) + i (1.061 \pm 0.010) \right) \times 10^{-3} \;, \\ \alpha_{\pi^0\pi^0} &= \left((0.493 \pm 0.005) + i (0.471 \pm 0.005) \right) \times 10^{-3} \;, \\ \alpha_{\pi^+\pi^-\pi^0} &= \left((0 \pm 2) + i (0 \pm 2) \right) \times 10^{-6}, \\ |\alpha_{\pi^0\pi^0\pi^0}| &< 7 \times 10^{-6} \quad \text{at } 95\% \; \text{CL} \;. \end{split} \tag{4}$$

The semileptonic contribution to the right-handed side of Eq. (2) requires the determination of several observables: we define [2,3]

$$\mathcal{A}(K^{0} \to \pi^{-}l^{+}\nu) = \mathcal{A}_{0}(1-y) ,$$

$$\mathcal{A}(K^{0} \to \pi^{+}l^{-}\nu) = \mathcal{A}_{0}^{*}(1+y^{*})(x_{+}-x_{-})^{*} ,$$

$$\mathcal{A}(\overline{K}^{0} \to \pi^{+}l^{-}\nu) = \mathcal{A}_{0}^{*}(1+y^{*}) ,$$

$$\mathcal{A}(\overline{K}^{0} \to \pi^{-}l^{+}\nu) = \mathcal{A}_{0}(1-y)(x_{+}+x_{-}) ,$$
(5)

where x_+ (x_-) describes the violation of the $\Delta S = \Delta Q$ rule in CPT-conserving (violating) decay amplitudes, and y parametrizes CPT violation for $\Delta S = \Delta Q$ transitions. Taking advantage of their tagged $K^0(\overline{K}^0)$ beams, CPLEAR has measured $\Im(x_+)$, $\Re(x_-)$, $\Im(\delta)$, and $\Re(\delta)$ [11]. These determinations have been improved in Ref. 4 by including the information $A_S - A_L = 4[\Re(\delta) + \Re(x_-)]$, where $A_{L,S}$ are the K_L and K_S semileptonic charge asymmetries, respectively, from the PDG [12] and KLOE [13]. Here we are also including the T-violating asymmetry measurement from CPLEAR [14].

Table 1: Values, errors, and correlation coefficients for $\Re(\delta)$, $\Im(\delta)$, $\Re(x_-)$, $\Im(x_+)$, and $A_S + A_L$ obtained from a combined fit, including KLOE [4] and CPLEAR [14].

| | value | Correlations coefficients |
|---------------|-----------------------------------|---------------------------------|
| $\Re(\delta)$ | $(3.0 \pm 2.3) \times 10^{-4}$ | 1 |
| $\Im(\delta)$ | $(-0.66 \pm 0.65) \times 10^{-2}$ | -0.21 1 |
| $\Re(x)$ | $(-0.30 \pm 0.21) \times 10^{-2}$ | -0.21 -0.60 1 |
| $\Im(x_+)$ | $(0.02 \pm 0.22) \times 10^{-2}$ | $-0.38 \ -0.14 \ 0.47 \ 1$ |
| $A_S + A_L$ | $(-0.40 \pm 0.83) \times 10^{-2}$ | -0.10 -0.63 0.99 0.43 1 |

The value $A_S + A_L$ in Table 1 can be directly included in the semileptonic contributions to the Bell Steinberger relations in Eq. (2)

$$\sum_{\pi\ell\nu} \langle \mathcal{A}_L(\pi\ell\nu) \mathcal{A}_S^*(\pi\ell\nu) \rangle$$

$$= 2\Gamma(K_L \to \pi\ell\nu) (\Re(\epsilon) - \Re(y) - i(\Im(x_+) + \Im(\delta)))$$

$$= 2\Gamma(K_L \to \pi\ell\nu) ((A_S + A_L)/4 - i(\Im(x_+) + \Im(\delta))) . (6)$$

Defining

$$\alpha_{\pi\ell\nu} \equiv \frac{1}{\Gamma_S} \sum_{\pi\ell\nu} \langle \mathcal{A}_L(\pi\ell\nu) \mathcal{A}_S^*(\pi\ell\nu) \rangle + 2i \frac{\tau_{K_S}}{\tau_{K_L}} \mathcal{B}(K_L \to \pi\ell\nu) \Im(\delta) ,$$
(7)

we find:

$$\alpha_{\pi\ell\nu} = ((-0.2 \pm 0.5) + i(0.1 \pm 0.5)) \times 10^{-5}$$
.

Inserting the values of the α parameters into Eq. (2), we find

$$\Re(\epsilon) = (161.1 \pm 0.5) \times 10^{-5},$$

 $\Im(\delta) = (-0.7 \pm 1.4) \times 10^{-5}.$ (8)

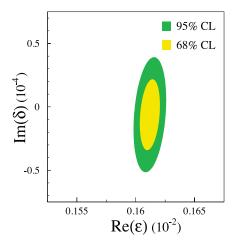

The complete information on Eq. (8) is given in Table 2.

Table 2: Summary of results: values, errors, and correlation coefficients for $\Re(\epsilon)$, $\Im(\delta)$, $\Re(\delta)$, and $\Re(x_-)$.

| | value | Correlations coefficients |
|-----------------|----------------------------------|---------------------------|
| $\Re(\epsilon)$ | $(161.1 \pm 0.5) \times 10^{-5}$ | +1 |
| $\Im(\delta)$ | $(-0.7\pm1.4)\times10^{-5}$ | +0.09 1 |
| $\Re(\delta)$ | $(2.4 \pm 2.3) \times 10^{-4}$ | +0.08 -0.12 1 |
| $\Re(x)$ | $(-4.1 \pm 1.7) \times 10^{-3}$ | + 0.14 0.22 -0.43 1 |

Now the agreement with CPT conservation, $\Im(\delta) = \Re(\delta) = \Re(x_-) = 0$, is at 18% C.L.

The allowed region in the $\Re(\epsilon) - \Im(\delta)$ plane at 68% CL and 95% C.L. is shown in the top panel of Fig. 1.

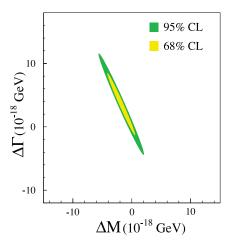

Figure 1: Top: allowed region at 68% and 95% C.L. in the $\Re(\epsilon)$, $\Im(\delta)$ plane. Bottom: allowed region at 68% and 95% C.L. in the $\Delta M, \Delta \Gamma$ plane.

The process giving the largest contribution to the size of the allowed region is $K_L \to \pi^+\pi^-$, through the uncertainty on ϕ_{+-} .

The limits on $\Im(\delta)$ and $\Re(\delta)$ can be used to constrain the $K^0-\overline{K}^0$ mass and width difference

$$\delta = \frac{i(m_{K^0} - m_{\overline{K}^0}) + \frac{1}{2}(\Gamma_{K^0} - \Gamma_{\overline{K}^0})}{\Gamma_S - \Gamma_L} \cos \phi_{SW} e^{i\phi_{SW}} [1 + \mathcal{O}(\epsilon)].$$

The allowed region in the $\Delta M=(m_{K^0}-m_{\overline{K}^0}), \Delta \Gamma=(\Gamma_{K^0}-\Gamma_{\overline{K}^0})$ plane is shown in the bottom panel of Fig. 1. As a result, we improve on the previous limits (see for instance, P. Bloch in Ref. 12) and in the limit $\Gamma_{K^0}-\Gamma_{\overline{K}^0}=0$ we obtain

$$-4.0\times 10^{-19}~{\rm GeV} < m_{K^0} - m_{\overline{K}^0} < 4.0\times 10^{-19}~{\rm GeV}~~{\rm at}~95~\%~{\rm C.L}\,.$$

CP-VIOLATION PARAMETERS

Re(ϵ)DOCUMENT IDTECN1.596 \pm 0.0132 AMBROSINO 06HKLOE• • • We do not use the following data for averages, fits, limits, etc. 1.664 \pm 0.0103 LAI05ANA48

 2 AMBROSINO 06H uses Bell-Steinberger relations with the following measurements: B($K_L^0 \to \pi^+\pi^-)$ in AMBROSINO 06F, B($K_S^0 \to \pi^0\pi^0\pi^0)$ in AMBROSINO 05B, the K_S^0 -semileptonic charge asymmetry in AMBROSINO 06E, and K^0 -semileptonic results in ANGELOPOULOS 98F.

 3 LAI 05A values are obtained through unitarity (Bell-Steinberger relations), improving determination of η_{000} and combining other data from PDG 04 and APOSTOLAKIS 99B.

CPT-VIOLATION PARAMETERS

In K^0 – \overline{K}^0 mixing, if *CP*-violating interactions include a T conserving part then

$$\begin{split} |\mathcal{K}_{\mathcal{S}}\rangle &= [|\mathcal{K}_{1}\rangle + (\epsilon+\delta)|\mathcal{K}_{2}\rangle]/\sqrt{1+|\epsilon+\delta|^{2}} \\ |\mathcal{K}_{L}\rangle &= [|\mathcal{K}_{2}\rangle + (\epsilon-\delta)|\mathcal{K}_{1}\rangle]/\sqrt{1+|\epsilon-\delta|^{2}} \\ \text{there} \\ |\mathcal{K}_{1}\rangle &= [|\mathcal{K}^{0}\rangle + |\overline{\mathcal{K}^{0}}\rangle]/\sqrt{2} \end{split}$$

 $\begin{aligned} |\kappa_1\rangle &= [|\kappa^0\rangle + |\overline{\kappa}^0\rangle]/\sqrt{2} \\ |\kappa_2\rangle &= [|\kappa^0\rangle - |\overline{\kappa}^0\rangle]/\sqrt{2} \end{aligned}$

 $|\overline{K}^0\rangle = CP|K^0\rangle.$

The parameter δ specifies the *CPT*-violating part.

 K^{0}, K^{0}_{s}

Estimates of δ are given below assuming the validity of the $\Delta S = \Delta Q$ rule. See also THOMSON 95 for a test of *CPT*-symmetry conservation in K^0 decays using the Bell-Steinberger relation.

REAL PART OF δ

A nonzero value violates CPT invariance.

- 1 The two ABOUZAID 11 values use the same full KTeV dataset from 1996, 1997, and 1999. The first enters the "assuming CPT" fit and the second enters the "not assuming $_{\rm CPT'}$ fit.
- ²ABOUZAID 11 fit has Δm , τ_5 , ϕ_ϵ , $\mathrm{Re}(\epsilon'/\epsilon)$, and $\mathrm{Im}(\epsilon'/\epsilon)$ as free parameters. See $\mathrm{Im}(\epsilon'/\epsilon)$ in the " K_L^0 CP violation" section for correlation information.
- ³ABOUZAID 11 fit has Δm and τ_S free but constrains ϕ_ϵ to the Superweak value, i.e. assumes *CPT*. This τ_S value is correlated with their $\Delta m = m_{K_L^0} m_{K_S^0}$ measurement
- in the K_L^0 listings. The correlation coefficient $ho(au_{\rm S}$, $\Delta m)=-0.670$.
- 4 Fit to the proper time distribution. 5 This ALAVI-HARATI 03 fit has Δm and τ_S free but constrains ϕ_{+-} to the Superweak value, i.e. assumes CPT. This τ_S value is correlated with their $\Delta m = m_{K_L^0} m$
- $m_{K_L^0}$ measurement in the K_L^0 listings. The correlation coefficient $ho(au_s,\Delta m)=-0.396$. Superseded by ABOUZAID 11.
- 6 This ALAVI-HARATI 03 fit has $\Delta m, \ \phi_{+-}$, and τ_{K_S} free. See ϕ_{+-} in the " κ_L CP violation" section for correlation information. Superseded by ABOUZAID 11.
- $^7\,\text{ARONSON}$ 82 find that $\,\mathcal{K}_S^0\,$ mean life may depend on the kaon energy.
- 8 CARITHERS 75 measures the Δm dependence of the total decay rate (inverse mean life) to be $\Gamma(K_S^0) = [(1.122 \pm 0.004) + 0.16(\Delta m - 0.5348)/\Delta m] 10^{10}/s$, or, in terms of mean life, CARTHERS 75 measures $\tau_S = (0.8913 \pm 0.0032) - 0.238 [\Delta m - 0.5348]$ mean life, CARTHERS 15 ineasures $\tau_5 = (0.0913 \pm 0.0002) - 0.250$ [$\Delta m = (10^{-10} \text{ s})$. We have adjusted the measurement to use our best values of ($\Delta m = 0.5293 \pm 0.0009$) ($10^{10} \ h \ s^{-1}$). Our first error is their experiment's error and our second error is the systematic error from using our best values.

 9 HILL 68 has been changed by the authors from the published value (0.865 \pm 0.009) because of a correction in the shift due to η_+ . SKJEGGESTAD 72 and HILL 68 give detailed discussions of systematics encountered in this type of experiment.
- $^{10}\,\mathrm{Pre}\text{-}1971$ experiments are excluded from the average because of disagreement with later more precise experiments.

CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 5 measurements and one constraint to determine 4 parameters. The overall fit has a χ^2 = 0.1 for 2 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv$ $\Gamma_i/\Gamma_{
m total}$. The fit constrains the x_i whose labels appear in this array to sum to

K FORM FACTORS

For discussion, see note on $\mathit{K}_{\ell 3}$ form factors in the K^{\pm} section of the Particle Listings above. Because the semileptonic branching fraction is smaller in K_0^0 than K_0^0 by the ratio of the mean lives, the K_0^0 semileptonic form factor has so far been measured only in the K_{e3} mode using the linear expansion $f_+(t)=f_+(0)$ $(1+\lambda_+\,t\,/m_{\pi^+}^2)$, which gives the vector form factor $f_+(t)$ relative to its value at t=0.

CP VIOLATION IN $K_S \rightarrow 3\pi$

Written 1996 by T. Nakada (Paul Scherrer Institute) and L. Wolfenstein (Carnegie-Mellon University).

The possible final states for the decay $K^0 \to \pi^+\pi^-\pi^0$ have isospin I = 0, 1, 2, and 3. The I = 0 and I = 2 states have CP = +1 and K_S can decay into them without violating CPsymmetry, but they are expected to be strongly suppressed by centrifugal barrier effects. The I=1 and I=3 states, which have no centrifugal barrier, have CP = -1 so that the K_S decay to these requires ${\cal CP}$ violation.

In order to see CP violation in $K_S \to \pi^+\pi^-\pi^0$, it is necessary to observe the interference between K_S and K_L decay, which determines the amplitude ratio

$$\eta_{+-0} = \frac{A(K_S \to \pi^+ \pi^- \pi^0)}{A(K_L \to \pi^+ \pi^- \pi^0)} \ . \tag{1}$$

If η_{+-0} is obtained from an integration over the whole Dalitz plot, there is no contribution from the I=0 and I=2 final states and a nonzero value of η_{+-0} is entirely due to CP

Only I = 1 and I = 3 states, which are CP = -1, are allowed for $K^0 \to \pi^0 \pi^0 \pi^0$ decays and the decay of K_S into $3\pi^0$ is an unambiguous sign of CP violation. Similarly to η_{+-0} , η_{000} is defined as

$$\eta_{000} = \frac{A(K_S \to \pi^0 \pi^0 \pi^0)}{A(K_L \to \pi^0 \pi^0 \pi^0)} \ . \tag{2}$$

If one assumes that CPT invariance holds and that there are no transitions to I=3 (or to nonsymmetric I=1 states), it can be shown that

$$\eta_{+-0} = \eta_{000}$$

$$= \epsilon + i \frac{\operatorname{Im} a_1}{\operatorname{Re} a_1} .$$
(3)

With the Wu-Yang phase convention, a_1 is the weak decay amplitude for K^0 into I=1 final states; ϵ is determined from CP violation in $K_L \to 2\pi$ decays. The real parts of η_{+-0} and η_{000} are equal to Re(ϵ). Since currently-known upper limits on $|\eta_{+-0}|$ and $|\eta_{000}|$ are much larger than $|\epsilon|$, they can be interpreted as upper limits on $\text{Im}(\eta_{+-0})$ and $\text{Im}(\eta_{000})$ and so as limits on the CP-violating phase of the decay amplitude a_1 .

CP-VIOLATION PARAMETERS IN KO DECAY

$$\begin{array}{lll} \textbf{\textit{AS}} = \left[\ \Gamma(\textbf{\textit{K}}_{S}^{0} \rightarrow \boldsymbol{\pi}^{-} \, \mathbf{e}^{+} \, \boldsymbol{\nu}_{e}) - \Gamma(\textbf{\textit{K}}_{S}^{0} \rightarrow \boldsymbol{\pi}^{+} \, \mathbf{e}^{-} \, \boldsymbol{\mathcal{\nu}}_{e}) \ \right] \ / \ \text{SUM} \\ \text{Such asymmetry violates } \textit{CP}. \ \text{If } \textit{CPT} \text{ is assumed then } \textit{A}_{S} = 2 \ \text{Re}(\epsilon). \\ \frac{\textit{VALUE} \left(\text{units } 10^{-3} \right)}{1.5 \pm 9.6 \pm 2.9} & \frac{\textit{EVTS}}{13 \text{k}} & \frac{\textit{DOCUMENT ID}}{\text{AMBROSINO}} & \frac{\textit{TECN}}{\text{KLOE}} \\ \end{array}$$

PARAMETERS FOR $K_S^0 \rightarrow 3\pi$ DECAY -

| 1 | The two ABOUZAID 11 values use the same data. | The first enters the "assuming CPT" |
|---|--------------------------------------------------|-------------------------------------|
| | fit and the second enters the "not assuming CPT" | |

- ²ABOUZAID 11 fit has Δm , $au_{\mathcal{S}}$, ϕ_{ϵ} , $\mathrm{Re}(\epsilon'/\epsilon)$, and $\mathrm{Im}(\epsilon'/\epsilon)$ as free parameters. See $\operatorname{Im}(\epsilon'/\epsilon)$ in the " K_L^0 CP violation" section for correlation information.
- 3 ABOUZAID 11 fit has Δm and $\tau_{\rm S}$ free but constrains ϕ_{ϵ} to the Superweak value, i.e. assumes *CPT*. See " K_S^0 Mean Life" section for correlation information.
- 4 Fits Δm and ϕ_{+-} simultaneously. GIBBONS 93c systematic error is from B. Winstein via private communication. 20–160 GeV K beams.
- 5 GIBBONS 93 value assume $\phi_{+-}=\phi_{00}=\phi_{\rm SW}=(43.7\pm0.2)^\circ$, i.e. assumes *CPT*. 20-160 GeV K beams.
- 6 ZD-100 GeV / Dearns.

 These two experiments have a common systematic error due to the uncertainty in the momentum scale, as pointed out in WAHL 89.
- 7 GJESDAL 74 uses charge asymmetry in $K_{\ell 3}^0$ decays.
- 8 ALAVI-HARATI 03 fit Δm and $au_{K^0_S}$ simultaneously. ϕ_{+-} is constrained to the Superweak value, i.e. CPT is assumed. See " K_S^0 Mean Life" section for correlation information. Superseded by ABOUZAID 11. 9 ALAVI-HARATI 03 fit Δm , ϕ_{+-} , and τ_{K_S} simultaneously. See ϕ_{+-} in the " K_L CP
- violation" section for correlation information. Superseded by ABOUZAID 11.
- 10 ANGEL OPOULOS 01 uses strong interactions strangeness tagging at two different times. 11 Uses \overline{K}^0_{e3} and K^0_{e3} strangeness tagging at production and decay. Assumes CPT conservation on $\Delta S = -\Delta Q$ transitions.
- vation on $\Delta S = \Delta Q$ transitions. 12 ADLER 96c is the result of a fit which includes nearly the same data as entered into the "OUR FIT" value above. 13 ARONSON 82 find that Δm may depend on the kaon energy. 14 ARONSON 70 and CARNEGIE 71 use K_0^0 mean life = $(0.862 \pm 0.006) \times 10^{-10}$ s. We
- have not attempted to adjust these values for the subsequent change in the K^0_S mean

| | | | | | | | | |

- [a] The value is for the sum of the charge states or particle/antiparticle states indicated.
- [b] This mode includes gammas from inner bremsstrahlung but not the direct emission mode $K_L^0 \rightarrow \pi^+ \pi^- \gamma(DE)$.
- [c] See the Particle Listings below for the energy limits used in this mea-
- [d] Most of this radiative mode, the low-momentum γ part, is also included in the parent mode listed without γ 's.
- [e] Allowed by higher-order electroweak interactions.
- [f] Violates $\ensuremath{\mathit{CP}}$ in leading order. Test of direct $\ensuremath{\mathit{CP}}$ violation since the indirect CP-violating and CP-conserving contributions are expected to be suppressed.

CONSTRAINED FIT INFORMATION

An overall fit to the mean life and 15 branching ratios uses 27 measurements and one constraint to determine 11 parameters. The overall fit has a $\chi^2=$ 37.4 for 17 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$V_{ud}, V_{us}, \text{THE CABIBBO ANGLE},$ AND CKM UNITARITY

Updated March 2012 by E. Blucher (Univ. of Chicago) and W.J. Marciano (BNL)

The Cabibbo-Kobayashi-Maskawa (CKM) [1,2] three-generation quark mixing matrix written in terms of the Wolfenstein parameters (λ, A, ρ, η) [3] nicely illustrates the orthonormality constraint of unitarity and central role played by λ .

$$V_{\text{CKM}} = \begin{pmatrix} V_{ud} & V_{us} & V_{ub} \\ V_{cd} & V_{cs} & V_{cb} \\ V_{td} & V_{ts} & V_{tb} \end{pmatrix}$$

$$= \begin{pmatrix} 1 - \lambda^2/2 & \lambda & A\lambda^3(\rho - i\eta) \\ -\lambda & 1 - \lambda^2/2 & A\lambda^2 \\ A\lambda^3(1 - \rho - i\eta) & -A\lambda^2 & 1 \end{pmatrix} + \mathcal{O}(\lambda^4) \ . \ (1)$$

That cornerstone is a carryover from the two-generation Cabibbo angle, $\lambda = \sin(\theta_{\text{Cabibbo}}) = V_{us}$. Its value is a critical ingredient in determinations of the other parameters and in tests of CKM unitarity.

Unfortunately, the precise value of λ has been somewhat controversial in the past, with kaon decays suggesting [4] $\lambda \simeq 0.220$, while hyperon decays [5] and indirect determinations via nuclear β -decays imply a somewhat larger $\lambda \simeq 0.225-0.230$. That discrepancy is often discussed in terms of a deviation from the unitarity requirement

$$|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 1. (2)$$

For many years, using a value of V_{us} derived from $K \to \pi e \nu$ (K_{e3}) decays, that sum was consistently 2–2.5 sigma below unity, a potential signal [6] for new physics effects. Below, we discuss the current status of V_{ud} , V_{us} , and their associated unitarity test in Eq. (2). (Since $|V_{ub}|^2 \simeq 1 \times 10^{-5}$ is negligibly small, it is ignored in this discussion.)

V_{ud}

The value of V_{ud} has been obtained from superallowed nuclear, neutron, and pion decays. Currently, the most precise determination of V_{ud} comes from superallowed nuclear beta-decays [6] $(0^+ \to 0^+$ transitions). Measuring their half-lives, t, and Q values which give the decay rate factor, f, leads to a precise determination of V_{ud} via the master formula [7–9]

$$|V_{ud}|^2 = \frac{2984.48(5)\sec}{ft(1+RC)}$$
 (3)

where RC denotes the entire effect of electroweak radiative corrections, nuclear structure, and isospin violating nuclear effects. RC is nucleus-dependent, ranging from about +3.0% to +3.6% for the best measured superallowed decays. The most recent analysis of Hardy and Towner [10, 11] gives a weighted average (with errors combined in quadrature) of

$$V_{ud} = 0.97425(22)$$
 (superallowed), (4)

data set. 2 LAI 02B uses the absence of a signal in $K_L^0 \to \pi^0 \gamma \gamma$ with $m(\gamma \gamma) < m(\pi^0)$ and their a_V value to predict this value.

² Value obtained using data from February to April 2005.

 $^{^1}$ Using 2005 Run-I data. OGATA 11 also sets a limit on the $K_L^0 \to \pi^0\pi^0 X \to \text{invisible}$ particles process: the limit on the branching fraction varied from 7.0×10^{-7} to 4.0×10^{-5} for the mass of X ranging from 50 to 200 MeV/c².

 $^{^2}$ Observed 1 event with expected background of 0.43 \pm 0.35 events. NIX 07 also measured B(K $_0^1 \rightarrow \pi^0 \pi^0 P) < 1.2 \times 10^{-6}$ at 90% CL, where P is the pseudoscalar particle and $m_P < 100$ MeV.

which, assuming unitarity, corresponds to $\lambda = 0.2255(10)$. The new average value of V_{ud} is shifted upward compared to our 2007 value of 0.97418(27) primarily because of improvements in the experimental ft values and nuclear isospin breaking corrections employed. We note, however, that the possibility of additional nuclear coulombic corrections has been raised recently [12].

Combined measurements of the neutron lifetime, τ_n , and the ratio of axial-vector/vector couplings, $g_A \equiv G_A/G_V$, via neutron decay asymmetries can also be used to determine V_{ud} :

$$|V_{ud}|^2 = \frac{4908.7(1.9) \text{ sec}}{\tau_n (1+3q_A^2)},$$
 (5)

where the error stems from uncertainties in the electroweak radiative corrections [8] due to hadronic loop effects. Those effects have been recently updated and their error was reduced by about a factor of 2 [9], leading to a ± 0.0002 theoretical uncertainty in V_{ud} (common to all V_{ud} extractions). Using the world averages from this Review

$$\tau_n^{\text{ave}} = 880.1(1.1) \text{ sec}$$

$$g_A^{\text{ave}} = 1.2701(25) \tag{6}$$

leads to

$$V_{ud} = 0.9773(6)_{\tau_n}(16)_{q_A}(2)_{RC}$$
 (7)

with the error dominated by g_A uncertainties (which have been expanded due to experimental inconsistencies). The new shorter neutron lifetime average (since the last review) now leads to a value of V_{ud} that is inconsistent with the superallowed nuclear beta decay result in Eq. (4). That disagreement suggests that a shift of g_A to about 1.275 (consistent with more modern day measurements [14]) is likely. Future neutron studies are expected to resolve these inconsistencies and significantly reduce the uncertainties in g_A and τ_n , potentially making them the best way to determine V_{ud} .

The recently completed PIBETA experiment at PSI measured the very small $(\mathcal{O}(10^{-8}))$ branching ratio for $\pi^+ \to \pi^0 e^+ \nu_e$ with about $\pm 1/2\%$ precision. Their result gives [15]

$$V_{ud} = 0.9749(26) \left[\frac{BR(\pi^+ \to e^+ \nu_e(\gamma))}{1.2352 \times 10^{-4}} \right]^{\frac{1}{2}}$$
 (8)

which is normalized using the very precisely determined theoretical prediction for $BR(\pi^+ \to e^+\nu_e(\gamma)) = 1.2352(5) \times 10^{-4}$ [7], rather than the experimental branching ratio from this *Review* of $1.230(4)\times10^{-4}$ which would lower the value to $V_{ud}=0.9728(30)$. Theoretical uncertainties in that determination are very small; however, much higher statistics would be required to make this approach competitive with others.

V_{us}

 $|V_{us}|$ may be determined from kaon decays, hyperon decays, and tau decays. Previous determinations have most often used $K\ell 3$ decays:

$$\Gamma_{K\ell3} = \frac{G_F^2 M_K^5}{192\pi^3} S_{EW} (1 + \delta_K^{\ell} + \delta_{SU2}) C^2 |V_{us}|^2 f_+^2(0) I_K^{\ell}.$$
 (9)

Here, ℓ refers to either e or μ , G_F is the Fermi constant, M_K is the kaon mass, S_{EW} is the short-distance radiative correction, δ_K^{ℓ} is the mode-dependent long-distance radiative correction, $f_{+}(0)$ is the calculated form factor at zero momentum transfer for the $\ell\nu$ system, and I_K^{ℓ} is the phase-space integral, which depends on measured semileptonic form factors. For charged kaon decays, δ_{SU2} is the deviation from one of the ratio of $f_{+}(0)$ for the charged to neutral kaon decay; it is zero for the neutral kaon. C^2 is 1 (1/2) for neutral (charged) kaon decays. Most determinations of $|V_{us}|$ have been based only on $K \to \pi e \nu$ decays; $K \to \pi \mu \nu$ decays have not been used because of large uncertainties in I_K^{μ} . The experimental measurements are the semileptonic decay widths (based on the semileptonic branching fractions and lifetime) and form factors (allowing calculation of the phase space integrals). Theory is needed for S_{EW} , δ_K^{ℓ} , δ_{SU2} , and $f_+(0)$.

Many new measurements during the last few years have resulted in a significant shift in V_{us} . Most importantly, recent measurements of the $K \to \pi e \nu$ branching fractions are significantly different than earlier PDG averages, probably as a result of inadequate treatment of radiation in older experiments. This effect was first observed by BNL E865 [16] in the charged kaon system and then by KTeV [17,18] in the neutral kaon system; subsequent measurements were made by KLOE [19-22], NA48 [23-25], and ISTRA+ [26]. Current averages (e.g., by the PDG [27] or Flavianet [28]) of the semileptonic branching fractions are based only on recent, highstatistics experiments where the treatment of radiation is clear. In addition to measurements of branching fractions, new measurements of lifetimes [29] and form factors [30–34], resulted in improved precision for all of the experimental inputs to V_{us} . Precise measurements of form factors for $K_{\mu3}$ decay now make it possible to use both semileptonic decay modes to extract V_{us} .

Following the analysis of the Flavianet group [28], one finds the values of $|V_{us}|f_+(0)$ in Table 1. The average of these measurements gives

$$f_{+}(0)|V_{us}| = 0.21664(48). (10)$$

Figure 1 shows a comparison of these results with the PDG evaluation from 2002 [35], as well as $f_+(0)(1-|V_{ud}|^2-|V_{ub}|^2)^{1/2}$, the expectation for $f_+(0)|V_{us}|$ assuming unitarity, based on $|V_{ud}|=0.9742\pm0.0003,\ |V_{ub}|=(3.6\pm0.7)\times10^{-3}$, and the lattice calculation of $f_+(0)=0.9644\pm0.0049$ [36](Lattice calculations of $f_+(0)$ have improved significantly in recent years, and therefore replace the classic calculation of Leutwyler and Roos [37].) Combining the result in Eq. (10) with the above value of $f_+(0)$ gives

$$|V_{us}| = \lambda = 0.2246 \pm 0.0012. \tag{11}$$

Table 1: $|V_{us}|f_+(0)$ from $K_{\ell 3}$.

| Decay Mode | $ V_{us} f_+(0)$ |
|----------------|---------------------|
| $K^{\pm}e3$ | 0.2173 ± 0.0008 |
| $K^{\pm}\mu 3$ | 0.2176 ± 0.0011 |
| K_Le3 | 0.2163 ± 0.0006 |
| $K_L\mu 3$ | 0.2168 ± 0.0007 |
| K_Se3 | 0.2154 ± 0.0013 |
| Average | 0.2166 ± 0.0005 |

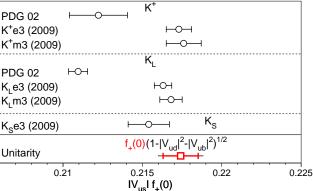

Figure 1: Comparison of determinations of $|V_{us}|f_+(0)$ from this review (labeled 2009), from the PDG 2002, and with the prediction from unitarity using $|V_{ud}|$ and the lattice calculation of $f_+(0)$ [36]. For $f_+(0)(1-|V_{ud}|^2-|V_{ub}|^2)^{1/2}$, the inner error bars are from the quoted uncertainty in $f_+(0)$; the total uncertainties include the $|V_{ud}|$ and $|V_{ub}|$ errors.

A value of V_{us} can also be obtained from a comparison of the radiative inclusive decay rates for $K \to \mu\nu(\gamma)$ and $\pi \to \mu\nu(\gamma)$ combined with a lattice gauge theory calculation of f_K/f_π via [42]

$$\frac{|V_{us}|f_K}{|V_{ud}|f_\pi} = 0.2387(4) \left[\frac{\Gamma(K \to \mu\nu(\gamma))}{\Gamma(\pi \to \mu\nu(\gamma))} \right]^{\frac{1}{2}}$$
(12)

with the small error coming from electroweak radiative corrections. Employing

$$\frac{\Gamma(K \to \mu\nu(\gamma))}{\Gamma(\pi \to \mu\nu(\gamma))} = 1.3337(46),\tag{13}$$

which averages in the KLOE result [43], $B(K \to \mu\nu(\gamma)) = 63.66(9)(15)\%$ and [44]

$$f_K/f_{\pi} = 1.189(7)$$
 (14)

along with the value of V_{ud} in Eq. (4) leads to

$$|V_{us}| = 0.2259(5)(13). (15)$$

It should be mentioned that hyperon decay fits suggest [5]

$$|V_{us}| = 0.2250(27)$$
 Hyperon Decays (16)

modulo SU(3) breaking effects that could shift that value up or down. We note that a recent representative effort [45] that incorporates SU(3) breaking found $V_{us} = 0.226(5)$. Similarly, inclusive strangeness changing tau decays give [46]

$$|V_{us}| = 0.2208(34)$$
 Tau Decays (17)

where the central value depends on the strange quark mass. However, a recent BaBar study [47] of $\tau \to K\nu/\tau \to \pi\nu$ using the lattice value of f_K/f_π from Eq. (14) finds $V_{us}=0.2255(24)$, in good agreement with other determinations.

Employing the value of V_{ud} in Eq. (4) and $V_{us} = 0.2252(9)$, the average of the $K\ell 3$ (Eq. (11)) and $K\mu 2$ (Eq. (15) determinations of V_{us} , leads to the unitarity consistency check

$$|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 0.9999(4)(4).$$
(18)

where the first error is the uncertainty from $|V_{ud}|^2$ and the second error is the uncertainty from $|V_{us}|^2$.

CKM Unitarity Constraints

The current good experimental agreement with unitarity, $|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 0.9999(6)$, provides strong confirmation of Standard Model radiative corrections (which range between 3-4% depending on the nucleus used) at better than the 50 sigma level [48]. In addition, it implies constraints on "New Physics" effects at both the tree and quantum loop levels. Those effects could be in the form of contributions to nuclear beta decays, K decays and/or muon decays, with the last of these providing normalization via the muon lifetime [49], which is used to obtain the Fermi constant, $G_{\mu} = 1.166371(6) \times 10^{-5} \mathrm{GeV}^{-2}$.

In the following sections, we illustrate the implications of CKM unitarity for (1) exotic muon decays [50](beyond ordinary muon decay $\mu^+ \to e^+ \nu_e \bar{\nu}_\mu$) and (2) new heavy quark mixing V_{uD} [51]. Other examples in the literature [52,53] include Z_χ boson quantum loop effects, supersymmetry, leptoquarks, compositeness etc.

Exotic Muon Decays

If additional lepton flavor violating decays such as $\mu^+ \to e^+ \bar{\nu}_e \nu_\mu$ (wrong neutrinos) occur, they would cause confusion in searches for neutrino oscillations at, for example, muon storage rings/neutrino factories or other neutrino sources from muon decays. Calling the rate for all such decays Γ (exotic μ decays), they should be subtracted before the extraction of G_μ and normalization of the CKM matrix. Since that is not done and unitarity works, one has (at one-sided 95% CL)

$$|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 1 - BR(\text{exotic } \mu \text{ decays}) \ge 0.9989$$
(19)

or

$$BR(\text{exotic } \mu \text{ decays}) < 0.001$$
. (20)

This bound is a factor of 10 better than the direct experimental bound on $\mu^+ \to e^+ \bar{\nu}_e \nu_\mu$.

New Heavy Quark Mixing

Heavy D quarks naturally occur in fourth quark generation models and some heavy quark "new physics" scenarios such as E_6 grand unification. Their mixing with ordinary quarks gives rise to V_{ud} which is constrained by unitarity (one sided 95% CL)

$$|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 1 - |V_{uD}|^2 > 0.9989$$

$$|V_{uD}| < 0.03.$$
(21)

A similar constraint applies to heavy neutrino mixing and the couplings $V_{\mu N}$ and $V_{e N}$.

 1 Result obtained using CI3pI model of CABIBBO 05 to include $\pi\pi$ rescattering effects. The systematic error includes an external error of 1.06×10^{-3} from the parametrization input of (a_0-a_2) $m_{\pi^+}=0.268\pm0.017$ from BATLEY 06B.

 2 LAI 01B and SOMALWAR 92 results do not include $\pi\pi$ final state rescattering effects. 3 SOMALWAR 92 chose m_{π^+} as normalization to make it compatible with the Particle Data Group $K_L^0\to~\pi^+\pi^-\pi^0$ definitions.

K⁰_L FORM FACTORS

For discussion, see note on form factors in the K^{\pm} section of the Particle

In the form factor comments, the following symbols are used.

 f_{\perp} and f_{\perp} are form factors for the vector matrix element.

 f_S and f_T refer to the scalar and tensor term.

$$f_0(t) = f_+(t) + f_-(t) t/(m_{K^0}^2 - m_{\pi^+}^2).$$

t= momentum transfer to the $\pi.$

 λ_+ and λ_0 are the linear expansion coefficients of f_+ and f_0

$$f_{+}(t) = f_{+}(0) \left(1 + \lambda_{+} t / m_{\pi^{+}}^{2}\right)$$

For quadratic expansion

$$f_{+}(t) = f_{+}(0) \left(1 + \lambda'_{+} t / m_{\pi^{+}}^{2} + \frac{\lambda''_{+}}{2} t^{2} / m_{\pi^{+}}^{4}\right)$$

as used by KTeV. If there is a non-vanishing quadratic term, then λ_{\pm}

represents an average slope, which is then different from λ'_{+} .

NA48 (
$$K_{e3}$$
) and ISTRA quadratic expansion coefficients are converted with $\lambda'_{+}{}^{PDG} = \lambda_{+}{}^{NA48}$ and $\lambda''_{+}{}^{PDG} = 2 \, \lambda'_{+}{}^{NA48}$ $\lambda''_{+}{}^{PDG} = (\frac{m_{\,\pi^{+}}}{m_{\,0}})^{2} \, \lambda_{+}{}^{ISTRA}$ and $\lambda''_{+}{}^{PDG} = 2 \, (\frac{m_{\,\pi^{+}}}{m_{\,\pi^{0}}})^{4} \, \lambda'_{+}{}^{ISTRA}$

ISTRA linear expansion coefficients are converted with $\lambda_{+}^{PDG}=(\frac{m_{\pi^{+}}}{m_{\pi^{0}}})^{2}~\lambda_{+}^{~ISTRA}$ and $\lambda_{0}^{~PDG}=(\frac{m_{\pi^{+}}}{m_{\pi^{0}}})^{2}~\lambda_{0}^{~ISTRA}$

The pole parametrization is

$$f_{+}(t) = f_{+}(0) \left(\frac{M_{V}^{2}}{M_{V}^{2} - t} \right)$$

$$f_{0}(t) = f_{0}(0) \left(\frac{M_{S}^{2}}{M_{S}^{2} - t} \right)$$

where M_{V} and M_{S} are the vector and scalar pole masses.

The dispersive parametrization is

$$\begin{split} f_+(t) &= f_+(0) \, \exp[\,\frac{t}{m_\pi^2} \, (A_+ \, + \, H(t)) \,\,]; \\ f_0(t) &= f_+(0) \, \exp[\,\frac{t}{m_K^2 - m_\pi^2} \, (\ln[\,C] \, - \, G(\,t)) \,\,], \end{split}$$

where Λ_+ is the slope parameter and $\ln[{\it C}\,] = \ln[\,{\it f}_0\,(m_K^2\,-\,m_\pi^2\,)\,]$

is the logarithm of the scalar form factor at the Callan-Treiman point

H(t) and G(t) are dispersive integrals

The following abbreviations are used:

DP = Dalitz plot analysis.

 $PI = \pi$ spectrum analysis.

 $MU = \mu$ spectrum analysis.

 $\mathsf{POL} = \mu$ polarization analysis.

BR = $K_{\mu 3}^0/K_{e3}^0$ branching ratio analysis.

 $\mathsf{E} \, = \mathsf{positron} \, \, \mathsf{or} \, \, \mathsf{electron} \, \, \mathsf{spectrum} \, \, \mathsf{analysis}.$ RC = radiative corrections.

 λ_+ (LINEAR ENERGY DEPENDENCE OF f_+ IN K^0_{03} DECAY)

CP VIOLATION IN K_L DECAYS

Updated April 2012 by L. Wolfenstein (Carnegie-Mellon University), C.-J. Lin (LBNL), and T.G. Trippe (LBNL).

The symmetries C (particle-antiparticle interchange) and P (space inversion) hold for strong and electromagnetic interactions. After the discovery of large C and P violation in the weak interactions, it appeared that the product CP was a good symmetry. In 1964 CP violation was observed in K^0 decays at a level given by the parameter $\epsilon \approx 2.3 \times 10^{-3}$.

A unified treatment of CP violation in K, D, B, and B_s mesons is given in "CP Violation in Meson Decays" by

² Superseded by ABOUZAID 08.

K_{I}^{0}

D. Kirkby and Y. Nir in this *Review*. A more detailed review including a thorough discussion of the experimental techniques used to determine CP violation parameters is given in a book by K. Kleinknecht [1]. Here we give a concise summary of the formalism needed to define the parameters of CP violation in K_L decays, and a description of our fits for the best values of these parameters.

1. Formalism for CP violation in Kaon decay:

CP violation has been observed in the semi-leptonic decays $K_L^0\to\pi^\mp\ell^\pm\nu$, and in the nonleptonic decay $K_L^0\to2\pi$. The experimental numbers that have been measured are

$$A_{L} = \frac{\Gamma(K_{L}^{0} \to \pi^{-}\ell^{+}\nu) - \Gamma(K_{L}^{0} \to \pi^{+}\ell^{-}\nu)}{\Gamma(K_{L}^{0} \to \pi^{-}\ell^{+}\nu) + \Gamma(K_{L}^{0} \to \pi^{+}\ell^{-}\nu)}$$
(1a)

$$\eta_{+-} = A(K_L^0 \to \pi^+ \pi^-) / A(K_S^0 \to \pi^+ \pi^-)$$

$$= |\eta_{+-}| e^{i\phi_{+-}}$$
(1b)

$$\eta_{00} = A(K_L^0 \to \pi^0 \pi^0) / A(K_S^0 \to \pi^0 \pi^0)$$

$$= |\eta_{00}| e^{i\phi_{00}} .$$
(1c)

CP violation can occur either in the $K^0 - \overline{K}^0$ mixing or in the decay amplitudes. Assuming CPT invariance, the mass eigenstates of the $K^0 - \overline{K}^0$ system can be written

$$|K_S\rangle = p|K^0\rangle + q|\overline{K}^0\rangle$$
, $|K_L\rangle = p|K^0\rangle - q|\overline{K}^0\rangle$. (2)

If CP invariance held, we would have q=p so that K_S would be CP-even and K_L CP-odd. (We define $|\overline{K}^0\rangle$ as CP $|K^0\rangle$). CP violation in $K^0 - \overline{K}^0$ mixing is then given by the parameter $\widetilde{\epsilon}$ where

$$\frac{p}{q} = \frac{(1+\widetilde{\epsilon})}{(1-\widetilde{\epsilon})} \,. \tag{3}$$

CP violation can also occur in the decay amplitudes

$$A(K^0 \to \pi \pi(I)) = A_I e^{i\delta_I} , \quad A(\overline{K}^0 \to \pi \pi(I)) = A_I^* e^{i\delta_I} ,$$
 (4)

where I is the isospin of $\pi\pi$, δ_I is the final-state phase shift, and A_I would be real if CP invariance held. The CP-violating observables are usually expressed in terms of ϵ and ϵ' defined by

$$\eta_{+-} = \epsilon + \epsilon', \quad \eta_{00} = \epsilon - 2\epsilon'.$$
(5a)

One can then show [2]

$$\epsilon = \widetilde{\epsilon} + i \text{ (Im } A_0/\text{Re } A_0),$$
(5b)

$$\sqrt{2}\epsilon' = ie^{i(\delta_2 - \delta_0)} (\operatorname{Re} A_2 / \operatorname{Re} A_0) \ (\operatorname{Im} A_2 / \operatorname{Re} A_2 - \operatorname{Im} A_0 / \operatorname{Re} A_0) ,$$
(5c)

$$A_L = 2 \operatorname{Re} \epsilon / (1 + |\epsilon|^2) \approx 2 \operatorname{Re} \epsilon .$$
 (5d)

In Eqs. (5a), small corrections [3] of order $\epsilon' \times \text{Re } (A_2/A_0)$ are neglected, and Eq. (5d) assumes the $\Delta S = \Delta Q$ rule.

The quantities Im A_0 , Im A_2 , and Im $\tilde{\epsilon}$ depend on the choice of phase convention, since one can change the phases of K^0 and \overline{K}^0 by a transformation of the strange quark state $|s\rangle \rightarrow |s\rangle e^{i\alpha}$; of course, observables are unchanged. It is possible by a choice of phase convention to set Im A_0 or Im A_2 or Im $\tilde{\epsilon}$ to zero, but none of these is zero with the usual phase conventions in the Standard Model. The choice Im $A_0 = 0$ is called the

Wu-Yang phase convention [4], in which case $\epsilon = \tilde{\epsilon}$. The value of ϵ' is independent of phase convention, and a nonzero value demonstrates CP violation in the decay amplitudes, referred to as direct CP violation. The possibility that direct CP violation is essentially zero, and that CP violation occurs only in the mixing matrix, was referred to as the superweak theory [5].

By applying CPT invariance and unitarity the phase of ϵ is given approximately by

$$\phi_{\epsilon} \approx \tan^{-1} \frac{2(m_{K_L} - m_{K_S})}{\Gamma_{K_S} - \Gamma_{K_L}} \approx 43.52 \pm 0.05^{\circ} ,$$
 (6a)

while Eq. (5c) gives the phase of ϵ' to be

$$\phi_{\epsilon'} = \delta_2 - \delta_0 + \frac{\pi}{2} \approx 42.3 \pm 1.5^{\circ} ,$$
 (6b)

where the numerical value is based on an analysis of π - π scattering using chiral perturbation theory [6]. The approximation in Eq. (6a) depends on the assumption that direct CP violation is very small in all K^0 decays. This is expected to be good to a few tenths of a degree, as indicated by the small value of ϵ' and of η_{+-0} and η_{000} , the CP-violation parameters in the decays $K_S \to \pi^+\pi^-\pi^0$ [7], and $K_S \to \pi^0\pi^0\pi^0$ [8]. The relation in Eq. (6a) is exact in the superweak theory, so this is sometimes called the superweak-phase $\phi_{\rm SW}$. An important point for the analysis is that $\cos(\phi_{\epsilon'}-\phi_{\epsilon})\simeq 1$. The consequence is that only two real quantities need be measured, the magnitude of ϵ and the value of (ϵ'/ϵ) , including its sign. The measured quantity $|\eta_{00}/\eta_{+-}|^2$ is very close to unity so that we can write

$$|\eta_{00}/\eta_{+-}|^2 \approx 1 - 6\text{Re}\left(\epsilon'/\epsilon\right) \approx 1 - 6\epsilon'/\epsilon$$
, (7a)

$$\operatorname{Re}(\epsilon'/\epsilon) \approx \frac{1}{3}(1 - |\eta_{00}/\eta_{+-}|)$$
 (7b)

From the experimental measurements in this edition of the *Review*, and the fits discussed in the next section, one finds

$$|\epsilon| = (2.228 \pm 0.011) \times 10^{-3}$$
, (8a)

$$\phi_{\epsilon} = (43.5 \pm 0.5)^{\circ} ,$$
 (8b)

$$\operatorname{Re}(\epsilon'/\epsilon) \approx \epsilon'/\epsilon = (1.66 \pm 0.23) \times 10^{-3}$$
, (8c)

$$\phi_{+-} = (43.4 \pm 0.5)^{\circ} , \qquad (8d)$$

$$\phi_{00} - \phi_{+-} = (0.34 \pm 0.32)^{\circ}$$
, (8e)

$$A_L = (3.32 \pm 0.06) \times 10^{-3}$$
 (8f)

Direct CP violation, as indicated by ϵ'/ϵ , is expected in the Standard Model. However, the numerical value cannot be reliably predicted because of theoretical uncertainties [9]. The value of A_L agrees with Eq. (5d). The values of ϕ_{+-} and $\phi_{00} - \phi_{+-}$ are used to set limits on CPT violation [see "Tests of Conservation Laws"].

2. Fits for K_L^0 CP-violation parameters:

In recent years, K_L^0 CP-violation experiments have improved our knowledge of CP-violation parameters, and their consistency with the expectations of CPT invariance and unitarity. To determine the best values of the CP-violation parameters in $K_L^0 \to \pi^+\pi^-$ and $\pi^0\pi^0$ decay, we make two types of fits, one for the phases ϕ_{+-} and ϕ_{00} jointly with Δm and τ_S , and the other for the amplitudes $|\eta_{+-}|$ and $|\eta_{00}|$ jointly with the $K_L^0 \to \pi\pi$ branching fractions.

Fits to ϕ_{+-} , ϕ_{00} , $\Delta\phi$, Δm , and τ_S data: These are joint fits to the data on ϕ_{+-} , ϕ_{00} , the phase difference $\Delta\phi = \phi_{00} - \phi_{+-}$, the $K_L^0 - K_S^0$ mass difference Δm , and the K_S^0 mean life τ_S , including the effects of correlations.

Measurements of ϕ_{+-} and ϕ_{00} are highly correlated with Δm and τ_S . Some measurements of τ_S are correlated with Δm . The correlations are given in the footnotes of the ϕ_{+-} and ϕ_{00} sections of the K_L^0 Listings, and the τ_S section of the K_S^0 Listings.

In most cases, the correlations are quoted as 100%, i.e., with the value and error of ϕ_{+-} or ϕ_{00} given at a fixed value of Δm and τ_S , with additional terms specifying the dependence of the value on Δm and τ_S . These cases lead to diagonal bands in Figs. 1 and 2. The KTeV experiment [10] quotes its results as values of Δm , τ_S , ϕ_ϵ , Re(ϵ'/ϵ), and Im(ϵ'/ϵ) with correlations, leading to the ellipses labeled "b." The correlations for the KTeV measurements are given in the Im(ϵ'/ϵ) section of the K_L^0 Listings. For small $|\epsilon'/\epsilon|$, $\phi_{+-} \approx \phi_\epsilon + \text{Im}(\epsilon'/\epsilon)$.

Table 1: References, Document ID's, and sources corresponding to the letter labels in the figures. The data are given in the ϕ_{+-} and Δm sections of the K_L Listings, and the τ_S section of the K_S Listings.

The data on τ_S , Δm , and ϕ_{+-} shown in Figs. 1 and 2 are combined with data on ϕ_{00} and $\phi_{00}-\phi_{+-}$ in two fits, one without assuming CPT, and the other with this assumption. The results without assuming CPT are shown as ellipses labeled "a." These ellipses are seen to be in good agreement with the superweak phase

$$\phi_{\text{SW}} = \tan^{-1} \left(\frac{2\Delta m}{\Delta \Gamma} \right) = \tan^{-1} \left(\frac{2\Delta m \tau_S \tau_L}{\hbar (\tau_L - \tau_S)} \right) .$$
 (9)

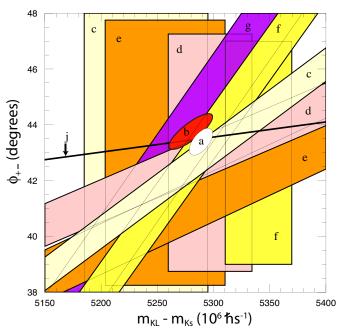

Figure 1: ϕ_{+-} vs Δm for experiments which do not assume CPT invariance. Δm measurements appear as vertical bands spanning $\Delta m \pm 1\sigma$, cut near the top and bottom to aid the eye. Most ϕ_{+-} measurements appear as diagonal bands spanning $\phi_{+-} \pm \sigma_{\phi}$. Data are labeled by letters: "b"–FNAL KTeV, "c"–CERN CPLEAR, "d"–FNAL E773, "e"–FNAL E731, "f"–CERN, "g"–CERN NA31, and are cited in Table 1. The narrow band "j" shows $\phi_{\rm SW}$. The ellipse "a" shows the $\chi^2=1$ contour of the fit result.

In Figs. 1 and 2, $\phi_{\rm SW}$ is shown as narrow bands labeled "j."

Table 2 column 2, "Fit w/o CPT," gives the resulting fitted parameters, while Table 3 gives the correlation matrix for this fit. The white ellipses labeled "a" in Fig. 1 and Fig. 2 are the $\chi^2=1$ contours for this fit.

For experiments which have dependencies on unseen fit parameters, that is, parameters other than those shown on the x or y axis of the figure, their band positions are evaluated using the fit results and their band widths include the fitted uncertainty in the unseen parameters. This is also true for the $\phi_{\rm SW}$ bands.

If CPT invariance and unitarity are assumed, then by Eq. (6a), the phase of ϵ is constrained to be approximately equal to

$$\phi_{\rm SW} = (43.5165 \pm 0.0002)^{\circ} + 54.1 (\Delta m - 0.5290)^{\circ} + 32.0 (\tau_{s} - 0.8958) \tag{10}$$

where we have linearized the Δm and τ_S dependence of Eq. (9). The error ± 0.0002 is due to the uncertainty in τ_L . Here Δm has units $10^{10}\,\hbar\,\mathrm{s^{-1}}$ and τ_S has units 10^{-10} s.

If in addition we use the observation that $Re(\epsilon'/\epsilon) \ll 1$ and $cos(\phi_{\epsilon'} - \phi_{\epsilon}) \simeq 1$, as well as the numerical value of $\phi_{\epsilon'}$ given in

 K_{I}^{0}

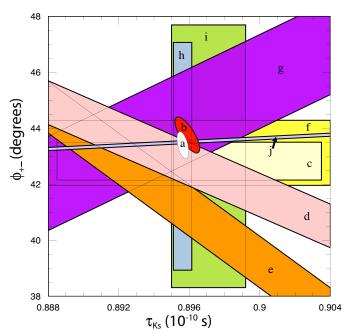

Figure 2: ϕ_{+-} vs τ_S . τ_S measurements appear as vertical bands spanning $\tau_S \pm 1\sigma$, some of which are cut near the top and bottom to aid the eye. Most ϕ_{+-} measurements appear as diagonal or horizontal bands spanning $\phi_{+-} \pm \sigma_{\phi}$. Data are labeled by letters: "b"–FNAL KTeV, "c"–CERN CPLEAR, "d"–FNAL E773, "e"–FNAL E731, "f"–CERN, "g"–CERN NA31, "h"–CERN NA48, "i"–CERN NA31, and are cited in Table 1. The narrow band "j" shows $\phi_{\rm SW}$. The ellipse "a" shows the fit result's $\chi^2=1$ contour.

Table 2: Fit results for ϕ_{+-} , Δm , τ_S , ϕ_{00} , $\Delta \phi = \phi_{00} - \phi_{+-}$, and ϕ_ϵ without and with the CPT assumption.

| Quantity(units) | Fit w/o CPT | Fit w/ CPT |
|------------------------------------------------|--------------------------------|-------------------------------------|
| $\overline{\phi_{+-}}(^{\circ})$ | $43.4 \pm 0.5 \text{ (S=1.2)}$ | $43.51 \pm 0.05 \text{ (S=1.2)}$ |
| $\Delta m (10^{10} \hbar \text{ s}^{-1})$ | 0.5289 ± 0.0010 | $0.5293 \pm 0.0009 \text{ (S=1.3)}$ |
| $\tau_{\scriptscriptstyle S}(10^{-10}{\rm s})$ | 0.89564 ± 0.00033 | $0.8954 \pm 0.0004 \; (S{=}1.1)$ |
| $\phi_{00}(^{\circ})$ | $43.7 \pm 0.6 \; (S{=}1.2)$ | $43.52 \pm 0.05 \text{ (S=1.3)}$ |
| $\Delta\phi(^{\circ})$ | 0.34 ± 0.32 | $0.006 \pm 0.014 \; (S{=}1.7)$ |
| $\phi_{\epsilon}(^{\circ})$ | $43.5 \pm 0.5 \text{ (S=1.3)}$ | $43.52 \pm 0.05 \text{ (S=1.2)}$ |
| χ^2 | 16.4 | 20.0 |
| # Deg. Free. | 14 | 16 |

Eq. (6b), then Eqs. (5a), which are sketched in Fig. 3, lead to the constraint

$$\phi_{00} - \phi_{+-} \approx -3 \operatorname{Im} \left(\frac{\epsilon'}{\epsilon} \right)$$

$$\approx -3 \operatorname{Re} \left(\frac{\epsilon'}{\epsilon} \right) \tan(\phi_{\epsilon'} - \phi_{\epsilon})$$

$$\approx 0.006^{\circ} \pm 0.008^{\circ} , \qquad (11)$$

In the fit assuming CPT, we constrain $\phi_{\epsilon} = \phi_{\rm SW}$ using the linear expression in Eq. (10), and constrain $\phi_{00} - \phi_{+-}$ using Eq. (11). These constraints are inserted into the Listings with the Document ID of SUPERWEAK 12. Some additional data for which the authors assumed CPT are added to this fit or substitute for other less precise data for which the authors did not make this assumption. See the Listings for details.

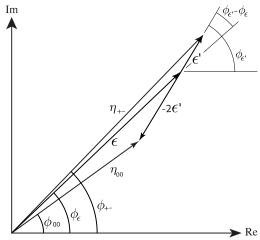

Figure 3: Sketch of Eqs. (5a). Not to scale.

The results of this fit are shown in Table 2, column 3, "Fit w/CPT," and the correlation matrix is shown in Table 4. The Δm precision is improved by the CPT assumption.

Table 3: Correlation matrix for the results of the fit without the CPT assumption

Fits for ϵ'/ϵ , $|\eta_{+-}|$, $|\eta_{00}|$, and B $(K_L \to \pi\pi)$

We list measurements of $|\eta_{+-}|$, $|\eta_{00}|$, $|\eta_{00}/\eta_{+-}|$, and ϵ'/ϵ . Independent information on $|\eta_{+-}|$ and $|\eta_{00}|$ can be obtained from measurements of the K_L^0 and K_S^0 lifetimes $(\tau_L, \, \tau_S)$, and branching ratios (B) to $\pi\pi$, using the relations

$$|\eta_{+-}| = \left[\frac{B(K_L^0 \to \pi^+ \pi^-)}{\tau_L} \frac{\tau_S}{B(K_S^0 \to \pi^+ \pi^-)} \right]^{1/2} , \quad (12a)$$

$$|\eta_{00}| = \left[\frac{\mathrm{B}(K_L^0 \to \pi^0 \pi^0)}{\tau_L} \frac{\tau_S}{\mathrm{B}(K_S^0 \to \pi^0 \pi^0)} \right]^{1/2} .$$
 (12b)

For historical reasons, the branching ratio fits and the CP-violation fits are done separately, but we want to include the influence of $|\eta_{+-}|$, $|\eta_{00}|$, $|\eta_{00}/\eta_{+-}|$, and ϵ'/ϵ measurements on ${\rm B}(K_L^0\to\pi^+\pi^-)$ and ${\rm B}(K_L^0\to\pi^0\pi^0)$ and vice versa. We approximate a global fit to all of these measurements by first performing two independent fits: 1) BRFIT, a fit to the K_L^0 branching ratios, rates, and mean life, and 2) ETAFIT, a fit to the $|\eta_{+-}|, |\eta_{00}|, |\eta_{+-}/\eta_{00}|$, and ϵ'/ϵ measurements. The results from fit 1, along with the K_S^0 values from this edition, are used to compute values of $|\eta_{+-}|$ and $|\eta_{00}|$, which are included as measurements in the $|\eta_{00}|$ and $|\eta_{+-}|$ sections with a document ID of BRFIT 12. Thus, the fit values of $|\eta_{+-}|$ and $|\eta_{00}|$ given in this edition include both the direct measurements and the results from the branching ratio fit.

The process is reversed in order to include the direct $|\eta|$ measurements in the branching ratio fit. The results from fit 2 above (before including BRFIT 12 values) are used along with the K_L^0 and K_S^0 mean lives and the $K_S^0 \to \pi\pi$ branching fractions to compute the K_L^0 branching ratio $\Gamma(K_L^0 \to \pi^0 \pi^0)/\Gamma(K_L^0 \to \pi^+ \pi^-)$. This branching ratio value is included as a measurement in the branching ratio section with a document ID of ETAFIT 12. Thus, the K_L^0 branching ratio fit values in this edition include the results of the direct measurement of $|\eta_{00}/\eta_{+-}|$ and ϵ'/ϵ . Most individual measurements of $|\eta_{+-}|$ and $|\eta_{00}|$ enter our fits directly via the corresponding measurements of $\Gamma(K_L^0 \to \pi^+\pi^-)/\Gamma(\text{total})$ and $\Gamma(K_L^0 \to \pi^0 \pi^0)/\Gamma(\text{total})$, and those that do not have too large errors to have any influence on the fitted values of these branching ratios. A more detailed discussion of these fits is given in the 1990 edition of this Review [20].

CP-VIOLATION PARAMETERS IN K1 DECAYS

CHARGE ASYMMETRY IN KO DECAYS -

Such asymmetry violates CP . It is related to $\mathrm{Re}(\epsilon)$.

$A_L=$ weighted average of $A_L(\mu)$ and $A_L(e)$

In previous editions and in the literature the symbol used for this asymmetry was δ_L or δ . We use A_L for consistency with B^0 asymmetry notation and with recent $K_S^{\vec{0}}$

 1 Value obtained from the NA48 measurements of $\Gamma(K_L^0\to\pi^+\pi^-)/\Gamma(K_L^0\to\pi e\nu_e)$ and $\tau_{K_S^0}$ and KLOE measurements of $B(K_S^0\to\pi^+\pi^-)$ and $\tau_{K_L^0}$. $\Gamma(K_L^0\to\pi^+\pi^-)$ is defined to include the inner bremsstrahlung component $\Gamma(K_L^0\to\pi^+\pi^-\gamma({\rm IB}))$ but

exclude the direct emission component B($K_S^0 \to \pi^+\pi^-(DE)$). Their $|\eta_{+-}|$ value is not directly used in our fit, but enters the fit via their branching ratio and lifetime

² AMBROSINO 06F uses KLOE branching ratios and τ_L together with τ_S from PDG 04. Their $|\eta_{+-}|$ value is not directly used in our fit, but enters the fit via their branching ratio and lifetime measurements.

ALEXOPOULOS 04 $|\eta_{+-}|$ uses their $\kappa_L^0 o \pi\pi$ branching fractions, $au_S = (0.8963 \pm 0.000)$ 0.0005) $\times\,10^{-10}\,\mathrm{s}$ from the average of KTeV and NA48 τ_S measurements, and assumes is not directly used in our fit, but enters our fit via their branching ratio measurements.

⁴ APOSTOLAKIS 99c report (2.264 \pm 0.023 \pm 0.026 + 9.1[au_s - 0.8934]) imes 10⁻³. We evaluate for our 2006 best value au_s = (0.8958 \pm 0.0005) imes 10⁻¹⁰ s. $^{5}\,\text{ADLER 95B report}\;(2.312\pm0.043\pm0.030\,-1[\Delta\mathit{m}-0.5274]+9.1[\tau_{\mathit{S}}-0.8926])\times10^{-3}.$ We evaluate for our 1996 best values $\Delta m = (0.5304 \pm 0.0014) \times 10^{-10} \, hs^{-1}$ and τ_S $= (0.8927 \pm 0.0009) \times 10^{-10} \, \mathrm{s}$. Superseded by APOSTOLAKIS 99c.

$|\epsilon| = (2|\eta_{+-}| + |\eta_{00}|)/3$

This expression is a very good approximation, good to about one part in 10^{-4} because of the small measured value of $\phi_{00}-\phi_{+-}$ and small theoretical ambiguities.

 1 APOSTOLAKIS 99c measures $\phi_{+-}=(43.19\pm0.53\pm0.28)\,+\,300\,\, [\Delta m-0.5301]\,\, (^\circ).$ We have adjusted the measurement to use our best values of $(\Delta m=0.5\,293\pm0.0009)\,\, (10^{10}\,\,\hbar\,\,\mathrm{s}^{-1}).$ Our first error is their experiment's error and our second error is the systematic error from using our best values.

 2 SCHWINGENHEUER 95 measures $\phi_{+-}=(43.53\pm0.76)~+173~[\Delta m-0.5282]-275~[\tau_S-0.8926]~(^\circ).$ We have adjusted the measurement to use our best values of $(\Delta m=0.5293\pm0.0009)~(10^{10}~h~s^{-1}),~(\tau_S=0.8954\pm0.0004)~(10^{-10}~s).$ Our first error is their experiment's error and our second error is the systematic error from using our best values

values. 3 These experiments measure ϕ_{+-} – ϕ_f and calculate the regeneration phase from the power law momentum dependence of the regeneration amplitude using analyticity and dispersion relations. SCHWINGENHEUER 95 [GIBBONS 93] includes a systematic error of 0.35° [0.5°] for uncertainties in their modeling of the regeneration amplitude.

 4 GIBBONS 93 measures $\phi_{+-}=(42.21\pm0.9)+189~[\Delta m-0.5257]-460~[\tau_S-0.8922]$ (°). We have adjusted the measurement to use our best values of $(\Delta m=0.5293\pm0.0009)~(10^{10}~h_{\rm S}^{-1}),~(\tau_S=0.8954\pm0.0004)~(10^{-10}~{\rm s}).$ Our first error is their experiment's error and our second error is the systematic error from using our best values. This is actually reported in SCHWINGENHEUER 95, footnote 8. GIBBONS 93 reports $\phi_{+-}~(42.2\pm1.4)^{\rm o}.$ They measure $\phi_{+}^{}-\phi_{f}^{}$ and calculate the regeneration phase ϕ_{f} from the power law momentum dependence of the regeneration amplitude using analyticity. An error of $0.6^{\rm o}$ is included for possible uncertainties in the regeneration phase.

 5 CAROSI 90 measures $\phi_{+-}=(46.9\pm1.4\pm0.7)~+579~[\Delta m-~0.5351]+303~[\tau_S-~0.8922]~(^\circ).$ We have adjusted the measurement to use our best values of $(\Delta m=~0.5293\pm0.0009)~(10^{10}~\hbar~s^{-1}),~(\tau_S=0.8954\pm0.0004)~(10^{-10}~s).$ Our first error is their experiment's error and our second error is the systematic error from using our best values.

 6 GEWENIGER 74B measures $\phi_{+-}=(49.4\pm1.0)~+565~[\Delta m-0.540]~(^\circ).$ We have adjusted the measurement to use our best values of $(\Delta m=0.5293\pm0.0009)~(10^{10}~\hbar~s^{-1}).$ Our first error is their experiment's error and our second error is the systematic error from using our best values.

⁷ Not independent of other phase parameters reported in ABOUZAID 11.

 8 ALAVI-HARATI 03 ϕ_{+-} is correlated with their $\Delta m=m_{K_L^0}-m_{K_S^0}$ and au_{K_S} mea-

surements in the K_L^0 and K_S^0 sections respectively. The correlation coefficients are $\rho(\phi_+,\Delta m)=+0.955$, $\rho(\phi_+-,\tau_S)=-0.871$, and $\rho(\tau_S,\Delta m)=-0.840$. CPT is not assumed. Uses scintillator Pb regenerator. Superseded by ABOUZAID 11.

 9 ADLER 96c measures $\phi_{+-}=(43.82\pm0.41)~+339~[\Delta m-0.5307]-252~[\tau_S-0.8922]~(^\circ). We have adjusted the measurement to use our best values of <math display="inline">(\Delta m=0.5293\pm0.0009)~(10^{10}~h~s^{-1}),~(\tau_S=0.8954\pm0.0004)~(10^{-10}~s).$ Our first error is their experiment's error and our second error is the systematic error from using our best values.

10 ADLER 96c is the result of a fit which includes nearly the same data as entered into the "OUR FIT" value in the 1996 edition of this Review (Physical Review **D54** 1 (1996)). $^{11} \text{ADLER 95B measures} \ \phi_{+-} = (42.7 \pm 0.9 \pm 0.6) \ + \ 316 \ [\Delta m - 0.5274] \ + \ 30 \ [\tau_S - 0.5274] \ + \ 30 \ [$

¹¹ ADLER 95B measures $\phi_{+-}=(42.7\pm0.9\pm0.6)+316$ [$\Delta m-0.5274$] +30 [$\tau_S-0.8926$] (°). We have adjusted the measurement to use our best values of ($\Delta m=0.5293\pm0.0009$) (10^{10} \hbar s $^{-1}$), ($\tau_S=0.8954\pm0.0004$) (10^{-10} s). Our first error is their experiment's error and our second error is the systematic error from using our best values.

10 values. 12 values. 12 ADLER 92B quote separately two systematic errors: ± 0.4 from their experiment and ± 1.0 degrees due to the uncertainty in the value of Δm .

13 KARLSSON 90 systematic error does not include regeneration phase uncertainty.

 14 CARITHERS 75 measures $\phi_{+-}=(45.5\pm2.8)+224$ [$\Delta m-0.5348$] $(^{\circ}).$ We have adjusted the measurement to use our best values of ($\Delta m=0.5293\pm0.0009)$ ($10^{10}~\hbar$ s $^{-1}$). Our first error is their experiment's error and our second error is the systematic error from using our best values. $\phi_f=-40.9\pm2.6^{\circ}.$

ϕ_{00} , PHASE OF η_{00}

See comment in ϕ_{+-} header above for treatment of Δm and τ_{S} dependence, as well as for the inclusion of data in both the "Assuming CPT" and "Not Assuming CPT"

OUR FIT is described in the note on "CP violation in K_L decays" in the K_L^0 Particle Listings.

DO CUMENT ID TECN COMMENT 43.52±0.05 OUR FIT Error includes scale factor of 1.3. Assuming CPT **43.7** \pm **0.6 OUR FIT** Error includes scale factor of 1.2.  1 CAROSI 90 measures $\phi_{00}=(47.1\pm2.1\pm1.0)~+579~[\Delta m-0.5351]+252~[\tau_S-0.8922]~(^\circ).$ We have adjusted the measurement to use our best values of $(\Delta m=0.5293\pm0.0009)~(10^{10}~\hbar~s^{-1}),~(\tau_S=0.8954\pm0.0004)~(10^{-10}~s).$ Our first error is their experiment's error and our second error is the systematic error from using our best values

 3 ANGELOPOULOS 98 measures $\phi_{00}=(42.0\pm5.6\pm1.9)~+~240~[\Delta m-~0.5307]~(^\circ).$ We have adjusted the measurement to use our best values of $(\Delta m=0.5293\pm0.0009)~(10^{10}~\hbar~s^{-1}).$ Our first error is their experiment's error and our second error is the systematic error from using our best values. The $\tau_{\rm S}$ dependence is negligible.

 4 ADLER 96B identified initial neutral kaon individually as being a K^0 or a \overline{K}^0 . The systematic uncertainty is $\pm 1.5^\circ$ combined in quadrature with $\pm 0.8^\circ$ due to Δm .

⁵ KARLSSON 90 systematic error does not include regeneration phase uncertainty.

$\phi_\epsilon=(2\phi_{+-}+\phi_{00})/3$

This expression is a very good approximation, good to about 10^{-3} degrees because of the small measured values of $\phi_{00}-\phi_{+-}$ and Re ϵ'/ϵ , and small theoretical ambiguities.

 Not assuming CPT

 1 SUPERWEAK 12 is a fake measurement used to impose the CPT or Superweak constraint $\phi_{+-}=\phi_{\rm SW}=\tan^{-1}[2\,\frac{\Delta_n}{\hbar}\,\left(\frac{\tau_S\tau_L}{(\tau_-\tau_S)}].$ This "measurement" is linearized using values near the RPP 2004 edition values of $\Delta m,\,\tau_S$ and τ_L , and then adjusted to our current values as described in the following "measurement". SUPERWEAK 12 measures $\phi_\epsilon=(43.5\,0258\pm0.00021)\,+\,54.1\,[\Delta m-0.5289]\,+\,32.0\,[\tau_S-0.89564]\,(^\circ).$ We have adjusted the measurement to use our best values of $(\Delta m=0.5293\pm0.0009)\,(10^{10}\,\hbar\,{\rm s}^{-1}),\,(\tau_S=0.8954\pm0.0004)\,(10^{-10}\,{\rm s}).$ Our first error is their experiment's error and our second error is the systematic error from using our best values.

 2 ABOUZAID 11 uses the full KTeV dataset collected in 1996, 1997, and 1999. See ${\rm Im}(\epsilon'/\epsilon)$ section for correlation information.

$\operatorname{Im}(\epsilon'/\epsilon) = -(\phi_{00} - \phi_{+-})/3$

For small $|\epsilon'/\epsilon|$, ${\rm Im}(\epsilon'/\epsilon)$ is related to the phases of η_{00} and η_{+-} by the above expression.

 $^{^1}$ SUPERWEAK 12 is a fake experiment to constrain $\phi_{00}-\phi_{+-}$ to a small value as described in the note "CP violation in K_L decays."

PHASE DIFFERENCE ϕ_{+-} - ϕ_{SW}

Test of *CPT*. The Superweak phase $\phi_{
m SW} \equiv an^{-1} \left(2\Delta m/\Delta\Gamma
ight)$ where $\Delta m = m_{K_0^0}$ $m_{K_S^0}$ and $\Delta\Gamma = \hbar(au_L - au_S)/(au_L au_S).$

 1 ALAVI-HARATIO3
 KTEV

 1 ALAVI-HARATI 03 fit is the same as their ϕ_{+-} , τ_{K_S} , Δm fit, except that the parameter $\phi_{+-} - \phi_{\mathrm{SW}}$ is used in place of ϕ .

$Re(\frac{2}{3}\eta_{+-} + \frac{1}{3}\eta_{00}) - \frac{A_L}{2}$ Test of *CPT*

VALUE (units 10^{-6}) $\frac{_{DOCUMENT\ ID}}{^{1}}\frac{_{DOCUMENT\ ID}}{^{1}}\frac{_{TECN}}{^{1}}\frac{_{COMMENT}}{^{1}}\frac{_{COMMENT}}{^{1}}$ -3 ± 35 $^1\,\mathrm{ALAVI}\text{-HARATI}$ 02 uses PDG 00 values of η_{+-} and $\eta_{00}.$

$\Delta S = \Delta Q \text{ IN } K^0 \text{ DECAYS}$

The relative amount of $\Delta S \neq \Delta Q$ component present is measured by the parameter x, defined as

$$x = A(\overline{K}^0 \to \pi^- \ell^+ \nu) / A(K^0 \to \pi^- \ell^+ \nu)$$
.

We list $Re\{x\}$ and $Im\{x\}$ for K_{e3} and $K_{\mu3}$ combined.

$x = A(\overline{K}^0 \rightarrow \pi^- \ell^+ \nu)/A(K^0 \rightarrow \pi^- \ell^+ \nu) = A(\Delta S = -\Delta Q)/A(\Delta S = \Delta Q)$

 $^{^2}$ SANDWEISS 73 value corrected from value quoted in their paper due to new value of Re(\$\xi\$). See footnote 4 of SCHMIDT 79.

²This SCHWINGENHEUER 95 values is the combined result of SCHWINGENHEUER 95 and GIBBONS 93, accounting for correlated systematic errors.

 $^{^{3}\,\}mathrm{Not}$ independent of other phase parameters reported in ABOUZAID 11.

 $^{^4}$ ALAVI-HARATI 03 fit Re($\epsilon'/\epsilon)$, Im($\epsilon'/\epsilon)$, Δm , τ_S , and ϕ_{+-} simultaneously, not assuming CPT. Phase difference is obtained from $\phi_{00}-\phi_{+-}\approx -3{\rm Im}(\epsilon'/\epsilon)$ for small $|\epsilon'/\epsilon|$. Superseded by ABOUZAID 11.

⁵ GIBBONS 93 give detailed dependence of systematic error on lifetime (see the section on the K_S^0 mean life) and mass difference (see the section on $m_{K_L^0}-m_{K_S^0}$.

 $^{^6}$ CAROSI 90 is excluded from the fit because it it is not independent of ϕ_{+-} and ϕ_{00}

 $[\]frac{1}{2}$ BURGUN 72 is a final result which includes BURGUN 71. $\frac{2}{3}$ First GRAHAM 72 value is second GRAHAM 72 value combined with MANTSCH 72. $\frac{3}{3}$ CHO 70 is analysis of unambiguous events in new data and HILL 67.

⁴BENNETT 69 is a reanalysis of BENNETT 68.

⁵ BALDO-CEOLIN 65 gives x and θ converted by us to Re(x) and Im(x).

 $^{^1}$ The Breit-Wigner parameters from a fit with seven intermediate resonances. The S-matrix pole position is $(764\pm63^{+71}_{-54})-i~(306\pm149^{+143}_{-85})$ MeV.

The second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of the second of t

from ABLIKIM 06c well describes the left slope of the $\kappa_S^0\pi^-$ invariant mass spectrum in $au^-
ightarrow au^0_S \pi^-
u_ au$ decay studied by EPIFA NOV 07.

⁶ S-matrix pole. Using Roy-Steiner equations (ROY 71) as well as unitarity, analyticity and crossing symmetry constraints.

- 7 Not seen by KOPP 01 using 7070 events of ${\it D}^{\,0} \rightarrow {\it K}^-\,\pi^+\,\pi^0.$ LINK 02E and LINK 051 show clear evidence for a constant non-resonant scalar amplitude rather than $K_0^*(800)$ in their high statistics analysis of D^+ ightarrow $\kappa^-\pi^+\mu^+\nu_{\mu^+}$
- 8 AUBERT 07T does not find evidence for the charged $K_0^*(800)$ using 11k events of $D^0 \to$
- 9 S-Matrix pole. Supersedes BUGG 06. Combined analysis of ASTON 88, ABLIKIM 06c, AITALA 06, and LINK 09 using an s-dependent width with couplings to $K\pi$ and $K\eta'$, and the Adler zero near thresholds.

 10 T-matrix pole.

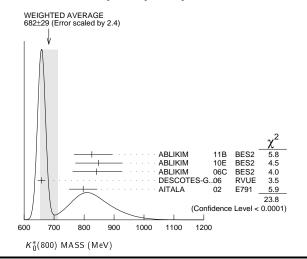

- 12 A Breit-Wigner mass and width. 12 S-matrix pole. Reanalysis of ASTON 88, AITALA 02, and ABLIKIM 06c using for the κ an s-dependent width with an Adler zero near threshold.
- 13 Breit-Wigner parameters. A significant S-wave can be also modeled as a non-resonant contribution.

 14 Using ASTON 88.
- 17 Using ASION 88.

 15 T-matrix pole. Reanalysis of data from LINGLIN 73, ESTABROOKS 78, and ASTON 88 in the unitarized ChPT model.

 16 T-matrix pole. Reanalysis of ASTON 88 data.

 17 Reanalysis of ASTON 88 using interfering Breit-Wigner amplitudes.

$K^*(892)^0$ mass (MeV)

- $^{
 m 1}$ Inclusive reaction. Complicated background and phase-space effects.
- ² Mass errors enlarged by us to Γ/\sqrt{N} . See note.
- ³ Number of events in peak reevaluated by us.
- ⁴ K-matrix pole.
- ⁵ From a partial wave amplitude analysis.
- ⁶ From a fit in the $K_0^*(800) + K^*(892) + K^*(1410)$ model.
- 7 From the pole position of the $K\,\pi$ vector form factor using EPIFANOV 07 and constraints from K_{I3} decays in ANTONELLI 10.
- ⁸ Systematic uncertainties not estimated.
- $^9\,{\sf From}$ the pole position of the $K\,\pi$ vector form factor in the complex s-plane and using
- EPIFANOV 07 data. $^{10}\,\text{Reanalysis}$ of EPIFANOV 07 using resonance chiral theory.
- 11 Calculated by us from the shift by 4.7 \pm 0.9 MeV (statistical uncertainty only) reported in BONVICINI 02 with respect to the world average value from PDG 00.
- 12 With mass and width of the $K^*(1410)$ fixed at 1412 MeV and 227 MeV, respectively.
- 13 From the isobar model with a complex pole for the κ .
- $^{14}\,\mathrm{Fit}$ to $\,\mathit{K}\,\pi$ mass spectrum includes a non-resonant scalar component.
- $^{15}\, {\sf From\ pole\ extrapolation}$.
- 16 This value comes from a fit with χ^2 of 178/117.

$K^*(892)$ MASSES AND MASS DIFFERENCES

Unrealistically small errors have been reported by some experiments. We use simple "realistic" tests for the minimum errors on the determination of a mass and width from a sample of N events:

$$\delta_{\min}(m) = \frac{\Gamma}{\sqrt{N}}, \quad \delta_{\min}(\Gamma) = 4\frac{\Gamma}{\sqrt{N}}.$$
 (1)

We consistently increase unrealistic errors before averaging. For a detailed discussion, see the 1971 edition of this Note.

CONSTRAINED FIT INFORMATION

An overall fit to the total width and a partial width uses 13 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 7.8$ for 11 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta
ho_i \delta
ho_j
angle / (\delta
ho_i \cdot \delta
ho_j)$, in percent, from the fit to parameters ho_i , including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$$x_5$$
 $\begin{bmatrix} -100 \\ 19 \\ x_2 \end{bmatrix}$

- ¹ S-Matrix pole. Supersedes BUGG 06. Combined analysis of ASTON 88, ABLIKIM 06c, AITALA 06, and LINK 09 using an s-dependent width with couplings to $K\pi$ and $K\eta'$, and the Adler zero near thresholds. 2 From the isobar model with a complex pole for the κ .
- ³ From a non-parametric analysis.
- ⁴ A Breit-Wigner mass and width.
- A Differentiation in mass and worth. S-matrix pole. Reanalysis of ASTON 88, AITALA 02, and ABLIKIM 06c including the κ with an s-dependent width and an Adler zero near threshold.
- ⁶ S-matrix pole. Using ASTON 88 and assuming $K_0^*(800)$, $K_0^*(1950)$.
- ⁷Using ASTON 88 and assuming $K_0^*(800)$.
- 8 T-matrix pole. Reanalysis of ASTON 88 data.
- ⁹Breit-Wigner fit. Using ASTON 88.
- 10 Assuming a low-mass scalar $K\pi$ resonance, $\kappa(800)$. 11 T-matrix pole. Using data from ESTABROOKS 78 and ASTON 88.
- $^{12}J^{P}$ not determined, could be $K_{2}^{*}(1430)$.
- ¹³T-matrix pole.
- $^{14}\,\mathrm{Uses}$ a model for the background, without this background they get a mass 1340 MeV,
- where the phase shift passes 90° . 15 Mass defined by pole position.
- $^{16}\,\mathrm{From}$ elastic $K\pi$ partial-wave analysis.

CONSTRAINED FIT INFORMATION

An overall fit to the total width, a partial width, and 10 branching ratios uses 31 measurements and one constraint to determine 8 parameters. The overall fit has a $\chi^2=$ 20.2 for 24 degrees of

The following off-diagonal array elements are the correlation coefficients $\left\langle \delta p_i \delta p_j \right
angle / (\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 4 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 =$ 2.9 for 2 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv$ $\widehat{\Gamma_i}/\Gamma_{\rm total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$$\begin{array}{c|cccc}
x_2 & -36 \\
x_3 & -39 & -72 \\
\hline
& x_1 & x_2
\end{array}$$

- $^1\,{\rm From}$ energy-independent partial-wave analysis. $^2\,{\rm From}$ a fit to $\,Y_6^2\,$ moment. $\,J^P\,\equiv\,3^-\,$ found.
- 3 Confirmed by phase shift analysis of ESTABROOKS 78, yields $J^P \equiv 3^-$.
- 4 From a partial wave amplitude analysis. 5 From a fit to the Y_6^0 moment.

- ⁶ From energy-independent partial-wave analysis. ⁷ From a fit to Y_6^2 moment. $J^P=3^-$ found.
- 8 From a partial wave amplitude analysis. 9 From a fit to Y_6^0 moment.
- $^{10}_{-}$ Errors enlarged by us to $4\Gamma/\sqrt{\textit{N}};$ see the note with the $\textit{K}^*(892)$ mass.
- 11 ESTABROOKS 78 find that BRANDENBURG 76D data are consistent with 175 MeV width. Not averaged.

K*(1780) DECAY MODES

| | Mode | Fraction (Γ_i/Γ) | Confidence level |
|----------------|------------------|------------------------------|------------------|
| Γ ₁ | Κρ | (31 ± 9)% | |
| Γ_2 | $K^*(892)\pi$ | (20 ± 5) % | |
| Γ_3 | $K\pi$ | (18.8± 1.0) % | |
| Γ_4 | $K\eta$ | (30 ±13) % | |
| Γ ₅ | $K_2^*(1430)\pi$ | < 16 % | 95 % |

CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 4 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2=$ 0.0 for 1 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta x_i \delta x_j
angle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv$ $\Gamma_i/\Gamma_{\rm total}$. The fit constrains the x_i whose labels appear in this array to sum to one

Meson Particle Listings K(3100)

K(3100)

¹ Supersedes ALEEV 90.

 $I^{G}(J^{PC}) = ?^{?}(?^{??})$

OMITTED FROM SUMMARY TABLE

Narrow peak observed in several $(\Lambda \overline{p} + pions)$ and $(\overline{\Lambda} p + pions)$ states in Σ^- Be reactions by BOURQUIN 86 and in $n\,p$ and $n\,\mathrm{A}$ reactions by ALEEV 93. Not seen by BOEHNLEIN 91. If due to strong decays, this state has exotic quantum numbers (B=0, Q=+1,S=-1 for $\Lambda \, \overline{p} \, \pi^+ \, \pi^+$ and $I \geq 3/2$ for $\Lambda \, \overline{p} \, \pi^-$). Needs confirmation.

D+ DECAY MODES

Most decay modes (other than the semileptonic modes) that involve a neutral K meson are now given as K_S^0 modes, not as \overline{K}^0 modes. Nearly always it is a K_S^0 that is measured, and interference between Cabibbo-allowed and doubly Cabibbo-suppressed modes can invalidate the assumption that $2\Gamma(K_S^0) = \Gamma(\overline{K^0})$.

| | Mode | Fraction (Γ_i/Γ) | Scale factor/ Confidence level |
|-----------------|---------------------------------------------------------|------------------------------|-----------------------------------|
| | Inclusive m | nodes | |
| Γ_1 | $D^+ ightarrow e^+$ semileptonic | (16.07 ± 0.30) % | |

- Γ_{135} Unaccounted decay modes (51.2 \pm 1.0) %
 - [a] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers.
 - [b] These subfractions of the $K^-2\pi^+$ mode are uncertain: see the Particle Listings
 - [c] Submodes of the $D^+ \to K^- 2\pi^+ \pi^0$ and $K_S^0 2\pi^+\pi^-$ modes were studied by ANJOS 92C and COFFMAN 92B, but with at most 142 events for the first mode and 229 for the second not enough for precise results. With nothing new for 18 years, we refer to our 2008 edition, Physics Letters **B667** 1 (2008), for those results.
 - [d] The unseen decay modes of the resonances are included.
 - [e] This is not a test for the $\Delta \it C\!=\!1$ weak neutral current, but leads to the $\pi^+\,\ell^+\,\ell^-$ final state.
 - [f] This mode is not a useful test for a $\Delta C=1$ weak neutral current because both quarks must change flavor in this decay.

CONSTRAINED FIT INFORMATION

An overall fit to 22 branching ratios uses 31 measurements and one constraint to determine 15 parameters. The overall fit has a $\chi^2=$ 32.1 for 17 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv$ $\Gamma_i/\Gamma_{
m total}$. The fit constrains the x_i whose labels appear in this array to sum to

DALITZ PLOT ANALYSIS FORMALISM

Revised March 2012 by D. Asner (Pacific Northwest National Laboratory) and C. Hanhart (Forschungszentrum Jülich).

Introduction: Weak nonleptonic decays of D and B mesons are expected to proceed dominantly through resonant two-body decays [1]; see Ref. 2 for a review of resonance phenomenology. The amplitudes are typically calculated with the Dalitz-plot analysis technique [3], which uses the minimum number of independent observable quantities. For three-body decays of a spin-0 particle to all pseudo-scalar final states, such as D or $B \to abc$, the decay rate [4] is

$$\Gamma = \frac{1}{(2\pi)^3 32\sqrt{s^3}} |\mathcal{M}|^2 dm_{ab}^2 dm_{bc}^2,$$
 (1)

where m_{ij} is the invariant mass of particles i and j. Here the prefactor contains all kinematic factors, while $|\mathcal{M}|^2$ contains the dynamics. The scatter plot in m_{ab}^2 versus m_{bc}^2 is the Dalitz plot. If $|\mathcal{M}|^2$ is constant, the kinematically allowed region of the plot will be populated uniformly with events. Any variation in the population over the Dalitz plot is due to dynamic rather than kinematic effects. It is straightforward to extend the formalism beyond three-body final states.

Formalism: The amplitude for the process $R \to rc, r \to ab$ where R is a D or B meson, r is an intermediate resonance, and a, b, c are pseudo-scalars, is given by

$$\mathcal{M}_r(J, L, l, m_{ab}, m_{bc}) = \sum_{\lambda} \langle ab | r_{\lambda} \rangle T_r(m_{ab}) \langle cr_{\lambda} | R_J \rangle \quad (2)$$

$$= Z(J, L, l, \vec{p}, \vec{q}) B_L^R(|\vec{p}|) B_L^r(|\vec{q}|) T_r(m_{ab}).$$

The sum is over the helicity states λ of r; J is the total angular momentum of R (for D and B decays, J=0); L is the orbital angular momentum between r and c; l is the orbital angular momentum between a and b; (the spin of r); \vec{p} and \vec{q} are the momenta of c and of a in the r rest frame; Z describes the angular distribution of the final-state particles; B_L^R and B_L^r are

D^{\pm}

the barrier factors for the production of rc and of ab; and T_r is the dynamical function describing the resonance r. T_r is a phenomenological object, with the resonances modeled often by a Breit-Wigner form, although some more recent analyses use a K-matrix formalism [5–7] with the P-vector approximation [8] to describe the $\pi\pi$ S-wave.

The nonresonant (NR) contribution to $D \to abc$ is parametrized as constant (S-wave), with no variation in magnitude or phase across the Dalitz plot. The available phase space is much greater for B decays than for D decays, and the nonresonant contribution to $B \to abc$ requires a more sophisticated parametrization. Experimentally, several parametrizations have been used [9,10]. Differences in the parametrizations of the NR contributions, and in Z, B_L , and T_r , as well as in the set of resonances r, complicate the comparison of results from different experiments.

Angular distribution Z: The tensor or Zemach formalism [11,12] and the helicity formalism [13,12] yield identical descriptions of the angular distributions for the decay process $R \to rc, r \to ab$ when a, b and c all have spin 0. The angular distributions for L=0,1, and 2 are given in Table 1. For a derivation of the expressions, see, e.g., Ref. 12. For final-state particles with non-zero spin (e.g., radiative decays), the helicity formalism is required.

Table 1: Angular distributions for L=0,1,2 for the decay process $R\to rc, r\to ab$ when a,b and c all have spin 0. Here θ is the angle between particles a and c in the rest frame of resonance $r,\sqrt{1+\zeta^2}=E_r/m_{ab}$ is a relativistic correction, where $E_r=(m_R^2+m_{ab}^2-m_c^2)/2m_R$ is the energy of resonance r in the rest frame of R.

| $\overline{J \to L + l}$ | Angular distribution |
|--------------------------|----------------------------------------------------------------|
| $0 \rightarrow 0 + 0$ | uniform |
| $0\!\to\!1\!+\!1$ | $(1+\zeta^2)\cos^2\theta$ |
| $0 \rightarrow 2+2$ | $\left(\zeta^2 + \frac{3}{2}\right)^2 (\cos^2 \theta - 1/3)^2$ |

Barrier Factor B_L : The maximum angular momentum L in a strong decay is limited by the linear momentum q—the relative momentum of the decay particles in the center of mass frame of the decaying resonance. Decay particles moving slowly with an impact parameter (meson radius) d of order 1 fm have difficulty generating sufficient angular momentum to conserve the spin of the resonance. The Blatt-Weisskopf [14,15] functions B_L , given in Table 2, weight the reaction amplitudes to account for this spin-dependent effect. These functions are normalized to give $B_L = 1$ for $z = (|q|d)^2 = 1$. Another common formulation, B'_L , also in Table 2, is normalized to give $B'_L = 1$ for $z = z_0 = (|q_0|d)^2$ where q_0 is the value of q when $m_{ab} = m_r$. An important difference between the B_L and the B'_L is that the former include explictly the centrifugal barrier,

while it is to be moved to the dynamical functions in the case of B'_L .

Table 2: Blatt-Weisskopf barrier factors weight the reaction amplitudes to account for spin-dependent effects (c.f. Sec. VIII.5 of Ref. 14). Two formulations with different normalization conditions (described in text) are shown. B_L is commonly used in Dalitz plot analyses; B_L' is commonly used with the helicity formalism.

| L | $B_L(q)$ | $B_L'(q,q_0)$ |
|---|-------------------------------------|--------------------------------------------|
| 0 | 1 | 1 |
| 1 | $\sqrt{\frac{2z}{1+z}}$ | $\sqrt{\frac{1+z_0}{1+z}}$ |
| 2 | $\sqrt{\frac{13z^2}{(z-3)^2 + 9z}}$ | $\sqrt{\frac{(z_0-3)^2+9z_0}{(z-3)^2+9z}}$ |
| | where $z = (q d)^2$ | and $z_0 = (q_0 d)^2$ |

Dynamical Function T_r : The dynamical function T_r is derived from the S-matrix formalism [5]. In general, the amplitude that a final state f couples to an initial state i is $S_{fi} = \langle f|S|i\rangle$, where the scattering operator S is unitary: $SS^{\dagger} = S^{\dagger}S = I$. The Lorentz-invariant transition operator \hat{T} is defined by separating the probability that f = i, yielding

$$S = I + 2iT = I + 2i\{\rho\}^{1/2} \hat{T}\{\rho\}^{1/2}, \qquad (3)$$

where I is the identity operator and ρ is the diagonal phasespace matrix. If channel i denotes the two-body state ab, then

$$\rho_{ii} = \rho_i = \frac{2q_i}{m_{ab}} \; \theta \left[m_{ab} - (m_a + m_b) \right] \,, \tag{4}$$

where m_{ab} is the invariant mass of the system;

$$q_i = \frac{1}{2m_{ab}} \sqrt{(m_{ab}^2 - (m_a + m_b)^2)(m_{ab}^2 - (m_a - m_b)^2)}$$
 (5)

is the momentum of a in the r rest frame, and $\theta[...]$ is the step function. In the single-channel case, unitarity allows one to express S through a single parameter, $S=e^{2i\delta}$, and

$$\hat{T} = \frac{1}{\rho} e^{i\delta} \sin \delta. \tag{6}$$

There are three common formulations of the dynamical function. The Breit-Wigner form—the first term in a Taylor expansion about a T-matrix pole—is the simplest. The K-matrix formalism [5] is more general (allowing more than one T-matrix pole and coupled channels while preserving unitarity). The Flatté distribution [16] is used to parametrize resonances near threshold, located at $s = (m_a + m_b)^2$, and is equivalent to a one-pole, two-channel K-matrix.

${\it Breit-Wigner\ Formulation:}$

The common formulation of a Breit-Wigner resonance decaying to spin-0 particles a and b is

$$T_r(m_{ab}) \propto \frac{1}{m_r^2 - m_{ab}^2 - im_r \Gamma_{ab}(m_{ab})}.$$
 (7)

A standard formulation for the "mass-dependent" width Γ_{ab} reads

$$\Gamma_{ab}(m_{ab}) = \sum_{i} \Gamma_i^r \left(\frac{q_i}{q_r}\right)^{2L_i + 1} \left(\frac{m_r}{m_{ab}}\right) B_{L_i}'(q_i, q_0)^2, \quad (8)$$

where q_i , L_i , Γ_i^r and $B'_{L_i}(q_i,q_0)$ are the momentum and angular momentum of the decay products, the partial width and Blatt-Weisskopf barrier factor (see Table 2) for the decay of resonance r into channel i, respectively. A Breit-Wigner parametrization best describes isolated, non-overlapping resonances far from the threshold of additional decay channels. For the $\rho(770)$ and $\rho(1450)$ a more complex parametrization suggested by Gounaris-Sakarai [17] is often used [18-22]. Unitarity is violated when the dynamical function is parametrized as the sum of two or more overlapping Breit-Wigners — see the discussion below Eq. (13). The proximity of a threshold to a resonance distorts the line shape from a simple Breit-Wigner. Here the Flatté formula provides a better description and is discussed below.

K-matrix Formulation

The T matrix can be written as

$$\hat{T} = (I - i\hat{K}\rho)^{-1}\hat{K},\tag{9}$$

where \hat{K} is the Lorentz-invariant K-matrix describing the scattering process and ρ is the phase-space factor defined below Eq. (3). Resonances appear as poles in the K-matrix:

$$\hat{K}_{ij} = \sum_{\alpha} \frac{\sqrt{m_{\alpha} \Gamma_{\alpha i}(m) m_{\alpha} \Gamma_{\alpha j}(m)}}{(m_{\alpha}^2 - m^2) \sqrt{\rho_i \rho_j}}.$$
 (10)

The K-matrix is real by construction, and so the associated T-matrix respects unitarity. However, in the given form it has the wrong analytic structure. To improve it, some authors use the analytic continuation for the momentum q_i , defined in Eq. (5), to below-threshold values, where for $m_a \neq m_b$ the phase space factor needs to be modified to avoid false singularities (see, e.g., Ref. 7, Sec. 2.1). For further improvements see below.

For a single pole in a single channel, $K = \rho \hat{K}$ is

$$K = \frac{m_0 \Gamma(m)}{m_0^2 - m^2} \tag{11}$$

and

$$T = K(1 - iK)^{-1} = \frac{m_0 \Gamma(m)}{m_0^2 - m^2 - i m_0 \Gamma(m)},$$
 (12)

which is the relativistic Breit-Wigner formula. For two poles in a single channel, K is

$$K = \frac{m_{\alpha}\Gamma_{\alpha}(m)}{m_{\alpha}^2 - m^2} + \frac{m_{\beta}\Gamma_{\beta}(m)}{m_{\beta}^2 - m^2}.$$
 (13)

If m_{α} and m_{β} are far apart relative to the widths, the T matrix is approximately the sum of two Breit-Wigners, $T(K_{\alpha} + K_{\beta}) \approx T(K_{\alpha}) + T(K_{\beta})$, each of the form of Eq. (12). This approximation is not valid for two nearby resonances, for it violates unitarity. For example, for $m = m_{\alpha}$ the full, unitary K-matrix expression gives Im(T) = 1, while the imaginary part of $T(K_{\alpha}) + T(K_{\beta})$ is $1 + (m_{\beta}\Gamma_{\beta})^2/[(m_{\beta}^2 - m_{\alpha}^2)^2 + (m_{\beta}\Gamma_{\beta})^2]$.

This formulation, which applies to S-channel production in two-body scattering, $ab \rightarrow cd$, can be generalized to describe the production of resonances in processes such as the decay of charm mesons. The key assumption here is that the two-body system described by the K-matrix does not interact with the rest of the final state [8]. The validity of this assumption varies with the production process and is appropriate for reactions such as $\pi^- p \to \pi^0 \pi^0 n$ in the several-GeV regime, and for semileptonic decays such as $D \to K\pi\ell\nu$. The assumption may be of limited validity for production processes such as $p\overline{p} \to \pi\pi\pi$, $D \to \pi\pi\pi$, $D \to K\pi\pi$ and $J/\psi \to \omega\pi\pi$. In the last two cases, additional three–body rescatterings were found to be relevant. In the J/ψ decays, they appeared where the two-body amplitudes were very small [23]; in the D decays, they were shown to lead to a significant difference between the $K\pi$ scattering phase and the phase extracted from the production process [24]. If threebody interactions are neglected, the two-body Lorentz-invariant amplitude, \hat{F} , is given by

$$\hat{F}_i = (I - i\hat{K}\rho)_{ij}^{-1}\hat{P}_j = (\hat{T}\hat{K}^{-1})_{ij}\hat{P}_j, \qquad (14)$$

where P is the production vector that parametrizes the resonance production in the open channels.

For the $\pi\pi$ S-wave, a common formulation of the K-matrix [7,20,21,25] is

$$K_{ij}(s) = \left[\sum_{\alpha} \left(\frac{g_i^{(\alpha)} g_j^{(\alpha)}}{m_{\alpha}^2 - s} \right) + f_{ij}^{sc} \frac{1 + s_0^{sc}}{s + s_0^{sc}} \right] \left[\frac{(s - s_A)}{(s + s_{A0})} \right]. \tag{15}$$

The factor $g_i^{(\alpha)}$ is the real coupling constant of the K-matrix pole m_α to meson channel i; the parameters f_{ij}^{sc} and s_0^{sc} describe a smooth part of the K-matrix elements; the second factor in square brackets, with $s_A \sim (0.1-0.5)m_\pi^2$ contains the Adler zero and at the same time suppresses a false kinematical singularity; e.g., in Ref. 25, $s_{A0}=0.15~{\rm GeV^2}$ and $s_A=0.5m_\pi^2$ were used. The number 1 has units ${\rm GeV^2}$.

The production vector, with i = 1 denoting $\pi\pi$, is

$$P_{j}(s) = \left[\sum_{\alpha} \left(\frac{\beta_{\alpha} g_{j}^{(\alpha)}}{m_{\alpha}^{2} - s} \right) + f_{1j}^{pr} \frac{1 + s_{0}^{pr}}{s + s_{0}^{pr}} \right], \tag{16}$$

where the free parameters of the Dalitz-plot fit are the complex production couplings β_{α} and the production-vector background parameters f_{1j}^{pr} and s_{0}^{pr} . All other parameters are fixed by scattering experiments. Ref. 6 describes the $\pi\pi$ scattering data with a 4-pole, 2-channel $(\pi\pi, K\bar{K})$ model, while Ref. 7 describes the scattering data with a 5-pole, 5-channel $(\pi\pi, K\bar{K}, \eta\eta, \eta'\eta')$ and $(\pi\pi, K\bar{K}, \eta\eta, \eta')$

D^{\pm}

CLEO [26] and the latter by FOCUS [21] and BABAR [20]. In both cases, only the $\pi\pi$ channel was analyzed. A more complete coupled-channel analysis would simultaneously fit all final states accessible by rescattering.

Flatté Formalism

The Flatté formulation is used when a second channel opens close to a resonance. This situation occurs in the $\pi\pi$ S-wave where the $f_0(980)$ is near the $K\overline{K}$ threshold, and in the $\pi\eta$ channel where the $a_0(980)$ also lies near the $K\overline{K}$ threshold. The T-matrix is parameterized as

$$\hat{T}(m_{ab})_{ij} = \frac{g_i g_j}{m_r^2 - m_{ab}^2 - i(\rho_1 g_1^2 + \rho_2 g_2^2)},$$
(17)

where $\rho_1 g_1^2 + \rho_2 g_2^2 = m_0 \Gamma_r$, when the phase spaces are evaluated at the resonance mass. For the $a_0(980)$ resonance, the relevant coupling constants are $g_1 = g_{\pi\eta}$ and $g_2 = g_{KK}$, and the phase space terms are $\rho_1 = \rho_{\pi\eta}$ and $\rho_2 = \rho_{KK}$, with ρ_i defined in Eq. (4). For the $f_0(980)$ the relevant coupling constants are $g_1 = g_{\pi\pi}$ and $g_2 = g_{KK}$, and the phase space terms are $\rho_1 = \rho_{\pi\pi}$ and $\rho_2 = \rho_{KK}$. The charged and neutral K channels are usually assumed to have the same coupling constant but different phase space factors, due to $m_{K^+} \neq m_{K^0}$; the result is

$$\rho_{KK} = \frac{1}{2} \left(\sqrt{1 - \left(\frac{2m_{K^{\pm}}}{m_{KK}}\right)^2} + \sqrt{1 - \left(\frac{2m_{K^0}}{m_{KK}}\right)^2} \right) . \tag{18}$$

The effect of using this expression compared to using the averaged kaon masses is confined in the region very near threshold and is significant only in between the two kaon thresholds. If the coupling of a resonance to the channel opening nearby is strong, the Flatté parametrization shows a scaling invariance and does not allow for an extraction of the parameters individually, but only of ratios [27].

Further improvements:

The K-matrix described above usually allows one to get a proper fit of physical amplitudes and it is easy to deal with. However, it also has an important deficit: it violates constraints from analyticity — e.g., ρ_{ii} has a pole at s=0, and for unequal masses develops an unphysical cut. An analytic continuation of the amplitudes into the complex plane is not controlled, and typically the parameters of broad resonances come out wrong (see, e.g., the minireview on scalar mesons). A method to improve the analytic properties was suggested in Refs. [25,28–30]. It basically amounts to replacing the phase-space factor $i\rho_i$ in Eqs. 9 and 14 with an analytic function that produces the identical imaginary part. In the simplest case of a channel with equal masses the expressions are

$$-\frac{\rho_i}{\pi}\log\left|\frac{1+\rho_i}{1-\rho_i}\right|,\ -\frac{2\rho_i}{\pi}\arctan\left(\frac{1}{\rho_i}\right),\ -\frac{\rho_i}{\pi}\log\left|\frac{1+\rho_i}{1-\rho_i}\right|+i\rho_i$$

for $m^2 < 0$, $0 < m^2 < (m_a + m_b)^2$, and $(m_a + m_b)^2 < m^2$, respectively. Here $\rho_i = \sqrt{|1 - (m_a + m_b)^2/m^2|}$ for all values of m^2 , extending the expression of Eq. (4) into the regime

below threshold. The more complicated expression for the case of different masses can be found, e.g., in Ref. 29.

Branching Ratios from Dalitz Plot Fits: A fit to the Dalitz plot distribution using either a Breit-Wigner or a K-matrix formalism factorizes into a resonant contribution to the amplitude \mathcal{M}_j and a complex coefficient, $a_j e^{i\delta_j}$, where a_j and δ_j are real. The definition of a rate of a single process, given a set of amplitudes a_j and phases δ_j , is the square of the relevant matrix element (see Eq. (1)). The "fit fraction" is usually defined as the integral over the Dalitz plot $(m_{ab} \text{ vs. } m_{bc})$ of a single amplitude squared divided by the integral over the Dalitz plot of the square of the coherent sum of all amplitudes, or

fit fraction_j =
$$\frac{\int \left| a_j e^{i\delta_j} \mathcal{M}_j \right|^2 dm_{ab}^2 dm_{bc}^2}{\int \left| \sum_k a_k e^{i\delta_k} \mathcal{M}_k \right|^2 dm_{ab}^2 dm_{bc}^2},$$
 (19)

where \mathcal{M}_j is defined in Eq. (2) and described in Ref. 31. In general, the sum of the fit fractions for all components will not be unity due to interference.

When the K-matrix of Eq. (9) is used to describe a wave (e.g., the $\pi\pi$ S-wave), then \mathcal{M}_j refers to the entire wave. In this case, it may not be straightforward to separate \mathcal{M}_j into a sum of individual resonances unless these are narrow and well separated.

Reconstruction Efficiency and Resolution: The efficiency for reconstructing an event as a function of position on the Dalitz plot is in general non-uniform. Typically, a Monte Carlo sample generated with a uniform distribution in phase space is used to determine the efficiency. The variation in efficiency across the Dalitz plot varies with experiment and decay mode. Most recent analyses utilize a full GEANT [32] detector simulation.

Finite detector resolution can usually be safely neglected, as most resonances are comparatively broad. Notable exceptions where detector resolution effects must be modeled are $\phi \to K^+K^-$, $\omega \to \pi^+\pi^-$, and $a_0 \to \eta\pi^0$. One approach is to convolve the resolution function in the Dalitz-plot variables m_{ab}^2 and m_{bc}^2 with the function that parametrizes the resonant amplitudes. In high-statistics data samples, resolution effects near the phase-space boundary typically contribute to a poor goodness of fit. The momenta of the final-state particles can be recalculated with a D or B mass constraint, which forces the kinematic boundaries of the Dalitz plot to be strictly respected. If the three-body mass is not constrained, then the efficiency (and the parametrization of background) may also depend on the reconstructed mass.

Backgrounds: The contribution of background to D and B samples varies by experiment and final state. The background naturally falls into six categories: (1) Purely combinatoric background containing no resonances. (2) Combinatoric background containing intermediate resonances, such as a real K^* or ρ , plus additional random particles. (3) Final states containing identical particles as in $D^0 \to K_S^0 \pi^0$ background to $D^0 \to \pi^+ \pi^- \pi^0$

and $B \to D\pi$ background to $B \to K\pi\pi$. (4) Mistagged decays such as a real $\overline{D}{}^0$ or $\overline{B}{}^0$ incorrectly identified as a D^0 or B^0 . (5) Particle misidentification of the decay products, such as $D^+ \to \pi^-\pi^+\pi^+$ or $D^+_s \to K^-K^+\pi^+$ reconstructed as $D^+ \to K^-\pi^+\pi^+$. (6) Background from decays of charged pions or kaons in flight.

The contribution from combinatoric background with intermediate resonances is distinct from the resonances in the signal because the former do not interfere with the latter since they are not from true resonances. The usual identification tag of the initial particle as a D^0 or a \overline{D}^0 is the charge of the distinctive slow pion in the decay sequence $D^{*+} \to D^0 \pi_s^+$ or $D^{*-} \to \overline{D}^0 \pi_s^-$. Another possibility is the identification or "tagging" of one of the D mesons from $\psi(3770) \to D^0 \overline{D}^0$, as is done for B mesons from $\Upsilon(4S)$. The mistagged background is subtle and may be mistakenly enumerated in the signal fraction determined by a D^0 mass fit. Mistagged decays contain true \overline{D}^0 's or \overline{B}^0 's and so the resonances in the mistagged sample exhibit interference on the Dalitz plot.

REVIEW OF D-MESON DALITZ PLOT ANALYSES

Revised April 2010 by D. Asner (Pacific Northwest National Laboratory)

The formalism of Dalitz-plot analysis is reviewed in the preceding note. Recent studies of multi-body decays of charm mesons probe a variety of physics, including γ/ϕ_3 , $D^0-\overline{D}^0$ mixing, searches for CP violation, doubly Cabibbo-suppressed decays, and properties of S-wave $\pi\pi$, $K\pi$, and $K\overline{K}$ resonances. In the following, we discuss: (1) $D^0 \to K_S^0\pi^+\pi^-$; (2) doubly Cabibbo-suppressed decays; and (3) CP violation. The properties of the light meson resonances determined in D-meson Dalitz-plot analyses are reported in the light unflavored meson section of this Review.

 $D^0 \to K_S^0 \pi^+ \pi^-$: Several experiments have analyzed $D^0 \to K_S^0 \pi^+ \pi^-$ decay. A CLEO analysis [1] included ten resonances: $K_S^0 \rho^0$, $K_S^0 \omega$, $K_S^0 f_0(980)$, $K_S^0 f_2(1270)$, $K_S^0 f_0(1370)$, $K^*(892)^- \pi^+$, $K_0^*(1430)^- \pi^+$, $K_2^*(1430)^- \pi^+$, $K^*(1680)^- \pi^+$, and the doubly Cabibbo-suppressed (DCS) mode $K^*(892)^+ \pi^-$. The CLEO model does not provide a good description of higher-statistics BABAR and Belle data samples. An improved description is obtained in three ways: First, by adding more Breit-Wigner resonances. Second, following the methodology of FOCUS [2], by applying a K-matrix model [3–5] to the $\pi\pi$ S-wave [6,7]. Third, by adding a parameterization to the $K\pi$ S-wave motivated by the LASS experiment [8].

A BABAR analysis [7,9,10] added to the CLEO model the $K^*(1410)^-\pi^+$, $K_S^0\rho^0(1450)$, the DCS modes $K_0^*(1430)^+\pi^-$ and $K_2^*(1430)^+\pi^-$, and two Breit-Wigner $\pi\pi$ S-wave contributions. A Belle analysis [11–13] included all the components of BABAR and added two more DCS modes, $K^*(1410)^+\pi^-$ and

 D^{\pm}

 $K^*(1680)^+\pi^-$. Recently, BABAR has modeled the $\pi\pi$ S-wave using a K-matrix model for the $\pi\pi$ and $K\pi$ S-waves [14].

The primary motivation for the analysis of the decay $D^0 \to K_S^0 \pi^+ \pi^-$ is to study $D^0 - \overline{D}{}^0$ oscillations and the CKM angles. The quasi-two-body intermediate states include both CP-even and CP-odd eigenstates as well as doubly Cabibbo-suppressed channels. Time-dependent analyses of the Dalitz plot from CLEO [15] and Belle [6] simultaneously determined the strong transition amplitudes and phases, the mixing parameters x and y without phase or sign ambiguity, and the CP-violating parameter |q/p| and $\operatorname{Arg}(q/p)$. See the note on " $D^0 - \overline{D}^0$ Mixing" for a discussion.

The CKM angle γ/ϕ_3 [16] and the quark-mixing parameter $\cos 2\beta/\phi_1$ [17] can be determined using the decays $B^- \to D^{(*)}K^{(*)-}$ and $\overline B{}^0 \to Dh^0$, respectively, followed by the decay $D \to K_S^0\pi^+\pi^-$. The Belle and BABAR experiments measured γ/ϕ_3 (Belle [11–13] and BABAR [7,9,10,14,18] and $\cos 2\beta/\phi_1$ (Belle [19], BABAR [20]). In these analyses, a large systematic uncertainty in the relative phase between the D^0 and $\overline D{}^0$ amplitudes point by point across the Dalitz plot remains to be fully understood.

The quantum entangled production of $D^0\overline{D}^0$ pairs from $\psi(3770)$ enables a model-independent determination of the D^0/\overline{D}^0 relative phase. Studying CP-tagged Dalitz plots [21,22] provides sensivity to the cosine of the relative phase, while studying double-tagged Dalitz plots [22] probes both the cosine and sine of the D^0/\overline{D}^0 phase difference. CLEO analyzed [23] the $D^0 \to K_S^0\pi^+\pi^-$ and $D^0 \to K_L^0\pi^+\pi^-$ samples using the CP-even tag modes K^+K^- , $\pi^+\pi^-$, $K_L^0\pi^0$ (vs. $K_S^0\pi^+\pi^-$ only), the CP-odd tag modes $K_S^0\pi^0$, $K_S^0\eta$, and the double-tag modes $(K_S^0\pi^+\pi^-)^2$ and $(K_S^0\pi^+\pi^-)(K_L^0\pi^+\pi^-)$. These measurements can reduce the model uncertainty on γ/ϕ_3 to about 3°.

Doubly Cabibbo-Suppressed Decays: There are two classes of multibody doubly Cabibbo-suppressed (DCS) decays of D mesons. The first consists of those in which the DCS and corresponding Cabbibo-favored (CF) decays populate distinct Dalitz plots; the pairs $D^0 \to K^+\pi^-\pi^0$ and $D^0 \to K^-\pi^+\pi^0$, or $D^+ \to K^+\pi^+\pi^-$ and $D^+ \to K^-\pi^+\pi^+$, are examples. Our average of three measurements of $\Gamma(D^0 \to K^+\pi^-\pi^0)/\Gamma(D^0 \to K^-\pi^+\pi^0)$ is $(2.20 \pm 0.10) \times 10^{-3}$. Our average of four measurements of $\Gamma(D^+ \to K^+\pi^-\pi^+)/\Gamma(D^+ \to K^-\pi^+\pi^+)$ is $(5.77 \pm 0.22) \times 10^{-3}$; see the Particle Listings.

The second class consists of decays in which the DCS and CF modes populate the same Dalitz plot; for example, $D^0 \to K^{*-}\pi^+$ and $D^0 \to K^{*+}\pi^-$ both contribute to $D^0 \to K^0_S\pi^+\pi^-$. In this class, the potential for interference of DCS and CF amplitudes increases the sensitivity to the DCS amplitude and allows direct measurement of the relative strong phases between amplitudes. CLEO [1] and Belle [6] have measured the relative phase between $D^0 \to K^*(892)^+\pi^-$ and $D^0 \to K^*(892)^-\pi^+$ to be $(189 \pm 10 \pm 3^{+15}_{-5})^\circ$ and $(171.9 \pm 1.3)^\circ$ (statistical error only). These results are close to the 180° expected from Cabibbo factors and a small strong phase.

In addition, Belle [6] has results for both the relative phase (statistical errors only) and ratio R (central values only) of the DCS fit fraction relative to the CF fit fractions for $K^*(892)^+\pi^-, K_0^*(1430)^+\pi^-, K_2^*(1430)^+\pi^-, K^*(1410)^+\pi^-, \text{ and }$ $K^*(1680)^+\pi^-$. The systematic uncertainties on R must be evaluated. The values for R in units of $\tan^4 \theta_c$ are 2.94 ± 0.12 , 22.0 ± 1.6 , 34 ± 4 , 87 ± 13 , and 500 ± 500 . For $K^{+}\pi^{-}$, the corresponding value for R_D is $(1.28 \pm 0.02) \times \tan^4 \theta_c$. Similarly, BABAR [7] has reported central values for R for $K^*(892)^+\pi^-$, $K_0^*(1430)^+\pi^-$, and $K_2^*(1430)^+\pi^-$. The values for R in units of $\tan^4 \theta_c$ are 3.45 ± 0.31, 7.7 ± 3.0, and 1.7 ± 1.7, respectively. Recently, BABAR [14] has used a K-matrix formalism to describe the $\pi\pi$ S-wave in $K_S^0\pi^+\pi^-$. The reported values for R in units of $\tan^4 \theta_c$ are 2.78 ± 0.11, 0.5 ± 0.2, and 1.4 ± 0.5, respectively. The large differences in R among these final states could point to an interesting role for hadronic effects.

There are other ways, not involving DCS decays, in which D^0 and $\overline{D}{}^0$ singly Cabibbo-suppressed decays can populate the same Dalitz plot. Examples are D^0 and $\overline{D}{}^0$ decays to $K_S^0K^+\pi^-$, or to $K_S^0K^-\pi^+$. These final states can be used to study $D^0-\overline{D}{}^0$ mixing and the CKM angle γ/ϕ_3 .

CP Violation: In the limit of CP conservation, charge conjugate decays will have the same Dalitz-plot distribution. The $D^{*\pm}$ tag enables the discrimination between D^0 and $\overline{D}{}^0$. The integrated CP violation across the Dalitz plot is determined in two ways. The first uses

$$\mathcal{A}_{CP} = \int \left(\frac{|\mathcal{M}|^2 - |\overline{\mathcal{M}}|^2}{|\mathcal{M}|^2 + |\overline{\mathcal{M}}|^2} \right) dm_{ab}^2 dm_{bc}^2 / \int dm_{ab}^2 dm_{bc}^2 , \quad (1)$$

where \mathcal{M} and $\overline{\mathcal{M}}$ have the same normalization and represent the D^0 and \overline{D}^0 Dalitz-plot amplitudes for the three-body decay $D \to abc$, and m_{ab} (m_{bc}) is the invariant mass of ab (bc). The second uses the asymmetry in the efficiency-corrected D^0 and \overline{D}^0 yields,

$$\mathcal{A}_{CP} = \frac{N_{D^0} - N_{\overline{D}^0}}{N_{D^0} + N_{\overline{D}^0}}.$$
 (2)

These expressions are less sensitive to CP violation than are the individual resonant submodes [24–26]. Our Particle Listings give limits on CP violation for 12 D^+ , 52 D^0 , and 13 D_S^+ decay modes. No evidence of CP violation has been observed in D-meson decays.

The possibility of interference between CP-conserving and CP-violating amplitudes provides a more sensitive probe of CP violation. The constraints on the square of the CP-violating amplitudes obtained in the resonant submodes of $D^0 \to K_S^0 \pi^+ \pi^-$ range from 3.5×10^{-4} to 28.4×10^{-4} at 95% confidence level [24]. A similar analysis has been performed by CLEO [25] searching for CP violation in $D^+ \to K^+ K^- \pi^+$. The constraints on the square of the CP-violating amplitudes in the resonant submodes range from 4×10^{-4} to 51×10^{-4} at 95%. BABAR finds no evidence for CP-violating amplitudes in the resonant submodes of $D^0 \to K^+ K^- \pi^0$ and $D^0 \to \pi^+ \pi^- \pi^0$ [26].

 $\Gamma \big((K^-\pi^+)_{S-\text{wave}} \pi^+ \big) / \Gamma \big(K^-2\pi^+ \big)$ This is the "fit fraction" from the Dalitz-plot analysis. The $K^-\pi^+$ S-wave includes a broad scalar κ $(\overline{K}_0^*(800))$, the $\overline{K}_0^*(1430)^0$, and non-resonant background.

 35 This LINK 09 model-independent partial-wave analysis of the $K^-\pi^+$ *S*-wave slices the

 $K^-\pi^+$ mass range into 39 bins. 36 The BONVICINI 08A QMIPWA (quasi-model-independent partial-wave analysis) of the $K^-\pi^+$ S-wave amplitude slices the $K^-\pi^+$ mass range into 26 bins but keeps the Breit-Wigner $\overline{K}_0^*(1430)^0$.

37 This LINK 07B fit uses a K matrix. The $K^-\pi^+$ S-wave fit fraction given above breaks down into $(207.3\pm25.5\pm12.4)\%$ isospin-1/2 and $(40.5\pm9.6\pm3.2)\%$ isospin-3/2 with large interference between the two. The isospin-1/2 component includes the κ (or $\overline{K}_0^*(800)^0$) and $\overline{K}_0^*(1430)^0$.

| $\Gamma(\overline{K}_0^*(800)^0\pi^+, \overline{K}_0^*(800) \to K^-\pi^+)/\Gamma(K^-2\pi^+)$ This is the "fit fraction" from the Dalitz-plot analysis. | | | | | | |

 04 FOCS
 Dalitz fit, 1527 ± 51 evts

 43 LINK 04 borrows a K-matrix parametrization from ANISOVICH 03 of the full π - π S-wave isoscalar scattering amplitude to describe the $\pi^+\pi^-$ S-wave component of the $\pi^+\pi^+\pi^-$ state. The fit fraction given above is a sum over five f_0 mesons, the $f_0(980)$, $f_0(1300)$, $f_0(1200-1600)$, $f_0(1500)$, and $f_0(1750)$. See LINK 04 for details and discussion.

 $\Gamma(\sigma\pi^+,\sigma\to\pi^+\pi^-)/\Gamma(2\pi^+\pi^-)$ This is the "fit fraction" from the Dalitz-plot analysis.

$D^0-\overline{D}{}^0$ MIXING

Revised March 2012 by D. Asner (Pacific Northwest National Laboratory)

The detailed formalism for $D^0-\overline{D}{}^0$ mixing is presented in the note on "CP Violation in Meson Decays" in this Review. For completeness, we present an overview here. The time evolution of the $D^0-\overline{D}{}^0$ system is described by the Schrödinger equation

$$i\frac{\partial}{\partial t} \left(\frac{D^{0}(t)}{\overline{D}^{0}(t)} \right) = \left(\mathbf{M} - \frac{i}{2} \Gamma \right) \left(\frac{D^{0}(t)}{\overline{D}^{0}(t)} \right), \tag{1}$$

where the **M** and Γ matrices are Hermitian, and CPT invariance requires that $M_{11}=M_{22}\equiv M$ and $\Gamma_{11}=\Gamma_{22}\equiv \Gamma$. The off-diagonal elements of these matrices describe the dispersive and absorptive parts of the mixing.

Because CP violation is expected to be quite small here, it is convenient to label the mass eigenstates by the CP quantum number in the limit of CP conservation. Thus, we write

$$|D_{1,2}\rangle = p|D^0\rangle \pm q|\overline{D}^0\rangle,$$
 (2)

where

$$\left(\frac{q}{p}\right)^2 = \frac{M_{12}^* - \frac{i}{2}\Gamma_{12}^*}{M_{12} - \frac{i}{2}\Gamma_{12}}.$$
 (3)

The normalization condition is $|p|^2 + |q|^2 = 1$. Our phase convention is $CP|D^0\rangle = +|\overline{D}^0\rangle$, and the sign is chosen so that D_1 has CP even, or nearly so.

 $^{^1}$ PERUZZI 77 and SCHINDLER 81 errors do not include the 0.13% uncertainty in the absolute SPEAR energy calibration. TRILLING 81 uses the high precision $J/\psi(1.5)$ and $\psi(2.5)$ measurements of ZHOLENTZ 80 to determine this uncertainty and combines the PERUZZI 77 and SCHINDLER 81 results to obtain the value quoted. TRILLING 81 enters the fit in the D^\pm mass, and PERUZZI 77 and SCHINDLER 81 enter in the $m_{D^\pm}-m_{D^0}$, below.

 D^0

The corresponding eigenvalues are

$$\omega_{1,2} \equiv m_{1,2} - \frac{i}{2}\Gamma_{1,2} = \left(M - \frac{i}{2}\Gamma\right) \pm \frac{q}{p}\left(M_{12} - \frac{i}{2}\Gamma_{12}\right),$$
 (4)

where $m_{1,2}$ and $\Gamma_{1,2}$ are the masses and widths of the $D_{1,2}$. We define dimensionless mixing parameters x and y by

$$x \equiv (m_1 - m_2)/\Gamma = \Delta m/\Gamma \tag{5}$$

and

$$y \equiv (\Gamma_1 - \Gamma_2)/2\Gamma = \Delta\Gamma/2\Gamma, \tag{6}$$

where $\Gamma \equiv (\Gamma_1 + \Gamma_2)/2$. If CP is conserved, then M_{12} and Γ_{12} are real, $\Delta m = 2M_{12}$, $\Delta \Gamma = 2\Gamma_{12}$, and $p = q = 1/\sqrt{2}$. The signs of Δm and $\Delta \Gamma$ are to be determined experimentally.

The parameters x and y are measured in several ways. The most precise values are obtained using the time dependence of D decays. Since $D^0 - \overline{D}{}^0$ mixing is a small effect, the identifying tag of the initial particle as a D^0 or a \overline{D}^0 must be extremely accurate. The usual tag is the charge of the distinctive slow pion in the decay sequence $D^{*+} \to D^0 \pi^+$ or $D^{*-} \to \overline{D}{}^0 \pi^-$. In current experiments, the probability of mistagging is about 0.1%. The large data samples produced at the B-factories allow the production flavor to also be determined by fully reconstructing charm on the "other side" of the event—significantly reducing the mistag rate [1]. Another tag of comparable accuracy is identification of one of the D's produced from $\psi(3770) \to D^0 \overline{D}{}^0$ decays. Although time-dependent analyses are not possible at symmetric charm-threshold facilities (the D^0 and \overline{D}^0 do not travel far enough), the quantum-coherent $C = -1 \ \psi(3770) \rightarrow D^0 \overline{D}{}^0$ state provides time-integrated sensitivity [2,3].

Time-Dependent Analyses: We extend the formalism of this Review's note on "CP Violation in Meson Decays." In addition to the "right-sign" instantaneous decay amplitudes $\overline{A}_f \equiv \langle f|H|\overline{D}^0\rangle$ and $A_{\overline{f}} \equiv \langle \overline{f}|H|D^0\rangle$ for CP conjugate final states $f=K^+\pi^-,\ldots$ and $\overline{f}=K^-\pi^+,\ldots$, we include "wrongsign" amplitudes $\overline{A}_{\overline{f}} \equiv \langle \overline{f}|H|\overline{D}^0\rangle$ and $A_f \equiv \langle f|H|D^0\rangle$.

It is conventional to normalize the wrong-sign decay distributions to the integrated rate of right-sign decays and to express time in units of the precisely measured neutral D-meson mean lifetime, $\tau_{D^0} = 1/\Gamma = 2/(\Gamma_1 + \Gamma_2)$. Starting from a pure $|D^0\rangle$ or $|\overline{D}^0\rangle$ state at t=0, the time-dependent rates of decay to wrong-sign final states relative to the integrated right-sign decay rates are, to leading order:

$$r(t) \equiv \frac{\left| \langle f|H|D^{0}(t)\rangle \right|^{2}}{\left| \overline{A}_{f} \right|^{2}} = \left| \frac{q}{p} \right|^{2} \left| g_{+}(t) \lambda_{f}^{-1} + g_{-}(t) \right|^{2}, \quad (7)$$

and

$$\overline{r}(t) \equiv \frac{\left| \langle \overline{f} | H | \overline{D}^{0}(t) \rangle \right|^{2}}{\left| A_{\overline{f}} \right|^{2}} = \left| \frac{p}{q} \right|^{2} \left| g_{+}(t) \lambda_{\overline{f}} + g_{-}(t) \right|^{2}. \tag{8}$$

where

$$\lambda_f \equiv q \overline{A}_f / p A_f \,, \quad \lambda_{\bar{f}} \equiv q \overline{A}_{\bar{f}} / p A_{\bar{f}} \,,$$
 (9)

and

$$g_{\pm}(t) = \frac{1}{2} \left(e^{-iz_1 t} \pm e^{-iz_2 t} \right), \quad z_{1,2} = \frac{\omega_{1,2}}{\Gamma}.$$
 (10)

Note that a change in the convention for the relative phase of D^0 and $\overline{D}{}^0$ would cancel between q/p and \overline{A}_f/A_f and leave λ_f unchanged. We expand r(t) and $\overline{r}(t)$ to second order in x and y for modes in which the ratio of decay amplitudes, $R_D = |A_f/\overline{A}_f|^2$, is very small.

Semileptonic decays: Consider the final state $f=K^+\ell^-\bar{\nu}_\ell$, where $A_f=\overline{A}_{\overline{f}}=0$ in the Standard Model. The final state f is only accessible through mixing and r(t) is

$$r(t) = |g_{-}(t)|^{2} \left| \frac{q}{p} \right|^{2} \approx \frac{e^{-t}}{4} (x^{2} + y^{2}) t^{2} \left| \frac{q}{p} \right|^{2}$$
 (11)

For $\overline{r}(t)$ q/p is replaced by p/q. In the Standard Model, CP violation in charm mixing is small and $|q/p|\approx 1$. In the limit of CP conservation, $r(t)=\overline{r}(t)$, and the time-integrated mixing rate relative to the time-integrated right-sign decay rate for semileptonic decays is

$$R_M = \int_0^\infty r(t)dt = \left| \frac{q}{p} \right|^2 \frac{x^2 + y^2}{2 + x^2 - y^2} = \frac{1}{2} (x^2 + y^2).$$
 (12)

Table 1: Results for R_M in D^0 semileptonic decays.

| Year | Exper. | Final state(s) | $R_M \ (\times 10^{-3})$ | 90% C.L. |
|-------|--------------------------------|-----------------------------------|--------------------------------------|-----------------------------|
| 2008 | Belle [4] | $K^{(*)+}e^{-}\overline{\nu}_{e}$ | $0.13\pm0.22\pm0.20$ | $< 0.61 \times 10^{-3}$ |
| 2007 | BaBar [1] | $K^{(*)+}e^{-}\overline{\nu}_{e}$ | $0.04^{+0.70}_{-0.60}$ | $(-1.3, 1.2)\times 10^{-3}$ |
| 2005* | Belle [5] | $K^{(*)+}e^{-}\overline{\nu}_{e}$ | $0.02 \pm 0.47 \pm 0.14$ | $< 1.0 \times 10^{-3}$ |
| 2005 | CLEO [6] | $K^{(*)+}e^{-}\overline{\nu}_{e}$ | $1.6 \pm 2.9 \pm 2.9$ | $< 7.8 \times 10^{-3}$ |
| 2004* | BaBar [7] | $K^{(*)+}e^{-}\overline{\nu}_{e}$ | $2.3 \!\pm\! 1.2 \!\pm\! 0.4$ | $< 4.2 \times 10^{-3}$ |
| 2002* | $\mathrm{FOCUS}\left[8\right]$ | $K^+\mu^-\overline{\nu}_\mu$ | $-0.76^{+0.99}_{-0.93}$ | $<1.01\times10^{-3}$ |
| 1996 | E791 [9] | $K^+\ell^-\overline{\nu}_\ell$ | $(1.1^{+3.0}_{-2.7}) \times 10^{-3}$ | $<5.0\times10^{-3}$ |
| | HFAG [10] | | 0.13 ± 0.27 | |

*These measurements are excluded from the HFAG average. The FOCUS result is unpublished, the BaBar result has been superseded by Ref. 1, and the Belle result has been superseded by Ref. 4.

Table 1 summarizes results for R_M from semileptonic decays; the world average from the Heavy Flavor Averaging Group (HFAG) [10] is $R_M = (1.30 \pm 2.69) \times 10^{-4}$.

Wrong-sign decays to hadronic non-CP eigenstates: Consider the final state $f = K^+\pi^-$, where A_f is doubly Cabibbo-suppressed. The ratio of decay amplitudes is

$$\frac{A_f}{\overline{A}_f} = -\sqrt{R_D} e^{-i\delta_f}, \quad \left| \frac{A_f}{\overline{A}_f} \right| \sim O(\tan^2 \theta_c), \quad (13)$$

where R_D is the doubly Cabibbo-suppressed (DCS) decay rate relative to the Cabibbo-favored (CF) rate, δ_f is the strong phase difference between DCS and CF processes, and θ_c is the Cabibbo angle. The minus sign originates from the sign of V_{us} relative to V_{cd} .

 $D^{(}$

We characterize the violation of CP with the real-valued parameters A_M , A_D , and ϕ . We adopt the parametrization (see Refs. 11 and 12)

$$\left|\frac{q}{p}\right|^2 = \sqrt{\frac{1+A_M}{1-A_M}},\tag{14}$$

$$\lambda_f^{-1} \equiv \frac{pA_f}{q\overline{A}_f} = -\sqrt{R_D} \left(\frac{(1+A_D)(1-A_M)}{(1-A_D)(1+A_M)} \right)^{1/4} e^{-i(\delta_f + \phi)}, \tag{15}$$

$$\lambda_{\overline{f}} \equiv \frac{q\overline{A_{\overline{f}}}}{pA_{\overline{f}}} = -\sqrt{R_D} \left(\frac{(1 - A_D)(1 + A_M)}{(1 + A_D)(1 - A_M)} \right)^{1/4} e^{-i(\delta_f - \phi)}, \tag{16}$$

and A_D is a measure of direct CP violation, while A_M is a measure of CP violation in mixing. From these relations, we obtain

$$\sqrt{\frac{1+A_D}{1-A_D}} = \frac{|A_f/\overline{A}_f|}{|\overline{A}_f/A_f|} , \qquad (17)$$

The angle ϕ measures CP violation in interference between mixing and decay. While A_M is independent of the decay process, A_D and ϕ , in general, depend on f.

In general, $\lambda_{\overline{f}}$ and λ_f^{-1} are independent complex numbers. More detail on CP violation in meson decays can be found in Ref. 13. To leading order, for A_D and $A_M \ll 1$,

$$r(t) = e^{-t} \left[R_D(1 + A_D) + \sqrt{R_D(1 + A_M)(1 + A_D)} y_-' t + \frac{1}{2} (1 + A_M) R_M t^2 \right]$$
(18)

and

$$\overline{r}(t) = e^{-t} \left[R_D (1 - A_D) + \sqrt{R_D (1 - A_M)(1 - A_D)} y'_+ t + \frac{1}{2} (1 - A_M) R_M t^2 \right]$$
(19)

Here

$$y'_{\pm} \equiv y' \cos \phi \pm x' \sin \phi$$

= $y \cos(\delta_{K\pi} \mp \phi) - x \sin(\delta_{K\pi} \mp \phi)$, (20)

where

$$x' \equiv x \cos \delta_{K\pi} + y \sin \delta_{K\pi},$$

$$y' \equiv y \cos \delta_{K\pi} - x \sin \delta_{K\pi} \,, \tag{21}$$

and $R_M = (x^2 + y^2)/2 = (x'^2 + y'^2)/2$ is the mixing rate relative to the time-integrated Cabibbo-favored rate.

The three terms in Eq. (18) and Eq. (19) probe the three fundamental types of CP violation. In the limit of CP conservation, A_M , A_D , and ϕ are all zero. Then

$$r(t) = \overline{r}(t) = e^{-t} \left(R_D + \sqrt{R_D} y' t + \frac{1}{2} R_M t^2 \right),$$
 (22)

and the time-integrated wrong-sign rate relative to the integrated right-sign rate is

$$R = \int_0^\infty r(t) \, dt = R_D + \sqrt{R_D} \, y' + R_M \,. \tag{23}$$

The ratio R is the most readily accessible experimental quantity. In Table 2 are reported the measurements of R, R_D and A_D in $D^0 \to K^+\pi^-$, and their HFAG average [20] from a general fit; all allow for both mixing and CP violation. Typically, the fit parameters are R_D , x'^2 , and y'. Table 3 summarizes the results for x'^2 and y'. Allowing for CP violation, the separate contributions to R can be extracted by fitting the $D^0 \to K^+\pi^-$ and $\overline{D}^0 \to K^-\pi^+$ decay rates.

Table 2: Results for R, R_D , and A_D in $D^0 \rightarrow K^+\pi^-$.

| Year | Exper. | $R(\times 10^{-3})$ | $R_D(\times 10^{-3})$ | $A_D(\%)$ |
|-------|-------------------|---------------------------------|---------------------------------|-------------------------|
| 2007 | CDF [14] | 4.15 ± 0.10 | 3.04 ± 0.55 | _ |
| 2007 | BaBar [15] | $3.53 \pm 0.08 \pm 0.04$ | $3.03\pm0.16\pm0.10$ | $-2.1 \pm 5.2 \pm 1.5$ |
| 2006 | Belle [16] | $3.77\!\pm\!0.08\!\pm\!0.05$ | $3.64 \!\pm\! 0.17$ | $2.3 \!\pm\! 4.7$ |
| | ${\rm FOCUS}[17]$ | 0.01 | $5.17^{+1.47}_{-1.58} \pm 0.76$ | $13^{+33}_{-25} \pm 10$ |

| 1998 | E791[19] | $6.8^{+3.4}_{-3.3} \pm 0.7$ | _ | _ |
| | Average | 3.80 ± 0.05 | 3.31 ± 0.08 [20] | -1.7 ± 2.4 [20] |

^{*}These measurements are excluded from the HFAG average due to poor precision.

Table 3: Results on the time-dependence of r(t) in $D^0 \to K^+\pi^-$ and $\overline{D}{}^0 \to K^-\pi^+$ decays. The CDF result assumes no CP violation. The FOCUS, CLEO, and Belle results restrict x'^2 to the physical region. The confidence intervals from FOCUS, CLEO, and BaBar are obtained from the fit, whereas Belle uses a Feldman-Cousins method, and CDF uses a Bayesian method.

| Year Exper. | y' (%) | $x'^{2} (\times 10^{-3})$ |
|-----------------|----------------------------------|-------------------------------|
| 2007 CDF [14] | 0.85 ± 0.76 | -0.12 ± 0.35 |
| 2007 BaBar [15] | $0.97 \!\pm\! 0.44 \!\pm\! 0.31$ | $-0.22 \pm 0.30 \pm 0.21$ |
| 2006 Belle [16] | -2.8 < y' < 2.1 | < 0.72~(95%~C.L.) |
| 2005 FOCUS [17] | -11.2 < y' < 6.7 | < 8.0 (95% C.L.) |
| 2000 CLEO [18] | -5.8 < y' < 1.0 | $< 0.81 (95\% \mathrm{C.L.})$ |

Extraction of the mixing parameters x and y from the results in Table 3 requires knowledge of the relative strong phase $\delta_{K\pi}$. An interference effect that provides useful sensitivity to $\delta_{K\pi}$ arises in the decay chain $\psi(3770){\to}D^0\overline{D}^0{\to}(f_{CP})(K^+\pi^-)$, where f_{CP} denotes a CP-even or -odd eigenstate from D^0 decay, such as K^+K^- or $K^0_S\pi^0$, respectively [23]. Here, the amplitude relation

$$\sqrt{2} A(D_{\pm} \to K^{-} \pi^{+}) = A(D^{0} \to K^{-} \pi^{+}) \pm A(\overline{D}^{0} \to K^{-} \pi^{+}).$$
(24)

where D_{\pm} denotes a CP-even or -odd eigenstate, implies that

$$\cos \delta_{K\pi} = \frac{|A(D_+ \to K^- \pi^+)|^2 - |A(D_- \to K^- \pi^+)|^2}{2\sqrt{R_D} |A(D^0 \to K^- \pi^+)|^2}.$$
 (25)

This neglects CP violation and uses $\sqrt{R_D} \ll 1$.

For multibody final states, Eqs. (13)–(23) apply separately to each point in phase-space. Although x and y do not vary across the space, knowledge of the resonant substructure is

D^{0}

needed to extrapolate the strong phase difference δ from point to point to determine x and y.

A time-dependent analysis of the process $D^0 \to K^+\pi^-\pi^0$ from BaBar [21,22] determines the *relative* strong phase variation across the Dalitz plot and reports $x'' = (2.61^{+0.57}_{-0.68} \pm 0.39)\%$, and $y'' = (-0.06^{+0.55}_{-0.64} \pm 0.34)\%$, where x'' and y'' are defined as

$$x'' \equiv x \cos \delta_{K\pi\pi^0} + y \sin \delta_{K\pi\pi^0},$$

$$y'' \equiv y \cos \delta_{K\pi\pi^0} - x \sin \delta_{K\pi\pi^0},$$
(26)

in parallel to x', y', and $\delta_{K\pi}$ of Eq. (21). Here $\delta_{K\pi\pi^0}$ is the remaining strong phase difference between the DCS $D^0 \to K^+\rho^-$ and the CF $\overline{D}{}^0 \to K^+\rho^-$ amplitudes and does not vary across the Dalitz plot. Both strong phases, $\delta_{K\pi}$ and $\delta_{K\pi\pi^0}$, can be determined from time-integrated CP asymmetries in correlated $D^0\overline{D}{}^0$ produced at the $\psi(3770)$ [23,24].

Both the sign and magnitude of x and y without phase or sign ambiguity may be measured using the time-dependent resonant substructure of multibody D^0 decays [25,26]. In $D^0 \to K_S^0 \pi^+ \pi^-$, the DCS and CF decay amplitudes populate the same Dalitz plot, which allows direct measurement of the relative strong phases. CLEO [27], Belle [26], and BaBar [28] have measured the relative phase between $D^0 \to K^*(892)^-\pi^+$ and $D^0 \to K^*(892)^+\pi^-$ to be $(189 \pm 10 \pm 3^{+15}_{-5})^\circ$, $(171.9 \pm 1.3 \text{ (stat. only)})^\circ$, and $(177.6 \pm 1.1 \text{ (stat. only)})^\circ$, respectively. These results are close to the 180° expected from Cabibbo factors and a small strong phase. Table 4 summarizes the results of a time-dependent Dalitz-plot analyses.

Table 4: Results from time-dependent Dalitz-plot analysis of $D^0 \to K_S^0 \pi^+ \pi^-$ (CLEO and Belle) and $D^0 \to K_S^0 \pi^+ \pi^-, K_S^0 K^+ K^-$ (BaBar). The errors are statistical, experimental systematic, and decay-model systematic, respectively.

| | No CP Violation | | | | | | | |
|------|-----------------|----------------------------------------------------------|-----------------------------------------------------|--|--|--|--|--|
| Year | Exper. | $x \times 10^{-3}$ | $y \times 10^{-3}$ | | | | | |
| 2010 | BaBar [28] | $1.6 \pm 2.3 \pm 1.2 \pm 0.8$ | $5.7 \pm 2.0 \pm 1.3 \pm 0.7$ | | | | | |
| 2007 | Belle [26] | $8.0 \pm 2.9^{+0.9}_{-0.7}{}^{+1.0}_{-1.4}$ | $3.3 \pm 2.4^{+0.8}_{-1.2}{}^{+0.6}_{-0.8}$ | | | | | |
| 2005 | CLEO [25] | $19^{+32}_{-33} \pm 4 \pm 4$ | $-14 \pm 24 \pm 8 \pm 4$ | | | | | |
| | HFAG [20] | 4.2 ± 2.1 | 4.6 ± 1.9 | | | | | |
| - | | With CP Violation | 1 | | | | | |
| Year | Exper. | q/p | ϕ | | | | | |
| 2007 | Belle [26] | $0.86^{+0.30}_{-0.29}^{+0.06}_{-0.03}^{+0.06}_{\pm0.08}$ | $(-14^{+16}_{-18}{}^{+5}_{-3}{}^{+2}_{-4})^{\circ}$ | | | | | |

In addition, Belle [26] has results for both the relative phase (statistical errors only) and ratio R (central values only) of the DCS fit fraction relative to the CF fit fractions for $K^*(892)^+\pi^-$, $K_0^*(1430)^+\pi^-$, $K_2^*(1430)^+\pi^-$, $K^*(1410)^+\pi^-$, and $K^*(1680)^+\pi^-$. The systematic uncertainties on R must be evaluated. The values for R in units of $\tan^4\theta_c$ are 2.94 ± 0.12 , 22.0 ± 1.6 , 34 ± 4 , 87 ± 13 , and 500 ± 500 , respectively. For $K^+\pi^-$, the corresponding value for R_D is $(1.28 \pm 0.02) \times \tan^4\theta_c$.

Similarly, BaBar [28–30] has reported central values for R for $K^*(892)^+\pi^-$, $K_0^*(1430)^+\pi^-$, and $K_2^*(1430)^+\pi^-$. The large differences in R among these final states could point to an interesting role for hadronic effects.

Decays to CP Eigenstates: When the final state f is a CP eigenstate, there is no distinction between f and \overline{f} , and $A_f = A_{\overline{f}}$ and $\overline{A}_{\overline{f}} = \overline{A}_f$. We denote final states with CP eigenvalues ± 1 by f_{\pm} and write λ_{\pm} for $\lambda_{f_{\pm}}$.

The quantity y may be measured by comparing the rate for D^0 decays to non-CP eigenstates such as $K^-\pi^+$ with decays to CP eigenstates such as K^+K^- [12]. If decays to K^+K^- have a shorter effective lifetime than those to $K^-\pi^+$, y is positive.

In the limit of slow mixing $(x, y \ll 1)$ and the absence of direct CP violation $(A_D = 0)$, but allowing for small indirect CP violation $(|A_M|, |\phi| \ll 1)$, we can write

$$\lambda_{\pm} = \left| \frac{q}{p} \right| e^{\pm i\phi} \ . \tag{27}$$

In this scenario, to a good approximation, the decay rates for states that are initially D^0 and $\overline{D}{}^0$ to a CP eigenstate have exponential time dependence:

$$r_{\pm}(t) \propto \exp\left(-t/\tau_{\pm}\right) ,$$
 (28)

$$\overline{r}_{\pm}(t) \propto \exp\left(-t/\overline{\tau}_{\pm}\right) ,$$
 (29)

where τ is measured in units of $1/\Gamma$.

The effective lifetimes are given by

$$1/\tau_{\pm} = 1 \pm \left| \frac{q}{p} \right| (y \cos \phi - x \sin \phi) , \qquad (30)$$

$$1/\overline{\tau}_{\pm} = 1 \pm \left| \frac{p}{q} \right| (y \cos \phi + x \sin \phi) . \tag{31}$$

The effective decay rate to a CP eigenstate combining both D^0 and $\overline{D}{}^0$ decays is

$$r_{\pm}(t) + \overline{r}_{\pm}(t) \propto e^{-(1 \pm y_{CP})t}$$
 (32)

Here

$$y_{CP} = \frac{1}{2} \left(\left| \frac{q}{p} \right| + \left| \frac{p}{q} \right| \right) y \cos \phi - \frac{1}{2} \left(\left| \frac{q}{p} \right| - \left| \frac{p}{q} \right| \right) x \sin \phi \quad (33)$$

$$\approx y \cos \phi - A_M x \sin \phi$$
 (34)

If CP is conserved, $y_{CP} = y$.

All measurements of y_{CP} and A_{Γ} are relative to the $D^0 \to K^-\pi^+$ decay rate. Table 5 summarizes the current status of measurements. Belle [35], BaBar [32,34], and LHCb [31] have reported y_{CP} and the decay-rate asymmetry for CP even final states

$$A_{\Gamma} = \frac{\overline{\tau}_{+} - \tau_{+}}{\overline{\tau}_{+} + \tau_{+}} = \frac{(1/\tau_{+}) - (1/\overline{\tau}_{+})}{(1/\tau_{+}) + (1/\overline{\tau}_{+})}$$
(35)

$$=\frac{1}{2}\left(\left|\frac{q}{p}\right|-\left|\frac{p}{q}\right|\right)y\cos\phi-\frac{1}{2}\left(\left|\frac{q}{p}\right|+\left|\frac{p}{q}\right|\right)x\sin\phi \ \ (36)$$

$$\approx A_M y \cos \phi - x \sin \phi$$
 (37)

Table 5: Results for y_{CP} from $D^0 \rightarrow K^+K^-$ and $\pi^+\pi^-$.

| Year | Exper. | final state(s) | $y_{CP}(\%)$ | $A_{\Gamma}(\times 10^{-3})$ |

^{*}This measurement is included in the result reported by Ref. 32.

Belle [33] has also reported y_{CP} for the final state $K_S^0K^+K^-$ which is dominated by the CP odd final state $K_S^0\phi$. If CP is conserved, $A_{\Gamma}=0$.

Substantial work on the time-integrated CP asymmetries in decays to CP eigenstates are consistent [40]. Recently, LHCb has reported 3.5σ evidence for the difference in time-integrated CP asymmetry, $\Delta A_{CP} = A_K - A_\pi$, between $D^0 \to K^-K^+$ and $D^0 \to \pi^-\pi^+$, yielding $\Delta A_{CP} = [-0.82 \pm 0.21(stat.) \pm 0.11(sys.)]\%$ [41]. Subsequently, CDF has reported $\Delta A_{CP} = [-0.62 \pm 0.21(stat.) \pm 0.10(sys.)]\%$ [42].

Coherent $D^0\overline{D}^0$ Analyses: Measurements of R_D , $\cos \delta_{K\pi}$, $\sin \delta_{K\pi}$, x, and y can be determined simultaneously from a combined fit to the time-integrated single-tag (ST) and double-tag (DT) yields in correlated $D^0\overline{D}^0$ produced at the $\psi(3770)$ [23,24].

Due to quantum correlations in the C=-1 and C=+1 $D^0\overline{D}{}^0$ pairs produced in the reactions $e^+e^-\to D^0\overline{D}{}^0(\pi^0)$ and $e^+e^-\to D^0\overline{D}{}^0\gamma(\pi^0)$, respectively, the time-integrated $D^0\overline{D}{}^0$ decay rates are sensitive to interference between amplitudes for indistinguishable final states. The size of this interference is governed by the relevant amplitude ratios and can include contributions from $D^0-\overline{D}{}^0$ mixing.

The following categories of final states are considered:

f or \bar{f} : Hadronic states accessed from either D^0 or \overline{D}^0 decay but that are not CP eigenstates. An example is $K^-\pi^+$, which results from Cabibbo-favored D^0 transitions or DCS \overline{D}^0 transitions.

 ℓ^+ or ℓ^- : Semileptonic or purely leptonic final states, which, in the absence of mixing, tag unambiguously the flavor of the parent D^0 .

 f_+ or f_- : CP-even and CP-odd eigenstates, respectively.

The decay rates for $D^0\overline{D}^0$ pairs to all possible combinations of the above categories of final states are calculated in Ref. 2, for both C=-1 and C=+1, reproducing the work of Ref. 3. Such $D^0\overline{D}^0$ combinations, where both D final states are specified, are double tags. In addition, the rates for single tags, where either the D^0 or \overline{D}^0 is identified and the other neutral D decays generically are given in Ref. 2.

CLEO-c has reported results using 818 pb⁻¹ of $e^+e^- \rightarrow \psi(3770)$ data [43–45], where the quantum-coherent $D^0\overline{D}^0$ pairs are in the C=-1 state. The values of $y,\ R_M,\ \cos\delta_{K\pi}$, and $\sin\delta_{K\pi}$ are determined from a combined fit to the ST (hadronic only) and DT yields. The hadronic final states included are $K^-\pi^+(f),\ K^+\pi^-(\bar{f}),\ K^-K^+(f_+),\ \pi^+\pi^-(f_+),\ K^0_S\pi^0\pi^0$ $(f_+),\ K^0_L\pi^0(f_+),\ K^0_L\pi^0(f_+),\ K^0_L\pi^0(f_+),\ K^0_S\pi^0(f_-),\ K^0_S\pi^0(f_-),\ K^0_S\pi^0(f_-),\ And\ K^0_L\pi^0\pi^0(f_-),\ and\ K^0_S\pi^+\pi^-$ (mixure of $f,\bar{f},\ f_+$, and f_-). The two flavored final states, $K^-\pi^+$ and $K^+\pi^-$, can be reached via CF or DCS transitions.

Semileptonic DT yields are also included, where one D is fully reconstructed in one of the hadronic modes listed above, and the other D is partially reconstructed in either $D \to Ke\nu$ or $D \to K\mu\nu$. When the lepton is accompanied by a flavor tag $(D \to K^-\pi^+ \text{ or } K^+\pi^-)$, both the "right-sign" and "wrongsign" DT samples are used, where the electron and kaon charges are the same and opposite, respectively.

The main results of the CLEO-c analysis are the determination of $\cos \delta_{K\pi} = 0.98^{+0.27}_{-0.20} \pm 0.08$, $\sin \delta_{K\pi} = -0.04 \pm 0.49 \pm 0.08$, and World Averages for the mixing parameters from an "extended" fit that combines the CLEO-c data with previous mixing and branching-ratio measurements [45]. These fits allow $\cos \delta_{K\pi}$, $\sin \delta_{K\pi}$ and x^2 to be unphysical. Constraining $\cos \delta_{K\pi}$ and $\sin \delta_{K\pi}$ to [-1,+1]—that is interpreting $\delta_{K\pi}$ as an angle—yields $\delta_{K\pi} = (15^{+11}_{-17} \pm 7)^{\circ}$. Note that measurements of y (Table 4 and Table 5) and y' (Table 3) contribute to the determination of $\delta_{K\pi}$.

Summary of Experimental Results: Several recent results indicate that charm mixing is at the upper end of the range of Standard Model estimates.

For $D^0 \to K^+\pi^-$, BaBar [15] and CDF [14] find evidence for oscillations with 3.9σ ($\Delta \text{Log}\mathcal{L}$) and 3.8σ (Bayesian), respectively. The most precise measurement for mixing parameters is from Belle [16], which excludes $x'^2 = y' = 0$ at 2.1σ .

For y_{CP} in $D^0 \to K^+K^-$ and $\pi^+\pi^-$, Belle [35] and BaBar [32] find 3.2 σ and 4.1 σ effects. The most sensitive measurement of x and y is in $D^0 \to K_S^0\pi^+\pi^-$, $K_S^0K^+K^-$ from BaBar [28] and the no mixing solution is only excluded at 1.9 σ . The current situation would benefit from better knowledge of the strong phase difference $\delta_{K\pi}$ than provided by the current CLEO-c result [45]. This would allow one to unfold x and y from the $D^0 \to K^+\pi^-$ measurements of x'^2 and y', and directly compare them to the $D^0 \to K_S^0\pi^+\pi^-$ results.

The experimental data consistently indicate that the D^0 and $\overline{D}{}^0$ do mix. The mixing is presumably dominated by long-range processes. Under the assumption that the observed mixing is due entirely to short-range processes, significant constraints on a variety of new physics models are obtained [46]. A serious limitation to the interpretation of charm oscillations in terms of New Physics is the theoretical uncertainty of the Standard Model prediction. However, recent evidence opens the window to searches for CP violation in mixing, which would provide unequivocal evidence of New Physics. The evidence for time

D^0

integrated CP-violation, $\Delta A_{CP} \neq 0$, observed by LHCb is intriguing. This result is marginally consistent with Standard Model expectation [47–49].

HFAG Averaging of Charm Mixing Results:

The Heavy Flavor Averaging Group (HFAG) has made a global fit to all mixing measurements to obtain values of $x,\ y,\ \delta_{K\pi},\ \delta_{K\pi\pi^0},\ R_D,\ A_D\equiv (R_D^+-R_D^-)/(R_D^++R_D^-),\ |q/p|,$ Arg $(q/p)\equiv\phi,$ and the time-integrated CP asymmetries A_K and $A_\pi.$ Correlations among observables are taken into account by using the error matrices from the experiments. The measurements of $D^0\to K^{(*)}+\ell^-\overline{\nu},\ K^+K^-,\ \pi^+\pi^-,\ K^+\pi^-,\ K^+\pi^-\pi^0,\ K^+\pi^-\pi^+\pi^-,\ K_S^0\pi^+\pi^-,\ {\rm and}\ K_S^0K^+K^-$ decays, as well as CLEO-c results for double-tagged branching fractions measured at the $\psi(3770)$ are used.

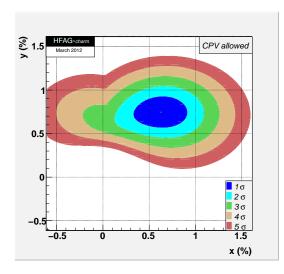

Figure 1: Two-dimensional 1σ - 5σ contours for (x,y) from measurements of $D^0 \rightarrow K^{(*)+}\ell\nu$, h^+h^- , $K^+\pi^-$, $K^+\pi^-\pi^0$, $K^+\pi^-\pi^+\pi^-$, $K^0_S\pi^+\pi^-$, and $K^0_SK^+K^-$ decays, and double-tagged branching fractions measured at the $\psi(3770)$ resonance (from HFAG [20]).

Table 6: HFAG Charm Mixing Average allowing for CP violation [20].

| Parameter | HFAG average | 95% C.L. interval |
|------------------------------|------------------------|-------------------|
| x(%) | $0.63^{+0.19}_{-0.20}$ | [0.24, 0.99] |
| y(%) | 0.75 ± 0.12 | [0.51, 0.98] |
| $R_D(\%)$ | 0.331 ± 0.008 | [0.315, 0.347] |
| $\delta_{K\pi}(^{\circ})$ | $22.1^{+9.7}_{-11.1}$ | [-2.6, 40.6] |
| $\delta_{K\pi\pi^0}(^\circ)$ | 19 ± 22 | [-26, 62] |
| $A_D(\%)$ | -1.7 ± 2.4 | [-6.4, 3.0] |
| q/p | $0.88^{+0.18}_{-0.16}$ | [0.59, 1.26] |
| $\phi(^{\circ})$ | $-10.1^{+9.5}_{-8.9}$ | [-27.4, 8.7] |
| A_K | -0.31 ± 0.24 | [-0.78, 0.15] |
| A_{π} | 0.36 ± 0.25 | [-0.13, 0.86] |

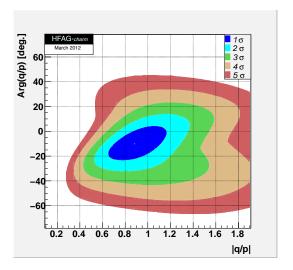

Figure 2: Two-dimensional 1σ -5 σ contours for $(|q/p|, \operatorname{Arg}(q/p))$ from measurements of $D^0 \to K^{(*)}+\ell\nu$, h^+h^- , $K^+\pi^-$, $K^+\pi^-\pi^0$, $K^+\pi^-\pi^+\pi^-$, $K^0_S\pi^+\pi^-$, and $K^0_SK^+K^-$ decays, and double-tagged branching fractions measured at the $\psi(3770)$ resonance (from HFAG [20]) .

For the global fit, confidence contours in the two dimensions (x,y) and $(|q/p|,\phi)$ are obtained by letting, for any point in the two-dimensional plane, all other fit parameters take their preferred values. Figures 1 and 2 show the resulting 1-to-5 σ contours. The fits exclude the no-mixing point (x=y=0) at 10.2σ , whether or not CP violation is allowed. The parameters x and y differ from zero by 2.7σ and 6.0σ , respectively. One-dimensional likelihood functions for parameters are obtained by allowing, for any value of the parameter, all other fit parameters to take their preferred values. The resulting likelihood functions give central values, 68.3% C.L. intervals, and 95% C.L. intervals as listed in Table 6.

From the results of the HFAG averaging, the following can be concluded: (1) Since CP violation is small and y_{CP} is positive, the CP-even state is shorter-lived, as in the $K^0\overline{K}^0$ system; (2) However, since x appears to be positive, the CP-even state is heavier, unlike in the $K^0\overline{K}^0$ system; (3) The strong phase difference $\delta_{K\pi}$ is consistent with the SU(3) expectation of zero but large values are not excluded; (4) There is no evidence yet for CP-violation in $D^0\overline{D}^0$ mixing. Observing CP-violation in mixing at the current level of sensitivity would indicate new physics.

$\left|m_{D_1^0}-m_{D_2^0}\right|=x\ \Gamma$

The D_1^0 and D_2^0 are the mass eigenstates of the D^0 meson, as described in the note on " D^0 - \overline{D}^0 Mixing,' above. The experiments usually present $x \equiv \Delta m/\Gamma$. Then $\Delta m = x \Gamma = x \hbar/\tau$.

"OUR EVALUATION" comes from averages provided by the Heavy Flavor Averaging Group, see the note on " \mathcal{D}^0 - $\overline{\mathcal{D}}^0$ Mixing."

 1 DEL-AMO-SANCHEZ 10D uses 540,800 \pm 800 K_S^0 π^+ π^- and 79,900 \pm 300 K_S^0 K^+ K^- events in a time-dependent amplitude analysis of the D^0 and \overline{D}^0 Dalitz plots. No evidence was found for $\it CP$ violation, and the values here assume no such violation.

 2 The ASNER 05 and ZHANG 07B values are from the time-dependent Dalitz-plot analysis of $D^0 \rightarrow \ K^0_0 \pi^+ \pi^-$. Decay-time information and interference on the Dalitz plot are used to distinguish doubly Cabibbo-suppressed decays from mixing and to measure the relative phase between $D^0 \rightarrow \ K^{*+} \pi^-$ and $\overline{D}^0 \rightarrow \ K^{*+} \pi^-$. This value allows CP violation and is sensitive to the sign of Δm .

 3 The AUBERT 09AN values are inferred from the branching ratio $\Gamma(D^0\to K^+\pi^-\pi^0$ via $\overline{D}^0)/\Gamma(D^0\to K^-\pi^+\pi^0)$ given near the end of this Listings. Mixing is distinguished from DCS decays using decay-time information. Interference between mixing and DCS is allowed. The phase between $D^0\to K^+\pi^-\pi^0$ and $\overline{D}^0\to K^+\pi^-\pi^0$ is assumed to be small. The width difference here is $y^{\prime\prime}$, which is not the same as y_{CP} in the note on $D^0-\overline{D}^0$ mixing.

 4 LOWREY 09 uses quantum correlations in $e^+e^-\to D^0\overline{D}^0$ at the $\psi(3770)$. See below for coherence factors and average relative strong phases for both $D^0\to K^-\pi^+\pi^0$ and $D^0\to K^-\pi^-2\pi^+$. A fit that includes external measurements of charm mixing parameters gets $\Delta m=(2.34\pm0.61)\times10^{10}~\hbar\,\mathrm{s}^{-1}$.

⁵ The AUBERT 03z, LI 05A, and ZHANG 06 limits are inferred from the $D^0-\overline{D}^0$ mixing ratio $\Gamma(K^+\pi^-)$ (via \overline{D}^0))/ $\Gamma(K^-\pi^+)$ given near the end of this D^0 Listings. Decaytime information is used to distinguish DCS decays from $D^0-\overline{D}^0$ mixing. The limit allows interference between the DCS and mixing ratios, and also allows CP violation. AUBERT 03z assumes the strong phase between $D^0\to K^+\pi^-$ and $\overline{D}^0\to K^+\pi^-$ amplitudes is small; if an arbitrary phase is allowed, the limit degrades by 20%. The LI 05A and ZHANG 06 limits are valid for an arbitrary strong phase. 6 This LINK 05H limit is inferred from the $D^0-\overline{D}^0$ mixing ratio $\Gamma(K^+\pi^-)$ (via \overline{D}^0) with \overline{D}^0 mixing ratio $\Gamma(K^+\pi^-)$ (via \overline{D}^0) with \overline{D}^0 0.

⁶This LINK 05H limit is inferred from the $D^0-\overline{D}^0$ mixing ratio $\Gamma(K^+\pi^-)$ (via $\overline{D}^0))/\Gamma(K^-\pi^+)$ given near the end of this D^0 Listings. Decay-time information is used to distinguish DCS decays from $D^0-\overline{D}^0$ mixing. The limit allows interference between the DCS and mixing ratios, and also allows CP violation. The strong phase between $D^0\to K^+\pi^-$ and $\overline{D}^0\to K^+\pi^-$ is assumed to be small. If an arbitrary relative strong phase is allowed, the limit degrades by 25%.

⁸ AITALA 98 allows interference between the doubly Cabibbo-suppressed and mixing amplitudes, and also allows *CP* violation in this term, but assumes that $A_D = A_R = 0$. See the note on " $D^0 - \overline{D}^0$ Mixing," above.

⁹ This limit is inferred from R_M for $f=K^+\pi^-$ and $f=K^+\pi^-\pi^+\pi^-$. See the note on " $D^0-\overline{D}^0$ Mixing," above. Decay-time information is used to distinguish doubly Cabibbosuppressed decays from $D^0-\overline{D}^0$ mixing.

This limit is inferred from R_M for $f=K^+\ell^-\overline{\nu}_\ell$. See the note on " $D^0-\overline{D}^0$ Mixing,"

 D^0

$(\Gamma_{D_1^0} - \Gamma_{D_2^0})/\Gamma = 2y$

The D_1^0 and D_2^0 are the mass eigenstates of the D^0 meson, as described in the note on " $D^0 - \overline{D}^0$ Mixing," above.

Due to the strong phase difference between ${\it D}^{\,0} \,
ightarrow \, {\it K}^{\,+} \, \pi^{\,-}$ and ${\it \overline{D}}^{\,0} \,
ightarrow$ $K^+\pi^-$, we exclude from the average those measurements of y' that are inferred from the D^0 - \overline{D}^0 mixing ratio $\Gamma(K^+\pi^-)$ via $\overline{D}^0)$ / $\Gamma(K^+\pi^-)$ given near the end of this D^0 Listings.

Some early results have been omitted. See our 2006 Review (Journal of Physics, G 33 1 (2006)).

"OUR EVALUATION" comes from averages provided by the Heavy Flavor Averaging Group, see the note on " D^0 - \overline{D}^0 Mixing."

 1 Compared the lifetimes of D^0 decay to the *CP* eigenstate K^+K^- with D^0 decay to

 $^{+}K^-$. The values here assume no CP violation. 2 DEL-AMO-SANCHEZ 10D uses 540,800 \pm 800 $K_{S}^{0}\pi^{+}\pi^{-}$ and 79,900 \pm 300 $K_{S}^{0}K^{+}K^{-}$ events in a time-dependent amplitude analyses of the D^0 and $\overline{D}{}^0$ Dalitz plots. No

evidence was found for CP violation, and the values here assume no such violation. ³ This combines the $y_{CP}=(\tau_{K\pi}/\tau_{KK})-1$ using untagged $K^-\pi^+$ and K^-K^+ events of AUBERT 09AI with the disjoint y_{CP} using tagged $K^-\pi^+$, K^-K^+ , and $\pi^-\pi^+$ events of AUBERT 08U. ⁴ ZUPANC 09 uses a method based on measuring the mean decay time of $D^0 \to D^0$

 $K_S^0 K^+ K^-$ events for different $K^+ K^-$ mass intervals.

 5 STARIC 07 compares the lifetimes of ${\it D}^{\,0}$ decay to the ${\it CP}$ eigenstates ${\it K}^+{\it K}^-$ and $\pi^+\pi^-$ with D^0 decay to $K^-\pi^+$

⁶ The ASNER 05 and ZHANG 07B values are from the time-dependent Dalitz-plot analysis of $D^0 \to K^0_S \pi^+ \pi^-$. Decay-time information and interference on the Dalitz plot are used to distinguish doubly Cabibbo-suppressed decays from mixing and to measure the relative phase between $D^0 \to K^{*+}\pi^-$ and $\overline{D}^0 \to K^{*+}\pi^-$. This limit allows CP

violation. 7 LINK 00, AITALA 99E, and ABE 02I measure the lifetime difference between $D^0 \to K^-K^+$ (CP even) decays and $D^0 \to K^-\pi^+$ (CP mixed) decays, or $y_{CP} = \frac{[\Gamma(CP+)-\Gamma(CP-)]/[\Gamma(CP+)+\Gamma(CP-)]}{[\Gamma(CP+)+\Gamma(CP-)]}$. We list $2y_{CP} = \Delta\Gamma/\Gamma$

CSORNA 02 measures the lifetime difference between $D^0 \to K^-K^+$ and $\pi^-\pi^+$ (CP-even) decays and $D^0 \to K^-\pi^+$ (CP-mixed) decays, or $y_{CP} = \frac{[\Gamma(CP+)-\Gamma(CP-)]/[\Gamma(CP+)+\Gamma(CP-)]}{[\Gamma(CP+)+\Gamma(CP-)]}$. We list $2y_{CP} = \Delta\Gamma/\Gamma$.

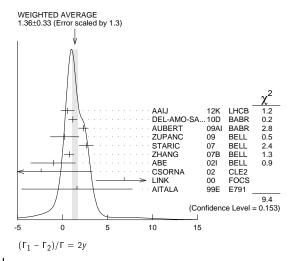

⁹ The AUBERT 09AN values are inferred from the branching ratio $\Gamma(D^0 \to K^+\pi^-\pi^0)$ via $\overline{D^0})/\Gamma(D^0\to K^-\pi^+\pi^0)$ given near the end of this Listings. Mixing is distinguished from DCS decays using decay-time information. Interference between mixing and DCS is allowed. The phase between $D^0\to K^+\pi^-\pi^0$ and $\overline{D}^0\to K^+\pi^-\pi^0$ is assumed to be small. The width difference here is y'', which is not the same as y_{CP} in the note on $D^0 - \overline{D}{}^0$ mixing.

 10 LOWREY 09 uses quantum correlations in $e^+e^- \to D^0 \overline{D}{}^0$ at the $\psi(3770)$. See below for coherence factors and average relative strong phases for both $D^0 \to K^-\pi^+\pi^0$ and $D^0 o K^-\pi^-2\pi^+$. A fit that includes external measurements of charm mixing parameters gets $2y = (1.62 \pm 0.32) \times 10^{-2}$

 11 The GODANG 00, AUBERT 03z, LINK 05H, LI 05A, ZHANG 06, AUBERT 07w, and AALTONEN 08E limits are inferred from the $D^0\!-\!\overline{D}^0$ mixing ratio $\Gamma(K^+\pi^-)$ (via $\overline{D}^0))/\Gamma(K^-\pi^+)$ given near the end of this D^0 Listings. Decay-time information is used to distinguish DCS decays from $D^0 - \overline{D}{}^0$ mixing. The limits allow interference between the DCS and mixing ratios, and all except AUBERT 07w and AALTONEN 08E also allow CP violation. The phase between $D^0 \to K^+ \pi^-$ and $\overline{D}{}^0 \to K^+ \pi^-$ is assumed to be small. This is a measurement of y^\prime and is not the same as the $y_{C\!P}$ of our note above on " $D^0 - \overline{D}{}^0$ Mixing."

 12 This value combines the results of AUBERT 08U and AUBERT 03P. 13 The ranges of AUBERT 032, LINK 05H, LI 05A, and ZHANG 06 measurements are for

195% confidence level. 14 AUBERT 03P measures Y $\equiv 2 \ \tau^0 \ / \ (\tau^+ + \tau^-) - 1$, where τ^0 is the $D^0 \to K^- \pi^+$ (and $\overline{D}{}^0 \to K^+\pi^-$) lifetime, and τ^+ and τ^- are the D^0 and $\overline{D}{}^0$ lifetimes to *CP*-even states (here K^-K^+ and $\pi^-\pi^+$). In the limit of *CP* conservation, $Y=y\equiv\Delta\Gamma/2\Gamma$ (we list $2y = \Delta\Gamma/\Gamma$). AUBERT 03P also uses $\tau^+ - \tau^-$ to get $\Delta Y = -0.008 \pm 0.006 \pm 0.002$.

The mass eigenstates D_1^0 and D_2^0 are related to the ${\it C}=\pm 1$ states by $|D_{1,2}>=$ p $|D^0\rangle + q |\overline{D}^0\rangle$. See the note on " $D^0-\overline{D}^0$ Mixing" above.

"OUR EVALUATION" comes from averages provided by the Heavy Flavor Averaging Group. This would include as-yet-unpublished results, see the note on " \mathcal{D}^0 - $\overline{\mathcal{D}}^0$

DO CUMENT ID TECN COMMENT **0.88** $^{+0.16}_{-0.15}$ **OUR EVALUATION** HFAG fit; see the note on " $D^0 - \overline{D}{}^0$ Mixing." $^{
m 1}$ ZHANG 07B BELL $e^+e^- \approx \Upsilon(4S)$

 1 The phase of p/q is $(-14^{+16}_{-18}\pm 5)^\circ$. The ZHANG 07B value is from the time-dependent Dalitz-plot analysis of $D^0\to \kappa^0_S\pi^+\pi^-$. Decay-time information and interference on the Dalitz plot are used to distinguish doubly Cabibbo-suppressed decays from mixing and to measure the relative phase between $D^0 \to K^{*+}\pi^-$ and $\overline{D}^0 \to K^{*+}\pi^-$. This

 ${\sf A}_{\Gamma}$ is the decay-rate asymmetry for *CP*-even final states ${\sf A}_{\Gamma}=(\overline{\tau}_+-\tau_+)/(\overline{\tau}_++\tau_+)$. See the note on " $D^0 - \overline{D}{}^0$ Mixing" above.

¹ ASNER 08 uses quantum correlations in $e^+e^- \rightarrow D^0 \overline{D}{}^0$ at the $\psi(3770)$, where decay rates of CP-tagged $K\pi$ final states depend on $\cos\delta$ because of interfering amplitudes. The above measurement implies $|\delta| < 75^\circ$ with a confidence level of 95%. A fit that includes external measurements of charm mixing parameters finds $\cos\delta = 1.10 \pm 0.35 \pm 0.35 \pm 0.35$ 0.07. See also the note on " $D^0 - \overline{D}^0$ Mixing" p. 783 in our 2008 Review (PDG 08).

 $^{^{11}}$ ANJOS 88c assumes that y=0. See the note on " D^0 - $\overline{D}{}^0$ Mixing," above. Without this assumption, the limit degrades by about a factor of two.

$D^0 ightarrow \ K^-\pi^+\pi^0$ coherence factor $R_{K\pi\pi^0}$

See the note on ' D^0 - \overline{D}^0 Mixing' for the definition. $R_{K\pi\pi^0}$ can have any value between 0 and 1. A value near 1 indicates the decay is dominated by a few intermediate states

D⁰ DECAY MODES

Most decay modes (other than the semileptonic modes) that involve a neutral K meson are now given as $K_{\mathcal{S}}^0$ modes, not as \overline{K}^0 modes. Nearly always and doubly Cabibbo-suppressed modes can invalidate the assumption that $2\Gamma(K_0^S)=\Gamma(\overline{K}^0).$ it is a K_S^0 that is measured, and interference between Cabibbo-allowed

 Γ_{271} Unaccounted decay modes

$$(38.2 \pm 1.3)\%$$
 S=1.

- [a] This value is obtained by subtracting the branching fractions for 2-, 4- and 6-prongs from unity.
- [b] This is the sum of our $K^-2\pi^+\pi^-$, $K^-2\pi^+\pi^-\pi^0$, $K^-K^-\pi^+\pi^-\pi^0$, $K^-K^-\pi^+\pi^-\pi^0$, $K^-K^-\pi^+\pi^-\pi^0$, branching fractions.
- [c] This is the sum of our $K^-3\pi^+2\pi^-$ and $3\pi^+3\pi^-$ branching fractions.
- [d] The branching fractions for the $K^-e^+\nu_e$, $K^*(892)^-e^+\nu_e$, $\pi^-e^+\nu_e$, and $\rho^-e^+\nu_e$ modes add up to 6.19 \pm 0.17 %.
- [e] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers.
- [f] This is a doubly Cabibbo-suppressed mode.
- [g] The two experiments measuring this fraction are in serious disagreement. See the Particle Listings .
- [h] Submodes of the $D^0 \to K_S^0 \pi^+ \pi^- \pi^0$ mode with a K^* and/or ρ were studied by COFFMAN 92B, but with only 140 events. With nothing new for 18 years, we refer to our 2008 edition, Physics Letters **B667** 1 (2008), for those results.
- [i] This branching fraction includes all the decay modes of the resonance in the final state.
- [j] The experiments on the division of this charge mode amongst its submodes disagree, and the submode branching fractions here add up to considerably more than the charged-mode fraction.
- [k] However, these upper limits are in serious disagreement with values obtained in another experiment.
- [/] This mode is not a useful test for a $\Delta C=1$ weak neutral current because both quarks must change flavor in this decay.
- $[\emph{m}]$ The value is for the sum of the charge states or particle/antiparticle states indicated.
- [n] This limit is for either D^0 or $\overline{D}{}^0$ to pe^- .
- [o] This limit is for either D^0 or $\overline{D}{}^0$ to $\overline{p}\,e^+$.

CONSTRAINED FIT INFORMATION

An overall fit to 52 branching ratios uses 104 measurements and one constraint to determine 31 parameters. The overall fit has a $\chi^2=99.0$ for 74 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\left\langle \delta x_i \delta x_j \right\rangle / (\delta x_i \cdot \delta x_j),$ in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\rm total}.$ The fit constrains the x_i whose labels appear in this array to sum to one

Doubly Cabibbo-suppressed / Mixing modes

$\Gamma(K^+\ell^-\overline{\nu}_\ell \text{ via } \overline{D}^0)/\Gamma(K^-\ell^+\nu_\ell)$

This is a limit on R_M without the complications of possible doubly Cabibbo-suppressed decays that occur when using hadronic modes. For the limits on $|m_1-m_2|$ and $(\Gamma_1-\Gamma_2)/\Gamma$ that come from the best mixing limit, see near the beginning of these D^0 Listings.

| $< 50 \times 10^{-4}$ | 90 | ² AITALA | 96c | E791 | π^- nucleus, 500 GeV |

96C E791 π^- nucleus, 500 GeV 1 The BITENC 08 right-sign sample includes about 15% of ${\it D}^0
ightarrow \, {\it K}^- \, \pi^0 \, \ell^+ \,
u_\ell$ and other

$\Gamma \left(K^+ \text{ or } K^*(892)^+ \, e^- \overline{\nu}_e \text{ via } \overline{D}{}^0 \right) / \left[\Gamma \left(K^- \, e^+ \, \nu_e \right) + \Gamma \left(K^*(892)^- \, e^+ \, \nu_e \right) \right]$ $\Gamma_{211}/(\Gamma_{18}+\Gamma_{20})$

This is a limit on R_M without the complications of possible doubly Cabibbo-suppressed decays that occur when using hadronic modes. The experiments use ${\it D^{*+}}
ightarrow {\it D^{\,0}}\,\pi^+$ (and charge conjugate) decays to identify the charm at production and the charge of the e to identify the charm at decay. These limits do not allow CP violation. For the limits on $|m_1 - m_2|$ and $(\Gamma_1 - \Gamma_2)/\Gamma$ that come from the best mixing limit, see near the beginning of these D^0 Listings.

 $\Gamma(K^+\pi^-)/\Gamma(K^-\pi^+)$ This is R, the time-integrated wrong-sign rate compared to the right-sign rate. See the note on " D^0 - \overline{D}^0 Mixing," near the start of the D^0 Listings.

The experiments here use the charge of the pion in $D^*(2010)^\pm \to (D^0 \text{ or } \overline{D}{}^0) \ \pi^\pm$ decay to tell whether a D^0 or a $\overline{D}{}^0$ was born. The $D^0 \to K^+\pi^-$ decay can occur directly by doubly Cabibbo-suppressed (DCS) decay, or indirectly by $D^0 \to \overline{D}{}^0$ mixing followed by $\overline{D}{}^0 \to K^+\pi^-$ decay. Some of the experiments can use the decaytime information to disentangle the two mechanisms. Here, we list the experimental branching ratio, which if there is no mixing is the DCS ratio. See the next data block for values of the DCS ratio R_D , and the following data block for limits on the mixing ratio R_M . See the section on CP-violating asymmetries near the end of this D^0 Listing for values of A_D , and the note on " D^0 - \overline{D}^0 Mixing" for limits on x' and y'.

Some early limits have been omitted from this Listing; see our 1998 edition (The European Physical Journal C3 1 (1998)) and our 2006 edition (Journal of Physics, G

 $1\,\mathrm{A\,NJOS}$ 88C uses decay-time information to distinguish doubly Cabibbo-suppressed (DCS) decays from $D^0 - \overline{D^0}$ mixing. However, the result assumes no interference between the DCS and mixing amplitudes (y'=0 in the note on " $D^0-\overline{D}^0$ Mixing" near the start of the $D^{\,0}$ Listings). When interference is allowed, the limit degrades to 0.007.

 $\Gamma(K^+\pi^- \text{ or } K^+\pi^+ 2\pi^- \text{ via } \overline{D}^0)/\Gamma(K^-\pi^+ \text{ or } K^- 2\pi^+\pi^-)$ This is a $D^0-\overline{D}{}^0$ mixing limit. For the limits on $|m_{D_1^0}-m_{D_2^0}|$ and $(\Gamma_{D_1^0}-\Gamma_{D_2^0})/\Gamma_{D^0}$

that come from the best mixing limit, see near the beginning of these \hat{D}^0 Listings.

CL% DO CUMENT ID TECN COMMENT

 \bullet \bullet \bullet We do not use the following data for averages, fits, limits, etc. \bullet \bullet

¹ AITALA < 0.0085 90 98 E791 π^{-} nucleus 500 GeV < 0.0037 2 ANJOS 90 88c E691 Photoproduction

¹ AITALA 98 uses decay-time information to distinguish doubly Cabibbo-suppressed decays from D^0 - \overline{D}^0 mixing. The fit allows interference between the two amplitudes, and also allows CP violation in this term. The central value obtained is $0.0039 + 0.0036 \pm 0.0016$. When interference is disallowed, the result becomes $0.0021 \pm 0.0009 \pm 0.0002$. 2 This combines results of ANJOS 88c on $K^+\pi^-$ and $K^+\pi^-\pi^+\pi^-$ (via \overline{D}^0) reported in the data block above (see footnotes there). It assumes no interference.

 $^{^2}$ This LI 05A result allows *CP* violation. The limit becomes < 0.00042 (95% CL) if *CP* violation is not allowed.

- ¹ This ZHANG 06 result allows mixing.
- 2 This LINK 05H result assumes no mixing. If mixing is allowed, it becomes $0.13^{+0.33}_{-0.25}$ \pm
- 3 This AUBERT 03z limit assumes no mixing. If mixing is allowed, the 95% confidence-level interval is $(-2.8 < A_D < 4.9)\times 10^{-3}$.
- ⁴ This GODANG 00 result assumes no $D^0-\overline{D}{}^0$ mixing; it becomes $-0.01^{+0.16}_{-0.17}\pm0.01$ when mixing is allowed. 5 This LI 05A result allows mixing.

 D^0

$A_{CP}(K_2^*(1430)^\mp\pi^\pm\to K_5^0\pi^+\pi^-)$ in $D^0\to K_2^*(1430)^-\pi^+$, $\overline{D}{}^0\to K_2^*(1430)^+\pi^-$

 1 This ASNER 04A limit comes from an amplitude analysis of the D^0 and $\overline D{}^0\to K^0_S\pi^+\pi^-$ Dalitz plots.

$A_{CP}(K^*(1680)^{\mp}\pi^{\pm} \rightarrow K_5^0\pi^{+}\pi^{-}) \text{ in } D^0 \rightarrow K^*(1680)^{-}\pi^{+}, \overline{D}{}^0 \rightarrow K^*(1680)^{+}\pi^{-}$

 1 This ASNER 04A limit comes from an amplitude analysis of the $\it D^0$ and $\it \overline{D}{}^0 \to \it K^0_S \, n^+ \, n^-$ Dalitz plots.

D⁰ CP-VIOLATING ASYMMETRY DIFFERENCES

$\Delta A_{CP} = A_{CP}(K^+K^-) - A_{CP}(\pi^+\pi^-)$

CP violation in these modes can come from the decay amplitudes (direct) and/or from mixing or interference of mixing and decay (indirect). The difference ΔA_{CP} is primarily sensitive to the direct component, and only retains a second-order dependence on the indirect component for measurements where the mean decay time of the K^+K^- and $\pi^+\pi^-$ samples are not identical. The results below are averaged assuming the indirect component can be neglected.

| VALUE (%) | EVTS | DO CUMENT ID | | TECN | COMMENT |

| $-0.46 \pm 0.31 \pm 0.12$ | ! | AALTONEN | 12B | CDF | Time-integrated |
| $+0.24\pm0.62\pm0.26$ | ı | ¹ AUBERT | 08м | BABR | Time-integrated |
| $-0.86\pm0.60\pm0.07$ | 120k | STARIC | 80 | BELL | Time-integrated |

 1 Calculated from the AUBERT 08M values of $A_{CP}({\it K}^+\,{\it K}^-)$ and $A_{CP}(\pi^+\pi^-).$ The systematic error here combines the systematic errors in quadrature, and therefore somewhat over-estimates it.

$D^0-\overline{D}{}^0$ T-VIOLATING DECAY-RATE ASYMMETRIES

 D^0 and \overline{D}^0 are distinguished by the charge of the parent $D^*\colon D^{*+}\to D^0\pi^+$ and $D^{*-}\to \overline{D}^0\pi^-$. Assuming *CPT* is good, *T* violation implies *CP* violation

$A_{Tviol}(K^+K^-\pi^+\pi^-)$ in D^0 , $\overline{D}{}^0 \to K^+K^-\pi^+\pi^-$

 $\begin{array}{lll} \mathsf{C}_T \equiv \vec{p}_{K^+} \cdot (\vec{p}_{\pi^+} \times \vec{p}_{\pi^-}) \text{ is a T-odd correlation of the K^+, π^+, and π^- momenta (evaluated in the D^0 rest frame) for the D^0. $\overline{\mathsf{C}}_T \equiv \vec{p}_{K^-} \cdot (\vec{p}_{\pi^-} \times \vec{p}_{\pi^+})$ is the corresponding quantity for the \overline{D}^0.} \end{array}$

 $\mathbf{A}_T \equiv \left[\Gamma(\mathbf{C}_T > 0) - \Gamma(\mathbf{C}_T < 0) \right] \ / \left[\Gamma(\mathbf{C}_T > 0) + \Gamma(\mathbf{C}_T < 0) \right]$

would, in the absence of strong phases, test for T violation in D^0 decays (the Γ 's are partial widths). With

 $\overline{A}_T \equiv \left[\Gamma(-\overline{C}_T > 0) - \Gamma(-\overline{C}_T < 0)\right] / \left[\Gamma(-\overline{C}_T > 0) + \Gamma(-\overline{C}_T < 0)\right],$

the asymmetry ${\bf A}_{Tviol}\equiv\frac{1}{2}({\bf A}_T-\overline{\bf A}_T)$ tests for T violation even with nonzero strong phases.

D⁰ CPT-VIOLATING DECAY-RATE ASYMMETRIES

$A_{CPT}(K^{\mp}\pi^{\pm})$ in $D^0 \to K^-\pi^+$, $\overline{D}{}^0 \to K^+\pi^-$

 $A_{CPT}(t)$ is defined in terms of the time-dependent decay probabilities $P(D^0 \to K^-\pi^+)$ and $\overline{P}(\overline{D}^0 \to K^+\pi^-)$ by $A_{CPT}(t) = (\overline{P}-P)/(\overline{P}+P)$. For small mixing parameters $x \equiv \Delta m/\Gamma$ and $y \equiv \Delta \Gamma/2\Gamma$ (as is the case), and times t, $A_{CPT}(t)$ reduces to [$y Re \ \xi - x Im \ \xi$] Γt , where ξ is the CPT-violating parameter.

The following is actually y $Re \xi$ - x $Im \xi$.

| Γ ₂ | $D^{0}\gamma$ | (38.1±2.9) % |

CONSTRAINED FIT INFORMATION

An overall fit to a branching ratio uses 3 measurements and one constraint to determine 2 parameters. The overall fit has a $\chi^2=$ 0.5 for 2 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\left<\delta x_i\delta x_j\right>/(\delta x_i\cdot\delta x_j)$, in percent, from the fit to the branching fractions, $x_i\equiv$ $\Gamma_i/\Gamma_{\mathrm{total}}$. The fit constrains the x_i whose labels appear in this array to sum to

$$x_2 \qquad \boxed{-100}$$

CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 6 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 =$ $0.3 \ \text{for 4 degrees of freedom.}$

The following off-diagonal array elements are the correlation coefficients $\left<\delta x_i\delta x_j\right>/(\delta x_i\cdot\delta x_j)$, in percent, from the fit to the branching fractions, $x_i\equiv$ $\Gamma_i/\Gamma_{
m total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$$\begin{array}{c|cccc} x_2 & -62 & \\ x_3 & -43 & -44 & \\ \hline & x_1 & x_2 & \end{array}$$

$D_1(2420)^0$ POLARIZATION AMPLITUDE A D_1

A polarization amplitude A_{D_1} is a parameter that depends on the initial polarization of the D_1 and is sensitive to a possible S-wave contribution to its decay. For D_1 decays the helicity angle, θ_h , distribution varies like $1+A_{D_1}{\cos^2\theta_h}$, where θ_h is the angle in the D^* rest frame between the two pions emitted by the $D_1 \rightarrow D^*\pi$ and the $D^* \rightarrow D\pi$.

Unpolarized D_1 decaying purely via D-wave is predicted to give A $_{D_1}=3$.

$D_1(2420)^{\pm}$ POLARIZATION AMPLITUDE A_{D1}

A polarization amplitude A_{D_1} is a parameter that depends on the initial polarization of the D_1 and is sensitive to a possible S-wave contribution to its decay. For D_1 decays the helicity angle, θ_h , distribution varies like

 $1+{\rm A}_{D_1}{\rm cos}^2\theta_h$, where θ_h is the angle in the D^* rest frame between the two pions emitted by the $D_1\to D^*\pi$ and the $D^*\to D\pi$.

Unpolarized D_1 decaying purely via D-wave is predicted to give $A_{D_1} = 3$.

Assuming $\Gamma(\Upsilon(4S) \to B^+B^-)$ / $\Gamma(\Upsilon(4S) \to B^0B^0) = 1.065 \pm 0.026$ and equa partial widths and helicity angle distributions for charged and neutral D_1 mesons.

 4 The states observed in the $D^*\pi$ and $D\pi$ final states are not necessarily the same.

D(2750) POLARIZATION AMPLITUDE AD

A polarization amplitude ${\rm A}_D$ is a parameter that depends on the initial polarization of the D(2750). For D(2750) decays the helicity angle, θ_H , distribution varies like $1+{\rm A}_D\cos(\theta_H)$, where θ_H is the angle in the D^* rest frame between the two pions emitted by the $D(2750)
ightarrow D^*\pi$ and $D^* \to D\pi.$

 $D_s^+ = c\overline{s}$, $D_s^- = \overline{c}s$, similarly for D_s^* 's

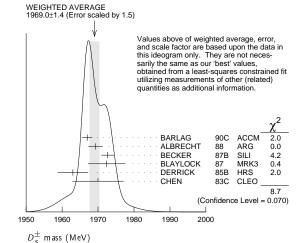

$$I(J^P) = 0(0^-)$$

The angular distributions of the decays of the ϕ and $\overline{K}^*(892)^0$ in the $\phi\pi^+$ and $K^+\overline{K}^*(892)^0$ modes strongly indicate that the spin is zero. The parity given is that expected of a $c\,\overline{s}$ ground state.

D_s^{\pm} MASS

The fit includes D^{\pm} , D^{0} , D_{s}^{\pm} , $D^{*\pm}$, D^{*0} , $D_{s}^{*\pm}$, $D_{1}(2420)^{0}$, $D_{2}^{*}(2460)^{0}$, and $D_{s1}(2536)^{\pm}$ mass and mass difference measurements. Measurements of the D_S^\pm mass with an error greater than 10 MeV are omitted from the fit and average. A number of early measurements have been omitted

- $\it [a]$ This is the purely $\it e^+$ semileptonic branching fraction: the $\it e^+$ fraction from au^+ decays has been subtracted off. The sum of our (non-au) e^+ exclusive fractions — an $e^+\nu_e$ with an $\eta, \eta', \phi, K^0, K^{*0}$, or $f_0(980)$ is $7.0 \pm 0.4 \%$
- [b] This fraction includes η from η' decays.
- [c] Two times (to include μ decays) the $\eta' e^+ \nu_e$ branching fraction, plus the $\eta' \pi^+$, $\eta' \rho^+$, and $\eta' K^+$ fractions, is (18.6 \pm 2.3)%, which considerably exceeds the inclusive η' fraction of $(11.7\pm1.8)\%$. Our best guess is that the $\eta' \rho^+$ fraction, (12.5 \pm 2.2)%, is too large.
- [d] This branching fraction includes all the decay modes of the final-state resonance.
- [e] A test for $u\overline{u}$ or $d\overline{d}$ content in the D_s^+ . Neither Cabibbo-favored nor Cabibbo-suppressed decays can contribute, and $\omega - \phi$ mixing is an unlikely explanation for any fraction above about 2×10^{-4} .
- [f] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the
- [g] We decouple the $D_c^+ \rightarrow \phi \pi^+$ branching fraction obtained from mass projections (and used to get some of the other branching fractions) from the $D_s^+ \to \phi \pi^+$, $\phi \to K^+ K^-$ branching fraction obtained from the Dalitz-plot analysis of $D_s^+ \to K^+ K^- \pi^+$. That is, the ratio of these two branching fractions is not exactly the $\phi \to K^+K^-$ branching fraction
- $[\hbar]$ This is the average of a model-independent and a \emph{K} -matrix parametrization of the $\pi^+\pi^-$ S-wave and is a sum over several f_0 mesons.
- [i] This mode is not a useful test for a $\Delta C=1$ weak neutral current because both quarks must change flavor in this decay.
- [j] This is not a test for the $\Delta C=1$ weak neutral current, but leads to the $\pi^+ \ell^+ \ell^-$ final state.

CONSTRAINED FIT INFORMATION

An overall fit to 16 branching ratios uses 17 measurements and one constraint to determine 12 parameters. The overall fit has a $\chi^2=2.4$ for 6 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\left\langle \delta x_i \delta x_j \right\rangle/(\delta x_i \cdot \delta x_j),$ in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}.$ The fit constrains the x_i whose labels appear in this array to sum to one.

D_S^+ BRANCHING FRACTIONS

Written April 2010 by J.L. Rosner (University of Chicago) and C.G. Wohl (LBNL).

More than a dozen papers on the D_s^+ , most of them from the CLEO experiment, have been published since the 2008 Review. We now know enough to attempt an overview of the branching fractions. Figure 1 shows a partial breakdown of the fractions. The rest of this note is about how the figure was constructed. The values shown make heavy use of CLEO measurements of inclusive branching fractions [1] For other data and references cited in the following, see the Listings.

Modes with leptons: The bottom $(20.0 \pm 0.9)\%$ of Fig. 1 shows the fractions for the exclusive modes that include leptons. Measured $e^+\nu_e$ fractions have been doubled to get the semileptonic $\ell^+\nu$ fractions. The sum of the exclusive $e^+\nu_e$ fractions is $(6.9 \pm 0.4)\%$, consistent with an inclusive semileptonic $e^+\nu_e$ measurement of $(6.5 \pm 0.4)\%$. There seems to be little missing here.

Inclusive hadronic $K\overline{K}$ fractions: The Cabibbo-favored $c \to s$ decay in D_s^+ decay produces a final state with both an s and an \overline{s} ; and thus decay modes with a $K\overline{K}$ pair or with an η , ω , η' , or ϕ predominate (see, for example, in Fig. 1 the fractions with leptons). We consider the $K\overline{K}$ modes first. A complete picture of the exclusive $K\overline{K}$ charge modes is not yet possible, because branching fractions for more than half of those modes have yet to be measured. However, CLEO has measured the inclusive K^+ , K^- , K^0_S , K^+K^- , $K^+K^0_S$, $K^-K^0_S$, and $2K^0_S$ fractions (which include modes with leptons) [1]. And each of these inclusive fractions f with a K^0_S is equal to the corresponding fraction with a K^0_L : $f(K^+K^0_L) = f(K^+K^0_S)$, $f(2K^0_L) = f(2K^0_S)$, etc. Therefore, of all inclusive fractions pairing a K^+ , K^0_S , or K^0_L with a K^- , K^0_S , or K^0_L , we know all but $f(K^0_SK^0_L)$.

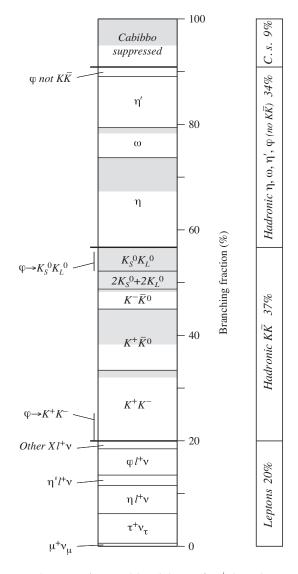

Figure : A partial breakdown of D_s^+ branching fractions. Shading indicates parts of bins allotted to as-yet unmeasured exclusive modes. The inclusive hadronic ϕ fraction is spread over three bins. See the text for further explanations.

We can get that fraction. The total K_S^0 fraction is

$$\begin{split} f(K_S^0) &= f(K^+ K_S^0) + f(K^- K_S^0) + 2 f(2K_S^0) + f(K_S^0 K_L^0) \\ &+ f(\text{single } K_S^0) \ , \end{split}$$

where $f(\operatorname{single} K_S^0)$ is the sum of the branching fractions for modes such as $K_S^0\pi^+2\pi^0$ with a K_S^0 and no second K. The $K_S^0\pi^+2\pi^0$ mode is in fact the only unmeasured single- K_S^0 mode (throughout, we shall assume that fractions for modes with a K or $K\overline{K}$ and more than three pions are negligible), and we shall take its fraction to be the same as for the $K_S^02\pi^+\pi^-$ mode, $(0.29\pm0.11)\%$. Any reasonable deviation from this value would be too small to matter much in the following. Adding the several small single- K_S^0 branching fractions, including those from semileptonic modes, we get $f(\operatorname{single} K_S^0) = (1.67\pm0.26)\%$.

 D_s^{\pm}

Using this, we have:

$$\begin{split} f(K_S^0 K_L^0) &= f(K_S^0) - f(K^+ K_S^0) - f(K^- K_S^0) - 2f(2K_S^0) \\ &- f(\text{single } K_S^0) \\ &= (19.0 \pm 1.1) - (5.8 \pm 0.5) - (1.9 \pm 0.4) \\ &- 2 \times (1.70 \pm 0.32) - (1.67 \pm 0.26) \\ &= (6.2 \pm 1.4)\% \; . \end{split}$$

Here and below we treat the errors as uncorrelated, although often they are not. However, our main aim is to get numbers for Fig. 1; errors will be secondary.

There is a check on our result: The ϕ inclusive branching fraction is $(15.7 \pm 1.0)\%$, of which 34%, or $(5.34 \pm 0.34)\%$ of D_s^+ decays, produces a $K_S^0 K_L^0$. Our $f(K_S^0 K_L^0) = (6.2 \pm 1.4)\%$ has to be at least this large—and it is.

We now make a table. The first column gives the various particle pairings; here we use $f(K^+\overline{K}^0)=2\,f(K^+K^0_S)$, and likewise for $f(K^-K^0)$. The second column gives the inclusive branching fractions; the third column gives the fractions for K^+K^- and $K^0_SK^0_L$ from $\phi\ell^+\nu$ decay; the last column subtracts these off to get the purely hadronic $K\overline{K}$ inclusive fractions.

$$\begin{array}{cccccccc} K^+K^- & 15.8 \; (0.7)\% & 2.44 \; (0.14)\% & 13.4 \; (0.7)\% \\ K^+\overline{K}^0 & 11.6 \; (1.0) & 11.6 \; (1.0) \\ K^-K^0 & 3.8 \; (0.8) & 3.8 \; (0.8) \\ K^0_SK^0_S + K^0_LK^0_L & 3.4 \; (0.64) & 3.4 \; (0.64) \\ K^0_SK^0_L & 6.2 \; (1.4) & 1.69 \; (0.10) & 4.5 \; (1.4) \; . \end{array}$$

The values in the last column are shown in Fig. 1. Their sum is $(36.7 \pm 2.1)\%$.

We can add more information to the figure by summing up measured branching fractions for exclusive modes within each bin:

 K^+K^- modes—The sum of measured $K^+K^-\pi^+$, $K^+K^-\pi^+\pi^0$, and $K^+K^-2\pi^+\pi^-$ branching fractions is $(12.0\pm0.6)\%$. That leaves $(1.4\pm0.9)\%$ for the $K^+K^-\pi^+2\pi^0$ mode, which is the only other K^+K^- mode with three or fewer pions. In Fig. 1, this unmeasured part of the K^+K^- bin is shaded.

 $K^+\overline{K}^0$ modes—Twice the sum of measured $K^+K^0_S$ and $K^+K^0_S\pi^+\pi^-$ branching fractions is $(4.9\pm0.3)\%$. This leaves $(6.7\pm1.0)\%$ for the unmeasured $K^+\overline{K}^0$ modes (there are four such modes with three or fewer pions). This is shaded in the figure.

 K^-K^0 modes—Twice the $K^-K^0_S 2\pi^+$ fraction is (3.28 \pm 0.24)%, which leaves about (0.5 \pm 0.8)% for $K^-K^0 2\pi^+\pi^0$, the only other K^-K^0 mode with three or fewer pions.

 $K^0\overline{K}^0$ modes—The only measurement of $K^0\overline{K}^0$ decays is of the $2K_S^02\pi^+\pi^-$ fraction, $(0.084\pm0.035)\%$; so nearly everything is shaded here. However, most of the $K_S^0K_L^0$ fraction is accounted for by ϕ decays (see below).

Inclusive hadronic η , ω , η' , and ϕ fractions: These are easier. We start with the inclusive branching fractions, and then, to avoid double counting, subtract: (1) fractions for modes

with leptons; (2) η mesons that are included in the inclusive η' fraction; and (3) K^+K^- and $K_S^0K_L^0$ from ϕ decays:

$$\begin{split} f(\eta \text{ hadronic}) &= f(\eta \text{ inclusive}) - 0.65 \, f(\eta' \text{ inclusive}) \\ &- f(\eta \ell^+ \nu) = (17.0 \pm 3.1)\% \\ f(\omega \text{ hadronic}) &= f(\omega \text{ inclusive}) - 0.03 \, f(\eta' \text{ inclusive}) \\ &= (5.7 \pm 1.4)\% \\ f(\eta' \text{ hadronic}) &= f(\eta' \text{ inclusive}) - f(\eta' \ell^+ \nu) \\ &= (9.7 \pm 1.9)\% \\ f(\phi \text{ hadronic}, \not \rightarrow K\overline{K}) &= 0.17 \, [f(\phi \text{ inclusive}) \\ &- f(\phi \ell^+ \nu)] &= (1.8 \pm 0.2)\% \; . \end{split}$$

The factors 0.65, 0.03, and 0.17 are the $\eta' \to \eta$, $\eta' \to \omega$, and $\phi \not\to K\overline{K}$ branching fractions. Figure 1 shows the results; the sum is $(34.2 \pm 3.9)\%$, which is about equal to the hadronic $K\overline{K}$ total.

Note that the bin marked ϕ near the top of Fig. 1 includes neither the $\phi \ell^+ \nu$ decays nor the 83% of other ϕ decays that produce a $K\overline{K}$ pair. Compared to the size of that ϕ bin, there is twice as much ϕ in the $K^0_S K^0_L$ bin, and nearly three times as much in the K^+K^- bin. These contributions are indicated in those bins.

Again, we can show how much of each bin is accounted for by measured exclusive branching fractions:

 η modes—The sum of $\eta \pi^+$, $\eta \rho^+$, and ηK^+ branching fractions is $(10.6 \pm 0.8)\%$, which leaves a good part of the inclusive hadronic η fraction, $(17.0 \pm 3.1)\%$, to be accounted for. This is shaded in the figure.

 ω modes—The sum of $\omega \pi^+$, $\omega \pi^+ \pi^0$, and $\omega 2\pi^+ \pi^-$ fractions is $(4.6 \pm 0.9)\%$, which is nearly as large as the inclusive hadronic ω fraction, $(5.7 \pm 1.4)\%$.

 η' modes—The sum of $\eta'\pi^+$, $\eta'\rho^+$, and $\eta'K^+$ fractions is $(16.5 \pm 2.2)\%$, which is much larger than the inclusive hadronic η' fraction, $(9.7 \pm 1.9)\%$. If an exclusive measurement is at fault, it almost has to be the $\eta'\rho^+$ fraction, which is $(12.5 \pm 2.2)\%$. It has been suggested that some of this signal might instead be misidentified kinematic reflections of other modes [2].

Cabibbo-suppressed modes: Remaining is $(9.1 \pm 4.5)\%$ for hadronic Cabibbo-suppressed modes having no η , ω , η' , or ϕ . The contributions are:

 $K^0 + pions$ —Above, we found that $f(\text{single } K_S^0) = (1.67 \pm 0.26)\%$; subtracting leptonic contributions leaves $(1.20 \pm 0.24)\%$. The hadronic single- K^0 fraction is twice this, $(2.40 \pm 0.48)\%$.

 $K^+ + pions$ —The $K^+\pi^0$ and $K^+\pi^+\pi^-$ fractions sum to $(0.77 \pm 0.05)\%$. Much of the $K^+n\pi$ modes, where $n \geq 3$, is already in the η , ω , and η' bins, and the rest is not measured. The total K^+ fraction wanted here is probably in the 1-to-2% range.

Multi-pions—The $2\pi^+\pi^-$, $\pi^+2\pi^0$, and $3\pi^+2\pi^-$ fractions total $(2.6\pm0.2)\%$. Modes not measured might double this.

 D_s^\pm

The sum of the three contributions is certainly not inconsistent with the Cabibbo-suppressed total of $(9.1 \pm 4.5)\%$. The sum of actually measured fractions is $(4.2 \pm 0.2)\%$.

A model: With CLEO about to publish inclusive branching fractions [1], Gronau and Rosner predicted those fractions using a "statistical isospin" model [2]. Consider, say, the $D_s^+ \to K\overline{K}\pi$ charge modes: the $K^+K^-\pi^+$ branching fraction is measured, the $K^+\overline{K}^0\pi^0$ and $K^0\overline{K}^0\pi^+$ fractions are not. The statistical isospin model assumes that all the independent isospin amplitudes for $D_s^+ \to K\overline{K}\pi$ decay are equal in magnitude and incoherent in phase—in which case, the ratio of the three fractions here is 3:3:2. (Actually, use was also made of the fact that $D_s^+ \to K\overline{K}\pi$ decay is dominated by $\phi\pi^+$, $K^+\overline{K}^{*0}$, and $K^{*+}\overline{K}^0$ submodes; but the estimated charge-mode ratios were not far from 3:3:2.) A different, quark-antiquark pair-production model was used to estimate systematic uncertainties.

In this way, unmeasured exclusive fractions were calculated from measured exclusive fractions (the latter were taken from the 2008 Review, and so did not benefit from recent results). In the hadronic sector, the measured total of 59.4% of D_s^+ decays led to an estimated total of 24.2% for unmeasured modes. Weighted counts of π^+ , K_S^0 , etc., were then made to get the inclusive fractions.

Of interest here is that the sum of all the exclusive fractions—a way-stop in getting the inclusive values—was a nearly correct 103%. In the absence of complete measurements, the model is a way to, in effect, average over ignorance. It probably works better summed over a number of charge-mode sets than in detail. It is known to sometimes give incorrect results when there are sufficient measurements to test it.

DECAY CONSTANTS OF CHARGED PSEUDO-SCALAR MESONS

Revised February 2012 by J. Rosner (Univ. Chicago) and S. Stone (Syracuse Univ.)

Introduction: Charged mesons formed from a quark and an antiquark can decay to a charged lepton pair when these objects annihilate via a virtual W boson [1]. Fig. 1 illustrates this process for the purely leptonic decay of a D^+ meson.

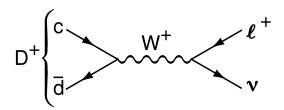

Figure 1: The annihilation process for pure D^+ leptonic decays in the Standard Model.

Similar quark-antiquark annihilations via a virtual W^+ to the $\ell^+\nu$ final states occur for the π^+ , K^+ , D_s^+ , and B^+ mesons. (Charge-conjugate particles and decays are implied.) Let P be any of these pseudoscalar mesons. To lowest order, the decay width is

$$\Gamma(P \to \ell \nu) = \frac{G_F^2}{8\pi} f_P^2 \ m_\ell^2 M_P \left(1 - \frac{m_\ell^2}{M_P^2} \right)^2 |V_{q_1 q_2}|^2 \ . \tag{1}$$

Here M_P is the P mass, m_ℓ is the ℓ mass, $V_{q_1q_2}$ is the Cabibbo-Kobayashi-Maskawa (CKM) matrix element between the constituent quarks $q_1\bar{q}_2$ in P, and G_F is the Fermi coupling constant. The parameter f_P is the decay constant, and is related to the wave-function overlap of the quark and antiquark.

The decay P^{\pm} starts with a spin-0 meson, and ends up with a left-handed neutrino or right-handed antineutrino. By angular momentum conservation, the ℓ^{\pm} must then also be left-handed or right-handed, respectively. In the $m_{\ell} = 0$ limit, the decay is forbidden, and can only occur as a result of the finite ℓ mass. This helicity suppression is the origin of the m_{ℓ}^2 dependence of the decay width.

There is a complication in measuring purely leptonic decay rates. The process $P \to \ell \nu \gamma$ is not simply a radiative correction, although radiative corrections contribute. The P can make a transition to a virtual P^* , emitting a real photon, and the P^* decays into $\ell \nu$, avoiding helicity suppression. The importance of this amplitude depends on the decaying particle and the detection technique. The $\ell \nu \gamma$ rate for a heavy particle such as B decaying into a light particle such as a muon can be larger than the width without photon emission [2]. On the other hand, for decays into a τ^\pm , the helicity suppression is mostly broken and these effects appear to be small.

Measurements of purely leptonic decay branching fractions and lifetimes allow an experimental determination of the product $|V_{q_1q_2}|f_P$. If the CKM element is well known from other

measurements, then f_P can be well measured. If, on the other hand, the CKM element is not well measured, having theoretical input on f_P can allow a determination of the CKM element. The importance of measuring $\Gamma(P \to \ell \nu)$ depends on the particle being considered. For example, the measurement of $\Gamma(B^- \to \tau^- \overline{\nu})$ provides an indirect determination of $|V_{ub}|$ provided that f_B is provided by theory. In addition, f_B is crucial for using measurements of $B^0 - \overline{B}^0$ mixing to extract information on the fundamental CKM parameters. Knowledge of f_{B_s} is also needed, but it cannot be directly measured as the B_s is neutral, so the violation of the SU(3) relation $f_{B_s} = f_B$ must be estimated theoretically. This difficulty does not occur for D mesons as both the D^+ and D_s^+ are charged, allowing the direct measurement of SU(3) breaking and a direct comparison with theory.

For B^- and D_s^+ decays, the existence of a charged Higgs boson (or any other charged object beyond the Standard Model) would modify the decay rates; however, this would not necessarily be true for the D^+ [3,4]. More generally, the ratio of $\tau\nu$ to $\mu\nu$ decays can serve as one probe of lepton universality [3,5].

As $|V_{ud}|$ has been quite accurately measured in superallowed β decays [6], with a value of 0.97425(22) [7], measurements of $\Gamma(\pi^+ \to \mu^+ \nu)$ yield a value for f_π . Similarly, $|V_{us}|$ has been well measured in semileptonic kaon decays, so a value for f_K from $\Gamma(K^- \to \mu^- \bar{\nu})$ can be compared to theoretical calculations. Lattice gauge theory calculations, however, have been claimed to be very accurate in determining f_K , and these have been used to predict $|V_{us}|$ [8].

 D^+ and D_s^+ decay constants: We review current measurements, starting with the charm system. The CLEO collaboration has performed the only measurement of the branching fraction for $D^+ \to \mu^+ \nu$ [9]. CLEO uses e^+e^- collisions at the $\psi(3770)$ resonant energy where D^-D^+ pairs are copiously produced. They fully reconstruct one of the D's, find a candidate muon track of opposite sign to the tag, and then use kinematical constraints to infer the existence of a missing neutrino and hence the $\mu\nu$ decay of the other D. They find $\mathcal{B}(D^+ \to \mu^+ \nu) = (3.82 \pm 0.32 \pm 0.09) \times 10^{-4}$. We use the well-measured D^+ lifetime of 1.040(7) ps, and assuming $|V_{cd}|$ equals $|V_{us}| = 0.2246(12)$ [7] minus higher order correction terms [10], we find $|V_{cd}| = 0.2245(12)$. The CLEO branching fraction result then translates into a value of

$$f_{D^+} = (206.7 \pm 8.5 \pm 2.5) \text{ MeV}$$
.

This result includes a 1% correction (lowering) of the rate due to the presence of the radiative $\mu^+\nu\gamma$ final state based on the estimate by Dobrescu and Kronfeld [11].

Before we compare this result with theoretical predictions, we discuss the D_s^+ . Measurements of $f_{D_s^+}$ have been made by several groups and are listed in Table 1 [12–16]. We exclude older values obtained by normalizing to D_s^+ decay modes that are not well defined. Many measurements, for example, used

the $\phi\pi^+$ mode. This decay is a subset of the $D_s^+ \to K^+K^-\pi^+$ channel which has interferences from other modes populating the K^+K^- mass region near the ϕ , the most prominent of which is the $f_0(980)$. Thus the extraction of effective $\phi\pi^+$ rate is sensitive to the mass resolution of the experiment and the cuts used to define the ϕ mass region [17,18]. The CLEO, BaBar, and Belle $\mu^+\nu$ results rely on fully reconstructing all the final-state particles except for the neutrino and using a missing-mass technique to infer the existence of the neutrino. CLEO uses $e^+e^- \to D_sD_s^*$ collisions at 4170 MeV, while Babar and Belle use $e^+e^- \to DKn\pi D_s^*$ collisions at energies near the $\Upsilon(4S)$.

Table 1: Experimental results for $\mathcal{B}(D_s^+ \to \mu^+ \nu)$, $\mathcal{B}(D_s^+ \to \tau^+ \nu)$, and $f_{D_s^+}$. Numbers for $f_{D_s^+}$ have been extracted using updated values for masses and $|V_{cs}|$ (see text). Radiative corrections and systematic uncertainties for errors on the D_s^+ lifetime and mass have been included. Common systematic errors in the CLEO results have been taken into account.

| Experiment | Mode | $\mathcal{B}(\%)$ | $f_{D_s^+} \; (\mathrm{MeV})$ |
|---------------|-----------------------------------------------|-----------------------------|-------------------------------|
| CLEO-c [12] | $\mu^+ \nu$ | $0.565 \pm 0.045 \pm 0.017$ | $257.6 \pm 10.3 \pm 4.3$ |
| BaBar [16] | $\mu^+ \nu$ | $0.602 \pm 0.038 \pm 0.034$ | $265.9 \pm 8.4 \pm 7.7$ |
| Belle [13] | $\mu^+ \nu$ | $0.638 \pm 0.076 \pm 0.057$ | $274 \pm 16 \pm 12$ |
| Average | $\mu^+ \nu$ | 0.589 ± 0.033 | 263.0 ± 7.3 |
| CLEO-c [12] | $\tau^+ \nu \ (\pi^+ \overline{\nu})$ | $6.42 \pm 0.81 \pm 0.18$ | $278.0 \pm 17.5 \pm 4.4$ |
| CLEO-c [14] | $\tau^+ \nu \ (\rho^+ \overline{\nu})$ | $5.52 \pm 0.57 \pm 0.21$ | $257.8 \pm 13.3 \pm 5.2$ |
| CLEO-c $[15]$ | $\tau^+ \nu \ (e^+ \nu \overline{\nu})$ | $5.30 \pm 0.47 \pm 0.22$ | $252.6 \pm 11.1 \pm 5.2$ |
| BaBar [16] | $\tau^+ \nu \ (e^+/\mu^+ \nu \overline{\nu})$ | $5.00 \pm 0.35 \pm 0.49$ | $245.4 \pm 8.6 \pm 12.2$ |
| Average | $\tau^+ \nu$ | 5.43 ± 0.31 | 255.7 ± 7.2 |

When selecting the $\tau^+ \to \pi^+ \bar{\nu}$ and $\tau^+ \to \rho^+ \bar{\nu}$ decay modes, CLEO uses both calculation of the missing-mass and the fact that there should be no extra energy in the event beyond that deposited by the measured tagged D_s^- and the τ^+ decay products. The $\tau^+ \to e^+ \nu \bar{\nu}$ mode, however, uses only no extra energy. BaBar measures $\Gamma(D_s^+ \to \tau^+ \nu)/\Gamma(D_s^+ \to \overline{K}^0 K^+)$ using the $\tau^+ \to e^+ \nu \bar{\nu}$ mode.

We extract the decay constant from the measured branching ratios using the D_s^+ mass of 1.96847(33) GeV, the τ^+ mass of 1.77682(16) GeV, and a lifetime of 0.500(7) ps. We use the first-order correction $|V_{cs}| = |V_{ud}| - |V_{cb}|^2/2$ [10]; taking $|V_{ud}| = 0.97425(22)$ [6], and $|V_{cb}| = 0.04$ from an average of exclusive and inclusive semileptonic B decay results as discussed in Ref. [19], we find $|V_{cs}| = 0.97345(22)$. CLEO has included the radiative correction of 1% in the $\mu^+\nu$ rate listed in the Table [11] (the $\tau^+\nu$ rates need not be corrected). Other theoretical calculations show that the $\mu^+\nu\gamma$ rate is a factor of 40–100 below the $\mu^+\nu$ rate for charm [20]. As this is a small effect we do not attempt to correct the other measurements.

The average decay constant cannot simply be obtained by averaging the values in Table 1 since there are correlated errors between the $\mu^+\nu$ and $\tau^+\nu$ values. Table 2 gives the average values of f_{D_s} where the experiments have included the correlations.

Table 2: Experimental results for $f_{D_s^+}$ taking into account the common systematic errors in the $\mu^+\nu$ and $\tau^+\nu$ measurements.

| Experiment | $f_{D_s^+} 	ext{ (MeV)}$ |
|-------------------------|---------------------------|
| CLEO-c | $259.0 \pm 6.2 \pm 3.0$ |
| BaBar | $258.8 \pm 6.4 \pm 7.5$ |
| Belle | $273.8 \pm 16.3 \pm 12.2$ |
| Average of $\mu^+\nu$ + | $\tau^+ \nu$ 260.0 ± 5.4 |

Our experimental average is

$$f_{D_{-}^{\pm}} = (260.0 \pm 5.4) \text{ MeV}.$$

Furthermore, the ratio of branching fractions is found to be

$$R \equiv \frac{\mathcal{B}(D_s^+ \to \tau^+ \nu)}{\mathcal{B}(D_s^+ \to \mu^+ \nu)} = 9.2 \pm 0.7,$$

where a value of 9.76 is predicted in the Standard Model. Assuming lepton universality then we can derive improved values for the leptonic decay branching fractions of

$${\cal B}(D_s^+\to \mu^+\nu) = (5.75\pm 0.24)\times 10^{-3}, \quad {\rm and} \quad$$

$$\mathcal{B}(D_s^+ \to \tau^+ \nu) = (5.61 \pm 0.24) \times 10^{-2}$$
.

The experimentally determined ratio of decay constants is $f_{D^{\pm}}/f_{D^{+}}=1.26\pm0.06.$

Table 3 compares the experimental $f_{D_s^+}$ with theoretical calculations [21–27]. While most theories give values lower than the $f_{D_s^+}$ measurement, the errors are sufficiently large, in most cases, to declare success.

Upper limits on f_{D^+} and f_{D_s} of 230 and 270 MeV, respectively, have been determined using two-point correlation functions by Khodjamirian [28]. Both the D^+ and D_s^+ values are safely below this limit.

Akeroyd and Chen [29] pointed out that leptonic decay widths are modified in two-Higgs-doublet models (2HDM). Specifically, for the D^+ and D_s^+ , Eq. (1) is modified by a factor r_q multiplying the right-hand side [30]:

$$r_q = \left[1 + \left(\frac{1}{m_c + m_q}\right) \left(\frac{M_{D_q}}{M_{H^+}}\right)^2 \left(m_c - \frac{m_q \tan^2 \beta}{1 + \epsilon_0 \tan \beta}\right)\right]^2,$$

Table 3: Theoretical predictions of $f_{D_s^+}$, f_{D^+} , and $f_{D_s^+}/f_{D^+}$. Quenched lattice calculations are omitted, while PQL indicates a partially-quenched lattice calculation. (Only selected results having errors are included.)

| Model | $f_{D_s^+}({ m MeV})$ | $f_{D^+}({ m MeV})$ | $f_{D_s^+}/f_{D^+}$ |
|---------------------------|--------------------------|-------------------------|-----------------------------|
| Experiment (our averages) | 260.0 ± 5.4 | 206.7 ± 8.9 | 1.26 ± 0.06 |
| Lattice (HPQCD) [21] | 248.0 ± 2.5 | 213 ± 4 | 1.164 ± 0.018 |
| Lattice (FNAL+MILC) [22] | 260.1 ± 10.8 | 218.9 ± 11.3 | 1.188 ± 0.025 |
| PQL [23] | 244 ± 8 | 197 ± 9 | 1.24 ± 0.03 |
| QCD sum rules [24] | 205 ± 22 | 177 ± 21 | $1.16 \pm 0.01 \pm 0.03$ |
| QCD sum rules [25] | $245.3 \pm 15.7 \pm 4.5$ | $206.2 \pm 7.3 \pm 5.1$ | $1.193 \pm 0.025 \pm 0.007$ |
| Field correlators [26] | 260 ± 10 | 210 ± 10 | 1.24 ± 0.03 |
| Light front [27] | 268.3 ± 19.1 | 206 (fixed) | 1.30 ± 0.04 |

where m_{H^+} is the charged Higgs mass, M_{D_q} is the mass of the D meson (containing the light quark q), m_c is the charm quark mass, m_q is the light-quark mass, and $\tan \beta$ is the ratio of the vacuum expectation values of the two Higgs doublets. In models where the fermion mass arises from coupling to more than one vacuum expectation value ϵ_0 can be non-zero, perhaps as large as 0.01. For the D^+ , $m_d \ll m_c$, and the change due to the H^+ is very small. For the D_s^+ , however, the effect can be substantial.

A major concern is the need for the Standard Model (SM) value of $f_{D_s^+}$. We can take that from a theoretical model. Our most aggressive choice is that of the unquenched lattice calculation [21], because it claims the smallest error. Since the charged Higgs would lower the rate compared to the SM, in principle, experiment gives a lower limit on the charged Higgs mass. However, the value for the predicted decay constant using this model is 2.0 standard deviations below the measurement. If this small discrepancy is to be taken seriously, either (a) the model of Ref. [21] is not representative; (b) no value of m_{H^+} in the two-Higgs doublet model will satisfy the constraint at 99% confidence level; or (c) there is new physics, different from the 2HDM, that interferes constructively with the SM amplitude such as in the R-parity-violating model of Akeroyd and Recksiegel [31].

To sum up, the situation is not clear. To set limits on new physics we need an independent calculation of f_{Ds} with comparable accuracy, and more precise measurements would also be useful.

The B^+ decay constant: The Belle and BaBar collaborations have found evidence for $B^- \to \tau^- \overline{\nu}$ decay in $e^+ e^- \to B^- B^+$ collisions at the $\Upsilon(4S)$ energy. The analysis relies on reconstructing a hadronic or semi-leptonic B decay tag, finding a τ candidate in the remaining track and or photon candidates, and examining the extra energy in the event which should be close to zero for a real τ^- decay to $e^- \nu \bar{\nu}$ or $\mu^- \nu \bar{\nu}$ opposite a B^+ tag. The results are listed in Table 4.

Table 4: Experimental results for $\mathcal{B}(B^- \to \tau^- \overline{\nu})$. We have computed an average for the two Belle measurements assuming that the systematic errors are fully correlated.

| Experiment | Tag | \mathcal{B} (units of 10^{-4}) |
|------------|--------------|-------------------------------------|
| Belle [32] | Hadronic | $1.79^{+0.56+0.46}_{-0.49-0.51}$ |
| Belle [33] | Semileptonic | $1.54^{+0.38+0.29}_{-0.37-0.31}$ |
| Belle | Our average | 1.62 ± 0.40 |
| BaBar [34] | Hadronic | $1.80^{+0.57}_{-0.54} \pm 0.26$ |
| BaBar [35] | Semileptonic | $1.7\pm0.8\pm0.2$ |
| BaBar | Average [34] | 1.76 ± 0.49 |
| | Our average | 1.68 ± 0.31 |

There are large backgrounds under the signals in all cases. The systematic errors are also quite large, on the order of 20%. Thus, the significance of the signals is not that large. Belle quotes 3.5σ and 3.6σ for their hadronic and semileptonic tags, while BaBar quotes 3.3σ and 2.3σ for these tags. We note that the four central values are remarkably close to the average considering the large errors on all the measurements. More accuracy would be useful to investigate the effects of new physics.

We extract a SM value using Eq. (1). Here theory provides a value of $f_B = (194 \pm 9)$ MeV [36]. We also need a value for $|V_{ub}|$. Here significant differences arise between using inclusive charmless semileptonic decays and the exclusive decay $B \rightarrow \pi \ell^+ \nu$ [37]. The inclusive decays give rise to a value of $|V_{ub}| = (4.27 \pm 0.38) \times 10^{-3}$ while the exclusive measurements yield $|V_{ub}| = (3.38 \pm 0.36) \times 10^{-3}$, where the errors are dominantly theoretical [38]. Their average, enlarging the error in the standard manner because the results differ, is $|V_{ub}| = (3.80 \pm 0.44) \times 10^{-3}$. Using these values and the PDG values for the B^+ mass and lifetime, we arrive at the SM prediction for the $\tau^-\bar{\nu}$ branching fraction of $(0.96 \pm 0.24) \times 10^{-4}$. This value is about

a factor of two smaller than the measurements. There is a 6.6% probability that the data and the SM prediction are consistent. This difference is more clearly seen by examining the correlation between the CKM angle β and $\mathcal{B}(B^- \to \tau^- \bar{\nu})$. The CKM fitter group provides a fit to a large number of measurements involving heavy quark transitions [39]. The point in Fig. 2 shows the directly measured values, while the predictions from their fit without the direct measurements are also shown. There is about a factor of two discrepancy between the measured value of $\mathcal{B}(B^- \to \tau^- \overline{\nu})$ and the fit prediction.

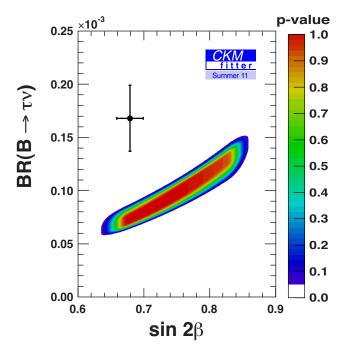

Figure 2: Measured and predicted values of $\mathcal{B}(B^- \to \tau^- \overline{\nu})$ versus $\sin 2\beta$ from the CKM fitter group [39]. The point with error bars shows the measured values, while the predictions are in shaded contours, with the shading related to the confidence level.

 π^+ and K^+ decay constants: The sum of branching fractions for $\pi^- \to \mu^- \bar{\nu}$ and $\pi^- \to \mu^- \bar{\nu} \gamma$ is 99.98770(4)%. The two modes are difficult to separate experimentally, so we use this sum, with Eq. (1) modified to include photon emission and radiative corrections [40]. The branching fraction together with the lifetime 26.033(5) ns gives

$$f_{\pi^-} = (130.41 \pm 0.03 \pm 0.20) \text{ MeV}$$
.

The first error is due to the error on $|V_{ud}|$, 0.97425(22) [6]; the second is due to the higher-order corrections, and is much larger.

Similarly, the sum of branching fractions for $K^- \to \mu^- \bar{\nu}$ and $K^- \to \mu^- \bar{\nu} \gamma$ is 63.55(11)%, and the lifetime is 12.3840(193) ns [41]. Measurements of semileptonic kaon decays provide a

value for the product $f_+(0)|V_{us}|$, where $f_+(0)$ is the form-factor at zero four-momentum transfer between the initial state kaon and the final state pion. We use a value for $f_+(0)|V_{us}|$ of 0.21664(48) [41]. The $f_+(0)$ must be determined theoretically. We follow Blucher and Marciano [7] in using the lattice calculation $f_+(0) = 0.9644 \pm 0.0049$ [42], since it appears to be more precise than the classic Leutwyler-Roos calculation $f_+(0) = 0.961 \pm 0.008$ [43]. [Other recent averages are 0.956 ± 0.008 [49] and 0.9588 ± 0.0044 [44].] Using the value from Ref. [42], the result is $|V_{us}| = 0.2246 \pm 0.0012$, consistent with the hyperon decay value of 0.2250 ± 0.0027 [45]. We derive

$$f_{K^-} = (156.1 \pm 0.2 \pm 0.8 \pm 0.2) \text{ MeV}$$
.

The first error is due to the error on Γ ; the second is due to the CKM factor $|V_{us}|$, and the third is due to the higher-order corrections. The largest source of error in these corrections depends on the QCD part, which is based on one calculation in the large N_c framework. We have doubled the quoted error here; this would probably be unnecessary if other calculations were to come to similar conclusions. A large part of the additional uncertainty vanishes in the ratio of the K^- and π^- decay constants, which is

$$f_{K^-}/f_{\pi^-} = 1.197 \pm 0.002 \pm 0.006 \pm 0.001$$
.

The first error is due to the measured decay rates; the second is due to the uncertainties on the CKM factors; the third is due to the uncertainties in the radiative correction ratio.

These measurements have been used in conjunction with calculations of f_K/f_π in order to find a value for $|V_{us}|/|V_{ud}|$. Three recent lattice predictions of f_K/f_π are 1.189 ± 0.007 [46], $1.192 \pm 0.007 \pm 0.006$ [47], and $1.197 \pm 0.002^{+0.003}_{-0.007}$ [48], yielding an average by the FLAG group of 1.195 ± 0.005 [49]. (A new average 1.1872 ± 0.0041 is quoted with statistical errors only [50]). Together with the precisely measured $|V_{ud}|$, this gives an independent measure of $|V_{us}|$ [8,41].

- P. del Amo Sanchez et al. (BaBar Collab.), Phys. Rev. D82, 091103 (2010) [arXiv:1008.4080] We do not use the previous BaBar result from a subsample of data as reported in J.P. Lee et al. (BaBar Collab.), [arXiv:1003.3063].
- See J. Alexander et al. (CLEO Collab.), Phys. Rev. Lett. 100, 161804 (2008).
- 18. We have not included a BaBar result: $\mathcal{B}(D_s^+ \to \mu^+ \nu) = (6.67 \pm 0.83 \pm 0.26 \pm 0.66) \times 10^{-3}$ and $f_{D_s^+} = (281 \pm 17 \pm 7 \pm 14)$ MeV based on $\mathcal{B}(D_s^+ \to \phi \pi^+) = (4.71 \pm 0.46)\%$. These measurements determined the ratio of the leptonic decay to a hadronic decay, usually $\Gamma(D_s^+ \to \ell^+ \nu)/\Gamma(D_s^+ \to \phi \pi^+)$. See B. Aubert *et al.* (BABAR Collab.), Phys. Rev. Lett. **98**, 141801 (2007).

the absence of strong phases, test for T violation in D_s^+ decays (the Γ 's are partial widths). With $\overline{A}_T \equiv [\Gamma(-\overline{C}_T > 0) - \Gamma(-\overline{C}_T < 0)] / [\Gamma(-\overline{C}_T > 0) + \Gamma(-\overline{C}_T < 0)]$, the asymmetry $A_{Tviol} \equiv \frac{1}{2}(A_T - \overline{A}_T)$ tests for T violation even with nonzero strong phases.

D*+ DECAY MODES

 D_s^{*-} modes are charge conjugates of the modes below.

| Mode | Fraction (Γ_i/Γ) |
|------------------------------------------------------------|------------------------------|
| $\begin{array}{c} D_s^+ \gamma \\ D_s^+ \pi^0 \end{array}$ | (94.2±0.7) % (5.8±0.7) % |

CONSTRAINED FIT INFORMATION

An overall fit to a branching ratio uses 2 measurements and one constraint to determine 2 parameters. The overall fit has a $\chi^2=$ 0.0 for 1 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\left\langle \delta x_i \delta x_j \right\rangle/(\delta x_i \cdot \delta x_j),$ in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}.$ The fit constrains the x_i whose labels appear in this array to sum to one.

$$x_2 \quad \boxed{-100}{x_1}$$

CONSTRAINED FIT INFORMATION

An overall fit to 7 branching ratios uses 8 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2=$ 3.4 for 4 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv$ $\Gamma_i/\Gamma_{
m total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$D_{s1}(2536)^{\pm}$

$$I(J^P) = 0(1^+)$$

J, P need confirmation.

Seen in $D^*(2010)^+ K^0$, $D^*(2007)^0 K^+$, and $D_s^+ \pi^+ \pi^-$. Not seen in $D^+ K^0$ or $D^0 K^+$. $J^P = 1^+$ assignment strongly favored.

$D_{s1}(2536)^{\pm}$ MASS

The fit includes D^{\pm} , D^{0} , D_{s}^{\pm} , $D^{*\pm}$, D^{*0} , $D_{s}^{*\pm}$, $D_{1}(2420)^{0}$, $D_{2}^{*}(2460)^{0}$, and $D_{s1}(2536)^{\pm}$ mass and mass difference measurements.

B-particle organization

Many measurements of B decays involve admixtures of B hadrons. Previously we arbitrarily included such admixtures in the B^\pm section, but because of their importance we have created two new sections: " B^\pm/B^0 Admixture" for T(4S) results and " $B^\pm/B^0/B_S^0$ /B-baryon Admixture" for results at higher energies. Most inclusive decay branching fractions and χ_D at high energy are found in the Admixture sections. $B^0-\overline{B}^0$ mixing data are found in the B^0 section, while $B^0_S-\overline{B}^0_S$ mixing data and $B-\overline{B}$ mixing data for a B^0/B_S^0 admixture are found in the B^0_S section. CP-violation data are found in the B^\pm_S , B^0 , and B^\pm B^0 Admixture sections. b-baryons are found near the end of the Baryon section. Recently, we also created a new section: " $V_{C,D}$ and $V_{U,D}$ CKM Matrix Elements."

The organization of the ${\cal B}$ sections is now as follows, where bullets indicate particle sections and brackets indicate reviews.

PRODUCTION AND DECAY OF b-FLAVORED HADRONS

Updated March 2012 by M. Kreps (U. of Warwick, Coventry, UK), J.G. Smith (U. of Colorado, Boulder, USA), and Y. Kwon (Yonsei U., Seoul, Korea).

The b quark belongs to the third generation of quarks and is the weak–doublet partner of the t quark. The existence of the third–generation quark doublet was proposed in 1973 by Kobayashi and Maskawa [1] in their model of the quark mixing matrix ("CKM" matrix), and confirmed four years later by the first observation of a $b\bar{b}$ meson [2]. In the KM model, CP violation is explained within the Standard Model (SM) by an irreducible phase of the 3×3 unitary matrix. The regular pattern of the three lepton and quark families is one of the most intriguing puzzles in particle physics. The existence of families gives rise to many of the free parameters in the SM, including the fermion masses, and the elements of the CKM matrix.

Since the b quark is the lighter element of the third–generation quark doublet, the decays of b-flavored hadrons occur via generation-changing processes through this matrix. Because of this, and the fact that the CKM matrix is close to a 3×3 unit matrix, many interesting features such as loop and box diagrams, flavor oscillations, as well as large CP asymmetries, can be observed in the weak decays of b-flavored hadrons.

The CKM matrix is parameterized by three real parameters and one complex phase. This complex phase can become a source of CP violation in B meson decays. A crucial milestone was the first observation of CP violation in the B meson system in 2001, by the BaBar [3] and Belle [4] collaborations. They measured a large value for the parameter $\sin 2\beta$ (= $\sin 2\phi_1$) [5], almost four decades after the discovery of a small CP asymmetry in neutral kaons. A more detailed discussion of the CKM matrix and CP violation can be found elsewhere in this Review [6,7].

The structure of this mini-review is organized as follows. After a brief description of theory and terminology, we discuss b-quark production and current results on spectroscopy

b-flavored hadrons

and lifetimes of b-flavored hadrons. We then discuss some basic properties of B-meson decays, followed by summaries of hadronic, rare, and electroweak penguin decays of B-mesons. There are separate mini-reviews for $B\overline{B}$ mixing [8] and the extraction of the CKM matrix elements V_{cb} and V_{ub} from B-meson decays [9] in this Review.

Theory and terminology: The ground states of b-flavored hadrons decay via weak interactions. In most hadrons, the b-quark is accompanied by light-partner quarks (d, u, or s), and the decay modes are well described by the decay of the b quark (spectator model) [10]. The dominant decay mode of a b quark is $b \to cW^{*-}$ (referred to as a "tree" or "spectator" decay), where the virtual W materializes either into a pair of leptons $\ell\bar{\nu}$ ("semileptonic decay"), or into a pair of quarks which then hadronizes. The decays in which the spectator quark combines with one of the quarks from W^* to form one of the final state hadrons are suppressed by a factor $\sim (1/3)^2$, because the colors of the two quarks from different sources must match ("color–suppression").

Many aspects of B decays can be understood through the Heavy Quark Effective Theory (HQET) [11]. This has been particularly successful for semileptonic decays. For further discussion of HQET, see for instance Ref. 12. For hadronic decays, one typically uses effective Hamiltonian calculations that rely on a perturbative expansion with Wilson coefficients. In addition, some form of the factorization hypothesis is commonly used. where, in analogy with semileptonic decays, two-body hadronic decays of B mesons are expressed as the product of two independent hadronic currents, one describing the formation of a charm meson (in case of the dominant $b \to cW^{*-}$ decays), and the other the hadronization of the remaining $\overline{u}d$ (or $\overline{c}s$) system from the virtual W^- . Qualitatively, for a B decay with a large energy release, the $\overline{u}d$ pair (produced as a color singlet) travels fast enough to leave the interaction region without influencing the charm meson. This is known to work well for the dominant spectator decays [13]. There are several common implementations of these ideas for hadronic B decays, the most common of which are QCD factorization (QCDF) [14], perturbative QCD (pQCD) [15], and soft collinear effective theory (SCET) [16].

The transition $b \to u$ is suppressed by $|V_{ub}/V_{cb}|^2 \sim (0.1)^2$ relative to $b \to c$ transitions. The transition $b \to s$ is a flavor-changing neutral-current (FCNC) process, and although not allowed in the SM as a tree-process, can occur via more complex loop diagrams (denoted "penguin" decays). The rates for such processes are comparable or larger than CKM-suppressed $b \to u$ processes. Penguin processes involving $b \to d$ transitions are also possible, and have been observed [17,18]. Other decay processes discussed in this Review include W-exchange (a W is exchanged between initial-state quarks), penguin annihilation (the gluon from a penguin loop attaches to the spectator quark, similar to an exchange diagram), and pure-annihilation (the initial quarks annihilate to a virtual W, which then decays).

Production and spectroscopy: The bound states of a \overline{b} antiquark and a u, d, s, or c quark are referred to as the B_u (B^+), B_d (B^0), B_s , and B_c mesons, respectively. The B_c is the heaviest of the ground–state b-flavored mesons, and the most difficult to produce: it was observed for the first time in the semileptonic mode by CDF in 1998 [19], but its mass was accurately determined only in 2006, from the fully reconstructed mode $B_c^+ \to J/\psi \pi^+$ [20].

The first excited meson is called the B^* meson, while B^{**} is the generic name for the four orbitally excited (L=1) B-meson states that correspond to the P-wave mesons in the charm system, D^{**} . Excited states of the B_s meson are similarly named B_s^* and B_s^{**} . Of the possible bound $\bar{b}b$ states, the Υ series (S-wave) and the χ_b (P-wave) are well studied. The pseudoscalar ground state η_b also has been observed by BaBar [21](and confirmed by CLEO [22]), indirectly through the decay $\Upsilon(3S) \to \gamma \eta_b$. See Ref. 23 for classification and naming of these and other states.

Experimental studies of b decays have been performed in e^+e^- collisions at the $\Upsilon(4S)$ (ARGUS, CLEO, Belle, BaBar) and $\Upsilon(5S)$ (CLEO, Belle) resonances, as well as at higher energies, at the Z resonance (SLC, LEP) and in $p\bar{p}$ collisions (Tevatron). The $e^+e^- \to b\bar{b}$ production cross-section at the Z, $\Upsilon(4S)$, and $\Upsilon(5S)$ resonances are about 6.6 nb, 1.1 nb, and 0.3 nb respectively. High-energy hadron collisions produce b-flavored hadrons of all species with much larger cross-sections: $\sigma(p\bar{p}\to bX,|\eta|<1)\sim 30~\mu b$ at the Tevatron ($\sqrt{s}=1.96~{\rm TeV}$), and even higher at the energies of the LHC pp collider (up to a factor of ten at $\sqrt{s}=14~{\rm TeV}$).

BaBar and Belle have accumulated respectively 560 fb⁻¹ and 1020 fb⁻¹ of data, of which 433 fb⁻¹ and 710 fb⁻¹ respectively are at the $\Upsilon(4S)$ resonance; CDF and D0 have currently accumulated about 10 fb⁻¹ each. At the LHC, CMS and AT-LAS have collected 5 fb⁻¹ of data and LHCb has collected about 1 fb $^{-1}$. These numbers indicate that the majority of b-quarks have been produced in hadron collisions, but the large backgrounds cause the hadron collider experiments to have lower selection efficiency. Only the few decay modes for which triggering and reconstruction are easiest have been studied so far in hadron collisions. These have included final states with leptons, and exclusive modes with all charged particles in the final state. In contrast, detectors operating at e^+e^- colliders ("B-Factories") have a high efficiency for most decays, and have provided large samples of a rich variety of decays of B^0 and B^+ mesons.

In hadron collisions, most production happens as $b\overline{b}$ pairs, either via s-channel production or gluon–splitting, with a smaller fraction of single b-quarks produced by flavor excitation. The total b-production cross section is an interesting test of our understanding of QCD processes. For many years, experimental measurements have been several times higher than predictions. With improved measurements [24], more accurate input parameters, and more advanced calculations [25], the discrepancy between theory and data is now much reduced, although the

presence of inconsistencies among existing measurements makes further studies desirable.

Each quark of a $b\overline{b}$ pair produced in hadron collisions hadronizes separately and incoherently from the other, but it is still possible, although difficult, to obtain a statistical indication of the charge of a produced b/\overline{b} quark ("flavor tag" or "charge tag") from the accompanying particles produced in the hadronization process, or from the decay products of the other quark. The momentum spectrum of produced b-quarks typically peaks near the b-quark mass, and extends to much higher momenta, dropping by about a decade for every ten GeV. This implies typical decay lengths of the order of a millimeter; the resolution for the decay vertex must be more precise that this to resolve the fast oscillations of B_s mesons.

In e^+e^- colliders, since the B mesons are very slow in the $\Upsilon(4S)$ rest frame, asymmetric beam energies are used to boost the decay products to improve the precision of time-dependent measurements that are crucial for the study of CP violation. At KEKB, the boost is $\beta\gamma=0.43$, and the typical B-meson decay length is dilated from $\approx 20~\mu m$ to $\approx 200~\mu m$. PEP-II uses a slightly larger boost, $\beta\gamma=0.55$. The two B mesons produced in $\Upsilon(4S)$ decay are in a coherent quantum state, which makes it easier than in hadron collisions to infer the charge state of one B meson from observation of the other; however, the coherence also requires determination of the decay time of both mesons, rather than just one, in order to perform time-dependent CP-violation measurements.

For the measurement of branching fractions, the initial composition of the data sample must be known. The $\Upsilon(4S)$ resonance decays predominantly to $B^0\overline{B}^0$ and B^+B^- ; the current experimental upper limit for non- $B\overline{B}$ decays of the $\Upsilon(4S)$ is less than 4% at the 95% confidence level (CL) [26]. The only known modes of this category are decays to lower Υ states and a pion pair, observed with branching fractions of order 10^{-4} [27]. The ratio f_+/f_0 of the fractions of charged to neutral B productions from $\Upsilon(4S)$ decays has been measured by CLEO, BaBar, and Belle in various ways. They typically use pairs of isospin-related decays of B^+ and B^0 , such that it can be assumed that $\Gamma(B^+ \to x^+) = \Gamma(B^0 \to x^0)$. In this way, the ratio of the number of events observed in these modes is proportional to $(f_+\tau_+)/(f_0\tau_0)$ [28–31]. BaBar has also performed an independent measurement of f_0 with a different method that does not require isospin symmetry or the value of the lifetime ratio, based on the number of events with one or two reconstructed $B^0 \to D^{*-}\ell^+\nu$ decays [32]. The combined result, from the current average of τ_+/τ_0 , is $f_+/f_0 = 1.055 \pm$ 0.025 [33]. Though the current 2.2σ discrepancy with equal production of B^+B^- and $B^0\overline{B}^0$ pairs is somewhat larger than previous averages, we still assume $f_{+}/f_{0}=1$ in this mini-review except where explicitly stated otherwise. This assumption is also supported by the near equality of the B^+ and B^0 masses: our fit of CLEO, ARGUS, and CDF measurements yields $m(B^0) =$ $5279.50 \pm 0.33 \text{ MeV}/c^2$, $m(B^+) = 5279.13 \pm 0.31 \text{ MeV}/c^2$, and $m(B^0)-m(B^+)=0.37\pm0.24~{\rm MeV}/c^2$. The latest measurement

from the LHCb agrees well with those and further improves precision [34].

CLEO and Belle have also collected some data at the $\Upsilon(5S)$ resonance [35,36]. Belle has accumulated more than 100 fb^{-1} at this resonance. This resonance does not provide the simple final states of the $\Upsilon(4S)$: there are seven possible final states with a pair of non-strange B mesons and three with a pair of strange B mesons $(B_s^*\overline{B}_s^*, B_s^*\overline{B}_s, \text{ and } B_s\overline{B}_s)$. The fraction of events with a pair of B_s mesons over the total number of events with a pair of b-flavored hadrons has been measured to be $f_s[\Upsilon(5S)] = 0.199 \pm 0.030$, of which 90% is $B_s^* \bar{B}_s^*$ events. A few branching fractions of the B_s have been measured in this way; if the precision of f_s were improved, they would become the most accurate. Belle has observed a few new B_s modes that are difficult to reconstruct in hadron colliders and the most precise mass measurement of the B_s^* meson has been obtained [36,37]. However, the small boost of B_s mesons produced in this way prevents resolution of their fast oscillations for time-dependent measurements; these are only accessible in hadron collisions or at the Z peak.

In high-energy collisions, the produced b or \bar{b} quarks can hadronize with different probabilities into the full spectrum of b-hadrons, either in their ground or excited states. Table 1 shows the measured fractions f_d , f_u , f_s , and $f_{\rm baryon}$ of B^0 , B^+ , B_s^0 , and b baryons, respectively, in an unbiased sample of weakly decaying b hadrons produced at the Z resonance or in $p\bar{p}$ collisions [33]. The results were obtained from a fit where the sum of the fractions were constrained to equal 1.0, neglecting production of B_c mesons. The observed yields of B_c mesons at the Tevatron [19] yields $f_c = 0.2\%$, in agreement with expectations [38], and well below the current experimental uncertainties in the other fractions.

Table 1: Fractions of weakly-decaying b-hadron species in $Z \to b\overline{b}$ decay, in $p\overline{p}$ collisions at $\sqrt{s}=1.8$ TeV and combination of fractions in $Z \to b\overline{b}$ decay at Tevatron, $p\overline{p}$ and pp collisions at LHC.

| b hadron | Fraction at Z $[\%]$ | Fraction at $\overline{p}p[\%]$ | Combined $[\%]$ |
|------------|----------------------|---------------------------------|-----------------|
| B^+, B^0 | 40.3 ± 0.9 | 33.9 ± 3.9 | 40.1 ± 0.8 |
| B_s | 10.3 ± 0.9 | 11.1 ± 1.4 | 10.5 ± 0.6 |
| b baryons | 9.0 ± 1.5 | 21.2 ± 6.9 | 9.3 ± 1.6 |

The combined values assume identical hadronization in $p\overline{p}$ collisions and in Z decay. These could in principle differ, because of the different momentum distributions of the b-quark in these processes; the sample used in the $p\overline{p}$ measurements has momenta close to the b mass, rather than $m_Z/2$. A test of the agreement between production fractions may be given by comparison of values of the average time-integrated mixing probability parameter $\bar{\chi} = f_d \chi_d + f_s \chi_s$ [8]. This is an important input in the determination of the world-averages of production fractions. The current measurements of $\bar{\chi}$ from LEP and the

b-flavored hadrons

Tevatron differ by 1.8 σ [33]. This slight discrepancy increases the uncertainty in the combined fractions in Table 1. It should be noted that the combination is not well defined as both the CDF and LHCb experiments observe a significant dependence of the Λ_b production fraction on transverse momentum. With the availability of large samples of b-flavored mesons and baryons at $p\overline{p}$ colliders, the limited knowledge of these fractions has become an important limiting factor in the determination of their branching fractions.

Excited B-meson states have been observed by CLEO, LEP, CUSB, D0, and CDF. The current world average of the B^* -B mass difference is $45.78 \pm 0.35 \text{ MeV}/c^2$. Evidence for B^{**} (L=1) production has been initially obtained at LEP [39], as a broad resonance in the mass of an inclusively reconstructed bottom hadron candidate combined with a charged pion from the primary vertex. Detailed results from exclusive modes have been obtained at the Tevatron, allowing separation of the narrow states B_1 and B_2^* and also a measurement of the B_2^* width [40].

Also the narrow B_s^{**} states, first sighted by OPAL as a single broad enhancement in the B^+K mass spectrum [41], have now been clearly observed and separately measured at the Tevatron [42]: $M(B_{s1}) = 5829.4 \pm 0.7 \text{ MeV}/c^2 \text{ (CDF)}$ and $M(B_{s2}^*) = 5839.7 \pm 0.7 \text{ MeV}/c^2 \text{ (CDF)}$, $M(B_{s2}^*) = 5839.6 \pm 1.1 \pm 0.7 \text{ MeV}/c^2 \text{ (D0)}$.

Baryon states containing a b quark are labeled according to the same scheme used for non-b baryons, with the addition of a b subscript [23]. For many years, the only well-established bbaryon was the Λ_b^0 (quark composition udb), with only indirect evidence for Ξ_b (dsb) production from LEP [43]. This situation has changed dramatically in the past few years due to the large samples being accumulated at the Tevatron and LHCb. Clear signals of four strongly-decaying baryon states, Σ_h^+ , Σ_h^{*+} $(uub), \Sigma_b^-, \Sigma_b^{*-}$ (ddb) have been obtained by CDF in $\Lambda_b^0 \pi^{\pm}$ final states [44]. The strange bottom baryon Ξ_b^{\pm} was observed in the exclusive mode $\Xi_b^{\pm} \to J/\psi \Xi^{\pm}$ by D0 [45], and CDF [46]. More recently CDF has also observed the Ξ_b in the $\Xi_c \pi$ final state [47]. The relative production of Ξ_b and Λ_b baryons has been found to be consistent with the B_s to B_d production ratio [45]. Observation of the doubly-strange bottom baryon Ω_b^- has been published by both D0 [48] and CDF [49]. However the masses measured by the two experiments show a large discrepancy. The resolution appears to be provided by LHCb; they recently presented a preliminary measurement of the Ω_b^- mass consistent with the CDF measurement [50]. Apart from the discrepancy on Ω_b^- mass, the masses of all these new baryons have been measured to a precision of a few MeV/c^2 , and found to be in agreement with predictions from HQET.

Lifetimes: Precise lifetimes are key in extracting the weak parameters that are important for understanding the role of the CKM matrix in CP violation, such as the determination of V_{cb} and $B_s\overline{B}_s$ mixing parameters. In the naive spectator model, the heavy quark can decay only via the external spectator

mechanism, and thus, the lifetimes of all mesons and baryons containing b quarks would be equal. Non–spectator effects, such as the interference between contributing amplitudes, modify this simple picture and give rise to a lifetime hierarchy for b-flavored hadrons similar to the one in the charm sector. However, since the lifetime differences are expected to scale as $1/m_Q^2$, where m_Q is the mass of the heavy quark, the variations in the b system are expected to be only 10% or less [51]. We expect:

$$\tau(B^+) > \tau(B^0) \approx \tau(B_s) > \tau(\Lambda_b^0) \gg \tau(B_c^+)$$
. (1)

For the B_c^+ , both quarks decay weakly, so the lifetime is much shorter.

Measurements of the lifetimes of the different b-flavored hadrons thus provide a means to determine the importance of non-spectator mechanisms in the b sector. Over the past decade, the precision of silicon vertex detectors and the increasing availability of fully–reconstructed samples has resulted in much-reduced statistical and systematic uncertainties (\sim 1%). The averaging of precision results from different experiments is a complex task that requires careful treatment of correlated systematic uncertainties; the world averages given in Table 2 have been determined by the Heavy Flavor Averaging Group (HFAG) [33].

Table 2: Summary of inclusive and exclusive world-average b-hadron lifetime measurements. For the two B_s averages, see text below.

| $\begin{array}{llll} \text{Particle} & \text{Lifetime [ps]} \\ \hline B^+ & 1.641 \pm 0.008 \\ B^0 & 1.519 \pm 0.007 \\ B_s & \text{(flavor-specific)} & 1.463 \pm 0.032 \\ B_s & (1/\Gamma_s) & 1.495 \pm 0.015 \\ B_c^+ & 0.453 \pm 0.041 \\ \Lambda_b^0 & 1.425 \pm 0.032 \\ \Xi_b^- & 1.56^{+0.27}_{-0.25} \\ \Omega_b^- & 1.13^{+0.53}_{-0.40} \\ \hline \Xi_b & \text{mixture} & 1.49^{+0.19}_{-0.18} \\ b\text{-baryon mixture} & 1.382 \pm 0.029 \\ b\text{-hadron mixture} & 1.568 \pm 0.009 \\ \hline \end{array}$ | | |

| | o-nadron mixture | 1.008 ± 0.009 |

The short B_c^+ lifetime is in good agreement with predictions [52]. For precision comparisons with theory, lifetime ratios are more sensitive. Experimentally we find:

$$\begin{split} \frac{\tau_{B^+}}{\tau_{B^0}} &= 1.079 \pm 0.007 \,,\; \frac{\tau_{B_s}}{\tau_{B^0}} = 0.984 \pm 0.011 \,,\\ \frac{\tau_{\Lambda_b}}{\tau_{B^0}} &= 0.938 \pm 0.022 \,, \end{split}$$

while theory makes the following predictions [51,53]

$$\frac{\tau_{B^+}}{\tau_{B^0}} = 1.06 \pm 0.02 \; , \; \; \frac{\tau_{B_s}}{\tau_{B^0}} = 1.00 \pm 0.01 \; , \; \; \frac{\tau_{\Lambda_b}}{\tau_{B^0}} = 0.88 \pm 0.05.$$

The ratio of B^+ to B^0 lifetimes has a precision of better than 1%, and is significantly different from 1.0, in agreement with predictions [51]. The ratio of B_s to B^0 lifetimes is expected to be very close to 1.0; while there used to be mild tension between experiment and theory, the discrepancy is disappearing with newer measurements with large samples of fully reconstructed B_s decays [54]. The Λ_b lifetime has a history of discrepancies. Predictions were higher than data before the introduction of higher-order effects lowered them. The precision of the measurements has recently been improved by more than a factor of two by two CDF measurements [57,58]. The measurements are in marginal agreement with each other and previous measurements; the new world average is somewhat larger than the theoretical predictions. The most significant discrepancy comes from the CDF measurement in $\Lambda_b \to J/\psi \Lambda$ channel which differs by 3.3σ from the average of all other measurements. With more data available at both D0 and CDF and large samples available at LHCb, new results will hopefully resolve this discrepancy in the near future.

Neutral B mesons are two-component systems similar to neutral kaons, with a light (L) and a heavy (H) mass eigenstate, and independent decay widths Γ_L and Γ_H . The SM predicts a non-zero width difference $\Delta\Gamma = \Gamma_L - \Gamma_H > 0$ for both B_s and B_d . For B_d , $\Delta \Gamma_d/\Gamma_d$ is expected to be $\sim 0.2\%$. Analysis of BaBar and DELPHI data on CP-specific modes of the B^0 yield a combined result: $\Delta \Gamma_d / \Gamma_d = 0.015 \pm 0.018$ [33]. The issue is much more interesting for the B_s , since the SM expectation for $\Delta\Gamma_s/\Gamma_s$ is of order 10%. This potentially nonnegligible difference requires care when defining the B_s lifetime. As indicated in Table 2, two different lifetimes are defined for the B_s meson: one is defined as $1/\Gamma_s$, where Γ_s is the average width of the two mass eigenstates $(\Gamma_L + \Gamma_H)/2$; the other is obtained from "flavor-specific" (e.g., semileptonic) decays and depends both on Γ_s and $\Delta\Gamma_s$. Experimentally, the quantity $\Delta\Gamma_s$ can be accessed by measuring lifetimes in decays into CPeigenstates, which in the standard model are expected to be close approximations to the mass eigenstates. This has been done with the $J/\psi\phi$ mode, where the two CP eigenstates are distinguished by angular distributions, and in $B_s \to K^+K^$ or $B_s \to J/\psi f_0(980)$ which are CP-eigenstates. The current experimental information is dominated by measurements on the $J/\psi\phi$ mode performed by CDF, D0 and LHCb experiments. By appropriately combining all published measurements of $J/\psi\phi$ lifetimes and flavor-specific lifetimes, the HFAG group obtains a world-average $\Delta\Gamma_s/\Gamma_s=0.092^{+0.051}_{-0.054}$ [33], which is compatible with zero; the latest theoretical predictions yield $\Delta\Gamma_s/\Gamma_s = 0.133 \pm 0.032$ [59], in agreement with measurements within the large uncertainties on both. From the theoretical point of view, the best quantity to use is $\Delta\Gamma_s/\Delta M_s$, which is much less affected by hadronic uncertainties [59]. Exploiting the very accurate measurement of ΔM_s now available [60], this can be turned into a SM prediction with an uncertainty of only 20%: $\Delta\Gamma_s/\Gamma_s = 0.137 \pm 0.027$. This is likely to be of importance in future comparisons, as the experimental precision improves with the growth of Tevatron samples. Further improvements are coming from lifetime measurements in the CP-eigenstates

such as $B_s \to K^+K^-$ [61] and $B_s \to J/\psi f_0(980)$ [62], and alternative (model–dependent) determinations via the $B_s \to D_s^{(*)+}D_s^{(*)-}$ branching fraction [63].

The width difference $\Delta\Gamma_s$ is connected to the B_s mixing phase ϕ_s by $\Delta\Gamma_s = \Gamma_{12}\cos\phi_s$, where Γ_{12} is the off-diagonal term of the decay matrix [6,8,59]. The early measurements by CDF [64] and D0 [65] have produced CL contours in the $(\phi_s, \Delta\Gamma)$ plane, and both observe a mild deviation, in the same direction, from the expectation of the Standard model of the phase ϕ_s near $\Delta\Gamma$ = 0. The possibility of a large value of ϕ_s has attracted significant interest, as it would be very clean evidence for the existence of new sources of CP violation beyond the standard model. However the latest measurements from CDF [66], D0 [67] and LHCb [68], which provide significant improvements over initial measurements, show good agreement with the standard model. The LHCb experiment also used the decay $B_s \to J/\psi f_0(980)$ to measure ϕ_s [69]. While this measurement is not as precise as the one from $B_s \to J/\psi \phi$, it does not require analysis of angular distributions, which simplifies the analysis. It should be noted that all above measurements have a two-fold ambiguity in their results. We can resolve this ambiguity using the interferance between the decays to $J/\psi\phi$ and $J/\psi K^+K^-$, where K^+K^- is in relative S-wave state. This has been used by LHCb experiment to determine the sign of the $\Delta\Gamma_s$ to be positive [70].

B meson decay properties: Semileptonic B decays $B \rightarrow$ $X_c\ell\nu$ and $B\to X_u\ell\nu$ provide an excellent way to measure the magnitude of the CKM elements $|V_{cb}|$ and $|V_{ub}|$ respectively, because the strong interaction effects are much simplified due to the two leptons in the final state. Both exclusive and inclusive decays can be used, and the nature of uncertainties are quite complementary. For exclusive decay analysis, knowledge of the form factors for the exclusive hadronic system $X_{c(u)}$ is required. For inclusive analysis, it is usually necessary to restrict the available phase-space of the decay products to suppress backgrounds; subsequently uncertainties are introduced in the extrapolation to the full phase-space. Moreover, restriction to a small corner of the phase-space may result in breakdown of the operator-product expansion scheme, thus making theoretical calculations unreliable. A more detailed discussion of Bsemileptonic decays and the extraction of $|V_{cb}|$ and $|V_{ub}|$ is given elsewhere in this Review [9].

On the other hand, hadronic decays of B are complicated because of strong interaction effects caused by the surrounding cloud of light quarks and gluons. While this complicates the extraction of CKM matrix elements, it also provides a great opportunity to study perturbative and non-perturbative QCD, hadronization, and Final State Interaction (FSI) effects. Purepenguin decays were first established by the observation of $B \to K^*\gamma$ [71]. Some observed decay modes such as $B^0 \to D_s^-K^+$, may be interpreted as evidence of a W-exchange process [72]. The evidence for the decay $B^+ \to \tau^+\nu$ from Belle [73] and BaBar [74] is the first sign of a pure annihilation decay. There

b-flavored hadrons

is growing evidence that penguin annihilation processes may be important in decays with two vector mesons in the final state [75].

Hadronic decays: Most of the hadronic B decays involve $b \to c$ transition at the quark level, resulting in a charmed hadron or charmonium in the final state. Other types of hadronic decays are very rare and will be discussed separately in the next section. The experimental results on hadronic Bdecays have steadily improved over the past few years, and the measurements have reached sufficient precision to challenge our understanding of the dynamics of these decays. With the good neutral particle detection and hadron identification capabilities of B-factory detectors, a substantial fraction of hadronic Bdecay events can be fully reconstructed. Because of the kinematic constraint of $\Upsilon(4S)$, the energy sum of the final-state particles of a B meson decay is always equal to one half of the total energy in the center of mass frame. As a result, the two variables, ΔE (energy difference) and M_B (B candidate mass with a beam-energy constraint) are very effective for suppressing combinatorial background both from $\Upsilon(4S)$ and $e^+e^- \to q\bar{q}$ continuum events. In particular, the energy-constraint in M_B improves the signal resolution by almost an order of magnitude.

The kinematically clean environment of B meson decays provides an excellent opportunity to search for new states. For instance, quark-level $b \to c\bar{c}s$ decays have been used to search for new charmonium and charm-strange mesons and study their properties in detail. In 2003, BaBar discovered a new narrow charm-strange state $D_{sJ}^*(2317)$ [76], and CLEO observed a similar state $D_{sJ}(2460)$ [77]. The properties of these new states were studied in the B meson decays, $B \to DD_{sJ}^*(2317)$ and $B \to DD_{sJ}(2460)$ by Belle [78]. Further studies of $D_{sJ}^{(*)}$ meson production in B decays have been made by Belle [79] and BaBar [80]. Now these charm-strange meson states are identified as $D_{s0}^*(2317)$ and $D_{s1}(2460)$, respectively.

More recently, Belle observed a new D_{sJ} meson produced in $B^+ \to \bar{D}^0 D_{sJ} \to \bar{D}^0 D^0 K^+$ [81]. Combined with a subsequent measurement by BaBar [82], the mass and width of this state are determined to be 2709^{+9}_{-6} MeV/ c^2 and 125 ± 30 MeV, respectively. An analysis of the helicity angle distribution determines its spin-parity to be 1^- .

A variety of exotic particles have been discovered in B decays. Belle found the X(3872) state [83], which is confirmed by CDF [84] and BaBar [85]. Analyzing their full $\Upsilon(4S)$ data sample, Belle finds a new upper limit on the width of X(3872) to be $\Gamma_{X(3872)} < 1.2$ MeV [86], improving on the existing limit by nearly a factor of 2. Radiative decays of X(3872) can play a crucial role in understanding the nature of the particle. For example, in the molecular model the decay of X(3872) to $\psi'\gamma$ is expected to be highly suppressed in comparison to the decay to $J/\psi\gamma$ [87]. BaBar has seen the evidence for the decay to $J/\psi\gamma$ [88]. The ratio $R \equiv \mathcal{B}(X(3872) \to \psi'\gamma)/\mathcal{B}(X(3872) \to J/\psi\gamma)$ is measured to be 3.4 ± 1.4 by BaBar [89], while Belle obtains R < 2.1 at 90% CL [90].

Belle has observed a near-threshold enhancement in the $J/\psi\omega$ invariant mass for $B\to J/\psi\omega K$ decays [91]. BaBar has studied $B\to J/\psi\pi^+\pi^-K$, finding an excess of $J/\psi\pi^+\pi^-$ events with a mass just above 4.2 GeV/ c^2 ; this is consistent with the Y(4260) that was observed by BaBar in ISR (Initial State Radiation) events [93]. A Belle study of $B\to \psi'K\pi^\pm$ [94] finds a state called $X(4430)^\pm$ that decays to $\psi'\pi^\pm$. Since it is charged, it could not be a charmonium state. This state was searched for by BaBar with similar sensitivity but was not found [95]. In a Dalitz plot analysis of $\overline{B}^0\to \chi_{c1}K^-\pi^+$, Belle has observed two resonance-like structures in the $\chi_{c1}\pi^+$ mass distribution [96], labelled as $X(4050)^\pm$ and $X(4250)^\pm$ in this Review, while no evidence is found by BaBar in a search with similar sensitivity [97].

The hadronic decays $\overline{B}^0 \to D^{(*)0}h^0$, where h^0 stands for light neutral mesons such as $\pi^0, \eta^{(')}, \rho^0, \omega$, proceed through color-suppressed diagrams, hence they provide useful tests on the factorization models. Both Belle and BaBar have made comprehensive measurements of such color-suppressed hadronic decays of \overline{B}^0 [98].

Information on B_s and Λ_b decays is limited, though improving with recent studies of large samples at the Tevatron and LHC experiments. Recent additions are decays of $B_s \to J/\psi f_0(980)$ [62,99], $B_s \to J/\psi f_2'(1525)$ [100], and $\Lambda_b \to \Lambda_c \pi^+ \pi^- \pi^-$ [101]. For the later, not only the total rate is measured, but also structure involving decays through excited Λ_c and Σ_c baryons.

There have been hundreds of publications on hadronic B decays to open-charm and charmonium final states mostly from the B-factory experiments. These results are nicely summarized in a recent report by HFAG [33].

Rare B decays: All B-meson decays that do not occur through the $b \to c$ transition are usually called rare B decays. These include both semileptonic and hadronic $b \to u$ decays that are suppressed at leading order by the small CKM matrix element V_{ub} , as well as higher-order $b \to s(d)$ processes such as electroweak and gluonic penguin decays.

Charmless B meson decays into two-body hadronic final states such as $B \to \pi\pi$ and $K\pi$ are experimentally clean, and provide good opportunities to probe new physics and search for indirect and direct CP violations. Since the final state particles in these decays tend to have larger momenta than average Bdecay products, the event environment is cleaner than for $b \rightarrow c$ decays. Branching fractions are typically around 10^{-5} . Over the past decade, many such modes have been observed by BaBar, Belle, and CLEO. More recently, comparable samples of the modes with all charged final particles have been reconstructed in $p\bar{p}$ collisions by CDF by triggering on the impact parameter of the charged tracks. This has also allowed observation of charmless decays of the B_s , in final states such as $\phi\phi$ [102], K^+K^- [103], and $K^-\pi^+$ [104], and of charmless decays of the Λ_b^0 baryon [104]. Charmless B_s modes are related to corresponding B^0 modes by U-spin symmetry, and are determined

by similar amplitudes. Combining the observables from B_s and B^0 modes is a further way of eliminating hadronic uncertainties and extracting relevant CKM information [105].

Because of relatively high-momenta for final state particles, the dominant source of background in e^+e^- collisions is $q\bar{q}$ continuum events; sophisticated background suppression techniques exploiting event shape variables are essential for these analyses. In hadron collisions, the dominant background comes from QCD or partially reconstructed heavy flavors, and is similarly suppressed by a combination of kinematic and isolation requirements. The results are in general consistent among the experiments.

BaBar [106] and Belle [107] have observed the decays $B^+ \to \overline{K}^0 K^+$ and $B^0 \to K^0 \overline{K}^0$. The world-average branching fractions are $\mathcal{B}(B^0 \to K^0 \overline{K}^0) = (0.96^{+0.20}_{-0.18}) \times 10^{-6}$ and $\mathcal{B}(B^+ \to \overline{K}^0 K^+) = (1.36 \pm 0.27) \times 10^{-6}$. These are the first observations of hadronic $b \to d$ transitions, with significance $> 5\sigma$ for all four measurements. CP asymmetries have even been measured for these modes, though with large errors.

Most rare decay modes including $B^0 \to K^+\pi^-$ have contributions from both $b \to u$ tree and $b \to sg$ penguin processes. If the size of the two contributions are comparable, the interference between them may result in direct CP violation, seen experimentally as a charge asymmetry in the decay rate measurement. BaBar [108], Belle [109], and CDF [103] have measured the direct CP violating asymmetry in $B^0 \to K^+\pi^-$ decays. The BaBar and Belle measurements constitute observation of direct CP violation with a significance of more than 5σ . The world average for this quantity is now rather precise, -0.098 ± 0.013 . There are sum rules [110] that relate the decay rates and decay-rate asymmetries between the four $K\pi$ charge states. The experimental measurements of the other three modes are not yet precise enough to test these sum rules.

There is now evidence for direct CP violation in three other decays: $B^+ \to \rho^0 K^+$ [111], $B^+ \to \eta K^+$ [112], and $B^0 \to \eta K^{*0}$ [113]. The significance is typically 3–4 σ , though the significance for the $B^+ \to \eta K^+$ decay is now nearly 5σ with the recent Belle measurement [112]. In at least the first two cases, a large direct CP violation might be expected since the penguin amplitude is suppressed so the tree and penguin amplitudes may have comparable magnitudes.

The decay $B^0 \to \pi^+\pi^-$ can be used to extract the CKM angle α . This is complicated by the presence of significant contributions from penguin diagrams. An isospin analysis [114] can be used to untangle the penguin complications. The decay $B^0 \to \pi^0\pi^0$, which is now measured by both BaBar and Belle, is crucial in this analysis. Unfortunately the amount of penguin pollution in the $B \to \pi\pi$ system is rather large. In the past few years, measurements in the $B^0 \to \rho\rho$ system have produced more precise values of α , since penguin amplitudes are generally smaller for decays with vector mesons. An important ingredient in the analysis is the $B^0 \to \rho^0 \rho^0$ branching fraction. The average of measurements from BaBar and Belle BaBar [115] yields a branching fraction of $(0.73\pm0.28)\times10^{-6}$. This is only 3% of the

 $\rho^+\rho^-$ branching fraction, much smaller than the corresponding ratio in the $\pi\pi$ system.

The decay $B \to a_1 \pi$ has been seen by BaBar. An analysis of the time evolution of this decay [116] together with measurements of other related decays has been used to measure the CKM angle α [117] in agreement with the more precise measurements from the $\rho\rho$ system.

Since $B\to\rho\rho$ has two vector mesons in the final state, the CP eigenvalue of the final state depends on the longitudinal polarization fraction f_L for the decay. Therefore, a measurement of f_L is needed to extract the CKM angle α . Both BaBar and Belle have measured f_L for the decays $\rho^+\rho^-$ and $\rho^+\rho^0$ and in both cases the measurements show $f_L>0.9$, making a complete angular analysis unnecessary.

By analyzing the angular distributions of the B decays to two vector mesons, we can learn a lot about both weakand strong-interaction dynamics in B decays. Decays that are penguin-dominated surprisingly have values of f_L near 0.5. The list of such decays has now grown to include $B \to \phi K^*$, $B \to \rho K^*$, and $B \to \omega K^*$. The reasons for this "polarization puzzle" are not fully understood. A detailed description of the angular analysis of B decays to two vector mesons can be found in a separate mini-review [118] in this Review.

There has been substantial progress in measurements of many other rare-B decays. The decay $B \to \eta' K$ stood out as the largest rare-B decay for many years. The reasons for the large rate are now largely understood [14,119]. However, there are now measurements of several 3-body or quasi-3-body modes with similarly large branching fractions. States seen so far include $K\pi\pi$ (three charge states) [120], KKK (four charge states) [121], and $K^*\pi\pi$ (two charged states) [122]. Many of these analyses now include Dalitz plot treatments with many intermediate resonances. There has also been an observation of the decay $B^+ \to K^+K^-\pi^+$ by BaBar [123], noteworthy because an even number of kaons is typically indicative of suppressed $b \to d$ transitions as discussed above.

Belle [73] and BaBar [74] have found evidence for $B^+ \to \tau^+\nu$; the average branching fraction, with a significance of nearly 5σ is $(165\pm34)\times10^{-6}$. This is somewhat larger than, though consistent with, the value expected in the SM. This is the first observation of a pure annihilation decay. A substantial region of parameter space of charged Higgs mass vs. $\tan\beta$ is excluded by the measurements of this mode.

Electroweak penguin decays: More than a decade has passed since the CLEO experiment first observed an exclusive radiative $b \to s \gamma$ transition, $B \to K^*(892) \gamma$ [71], thus providing the first evidence for the one-loop FCNC electromagnetic penguin decay. Using much larger data samples, both Belle and BaBar have updated this analysis [124] with an average branching raction $\mathcal{B}(B^0 \to K^{*0} \gamma) = (43.3 \pm 1.5) \times 10^{-6}$, and have added several new decay modes such as $B \to K_1 \gamma$, $K_2^*(1430) \gamma$, etc. [125]. With a sample of 24 fb⁻¹ at $\Upsilon(5S)$, Belle observed the radiative penguin decay of $B_s \to \phi \gamma$ with a branching fraction $(57^{+22}_{-19}) \times 10^{-6}$ [126].

b-flavored hadrons

Compared to $b \to s\gamma$, the $b \to d\gamma$ transitions such as $B \to \rho\gamma$, are suppressed by the small CKM element V_{td} . Both Belle and BaBar have observed these decays [17,18]. The world average $\mathcal{B}(B \to (\rho,\omega)\gamma) = (1.28 \pm 0.21) \times 10^{-6}$. This can be used to calculate $|V_{td}/V_{ts}|$ [127]; the measured values are $0.233^{+0.033}_{-0.032}$ from BaBar [18] and $0.195^{+0.025}_{-0.024}$ from Belle [17].

The observed radiative penguin branching fractions can constrain a large class of SM extensions [128]. However, due to the uncertainties in the hadronization, only the inclusive $b \to s \gamma$ rate can be reliably compared with theoretical calculations. This rate can be measured from the endpoint of the inclusive photon spectrum in B decay. By combining the measurements of $B \to X_s \gamma$ from CLEO, BaBar, and Belle experiments [129,130], HFAG obtains the new average: $\mathcal{B}(B \to X_s \gamma) = (3.55 \pm 0.24 \pm 0.09) \times 10^{-4}$ [33] for $E_{\gamma} \geq 1.6$ GeV. Consistent results have been reported by ALEPH for inclusive b-hadrons produced at the Z. The measured branching fraction can be compared to theoretical calculations. Recent calculations of $\mathcal{B}(b \to s \gamma)$ at NNLO level predict the values of $(3.15 \pm 0.23) \times 10^{-4}$ [131] and $(2.98 \pm 0.26) \times 10^{-4}$ [132], where the latter is calculated requiring $E_{\gamma} > 1.6$ GeV.

The CP asymmetry in $b \to s\gamma$ is extensively studied theoretically both in the SM and beyond [133]. According to the SM, the CP asymmetry in $b \to s\gamma$ is smaller than 1%, but some non-SM models allow significantly larger CP asymmetry ($\sim 10\%$) without altering the inclusive branching fraction. The current world average is $A_{CP} = -0.012 \pm 0.028$, again dominated by BaBar and Belle [134]. In addition to the CP asymmetry, BaBar also measured the isospin asymmetry $\Delta_{0-} = 0.06 \pm 0.17$ in $b \to s\gamma$ by measuring the companion B with full reconstruction in the hadronic decay modes [135].

In addition, all three experiments have measured the inclusive photon energy spectrum for $b \to s \gamma$, and by analyzing the shape of the spectrum they obtain the first and second moments for photon energies. Belle has measured these moments covering the widest range in the photon energy (1.7 < E_{γ} < 2.8 GeV) [130]. These results can be used to extract non-perturbative HQET parameters that are needed for precise determination of the CKM matrix element V_{ub} .

Additional information on FCNC processes can be obtained from $B \to X_s \ell^+ \ell^-$ decays, which are mediated by electroweak penguin and W-box diagrams. Their branching fractions have been measured by Belle [136], BaBar [137], and CDF [138]. Average branching fractions over all charged and neutral modes have been determined from BaBar and Belle data for $B \to K\ell^+\ell^-$: $(0.45\pm0.04)\times10^{-6}$ and for $B\to K^*(892)\ell^+\ell^-$: $(1.08\pm0.11)\times10^{-6}$, consistent with the SM expectation. B-factory experiments also measured the branching fractions for inclusive $B\to X_s\ell^+\ell^-$ decays [139], with an average of $(3.66^{+0.76}_{-0.77})\times10^{-6}$ [140]. Recently corresponding decays of B_s and Λ_b were observed [138,141]. Branching fraction for the decay $B_s\to\phi\mu^+\mu^-$ is measured to be $(1.47\pm0.24\pm0.46)\times10^{-6}$ and for the decay $\Lambda_b\to\Lambda\mu^+\mu^-$ to be $(1.73\pm0.42\pm0.55)\times10^{-6}$. Excitment was generated by measurements of forward-backward

asymmetry in $B \to K^*(892)\ell^+\ell^-$ decays, which exhibited mild tension with the standard model in earlier measurements. The most recent measurements by CDF [142] and LHCb [143] agree with standard model, suggesting that the earlier discrepancy was mainly due to statistical fluctuations.

Finally the decays $B_{(s)}^0 \to e^+e^-$ and $\mu^+\mu^-$ are interesting since they only proceed at second order in weak interactions in the SM, but may have large contributions from supersymmetric loops, proportional to $(\tan \beta)^6$. Experiments at Tevatron, Bfactories and now also LHC have obtained results that exclude a portion of the region allowed by SUSY models. The most stringent limits in these modes are obtained by LHCb. The limits in the $\mu^{+}\mu^{-}$ mode are: $< 1.4 \times 10^{-8}$ and $< 3.2 \times 10^{-9}$ at 95% confidence level, respectively, for B_s and B^0 [144]. For the B_s mode, the result is about factor of five above SM predictions [145]. It should be noted, that the most recent search by CDF observes an excess above expected background [146]. While the branching fraction for decay $B_s \to \mu^+ \mu^-$ of $(1.8^{+1.1}_{-0.9}) \times 10^{-8}$ is extracted, CDF concludes that most plausible explanation for the excess is a statistical fluctuation. The limits for the $e^+e^$ modes are: $< 2.8 \times 10^{-7}$ and $< 8.3 \times 10^{-8}$, respectively, for B_s and B^0 [147]. There are also limits for lepton flavor-violating channels $B_{(s)}^0 \to e^+\mu^-$, which are around 10^{-7} [147].

Summary and Outlook: The study of B mesons continues to be one of the most productive fields in particle physics. With the two asymmetric B-factory experiments Belle and BaBar, we now have a combined data sample of well over 1 ab⁻¹. CP violation has been firmly established in many decays of B mesons. Evidence for direct CP violation has been observed. Many rare decays resulting from hadronic $b \to u$ transitions and $b \to s(d)$ penguin decays have been observed, and the emerging pattern is still full of surprises. Despite the remarkable successes of the B-factory experiments, many fundamental questions in the flavor sector remain unanswered.

At Fermilab, CDF and D0 each has accumulated about 10 fb^{-1} , which is the equivalent of about 10^{12} *b*-hadrons produced. In spite of the low trigger efficiency of hadronic experiments, a selection of modes have been reconstructed in large quantities, giving a start to a program of studies on B_s and *b*-flavored baryons, in which a first major step has been the determination of the B_s oscillation frequency.

As Tevatron and B-factories stop their taking data, the new experiments at the LHC have become very active. The LHC accelerator performed very well in 2011. The general purpose experiments ATLAS and CMS collected about 5 fb⁻¹ while LHCb collected about 1 fb⁻¹. LHCb, which is almost fully dedicated to studies of b- and c-hadrons, has a very large data sample. Of particular note is the sensitivity of the LHC experiments for the decay $B_s \to \mu^+\mu^-$ which is expected to approach the standard model level in 2012.

In addition, two projects for next generation high-luminosty B-factories at KEK and Frascati are approved. Their aim to increase samples to $\sim 50~{\rm ab^{-1}}$ will make it possible to explore the

Meson Particle Listings b-flavored hadrons

indirect evidence of new physics beyond the SM in the heavy-flavor particles $(b, c, \text{ and } \tau)$, in a way that is complementary to the LHC.

These experiments promise a rich spectrum of rare and precise measurements that have the potential to fundamentally affect our understanding of the SM and CP-violating phenomena.

A NOTE ON HFAG ACTIVITIES

The Heavy Flavor Averaging Group (HFAG) has been formed, continuing the activities of the LEP Heavy Flavor Steering group, to provide the averages for measurements dedicated to the b-flavor related quantities. The HFAG consists of representatives and contacts from the experimental groups: BaBar, Belle, CDF, CLEO, DØ, LEP, SLD, and LHCb.

In the averaging the input parameters used in the various analyses are adjusted (rescaled) to common values, and all known correlations are taken into account. The HFAG has seven sub-groups providing averages for b-hadron lifetimes and B-oscillation parameters, CP-violation measurements, semileptonic parameters, rare branching fractions, b-hadron decays to charm, charm mixing and decays, and τ decays. The averages provided by the HFAG are listed as "OUR EVALUATION" with a corresponding note.

The most up-to-date and complete listing of averages and more detailed information on the averaging procedures are available at:

http://www.slac.stanford.edu/xorg/hfag .

$$I(J^P) = \frac{1}{2}(0^-)$$

Quantum numbers not measured. Values shown are quark-model

See also the B^{\pm}/B^0 ADMIXTURE and $B^{\pm}/B^0/B_s^0/b$ -baryon AD-MIXTURE sections.

B± MASS

The fit uses $m_{B^+},\,(m_{B^0}-m_{B^+}),$ and m_{B^0} to determine $m_{B^+},\,m_{B^0},$ and the mass difference.

- 1 Uses $B^{+} \rightarrow J/\psi K^{+}$ fully reconstructed decays.
- ²Uses exclusively reconstructed final states containing a $J/\psi \rightarrow \mu^+\mu^-$ decays.
- 3 CSORNA 00 uses fully reconstructed 526 $B^+ o J/\psi^{(\prime)}$ K^+ events and invariant masses without beam constraint. 4 ALBRECHT 90J assumes 10580 for $\Upsilon(4S)$ mass. Supersedes ALBRECHT 87c and
- Found using fully reconstructed decays with $J/\psi(1S)$. ALBRECHT 87D assume $m_{\Upsilon(4S)}$ = 10577 MeV

B± MEAN LIFE

See $B^{\pm}/B^0/B_{\rm c}^0/b$ -baryon ADMIXTURE section for data on B-hadron mean life averaged over species of bottom particles

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors

- ¹ Measured mean life using fully reconstructed decays $(J/\psi K^{(*)})$.
- 2 Measured using $B^- \to \ D^0 \, \pi^-$ with $D^0 \to \ \ K^- \, \pi^+$ events that were selected using a silicon vertex trigger.
- ³ Measurement performed using a combined fit of *CP*-violation, mixing and lifetimes
- 4 Measurement performed using an inclusive reconstruction and \emph{B} flavor identification
- Measured mean life using fully reconstructed decays.
- 6 Events are selected in which one B meson is fully reconstructed while the second B meson is reconstructed inclusively.
- Oata analyzed using D / D* ℓX event vertices.
- B Data analyzed using charge of secondary vertex. 9 ABREU 95Q assumes B($B^0 \to D^{**-}\ell^+\nu_\ell$) = 3.2 \pm 1.7%.
- $^{
 m 10}\,{
 m Data}$ analyzed using vertex-charge technique to tag ${\it B}$ charge.
- ¹¹ Combined result of $D/D^*\ell X$ analysis and fully reconstructed B analysis.
- 12 Combined ABREU 95Q and ADAM 95 result.

B+ DECAY MODES

B - modes are charge conjugates of the modes below. Modes which do not identify the charge state of the B are listed in the B^\pm/B^0 ADMIXTURE

The branching fractions listed below assume 50% $B^{0}\,\overline{B}^{0}$ and 50% $B^{+}\,B^{-}$ production at the $\Upsilon(4S)$. We have attempted to bring older measurements up to date by rescaling their assumed $\Upsilon(4S)$ production ratio to 50:50 and their assumed D, D_S, D*, and ψ branching ratios to current values whenever this would affect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state

For inclusive branching fractions, e.g., $B \to D^\pm$ anything, the values usually are multiplicities, not branching fractions. They can be greater

- [a] An ℓ indicates an e or a μ mode, not a sum over these modes.
- [b] An $CP(\pm 1)$ indicates the CP=+1 and CP=-1 eigenstates of the $D^0-\overline{D}{}^0$ system.
- [c] D denotes D^0 or \overline{D}^0 .
- [d] D_{CP+}^{*0} decays into $D^0\pi^0$ with the D^0 reconstructed in $C\!P$ -even eigenstates K^+K^- and $\pi^+\pi^-$.
- [e] \overline{D}^{**} represents an excited state with mass 2.2 < M < 2.8 GeV/c².
- [f] $X(3872)^+$ is a hypothetical charged partner of the X(3872).
- $[g] \Theta(1710)^{++}$ is a possible narrow pentaquark state and G(2220) is a possible glueball resonance.
- [h] $(\overline{\Lambda}_c^- p)_s$ denotes a low-mass enhancement near 3.35 GeV/c².

CONSTRAINED FIT INFORMATION

An overall fit to 18 branching ratios uses 48 measurements and one constraint to determine 12 parameters. The overall fit has a $\chi^2 = 38.8$ for 37 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv$ $\Gamma_i/\Gamma_{
m total}$. The fit constrains the x_i whose labels appear in this array to sum to

- 1 URQUIJO 07 report a measurement of (10.34 \pm 023 \pm 0.25)% for the partial branching fraction of $B^+\to~e^+\nu_e\,X_{\rm C}$ decay with electron energy above 0.6 GeV. We converted the result to $B^{\,+}\,\rightarrow\,\,e^{\,+}\,\overline{\nu_e\,X}$ branching fraction.
- 2 The measurements are obtained for charged and neutral B mesons partial rates of semileptonic decay to electrons with momentum above 0.6 GeV/c in the B rest frame. The best precision on the ratio is achieved for a momentum threshold of 1.0 GeV: B($B^+
 ightarrow$ $\label{eq:epsilon} {\rm e}^+\,\nu_e\,X)\;/\;{\rm B}(B^0\to\;{\rm e}^+\,\nu_e\,X)\,=\,1.074\,\pm\,0.041\,\pm\,0.026.$
- 3 ARTUSO 97 uses partial reconstruction of $B\to D^*\ell\nu_\ell$ and branching ratio from BARISH 96B (0.1049 \pm 0.0017 \pm 0.0043). and inclusive semileptonic
- ⁴ The measurements are obtained for charged and neutral B mesons partial rates of semileptonic decay to electrons with momentum above 0.6 GeV/c in the B rest frame, and their ratio of B(B⁺ $\to e^+ \nu_e X)/B(B^0 \to e^+ \nu_e X) = 1.08 \pm 0.05 \pm 0.02$.

- 1 Measured using the dependence of $B^- o D^{*0} \, e^- \overline{
 u}_e$ decay differential rate and the form factor description by CAPRINI 98.
- ² Simultaneous measurements of both $B^0 \to D^*(2010)^- \ell \nu$ and $B^+ \to \overline{D}(2007)^0 \ell \nu$.
- 3 ALBRECHT 92c reports $0.058 \pm 0.014 \pm 0.013$. We rescale using the method described in STONE 94 but with the updated PDG 94 B($D^0 \rightarrow K^- \pi^+$). Assumes equal production of $B^0\overline{B}^0$ and B^+B^- at the $\Upsilon(4S)$
- ⁴ Uses a fully reconstructed B meson as a tag on the recoil side.
- 5 The results are based on the same analysis and data sample reported in ADAM 03. 6 BARISH 95 use B($D^0\to K^-\pi^+)=(3.91\pm0.08\pm0.17)\%$ and B($D^{*0}\to D^0\pi^0)=(63.6\pm2.3\pm3.3)\%$.
- ⁷Combining $\overline{D}^{*0}\ell^+\nu_\ell$ and $\overline{D}^{*-}\ell^+\nu_\ell$ SANGHERA 93 test $V\!-\!A$ structure and fit the decay angular distributions to obtain $A_{FB}=3/4*(\Gamma^--\Gamma^+)/\Gamma=0.14\pm0.06\pm0.03$.

Assuming a value of V_{CD} , they measure V, A_1 , and A_2 , the three form factors for the $D^*\ell\nu_\ell$ decay, where results are slightly dependent on model assumptions.

⁸ Assumes equal production of $B^0 \overline{B^0}$ and $B^+ B^-$ at the $\Upsilon(4S)$. Uncorrected for D and D^* branching ratio assumptions.

 9 ANTREASYAN 90B is average over B and $\overline{D}*(2010)$ charge states.

 $^1B^+$ and B^0 decays combined assuming isospin symmetry. Systematic errors include both

experimental and form-factor uncertainties. 2 The signal events are tagged by a second $^{\it B}$ meson reconstructed in the semileptonic mode $B o D^{(*)} \ell
u_\ell$

 3 Derived based in the reported B^0 result by assuming isospin symmetry: $\Gamma(B^0
ightarrow$ $\rho^-(\ell^+\nu)=2\Gamma(B^+\to\rho^0(\ell^+\nu)\approx 2\Gamma(B^+\to\omega\ell^+\nu)$. 4 BEAN 93B limit set using ISGW Model. Using isospin and the quark model to combine

 $\Gamma(\omega^0\ell^+\nu_\ell)$ and $\Gamma(\rho^-\ell^+\nu_\ell)$ with this result, they obtain a limit <(1.6–2.7) \times 10⁻⁴ at 90% CL for $B^+\to \rho^0\ell^+\nu_\ell$. The range corresponds to the ISGW, WSB, and KS models. An upper limit on $\left|V_{ub}/V_{cb}\right| < 0.8$ –0.13 at 90% CL is derived as well.

 1 Assumes equal production of B^+ and B^0 at the arGamma(4S).

Requires one reconstructed semileptonic B decay $B^- \to D^0 \ell^- \overline{\nu}_\ell X$ in the recoil. Requires one reconstructed semileptonic B decay $B^- \to D^{(*)0} \ell^- \overline{\nu}_\ell X$ in the recoil.

 4 The analysis is based on a sample of events with one fully reconstructed tag B in a hadronic decay mode $B^-\to D^{(*)0}\,X^-.$

nationic decay mode $B\to D^+ \Lambda^- \Lambda^-$.

5 The energy-flow and b-tagging algorithms were used.

6 ACCIARRI 97F uses missing-energy technique and $f(b\to B^-)=(38.2\pm 2.5)\%$.

7 ALBRECHT 95D uses full reconstruction of one B decay as tag.

8 BUSKULIC 95 uses same missing-energy technique as in $\overline{b}\to \tau^+\nu_{\tau} X$, but analysis is restricted to endpoint region of missing-energy distribution.

$\Gamma(\ell^+ \nu_\ell \gamma) / \Gamma_{\text{total}}$

VALUE DOCUMENT ID TECN COMMENT $<15.6 \times 10^{-6}$ 1 AUBERT 90 09AT BABR $e^+e^- \rightarrow \Upsilon(4S)$
