I. Introduction

Understanding the mechanism that breaks electroweak symmetry and generates the masses of the known elementary particles is one of the most fundamental problems in particle physics. The Higgs mechanism [1] provides a general framework to explain the observed masses of the W^{\pm} and Z gauge bosons by means of charged and neutral Goldstone bosons that are manifested as the longitudinal components of the gauge bosons. These Goldstone bosons are generated by the underlying dynamics of electroweak symmetry breaking (EWSB). However, the fundamental dynamics of the electroweak symmetry breaking are unknown. There are two main classes of

theories proposed in the literature, those with weakly coupled dynamics—such as in the Standard Model (SM) [2]—and those with strongly coupled dynamics; both classes are summarized below

In the SM, the electroweak interactions are described by a gauge field theory based on the $\mathrm{SU}(2)_L \times \mathrm{U}(1)_Y$ symmetry group. The Higgs mechanism posits a self-interacting complex doublet of scalar fields, and renormalizable interactions are arranged such that the neutral component of the scalar doublet acquires a vacuum expectation value $v \approx 246$ GeV, which sets the scale of EWSB. Three massless Goldstone bosons are generated, which are absorbed to give masses to the W^\pm and Z gauge bosons. The remaining component of the complex doublet becomes the Higgs boson—a new fundamental scalar particle. The masses of all fermions are also a consequence of EWSB since the Higgs doublet is postulated to couple to the fermions through Yukawa interactions. If the Higgs boson mass m_H is below ~ 180 GeV, all fields remain weakly interacting up to the Planck scale, $M_{\rm Pl}$.

The validity of the SM as an effective theory describing physics up to the Planck scale is questionable, however, because of the following "naturalness" argument. All fermion masses and dimensionless couplings are logarithmically sensitive to the scale Λ at which new physics becomes relevant. In contrast, scalar squared masses are quadratically sensitive to Λ . Thus, the observable SM Higgs mass has the following form:

$$m_H^2 = m_{H_0}^2 + \frac{kg^2\Lambda^2}{16\pi^2},$$

where m_{H_0} is a fundamental parameter of the theory. The second term is a one-loop correction in which q is an electroweak coupling and k is a constant, presumably of $\mathcal{O}(1)$, that is calculable within the low-energy effective theory. The two contributions arise from independent sources and one would not expect that the observable Higgs boson mass is significantly smaller than either of the two terms. Hence, if the scale of new physics Λ is much larger than the electroweak scale, unnatural cancellations must occur to remove the quadratic dependence of the Higgs boson mass on this large energy scale and to give a Higgs boson mass of order of the electroweak scale, as required from unitarity constraints [3,4], and as preferred by precision measurements of electroweak observables [5]. Most relevantly, recent results from direct Higgs searches at the Tevatron [6] and, in particular, at the LHC [7–10] strongly constrain the SM Higgs boson mass to be in the range 114-129 GeV, in excellent agreement with the indirect predictions from electroweak precision data. Thus, the SM is expected to be embedded in a more fundamental theory which will stabilize the hierarchy between the electroweak scale and the Planck scale in a natural way. A theory of that type would usually predict the onset of new physics at scales of the order of, or just above, the electroweak scale. Theorists strive to construct models of new physics that keep the successful features of the SM while curing its shortcomings, such as the absence of a dark matter candidate or a

¹ In the case of neutrinos, it is possible that the Higgs mechanism plays a role but is not entirely responsible for the generation of their observed masses.

Gauge & Higgs Boson Particle Listings Higgs Bosons — H^0 and H^{\pm}

detailed explanation of the observed baryon asymmetry of the universe.

In the weakly-coupled approach to electroweak symmetry breaking, supersymmetric (SUSY) extensions of the SM provide a possible explanation for the stability of the electroweak energy scale in the presence of quantum corrections [11,12]. These theories predict at least five Higgs particles [13]. The properties of the lightest Higgs scalar often resemble those of the SM Higgs boson, with a mass that is predicted to be less than 135 GeV [14] in the simplest supersymmetric model². Additional neutral and charged Higgs bosons are also predicted. Moreover, low-energy supersymmetry with a supersymmetry breaking scale of order 1 TeV allows for grand unification of the electromagnetic, weak and strong gauge interactions in a consistent way, strongly supported by the prediction of the electroweak mixing angle at low energy scales, with an accuracy at the percent level [22,23].

Alternatively new strong interactions near the TeV scale can induce strong breaking of the electroweak symmetry [24]. "Little Higgs" models have been proposed in which the scale of the new strong interactions is pushed up above 10 TeV [25–27], and the lightest Higgs scalar resembles the weakly-coupled SM Higgs boson.

Another approach to electroweak symmetry breaking has been explored in which extra space dimensions beyond the usual 3+1 dimensional space-time are introduced [28] with characteristic sizes of the fundamental Planck scale of order $(1 \text{ TeV})^{-1}$. In such scenarios, the mechanisms for electroweak symmetry breaking are inherently extra-dimensional and the resulting Higgs phenomenology can depart significantly from SM predictions [27,29].

Both in the framework of supersymmetric theories and in the strongly coupled dynamic approach there have been many studies based on effective theory approaches [18,20,21,30,31] that prove useful in exploring departures from the SM Higgs phenomenology in a more model independent way.

Prior to 1989, when the e^+e^- collider LEP at CERN came into operation, searches were sensitive only to Higgs bosons with masses of a few GeV and below [32]. In the LEP 1 phase, the collider operated at center-of-mass energies close to M_Z . During the LEP 2 phase, the energy was increased in steps, reaching 209 GeV in the year 2000 before the final shutdown. The combined data of the four LEP experiments, ALEPH, DELPHI, L3, and OPAL, were sensitive to neutral

Higgs bosons with masses up to about 115 GeV and to charged Higgs bosons with masses up to about 90 GeV [33,34].

The search for the Higgs boson continued at the Tevatron $p\overline{p}$ collider, which operated at a center-of-mass energy of 1.96 TeV until its shutdown in the Fall of 2011. The two experiments, CDF and DØ, each collected approximately 10 fb⁻¹ of data with the capability to probe a SM Higgs boson mass in the 90-185 GeV range. The combination of the results from CDF and DØ shows an excess of data events with respect to the background estimation in the mass range 115 GeV $< m_H <$ 135 GeV. The global significance for such an excess anywhere in the full mass range is approximately 2.2 standard deviations. The excess is concentrated in the $H \to b\bar{b}$ channel, although the results in the $H \to W^+W^-$ channel are also consistent with the possible presence of a low-mass Higgs boson. Other neutral and charged Higgs particles postulated in most theories beyond the SM are also searched for at the Tevatron. The Tevatron Higgs results are discussed in more detail later in this review. The final results are expected to be available by the end of 2012.

Searches for Higgs bosons are ongoing at the LHC pp collider. These searches have much higher sensitivity than the Tevatron searches and cover masses up to several hundred GeV. At present both LHC experiments, ATLAS and CMS, have searched for a SM Higgs boson produced mainly through gluon fusion, and decaying dominantly into gauge boson pairs. The initial results are compatible with the presence of a SM-like Higgs boson with a mass in the range 114-129 GeV, with most of the remaining mass values up to at least 500 GeV being excluded at the 95% C.L. by both experiments. Both LHC experiments observe small excesses, predominantly in the $\gamma\gamma$ and ZZ modes, which could be compatible with a Higgs boson with a mass near 125 GeV but are not yet conclusive. These results are discussed in more detail later in this review. If a signal is confirmed, the next step is to understand the precise nature of such a particle by scrutinizing the coupling strengths in the different production and decay channels. Searches are also conducted by both LHC collaborations for Higgs bosons produced via vector boson fusion and in association with a W or a Z boson. Decays to $b\bar{b}$ and $\tau^+\tau^-$ are searched for in addition to the more experimentally distinct boson pair signatures. With additional data, these searches will constrain the production rates and decay branching ratios of the Higgs boson. An exciting time lies ahead in the case of the discovery of a Higgs boson since we would need to understand its nature and the underlying new physics that might be related to it. Beyond a discovery, precision measurements will be crucial to completely understand the mechanism of electroweak symmetry breaking.

II. The Standard Model (SM) Higgs Boson

In the SM, the Higgs boson mass is given by $m_H = \sqrt{\lambda/2} v$, where λ is the Higgs self-coupling parameter and v is the vacuum expectation value of the Higgs field, $v = (\sqrt{2}G_F)^{-1/2} \approx$

² Larger values of the mass of the lightest Higgs boson, up to about 250 GeV, can be obtained in non-minimal SUSY extensions of the SM [15–21]. However, if the LHC's indications of a light Higgs boson are confirmed, the main motivation for non-minimal SUSY extensions would be to obtain a Higgs boson mass in the 120–130 GeV mass range without demanding heavy top quark superpartners, and thereby avoid the so-called little hierarchy problem.

Gauge & Higgs Boson Particle Listings Higgs Bosons — H^0 and H^{\pm}

246 GeV, fixed by the Fermi coupling G_F , which is determined with a precision of 0.6 ppm from muon decay measurements [35]. Since λ is presently unknown, the value of the SM Higgs boson mass m_H cannot be predicted. However, besides the upper bound on the Higgs boson mass from unitarity constraints [3,4], additional theoretical arguments place approximate upper and lower bounds on m_H [36]. There is an upper bound based on the perturbativity of the theory up to the scale Λ at which the SM breaks down, and a lower bound derived from the stability of the Higgs potential. If m_H is too large, then the Higgs self-coupling diverges at some scale Λ below the Planck scale. If m_H is too small, then the Higgs potential develops a second (global) minimum at a large value of the magnitude of the scalar field of order Λ . New physics must enter at a scale Λ or below, so that the global minimum of the theory corresponds to the observed $SU(2)_L \times U(1)_Y$ broken vacuum with v = 246 GeV. Given a value of Λ , one can compute the minimum and maximum allowed Higgs boson masses. Conversely, the value of m_H itself can provide an important constraint on the scale up to which the SM remains successful as an effective theory. In particular, a Higgs boson with mass in the range 130 GeV $\lesssim m_H \lesssim 180$ GeV would be consistent with an effective SM description that survives all the way to the Planck scale. For smaller Higgs mass values, the stability of our universe prefers new physics at a lower scale. The lower bound on m_H can be reduced to about 115 GeV [37] if one allows for the electroweak vacuum to be metastable, with a lifetime greater than the age of the universe. The main uncertainties in the stability and perturbativity bounds come from the uncertainties in the value of α_s and the top quark mass. As can be inferred from Fig. 1 [38], taking these uncertainties into account, a Higgs boson mass of about 125 GeV is close to the boundary of a SM that is consistent up to the Planck scale, and a SM that is unstable with a slow tunneling rate.

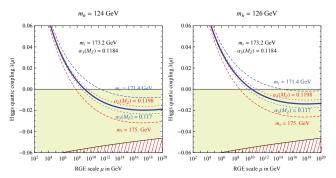

Figure 1: Renormalization group evolution of the Higgs self coupling λ , for $m_H=124~{\rm GeV}$ (left) and $m_H=126~{\rm GeV}$ (right), for the central values of m_t and α_S (solid curves), as well as for variations of m_t (dashed curves) and α_S (dotted curves). For negative values of λ , the lifetime of the SM vacuum due to quantum tunneling at zero temperature is longer than the age of the universe as long as λ remains above the region shaded in red. From Ref. 38.

The SM Higgs couplings to fundamental fermions are proportional to the fermion masses, and the couplings to bosons are proportional to the squares of the boson masses. In particular, the SM Higgs boson is a CP-even scalar, and its couplings to gauge bosons, Higgs bosons and fermions are given by:

$$\begin{split} g_{Hf\bar{f}} &= \frac{m_f}{v}, \quad g_{HVV} = \frac{2m_V^2}{v}, \quad g_{HHVV} = \frac{2m_V^2}{v^2} \\ g_{HHH} &= \frac{3m_H^2}{v} \quad g_{HHHH} = \frac{3m_H^2}{v^2} \end{split}$$

where $V=W^\pm$ or Z. In Higgs boson production and decay processes, the dominant mechanisms involve the coupling of the H to the W^\pm , Z and/or the third generation quarks and leptons. The Higgs boson's coupling to gluons, is induced at leading order by a one-loop graph in which the H couples to a virtual $t\bar{t}$ pair. Likewise, the Higgs boson's coupling to photons is also generated via loops, although in this case the one-loop graph with a virtual W^+W^- pair provides the dominant contribution [13]. Reviews of the SM Higgs boson's properties and phenomenology, with an emphasis on the impact of loop corrections to the Higgs boson decay rates and cross sections, can be found in Refs. [39–45].

The main Higgs boson production cross sections at an e^+e^- collider are the Higgs-strahlung process $e^+e^- \to ZH$ [4,46], and the WW fusion process [47] $e^+e^- \to \bar{\nu}_e\nu_eW^*W^* \to \bar{\nu}_e\nu_eH$. As center-of-mass energy \sqrt{s} is increased, the cross-section for the Higgs-strahlung process decreases as s^{-1} and is dominant at low energies, while the cross-section for the WW fusion process grows as $\ln(s/m_H^2)$ and dominates at high energies [48,49,50]. The ZZ fusion mechanism, $e^+e^- \to e^+e^-Z^*Z^* \to e^+e^-H$, also contributes to Higgs boson production, with a cross-section suppressed by an order of magnitude with respect to that of WW fusion. The process $e^+e^- \to t\bar{t}H$ [51,52] can become relevant for large $\sqrt{s} \simeq 800$ GeV for SM Higgs masses in the experimentally preferred region. For a more detailed discussion of Higgs production properties at lepton colliders see for example Refs. [44] and [45], and references therein.

At high-energy hadron colliders, the Higgs boson production mechanism with the largest cross section is $gg \to H + X$. This process is known at next-to-next-to-leading order (NNLO) in QCD, in the large top-mass limit, and at NLO in QCD for The NLO QCD corrections approxarbitrary top mass [53]. imately double the leading-order prediction, and the NNLO corrections add approximately 50% to the NLO prediction. NLO electroweak corrections range between 0 and 6% of the Mixed QCD-electroweak corrections $O(\alpha \alpha_s)$ LO term [54]. are computed in Ref. [55]. In addition, soft-gluon contributions to the cross sections have been resummed at next-toleading logarithmic (NLL), NNLL and partial NNNLL accuracy Updated predictions for the gluon fusion cross sections at NNLO or through soft-gluon resummation up to next-tonext-to-leading logarithmic accuracy (NNLL), and two-loop electroweak effects can be found in Refs. [55,57].

Gauge & Higgs Boson Particle Listings Higgs Bosons — H^0 and H^{\pm}

perturbative convergence is achieved by resumming the enhanced contributions arising from the analytic continuation of the gluon form factor [58]. Updated predictions to compute the gluon fusion cross sections at NNNLL in renormalization group improved perturbation theory and incorporating two-loop electroweak effects can be found in Ref. [59]. Some search strategies look for Higgs boson production in association with jets. In the heavy top quark mass limit, the Higgs boson production cross section in association with one jet is considered in Refs. [60–63] and in association with two jets in Refs. [64,65].

The other relevant Higgs boson production mechanisms at the Tevatron and the LHC are associated production with W and Z gauge bosons and vector boson fusion, and at a significantly smaller rate, the associated production with top quark pairs. The cross sections for the associated production processes $q\overline{q} \to W^{\pm}H + X$ and $q\overline{q} \to ZH + X$ [66,67,68] are known at NNLO for the QCD corrections and at NLO for the electroweak corrections [69,70]. The residual uncertainty is less than 5%. For the vector boson fusion processes $qq \rightarrow$ qqH+X, corrections to the production cross section are known at NNLO in QCD and at NLO for the electroweak corrections and the remaining theoretical uncertainties in the inclusive cross section are approximately 2% [71], but are larger if jets are required or vetoed [43]. The cross section for the associated production process $t\bar{t}H$ has been calculated at NLO in QCD [72], while the bottom fusion Higgs boson production cross section is known at NNLO in the case of five quark flavors [69,73,74]. The cross sections for the production of SM Higgs bosons are summarized in Fig. 2 for $p\overline{p}$ collisions at the Tevatron, and in Fig. 3 for pp collisions at $\sqrt{s} = 7$ TeV at the LHC [75,76]. Ref. [75] also includes cross sections computed at $\sqrt{s} = 8$ TeV, which are relevant for data collected in 2012.

The branching ratios for the most relevant decay modes of the SM Higgs boson as functions of m_H , including the most recent theoretical uncertainties, are shown in Fig. 4. The total decay width as function of m_H is shown in Fig. 5. Details of these calculations can be found in Refs. [40–44]. boson masses below 135 GeV, decays to fermion pairs dominate; the decay $H \to b\bar{b}$ has the largest branching ratio and the decay $H \to \tau^+ \tau^-$ is about an order of magnitude smaller. For these low masses, the total decay width is less than 10 MeV. For Higgs boson masses above 135 GeV, the W^+W^- decay dominates (below the W^+W^- threshold, one of the W bosons is virtual) with an important contribution from $H \to ZZ$, and the decay width rises rapidly, reaching about 1 GeV at $m_H = 200$ GeV and 100 GeV at $m_H = 500$ GeV. Above the $t\bar{t}$ threshold, the branching ratio into $t\bar{t}$ pairs increases rapidly as a function of the Higgs boson mass, reaching a maximum of about 20% at $m_H \sim 450$ GeV. Higgs boson decays into pairs of gluons, pairs of photons, and $Z\gamma$ are induced at one loop level. Higgs boson decay into a pair of photons is particularly relevant for the discovery potential of the LHC for a low-mass Higgs boson. In

spite of the small expected signal rate, the reconstructed mass resolution provides a way to separate signal from background, a means to calibrate the background rate with a signal-free sample of events, and a precise measurement of m_H once a signal is identified.

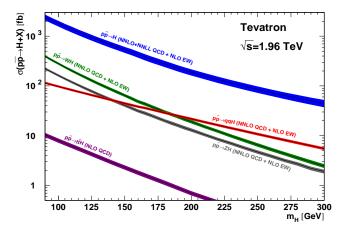

Figure 2: SM Higgs boson production cross sections for $p\overline{p}$ collisions at 1.96 TeV, including theoretical uncertainties [53,70–72].

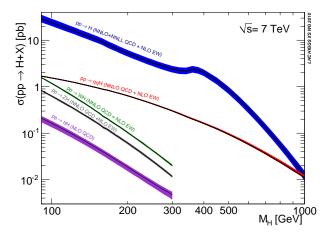

Figure 3: SM Higgs boson production cross sections for *pp* collisions at 7 TeV, including theoretical uncertainties [76].

II.1. Indirect Constraints on the SM Higgs Boson

Indirect experimental bounds for the SM Higgs boson mass are obtained from fits to precision measurements of electroweak observables. The Higgs boson contributes to the W^{\pm} and Z vacuum polarization through loop effects, leading to a logarithmic sensitivity of the ratio of the W^{\pm} and Z gauge boson masses on the Higgs boson mass. A global fit to the precision electroweak data accumulated in the last two decades at LEP, SLC, the Tevatron, and elsewhere, gives $m_H = 94^{+29}_{-24}$ GeV, or

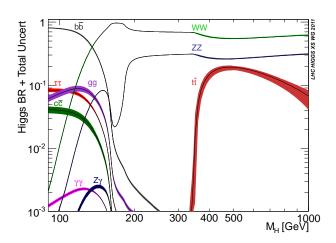

Figure 4: Branching ratios for the main decays of the SM Higgs boson, including theoretical uncertainties [40–44].

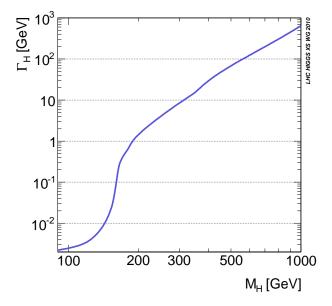

Figure 5: The total decay width of the SM Higgs boson, shown as a function of m_H [76].

 $m_H < 152$ GeV at 95% C.L. [5]. The top quark contributes to the W^\pm boson vacuum polarization through loop effects that depend quadratically on the top mass, which plays an important role in the global fit. A top quark mass of 173.2 ± 0.9 GeV [77] and a W^\pm boson mass of 80.385 ± 0.015 GeV [5] were used.

II.2. Searches for the SM Higgs Boson at LEP

The principal mechanism for producing the SM Higgs boson in e^+e^- collisions at LEP energies is Higgs-strahlung in the schannel, $e^+e^- \to HZ$. The Z boson in the final state is either

virtual (LEP 1), or on mass shell (LEP 2). At LEP energies, SM Higgs boson production via W^+W^- and ZZ fusion in the t-channel has a small cross section. The sensitivity of the LEP searches to the Higgs boson depends on the center-of-mass energy, \sqrt{s} . For $m_H < \sqrt{s} - M_Z$, the cross section is of order 1 pb or more, while for $m_H > \sqrt{s} - M_Z$, the cross section is smaller by at least an order of magnitude.

During the LEP 1 phase, the ALEPH, DELPHI, L3 and OPAL collaborations analyzed over 17 million Z decays and set lower bounds of approximately 65 GeV on the mass of the SM Higgs boson [78]. At LEP 2, substantial data samples were collected at center-of-mass energies up to 209 GeV. Data recorded at each center-of-mass energy were studied independently and the results from the four LEP experiments were then combined. The $\rm CL_s$ method [79] was used to compute the observed and expected limits on the Higgs boson production cross section as functions of the Higgs boson mass considered, and from that a lower bound on m_H was derived.

Higgs bosons with mass above $2m_{\tau}$ were searched for in four final state topologies: The four-jet topology in which $H \to b \overline{b}$ and $Z \to q \overline{q}$; the final states with tau leptons produced in the processes $H \to \tau^+ \tau^-$ where $Z \to q \overline{q}$, together with the mode $H \to b \overline{b}$ with $Z \to \tau^+ \tau^-$; the missing energy topology produced mainly in the process $H \to b \overline{b}$ with $Z \to \nu \overline{\nu}$, and finally the leptonic states $H \to b \overline{b}$ with $Z \to e^+ e^-$, $\mu^+ \mu^-$. At LEP 1, only the modes with $Z \to \ell^+ \ell^-$ and $Z \to \nu \overline{\nu}$ were used because the backgrounds in the other channels were prohibitive. For the data collected at LEP 2, all decay modes were used.

For very light Higgs bosons, with $m_H < 2m_\tau$, the decay modes exploited above are not kinematically allowed, and decays to jets, muon pairs, pion pairs, and lighter particles dominate, depending on m_H . For very low masses, OPAL's decay-mode independent search [80] for the Bjorken process $e^+e^- \to S^0Z$, where S^0 denotes a generic neutral scalar particle, provides sensitivity regardless of the branching fractions of the S^0 . This search is based on studies of the recoil mass spectrum in events with $Z \to e^+e^-$ and $Z \to \mu^+\mu^-$ decays, and on the final states $Z \to \nu\overline{\nu}$ and $S^0 \to e^+e^-$ or photons. Upper bounds on the $e^+e^- \to ZH$ cross section are obtained for scalar masses between 1 KeV and 100 GeV, and are below 0.05 times the SM prediction for $m_H < 80$ GeV, constraining the coupling of the Higgs boson to the Z.

The combination of the LEP data yields a 95% C.L. lower bound of 114.4 GeV for the mass of the SM Higgs boson [33]. The median limit one would expect to obtain in a large ensemble of identical experiments with no signal present is 115.3 GeV. An excess of data was seen consistent with a Higgs boson of mass $m_H \approx 115$ GeV. The significance of this excess is low, however. It is quantified by the background-only p-value [79], which is the probability to obtain data at least as signal-like as the observed data, assuming a signal is truly absent; a small p-value indicates data that are inconsistent with the background model but are more consistent with a signal model.

The background-only p-value for the excess in the LEP data is 9%.

II.3. Searches for the SM Higgs Boson at the Tevatron

As shown in Fig. 2, at the Tevatron, the most important SM Higgs boson production processes are gluon fusion $(gg \to H)$ and Higgs boson production in association with a vector boson $(W^{\pm}H \text{ or } ZH)$. Vector boson fusion (VBF) has a smaller cross section, but some search channels are optimized for it. For m_H less than about 135 GeV, the most sensitive analyses search for $W^{\pm}H$ and ZH with $H \to b\bar{b}$. The mode $gg \to H \to b\bar{b}$ is overwhelmed by the background from the inclusive production of $p\bar{p} \to b\bar{b} + X$ via the strong interaction. The associated production modes $W^{\pm}H$ and ZH allow use of the leptonic W and Z decays to purify the signal and reject QCD backgrounds.

The contribution of $H \to W^*W$ or WW is dominant at higher masses, $m_H > 135$ GeV. Using this decay mode, both the direct $(gg \to H)$ and the associated production $(p\overline{p} \to W^{\pm}H)$ or ZH) channels are explored, and the results of both Tevatron experiments, CDF and DØ, are combined to maximize the sensitivity to the Higgs boson.

The signal-to-background ratio is much smaller in the Tevatron searches than in the LEP analyses, and the systematic uncertainties on the estimated background rates are typically larger than the signal rates. In order to estimate the background rates in the selected samples more accurately, auxiliary measurements are made in data samples which are expected to be depleted in Higgs boson signal. These auxiliary samples are chosen to maximize the sensitivity to each specific background in turn. Monte Carlo simulations are used to extrapolate these measurements into the Higgs signal regions. The dominant physics backgrounds such as top-pair, diboson, $W^{\pm}b\overline{b}$, and single top production are estimated by Monte Carlo simulations in this way, i.e., after having been tuned or verified by corresponding measurements in dedicated analyses, thereby reducing the uncertainty on the total background estimate. Nearly all Tevatron analyses use multivariate analysis techniques (MVA's) to further separate signals from backgrounds and to provide the final discriminants whose distributions are used to compute limits, best-fit cross sections and uncertainties, and p-values. Separate MVA's are trained at each m_H in all the different sub-channels.

Both Tevatron experiments have updated their main search analyses to the full analyzable data sample of approximately $10~{\rm fb^{-1}}$. At Higgs boson masses of 150 GeV and below, the searches for associated production, $p\bar{p} \to W^{\pm}H, ZH$, are performed in different channels, as follows. The $WH \to \ell\nu b\bar{b}$ searches [81–85] select events with a charged lepton ($\ell=e$ or μ), large missing transverse energy, and at least two jets, at least one of which must be b-tagged. In order to improve the sensitivity of the searches, events with one b-tag are analyzed separately from those with two, and events with three jets are analyzed separately from those with two jets. Algorithms to identify b jets provide several levels of purity for each jet, and

this serves as another dimension along which to classify events. The quality and the type of the identified lepton also serves to classify events. An event with an isolated, high- p_T track is analyzed as if that track were a lepton, but such events are collected together in different sub-channels. The signals in such categories come from leptons which the detectors failed to reconstruct as leptons, and hadrons from τ lepton decay. The instrumental ("fake-lepton") backgrounds are higher for these selections, and so samples with well-identified leptons are kept separate from the isolated-track samples.

The $ZH \to \nu \bar{\nu} b \bar{b}$ searches [86–89] seek events in which no lepton or high- p_T isolated track is found. These searches also accept signals from $WH \to \ell \nu b \bar{b}$ in which the charged lepton is either not identified or falls outside the detector acceptances. Similar b-tagging categorization is applied to these searches. The $ZH \to \ell^+\ell^-b\bar{b}$ searches [90–93] seek leptonic decays of the Z boson. These events benefit from the absence of neutrinos, and so missing transverse energy can be interpreted as jet energy mismeasurement, and the jet energies are corrected accordingly, improving the dijet mass resolution. CDF searches for associated production and VBF in the all-hadronic mode, in which the W or the Z decays hadronically, and the H decays to $b\bar{b}$ [94,95].

A cross check of the procedures for searching for the SM Higgs boson in the $WH,ZH\to b\bar{b}$ channels, their background estimates, and combination procedures, is provided by measurements of WZ+ZZ production in b-tagged final states [96,97], and their combination [98]. In these analyses, the decay $Z\to b\bar{b}$ mimics the decay $H\to b\bar{b}$, and WW production is considered a background. The measured cross section is consistent with the SM expectations, giving confidence in the Higgs boson search procedures.

Both Tevatron experiments also search for $H \to \tau^+\tau^-$ in events with one or more associated jets [99–102]. As the ditau mass resolution is poor due to the presence of unmeasured neutrinos, the $Z \to \tau^+\tau^-$ background is large in the absence of the requirement of one or more additional jets, which purifies the sample in associated production and VBF. The process $gg \to H$ is considered as well, although the uncertainties on $gg \to H$ +jets are larger than the inclusive uncertainties.

The decay mode $H\to\gamma\gamma$ is searched for by both Tevatron collaborations [103–106]. Prompt diphoton production, $\pi^0\to\gamma\gamma$, and fake photons are the main backgrounds. The backgrounds have a smoothly varying shape as a function of $m_{\gamma\gamma}$, while the signal mass resolution is of order 3%. All Higgs boson production mechanisms are considered, but the signal-to-background ratio at the Tevatron is not sufficient for this channel to contribute significantly to the SM search. Nonetheless, the searches for $H\to\gamma\gamma$ provide powerful tests of models with enhanced BR($H\to\gamma\gamma$), described later.

Another process searched for at the Tevatron is $t\bar{t}H$ production with $H \to b\bar{b}$ [107,108]. The backgrounds in this channel are low and are dominated by $t\bar{t}b\bar{b}$, but the low signal

production rate and combinatoric ambiguity in assigning jets to the Higgs boson decay reduces the sensitivity.

For Higgs boson masses above 130 GeV, the searches for $H\to W^+W^-\to \ell^+\nu\ell^-\bar{\nu}$ [109–114] are the most sensitive. The candidate mass cannot be fully reconstructed in these events due to the presence of two neutrinos, but the lepton angles are correlated due to the scalar nature of the Higgs boson and the V-A $W\ell\nu$ coupling. The process $W^\pm H\to W^\pm W^+W^-$ gives rise to like-sign dilepton and trilepton final states which have very low backgrounds [110,115]. CDF also seeks $H\to ZZ\to \ell^+\ell^-\ell^+\ell^-$ [116] where $\ell=e$ or μ . The excellent mass resolution and low backgrounds help the sensitivity of the search, but low decay branching ratio for $Z\to \ell^+\ell^-$ reduces the sensitivity.

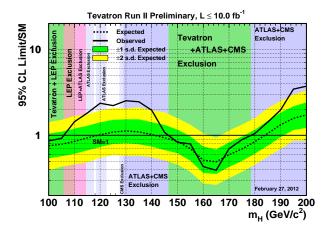

Figure 6: Observed and expected 95% C.L. upper limits on the ratios to the SM cross section, as functions of the Higgs boson mass for the combined CDF and D0 analyses [6]. The limits are expressed as a multiple of the SM prediction. The bands indicate the 68% and 95% probability regions where the limits can fluctuate, in the absence of signal. Also shown are the regions excluded by LEP, ATLAS, and CMS.

All of the searches for the SM Higgs boson at the Tevatron are combined together for maximum sensitivity [6,117,118]. The Tevatron combination excludes two ranges in m_H : between 100 GeV and 106 GeV, and between 147 GeV and 179 GeV. An excess of data is seen in the mass range 115 GeV $< m_H <$ 135 GeV, as shown in Fig. 6. with a maximum local significance of 2.7 standard deviations (sigma), at $m_H = 120$ GeV, where the expected local significance for a SM Higgs signal is 2.0 sigma. When corrected for the look-elsewhere effect (LEE) [119], which accounts for the possibility of selecting the strongest of the several random excess which may happen in the range 115 GeV $< m_H < 200$ GeV, the global significance of the

excess is 2.2 standard deviations³. The majority of the excess is contributed by the searches for $H \to b\bar{b}$. The best-fit cross section for Higgs boson production, normalized to the SM production rate, and assuming SM decay branching ratios and SM ratios between the production mechanisms, is shown in Fig. 7.

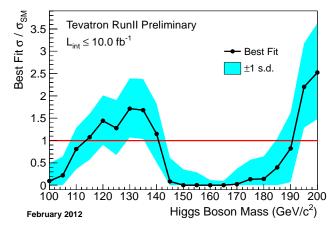

Figure 7: Best-fit cross section for the SM Higgs boson from the combined CDF and DØ searches, normalized to the SM production rates, assuming SM decay branching ratios and the SM ratio between the various production mechanisms [6]. The shaded region shows the 68% C.L. interval, as a function of the mass of the Higgs boson considered. In this fit, negative signal cross sections are not considered.

The channels used at the Tevatron for Higgs boson masses below 130 GeV are different from those dominantly used at the LHC, and thus provide complementary information on the couplings of the Higgs boson to gauge bosons and to b quarks.

II.4. SM Higgs Boson Searches at the LHC

At the LHC, the main production processes are the same as those at the Tevatron, but with a different order of importance: gluon fusion $(gg \to H)$, vector boson fusion (qqH) or $q\overline{q}H$ and Higgs boson production in association with a vector boson $(W^{\pm}H)$ or ZH or with a top-quark pair $(t\overline{t}H)$.

The higher center-of-mass energy of 7 TeV (8 TeV in 2012) and the fact that both beams consist of protons has a strong impact on the parton luminosities. The LHC experiments are sensitive to Higgs bosons with much higher masses than the Tevatron experiments. The gg luminosity is also enhanced at the LHC by the beam energy due to the large gluon PDF at lower parton momentum fraction x compared to that at higher x.

A variety of search channels are pursued by the LHC collaborations, ATLAS and CMS, with the channels' relative importances changing due to the branching ratios of the SM Higgs

³ In this Review, we use the phrase "local significance" to indicate a calculation of the significance not corrected for the LEE.

boson as functions of m_H . At low masses, $m_H < 120$ GeV, searches for $H \to \gamma \gamma$ provide the highest sensitivity, with searches for $H \to b\bar{b}$ and $H \to \tau^+\tau^-$ contributing as well. For higher masses, 120 GeV $< m_H < 200$ GeV, searches for $H \to W^+W^- \to \ell^+\nu\ell^-\nu$ are the most sensitive, with an important contribution from $H \to ZZ \to \ell^+\ell^-\ell^+\ell^-$ between 120 GeV and 150 GeV. At even higher masses, up to $m_H = 600$ GeV, the $H \to ZZ$ searches are the most sensitive.

Both LHC collaborations seek $H \to W^+W^- \to \ell^+\nu\ell^-\nu$ production [120–122]. This channel provides high sensitivity for Higgs boson masses for which $\mathrm{BR}(H \to W^+W^-)$ is large, $m_H > 135$ GeV. The main SM background, nonresonant W^+W^- production, is initiated primarily by $q\overline{q}$ and thus the signal to background ratio benefits at the LHC because of the initial state. The first LHC exclusion of Higgs boson masses was obtained in this search mode. CMS also contributes a search in the mode $W^\pm H \to W^\pm W^+W^-$ [123] in the trilepton final state. For ATLAS, the fully leptonic decay mode is supplemented with an $H \to W^+W^- \to \ell\nu jj$ search [124].

At higher masses, $m_H > 180$ GeV, ATLAS and CMS analyses seeking $H \to ZZ$ with $ZZ \to \ell^+\ell^-\ell^+\ell^-$ [125,126], $ZZ \to \ell^+\ell^-\nu\bar{\nu}$ [127,128], $ZZ \to \ell^+\ell^-q\bar{q}$ [129,130], and $ZZ \to \ell^+\ell^-\tau^+\tau^-$ [131] become the most sensitive. A small excess of events in the ATLAS $\ell^+\ell^-\ell^+\ell^-$ channel with reconstructed masses near 125 GeV is seen, with a local significance of ≈ 2 sigma. An excess with similar significance is seen in the CMS $H \to ZZ \to 4$ leptons searches at ~ 119 GeV.

ATLAS and CMS seek the process $H \to \gamma \gamma$ including the four production mechanisms, $gg \to H$, production in association with a W or Z boson, and VBF [132–134]. Events are divided into categories depending on the reconstructed photon type (barrel calorimeter or endcap), and the presence or absence of additional jets. The reconstructed mass resolution of the selected candidates varies between 1% and 3% depending on the event category and detector. ATLAS observes an excess of events with a local significance of 2.8σ which is maximized at m_H =126.5 GeV, while CMS observes an excess of events with a local significance of 2.9σ which is maximized at m_H =124 GeV. ATLAS computes the global significance, accounting for the probability of a background fluctuation anywhere in the range 110 GeV $< m_H < 150$ GeV at least as significant as the observed excess, to be 1.5 σ . CMS's global significance is 1.6σ using the same range of m_H .

ATLAS and CMS seek Higgs bosons produced in association with a leptonically decaying vector boson and which decay into $b\bar{b}$ [135,136]. Although these searches benefit from the higher production cross sections at the LHC as compared to the Tevatron, the background cross sections are relatively larger, as a larger fraction of W and Z bosons at the LHC are produced with accompanying jets, some of which contain heavy hadrons. The sensitivity of the searches is maximized by tagging jets containing B hadrons and using MVAs to separate the expected signals from the backgrounds. The achieved sensitivity, in units of the SM production rate, expressed as the 95% exclusion limit

expected in the absence of a signal, varies in the range 110 GeV $< m_H < 135$ GeV between 2.6 to 5.1 for ATLAS and between 2.7 to 6.7 for CMS. These results are both with 4.7 fb⁻¹ of analyzed data. With more data and improved analyses, the LHC will be able to measure the important decay branching ratio to $b\bar{b}$, where currently the Tevatron contributes the most.

Both ATLAS and CMS seek SM Higgs boson decays to $\tau^+\tau^-$ [137–139]. The selected events in these searches are categorized by the number of associated jets, which differentiates signals produced by $gg \to H$, associated production, and VBF from the backgrounds, which are dominated by $Z \to \tau^+ \tau^-$. The reconstructed di-tau masses are used as the discriminating variables. If the tau pair has a net transverse boost, then the missing transverse energy can be projected unambiguously on the directions of the two tau leptons, and the reconstructed mass resolution is much better than in the case of little transverse boost, in which case the degree to which the neutrino momenta cancel each other is unknown. With 4.7 fb⁻¹ of data, ATLAS's expected 95% C.L. limit varies between 3.2 and 7.9 times the SM rate for Higgs bosons with 100 GeV $< m_H < 150$ GeV, and with 4.6 fb^{-1} of data, CMS's expected limits vary between 3.3and 5.5 times the SM prediction for 110 GeV $< m_H < 145$ GeV. CMS also searches for $WH \to W\tau^+\tau^-$ [140] with a 95% C.L. sensitivity between 5 and 15 times the SM prediction in the range 100 GeV $< m_H < 140$ GeV using 4.7 fb⁻¹ of data.

Both ATLAS and CMS have combined their SM Higgs boson The most recent combination of ATLAS searches [7–10]. includes the full suite of channels mentioned above. As shown in Fig. 8, ATLAS excludes at the 95% C.L. the mass ranges $110.0 \text{ GeV} < m_H < 117.5 \text{ GeV}, 118.5 \text{ GeV} < m_H < 122.5 \text{ GeV},$ and 129 GeV $< m_H < 539$ GeV, and expects to exclude, in the absence of a signal, 120 GeV $< m_H < 555$ GeV. ATLAS's local p-values [79], computed with the likelihood ratio test statistic, are shown as functions of the tested m_H in Fig. 9. The local significance is maximal at $m_H = 126$ GeV, with a value of 2.9σ . The global significance is 1.3σ when the interval considered for the LEE correction is 110 GeV $< m_H < 146$ GeV, and becomes 0.5σ for the interval 110 GeV $< m_H < 600$ GeV. The best-fit production cross section as a multiple of the SM prediction is shown in Fig. 10. The excesses seen in the $H \to \gamma \gamma$ and $H \to ZZ \to \ell^+\ell^-\ell^+\ell^-$ searches are somewhat offset by a more background-like outcome in the $H \to W^+W^-$ searches.

The most recent combination of CMS includes the full suite of channels mentioned above. As shown in Fig. 11, CMS excludes at the 95% C.L. the mass range 127.5 GeV $< m_H < 600$ GeV, and expects to exclude 114.5 GeV $< m_H < 525$ GeV in the absence of a signal. CMS's local p-values [79], computed using the likelihood ratio test statistic, are shown as functions of the tested m_H in Fig. 12. The local significance is maximal at $m_H=125$ GeV, with a value of 2.8σ . The global significance becomes 2.1σ (0.8 σ) after correcting for LEE in the range 110 GeV $< m_H < 145$ GeV (110 GeV $< m_H < 600$ GeV). The best-fit production cross section CMS measures as a multiple of the SM prediction is shown in Fig. 13. A signal-like excess

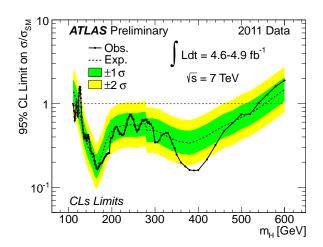

Figure 8: Observed and expected 95% C.L. upper limits on the ratios to the SM cross section, as functions of the Higgs boson mass for the combined ATLAS analyses [8].

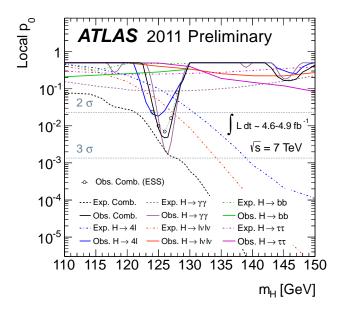

Figure 9: Local p-values for each of AT-LAS's SM Higgs boson search channels and the combination [8]. The observed p-values are shown with solid curves, and the median expected p-values assuming a signal is present at the SM strength are shown with dashed and dot-dashed curves. Dotted lines indicate the 2σ and 3σ thresholds. Hollow circles indicate p-values computed with ensemble tests taking into account energy scale systematic uncertainties (ESS).

is seen in the $H\to\gamma\gamma$ and $H\to W^+W^-$ searches, but the outcome in the $H\to ZZ$ search is less signal-like at $m_H=125~{\rm GeV}.$

In summary, beyond the region excluded by LEP, the region excluded at 95% C.L. by both ATLAS and CMS extends from

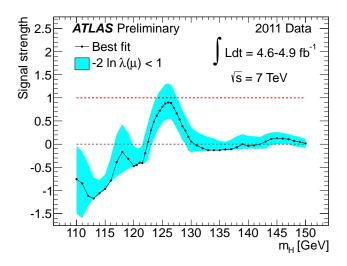

Figure 10: ATLAS SM best-fit cross sections [8].

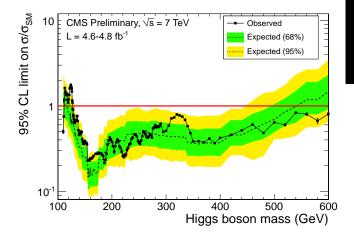

Figure 11: Observed and expected 95% C.L. upper limits on the ratios to the SM cross section, as functions of the Higgs boson mass for the combined CMS analyses [10].

129 GeV to 539 GeV. The observed and expected limits from the two LHC collaborations and the Tevatron are listed in Table 1 for the main channels and the combinations searching for the SM Higgs boson with $m_H=125$ GeV. The best-fit cross section is close to the SM prediction at the m_H corresponding to the most significant p-value for both LHC experiments. The data samples are not yet large enough to make a significant statement about the balance between the individual channels.

If a SM Higgs boson is discovered, its properties will be studied at the LHC. The decay branching ratios, and more generally, the couplings of the Higgs bosons to fermions and gauge bosons will be constrained by the measurements of the cross sections times branching ratios for the processes searched for above.

The mass of the Higgs boson will be measured by each LHC experiment with a precision of $\sim 0.1\%$, limited by the energy

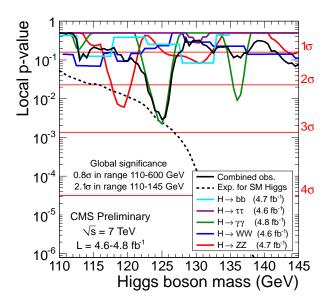

Figure 12: Local p-values for each of CMS's SM Higgs boson search channels and the combination [10]. The observed p-values are shown with solid curves, and the median expected p-value for the combined search assuming a signal is present at the SM strength is shown with a dashed curve. scale, in the currently allowed low mass range [141,142]. This projection is based on the invariant mass reconstruction from electromagnetic calorimeter objects, using the decays $H \to \gamma \gamma$ or $H \to ZZ^* \to 4\ell$. The precision would be degraded at higher masses because of the larger decay width, but even at $m_H \sim 700$ GeV a precision of 1% on m_H is expected to be achievable. The width of the SM Higgs boson may be too narrow to be

measured directly. The width could be constrained indirectly using partial width measurements [143,144]. For $300 < m_H < 700 \text{ GeV}$, a direct measurement of the decay width of an SM-like Higgs boson could be performed with a precision of about 6%.

The possibilities for measuring other properties of the Higgs boson, such as its spin, its CP eigenvalue, its couplings to bosons and fermions, and its self-coupling, have been investigated in numerous studies [141,142,145–148]. Given a sufficiently high integrated luminosity (300 fb⁻¹), most of these properties are expected to be accessible to analysis in the favored mass range 114 GeV < m_H < 129 GeV. The measurement of Higgs self-couplings, however, may suffer from poor sensitivity at the LHC, although a luminosity upgrade, the so-called Super-LHC, could allow for a more precise measurement. The results of these measurements could either establish the presence of a SM-like Higgs boson or point the way to new physics.

II.5 Models with a Fourth Generation of SM-Like Fermions

The SM Higgs boson production processes and branching ratios presented above are limited to the case of three generations of quarks and leptons. The existence of a fourth generation of fermions is compatible with present experimental bounds and would have direct consequences on the SM Higgs boson production and decay branching ratios [149], and hence on Higgs boson searches at LEP, the Tevatron, and the LHC [150,151]. Current experimental searches bound the fourth generation quark masses to be above the top quark mass [152]. These additional heavy quarks lead to new contributions in the loop-induced couplings of the Higgs boson to gluons and to photons.

In particular, they lead to a strong enhancement of the gluon fusion production rate and of the branching ratio of the Higgs boson decay into a pair of gluons. As a result, the branching ratios of Higgs boson decay to $b\bar{b}$, tau pairs, and pairs of W and Z bosons are reduced, although near $m_H \sim 2M_W$, the decay to a pair of W bosons still nearly saturates the decay width, even with the enhanced gluon decay. Due to a cancellation between the W and heavy fermion contributions, the photon decay channels may be further suppressed. The enhancement of the gluon fusion production rate makes the search channels using Higgs boson decays into tau leptons and W and Z bosons promising for a light Higgs boson. In addition, in the case of a fourth generation Majorana neutrino, exotic signals such as Higgs boson decay into same-sign dileptons may be possible. Interpretations of the experimental searches optimized for a minimal fourth-generation model (SM4) are available from the Tevatron [153] and CMS [10]. CMS excludes the Higgs boson in the SM4 model in the mass range 120 GeV $< m_H < 600$ GeV at the 95% C.L.

III. Higgs Bosons in the Minimal Supersymmetric Standard Model (MSSM)

Electroweak symmetry breaking driven by a weakly-coupled elementary scalar sector requires a mechanism to explain the smallness of the breaking scale compared with the Planck scale [154]. In addition, within supersymmetric extensions of the SM, the supersymmetry-breaking effects, whose origins may lie at energy scales much larger than 1 TeV, can induce a radiative breaking of the electroweak symmetry due to the effects of the large Higgs-top quark Yukawa coupling [155]. In this way, the electroweak symmetry breaking scale is intimately tied to the scale of supersymmetry breaking masses. Supersymmetry provides an explanation for the stability of the hierarchy of scales, provided that the supersymmetry-breaking masses, in particular those related to the stop sector, are at most in the TeV range [154].

A fundamental theory of supersymmetry breaking is unknown at this time. Nevertheless, one can parameterize the low-energy theory in terms of the most general set of soft supersymmetry-breaking renormalizable operators [156]. Minimal Supersymmetric extension of the Standard Model (MSSM) [12,157] associates a supersymmetric partner to each gauge boson and chiral fermion of the SM, and provides a realistic model of physics at the weak scale. However, even in this minimal model with the most general set of soft supersymmetry-breaking terms, more than 100 new parameters are introduced [158]. Fortunately, only a subset of these parameters impact the Higgs phenomenology through tree-level and quantum effects. Reviews of the properties and phenomenology of the Higgs bosons of the MSSM can be found for example in Refs. [44] and [159].

The MSSM contains the particle spectrum of a two-Higgs-doublet model (2HDM) extension of the SM and the corresponding supersymmetric partners. Two Higgs doublets, H_u

and H_d , are required to ensure an anomaly-free SUSY extension of the SM and to generate mass for both "up"-type and "down"-type quarks and charged leptons [13]. After the spontaneous breaking of the electroweak symmetry, five physical Higgs particles are left in the spectrum: one charged Higgs pair, H^{\pm} , one CP-odd scalar, A, and two CP-even states, H and h.

The supersymmetric structure of the theory imposes constraints on the Higgs sector of the model. In particular, the parameters of the Higgs self-interaction are given by the gauge coupling constants. As a result, all Higgs sector parameters at tree level are determined by only two free parameters: the ratio of the H_u and H_d vacuum expectation values, $\tan \beta = v_u/v_d$, with $v_u^2 + v_d^2 \approx (246 \text{ GeV})^2$; and one Higgs boson mass, conventionally chosen to be m_A . The other tree-level Higgs boson masses are then given in terms of these parameters

$$m_{H^\pm}^2=m_A^2+M_W^2$$

$$m_{H,h}^2 = \frac{1}{2} \left[m_A^2 + M_Z^2 \pm \sqrt{(m_A^2 + M_Z^2)^2 - 4(M_Z m_A \cos 2\beta)^2} \right]$$

and α is the angle that diagonalizes the CP-even Higgs squaredmass matrix. An important consequence of these mass formulae is that the mass of the lightest CP-even Higgs boson is bounded from above:

$$m_h \leq M_Z |\cos 2\beta|$$
.

This contrasts sharply with the SM, in which the Higgs boson mass is bounded from above only by perturbativity and unitarity considerations. In the large m_A limit, also called the decoupling limit [160], one finds $m_h^2 \simeq (M_Z \cos 2\beta)^2$ and $m_A \simeq m_H \simeq m_{H^\pm}$, up to corrections of $\mathcal{O}(M_Z^2/m_A)$. Below the scale m_A , the Higgs sector of the effective low-energy theory consists only of h, which behaves as the SM Higgs boson.

The phenomenology of the Higgs sector depends on the couplings of the Higgs bosons to gauge bosons, and fermions. The couplings of the two CP-even Higgs bosons to W^\pm and Z bosons are given in terms of the angles α and β by

$$g_{hVV} = g_V m_V \sin(\beta - \alpha)$$
 $g_{HVV} = g_V m_V \cos(\beta - \alpha)$,

where $g_V \equiv 2m_V/v$. There are no tree-level couplings of A or H^{\pm} to VV. The couplings of the Z boson to two neutral Higgs bosons, which must have opposite CP-quantum numbers, are given by

$$g_{hAZ} = g_Z \cos(\beta - \alpha)/2$$
 $g_{HAZ} = -g_Z \sin(\beta - \alpha)/2$.

Charged Higgs-W boson couplings to neutral Higgs bosons and four-point couplings of vector bosons and Higgs bosons can be found in Ref. 13.

The tree-level Higgs couplings to fermions obey the following property: the neutral components of one Higgs doublet couple exclusively to down-type fermion pairs while the neutral components of the other doublet couple exclusively to up-type fermion pairs [13,161]. This Higgs-fermion coupling structure defines the Type-II 2HDM [162], and differs from

Type-I 2HDM [163] in which one Higgs field couples to all fermions while the other field is decoupled from them. In the MSSM, fermion masses are generated when both neutral Higgs components acquire vacuum expectation values, and the relations between Yukawa couplings and fermion masses are (in third-generation notation)

$$h_b = \sqrt{2} m_b / v_d = \sqrt{2} m_b / (v \cos \beta)$$
$$h_t = \sqrt{2} m_t / v_u = \sqrt{2} m_t / (v \sin \beta).$$

Similarly, one can define the Yukawa coupling of the Higgs boson to τ -leptons (the latter is a down-type fermion).

The couplings of the neutral Higgs bosons to $f\bar{f}$ relative to the SM value, $gm_f/2M_W$, are given by

$$\begin{split} hb\bar{b}: & -\sin\alpha/\cos\beta = \sin(\beta-\alpha) - \tan\beta\cos(\beta-\alpha)\,, \\ ht\bar{t}: & \cos\alpha/\sin\beta = \sin(\beta-\alpha) + \cot\beta\cos(\beta-\alpha)\,, \\ Hb\bar{b}: & \cos\alpha/\cos\beta = \cos(\beta-\alpha) + \tan\beta\sin(\beta-\alpha)\,, \\ Ht\bar{t}: & \sin\alpha/\sin\beta = \cos(\beta-\alpha) - \cot\beta\sin(\beta-\alpha)\,, \\ Ab\bar{b}: & \gamma_5\tan\beta\,, \quad At\bar{t}: & \gamma_5\cot\beta\,, \end{split}$$

where the γ_5 indicates a pseudoscalar coupling. In each relation above, the factor listed for $b\bar{b}$ also pertains to $\tau^+\tau^-$. The charged Higgs boson couplings to fermion pairs are given by

$$g_{H^-t\bar{b}} = \frac{g}{\sqrt{2}M_W} \left[m_t \cot \beta P_R + m_b \tan \beta P_L \right] ,$$

$$g_{H^-\tau^+\nu} = \frac{g}{\sqrt{2}M_W} \left[m_\tau \tan \beta P_L \right] ,$$

with
$$P_{L,R} = (1 \mp \gamma_5)/2$$
.

The Higgs couplings to down-type fermions can be significantly enhanced at large $\tan \beta$ in the following two cases: (i) If $m_A \gg M_Z$, then $|\cos(\beta - \alpha)| \ll 1$, $m_H \simeq m_A$, and the $b\bar{b}H$ and $b\bar{b}A$ couplings have equal strength and are significantly enhanced by a factor of $\tan \beta$ relative to the corresponding SM coupling, whereas the VVH coupling is negligibly small. The values of the VVh and $b\bar{b}h$ couplings are equal to the corresponding couplings of the SM Higgs boson. (ii) If $m_A < M_Z$ and $\tan \beta \gg 1$, then $|\cos(\beta - \alpha)| \approx 1$ and $m_h \simeq m_A$. In this case, the $b\bar{b}h$ and $b\bar{b}A$ couplings have equal strength and are significantly enhanced by a factor of $\tan \beta$ relative to the corresponding SM coupling, while the VVh coupling is negligibly small. In addition, the VVH coupling is equal in strength to the corresponding SM VVH coupling and one can refer to Has a SM-like Higgs boson. The value of the $b\bar{b}H$ coupling can differ from the corresponding SM coupling and converges to it only for $m_A \ll M_Z$ for which $\tan \beta \sin(\beta - \alpha) \to 0$. Note that in both cases (i) and (ii) above, only two of the three neutral Higgs bosons have significantly enhanced couplings to $b\bar{b}$.

III.1. Radiatively-Corrected MSSM Higgs Masses and Couplings

Radiative corrections have a significant impact on the values of Higgs boson masses and couplings in the MSSM. Important contributions come from loops of third generation SM particles as well as their supersymmetric partners. The dominant effects to the Higgs mass arise from the incomplete cancellation between top and scalar-top (stop) loops and at large $\tan \beta$ also from sbottom and stau loops. The stop, sbottom and stau masses and mixing angles depend on the supersymmetric Higgsino mass parameter μ and on the soft-supersymmetrybreaking parameters [12,157]: M_Q , M_U , M_D , M_L , M_E , and A_t , A_b A_τ . The first three of these are the left-chiral and the two right-chiral top and bottom scalar quark mass parameters. The next two are the left-chiral stau/sneutrino and the rightchiral stau mass parameters, and the last three are the trilinear parameters that enter in the off-diagonal squark/slepton mixing elements: $X_t \equiv A_t - \mu \cot \beta$ and $X_{b,\tau} \equiv A_{b,\tau} - \mu \tan \beta$. The corrections affecting the Higgs boson masses, production, and decay properties depend on all of these parameters in various ways. At the two-loop level, also the masses of the gluino and the electroweak gaugino enter in the calculations. For simplicity, we shall initially assume that A_t , A_b , A_τ , μ , and the gluino and electroweak gaugino masses are real parameters. The impact of complex phases on MSSM parameters, which will induce *CP*-violation in the Higgs sector, is addressed below.

Radiative corrections to the Higgs boson masses have been computed using a number of techniques, with a variety of approximations; see Refs. [165–176]. They depend strongly on the top quark mass ($\sim m_{\rm t}^4$) and the stop mixing parameter X_t , and there is also a logarithmic dependence on the stop masses. One of the most striking effects is the increase of the upper bound of the light CP-even Higgs boson mass, as first noted in Refs. [165,166]. The value of m_h is maximized for large $m_A \gg M_Z$, when all other MSSM parameters are fixed. Moreover, $\tan \beta \gg 1$ also maximizes m_h , when all other parameters are held fixed. Taking m_A large (the decoupling limit) and $\tan \beta \gg 1$, the value of m_h can be further maximized at one-loop level for $X_t \simeq \sqrt{6}M_{\rm SUSY}$, where $M_{\rm SUSY} \simeq M_Q \simeq M_U \simeq M_D$ is an assumed common value of the soft SUSY-breaking squark mass parameters. This choice of X_t is called the "maximal-mixing scenario" which will be indicated by m_h -max. Instead, for $X_t = 0$, which is called the "no-mixing scenario," the value of m_h has its lowest possible value, for fixed m_A and all other MSSM parameters. The value of m_h also depends on the specific value of $M_{\rm SUSY}$, and, for example, raising $M_{\rm SUSY}$ from 1 TeV to 2 TeV can increase m_h by 2-5 GeV. Variation of the value of m_t by 1 GeV changes the value of m_h by about the same amount. As mentioned above, m_h also depends on μ and more weakly on the electroweak gaugino mass as well as the gluino mass at the two-loop level. For any given scenario defined by a full set of MSSM parameters, we will denote the maximum value of m_h by $m_h^{\max}(\tan \beta)$, for each value of $\tan \beta$. Allowing for the experimental uncertainty on m_t and for the uncertainty inherent in the theoretical analysis, one finds for $M_{SUSY} \lesssim 2$ TeV, large m_A and $\tan \beta \gg 1$, $m_h^{\text{max}} = 135 \text{ GeV}$ in the m_h -max scenario, and $m_h^{\text{max}} = 122 \text{ GeV}$ in the no-mixing scenario [177,178]. In

practice, parameter values leading to maximal mixing are not obtained in most models of supersymmetry breaking, so typical upper limits on m_h will lie between these two extremes [179]. In the large $\tan \beta$ regime light staus and/or sbottoms with sizable mixing, governed by the μ parameter, yield negative radiative corrections to the mass of the lightest Higgs boson, and can lower it by several GeV [173,180]. Hence, if the Higgs boson were to have a mass of about 125 GeV, a sizable mixing in the stop sector would be required [180,181] $(X_t \ge 1.5 M_{SUSY})$ or even larger if $\tan \beta$ is large). The relatively small mass of the lightest neutral scalar boson is a prediction for both the CP-conserving (CPC) and CP-violating (CPV) [182] MSSM scenarios. This is particularly interesting in the light of the intriguing excesses observed at the Tevatron and the LHC and given that masses above 130 GeV are strongly disfavored by LHC data.

Radiative corrections also modify significantly the values of the Higgs boson couplings to fermion pairs and to vector boson pairs. The tree-level Higgs couplings depend strongly on the value of $\cos(\beta - \alpha)$. In a first approximation, when radiative corrections of the Higgs squared-mass matrix are computed, the diagonalizing angle α is shifted from its tree-level value, and hence one may compute a "radiatively-corrected" value for $\cos(\beta - \alpha)$. This shift provides one important source of the radiative corrections to the Higgs couplings. In particular, depending on the sign of μX_t and the magnitude of $X_t/M_{\rm SUSY}$, modifications of α can lead to important variations of the SM-like Higgs boson coupling to bottom quarks and tau leptons [175]. Similar corrections to the mixing angle α can come for large tan beta from the stau/sbottom sector for sizable $A_{b,\tau}$ [180]. Additional contributions from the one-loop vertex corrections to tree-level Higgs couplings These contributions almust also be considered [170–189]. ter significantly the Higgs-fermion Yukawa couplings at large $\tan \beta$, both in the neutral and charged Higgs sector. Moreover, these radiative corrections can modify the basic relationship $g_{h,H,Ab\bar{b}}/g_{h,H,A\tau^+\tau^-} \propto m_b/m_\tau$, and change the main features of MSSM Higgs phenomenology.

III.2. Decay Properties and Production Mechanisms of MSSM Higgs Bosons

In the MSSM, neglecting CP-violating effects, one must consider the decay properties of three neutral Higgs bosons and one charged Higgs pair. In the region of parameter space where $m_A\gg m_Z$ and the masses of supersymmetric particles are large, the decoupling limit applies, and the decay rates of h into SM particles are nearly indistinguishable from those of the SM Higgs boson. Hence, the h boson will decay mainly to fermion pairs, since the mass, less than about 135 GeV, is below the W^+W^- threshold. The SM-like branching ratios of h are modified if decays into supersymmetric particles are kinematically allowed [190]. In addition, if light superpartners exist that can couple to photons and/or gluons, then the effective couplings to qq and $\gamma\gamma$ could deviate from the corresponding

SM predictions [180,191,192]. In the decoupling limit, the heavier Higgs states, H, A and H^{\pm} , are roughly mass degenerate, and their decay branching ratios strongly depend on $\tan \beta$ as discussed below. The AWW and AZZ couplings vanish, and the HWW and HZZ couplings are very small. For values of $m_A \sim \mathcal{O}(M_Z)$, all Higgs boson masses lie below 200 GeV. In this regime, there is a significant area of the parameter space in which none of the neutral Higgs boson decay properties approximates that of the SM Higgs boson. For $\tan \beta \gg 1$, the resulting predictions show marked differences from those for the SM Higgs boson [193]. Significant modifications to the $b\overline{b}$ and/or the $\tau^+\tau^-$ decay rates may occur via radiative effects.

After incorporating the leading radiative corrections to Higgs couplings from both QCD and supersymmetry, the following decay features are relevant in the MSSM. The decay modes $h, H, A \to b\overline{b}, \tau^+\tau^-$ dominate when $\tan \beta$ is large for all values of the Higgs boson masses. For small $\tan \beta$, these modes are significant for neutral Higgs boson masses below $2m_t$ (although there are other competing modes in this mass range), whereas the $t\bar{t}$ decay mode dominates above its kinematic threshold. In contrast to the SM Higgs boson, the vector boson decay modes of H are strongly suppressed at large m_H due to the suppressed HVV couplings in the decoupling limit. For the charged Higgs boson, $H^+ \to \tau^+ \nu_{\tau}$ dominates below the $t\bar{b}$ threshold, while $H^+ \to t\bar{b}$ dominates for large values of $m_{H^{\pm}}$. For low values of $\tan \beta$ ($\lesssim 1$) and low values of the charged Higgs boson mass (\lesssim 120 GeV), the decay mode $H^+ \to c\bar{s}$ becomes relevant.

In addition to the decay modes of the neutral Higgs bosons into fermion and gauge boson final states, additional decay channels may be allowed which involve scalars of the extended Higgs sector, e.g., $h \to AA$. Supersymmetric final states from Higgs boson decays into charginos, neutralinos and third-generation squarks and sleptons can be important if they are kinematically allowed [194]. One interesting possibility is a significant branching ratio for the decay of a neutral Higgs boson to the invisible mode $\tilde{\chi}_1^0 \tilde{\chi}_1^0$ (where the lightest neutralino $\tilde{\chi}_1^0$ is the lightest supersymmetric particle) [195], which poses a challenge at hadron colliders.

The production mechanisms for the SM Higgs boson at e^+e^- and hadron colliders can also be relevant for the production of the MSSM neutral Higgs bosons. However, one must take into account the possibility of enhanced or suppressed couplings with respect to those of the Standard Model, since these can significantly modify the production cross sections of neutral Higgs bosons. The supersymmetric-QCD corrections due to the exchange of virtual squarks and gluinos may modify the cross sections depending on the values of these supersymmetric particle masses. At both lepton and hadron colliders there are new mechanisms that produce two neutral Higgs bosons, as well as processes that produce charged Higgs bosons singly or in pairs. In the following we summarize the main processes

for MSSM Higgs boson production. For a more detailed discussion and consideration of state-of-the-art calculations, see Refs. [44,75,159].

The main production mechanisms for the neutral MSSM Higgs bosons at e^+e^- colliders are Higgs-strahlung $(e^+e^- \to Zh, ZH)$, vector boson fusion $(e^+e^- \to \nu\bar{\nu}h, \nu\bar{\nu}H)$ —with W^+W^- fusion about an order of magnitude larger than ZZ fusion—and s-channel Z boson exchange $(e^+e^- \to Ah, AH)$ [196]. For the Higgs-strahlung process, it is possible to reconstruct the mass and momentum of the Higgs boson recoiling against the particles from the Z boson decay, and hence sensitive searches for Higgs bosons decaying even to invisible final states can be applied.

The main charged Higgs boson production process at e^+e^- colliders is via s-channel γ or Z boson exchange $(e^+e^- \to H^+H^-)$. Charged Higgs bosons can also be produced in top quark decays via $t \to b + H^+$ if $m_H^\pm < m_t - m_b$ or via the one-loop process $e^+e^- \to W^\pm H^\mp$ [197,198], which allows the production of a charged Higgs boson with $m_H^\pm > \sqrt{s}/2$, even when H^+H^- production is kinematically forbidden. Other single charged Higgs production mechanisms include $t\bar{b}H^-/\bar{t}bH^+$ production [51], $\tau^+\nu H^-/\tau^-\bar{\nu}H^+$ production [199], and a variety of processes in which H^\pm is produced in association with a one or two other gauge and/or Higgs bosons [200].

At hadron colliders, the dominant neutral Higgs production mechanism over the majority of the MSSM parameter space is gluon-gluon fusion, mediated by triangle loops containing heavy top and bottom quarks and the corresponding supersymmetric partners [201]. Higgs boson radiation from bottom quarks becomes important for large $\tan \beta$, where at least two of the three neutral Higgs bosons have enhanced couplings to bottom-type fermions [202,203]. A more detailed discussion is presented in Sec. (III.3). The vector boson fusion and Higgsstrahlung production of the CP-even Higgs bosons as well as the associated production of neutral Higgs bosons with top quark pairs have lower production cross sections by least an order of magnitude with respect to the dominant ones, depending on the precise region of MSSM parameter space.

Charged Higgs bosons can be produced in several different modes at hadron colliders. If $m_{H^{\pm}} < m_t - m_b$, the charged Higgs boson can be produced in decays of the top quark via the decay $t \to bH^+$, which would compete with the SM process $t \to bW^+$. Relevant QCD and SUSY-QCD corrections to BR $(t \to H^+ b)$ have been computed [204–207]. For values of $m_{H^{\pm}}$ near m_t , width effects are important. In addition, the full $2 \to 3$ processes $pp/p\bar{p} \to H^+\bar{t}b + X$ and $pp/p\bar{p} \to$ $H^-t\bar{b}+X$ must be considered. If $m_{H^\pm}>m_t-m_b$, then charged Higgs boson production occurs mainly through radiation from a third generation quark. Charged Higgs bosons may also be produced singly in association with a top quark via the $2 \rightarrow 3$ partonic processes $gg, q\bar{q} \rightarrow t\bar{b}H^-$ (and the charge conjugate final states). For charged Higgs boson production cross section predictions for the Tevatron and the LHC, see Refs. [12,43,76,208–214]. Charged Higgs bosons can also be produced via associated production with W^{\pm} bosons through $b\overline{b}$ annihilation and gg-fusion [215]. They can also be produced in pairs via $q\overline{q}$ annihilation [216]. The inclusive H^+H^- cross section is less than the cross section for single charged Higgs associated production [216–218].

III.3. Searches for Neutral Higgs Bosons in the CP-Conserving (CPC) Scenario

Most of the experimental investigations carried out at LEP, the Tevatron, and the LHC, assume *CP*-conservation (*CPC*) in the MSSM Higgs sector. In many cases the search results are interpreted in a number of specific benchmark models where a representative set of the relevant SUSY breaking parameters are specified [177].

III.3.1. Searches for Neutral MSSM Higgs Bosons at LEP

In e^+e^- collisions at LEP energies, the main production mechanisms of the neutral MSSM Higgs bosons are the Higgs-strahlung processes $e^+e^- \to hZ$, HZ and the pair production processes $e^+e^- \to hA$, HA, while the fusion processes play a marginal role. Higgs boson decays to $b\bar{b}$ and $\tau^+\tau^-$ are used in these searches.

The searches and limits from the four LEP experiments are described in Refs. [219–222]. The combined LEP data did not contain any excess of events which would imply the production of a Higgs boson, and combined limits were derived [34]. For $m_A\gg M_Z$ the limit on m_h is nearly that of the SM searches, as $\sin^2(\beta-\alpha)\approx 1$. For high values of $\tan\beta$ and low m_A ($m_A\leq m_h^{max}$) the $e^+e^-\to hA$ searches become the most important, and the lightest Higgs h is non SM-like. In this region, the 95% C.L. mass bounds are $m_h>92.8$ GeV and $m_A>93.4$ GeV. In the m_h -max. scenario, values of $\tan\beta$ from 0.7 to 2.0 are excluded taking $m_t=174.3$ GeV, while a much larger $\tan\beta$ region is excluded for other benchmark scenarios such as the no-mixing one.

Neutral Higgs bosons may also be produced by Yukawa processes $e^+e^- \to f\overline{f}\phi$, where the Higgs particle $\phi \equiv h, H, A$, is radiated off a massive fermion $(f \equiv b \text{ or } \tau^\pm)$. These processes can be dominant at low masses, and whenever the $e^+e^- \to hZ$ and hA processes are suppressed. The corresponding ratios of the $f\overline{f}h$ and $f\overline{f}A$ couplings to the SM coupling are $\sin\alpha/\cos\beta$ and $\tan\beta$, respectively. The LEP data have been used to search for $b\overline{b}b\overline{b}, b\overline{b}\tau^+\tau^-$, and $\tau^+\tau^-\tau^+\tau^-$ final states [223,224]. Regions of low mass and high enhancement factors are excluded by these searches.

III.3.2. Searches for Neutral MSSM Higgs Bosons at Hadron Colliders

Over a large fraction of the MSSM parameter space, one of the CP-even neutral Higgs bosons (h or H) couples to the vector bosons with SM-like strength and has a mass below 135 GeV. Hence, if the current 95% C.L. exclusion limits for a SM Higgs boson from ATLAS and CMS are interpreted in terms of the SM-like supersymmetric Higgs boson, there is a region of SUSY parameter space beyond that excluded by LEP

that is strongly disfavored. In particular, the minimal mixing scenario with $M_{SUSY} \leq 2$ TeV is disfavored considering the LEP and ATLAS data. At the same time, if the excess of events observed in the Higgs boson searches in the diphoton and ZZ channels are confirmed, this could be interpreted as a SM-like MSSM Higgs boson.

Scenarios with enhanced Higgs boson production cross sections are studied at hadron colliders. The best sensitivity is in the regime with low to moderate m_A and with large $\tan \beta$ which enhances the couplings of the Higgs bosons to down-type fermions. The corresponding limits on the Higgs boson production cross section times the branching ratio of the Higgs boson into down-type fermions can be interpreted in MSSM benchmark scenarios [225]. If $\phi = A, H$ for $m_A > m_h^{\text{max}}$, and $\phi = A, h$ for $m_A < m_h^{\rm max}$, the most promising channels at the Tevatron are $b\bar{b}\phi, \phi \to b\bar{b}$ or $\phi \to \tau^+\tau^-$, with three tagged b-jets or $b\tau\tau$ in the final state, respectively, and the inclusive $p\overline{p} \to \phi \to \tau^+\tau^-$ process, with contributions from both $gg \to \phi$ and $b\bar{b}\phi$ production. Although Higgs boson production via gluon fusion has a higher cross section than via associated production, it cannot be used to study the $\phi \to b\bar{b}$ decay mode since the signal is overwhelmed by QCD background.

The CDF and DØ collaborations have searched for neutral Higgs bosons produced in association with bottom quarks and which decay into $b\overline{b}$ [226,227], or into $\tau^+\tau^-$ [228,229]. most recent searches in the $b\bar{b}\phi$ channel with $\phi \to b\bar{b}$ analyze approximately 2.6 fb⁻¹ of data (CDF) and 5.2 fb⁻¹ (DØ), seeking events with at least three b-tagged jets. The cross section is defined such that at least one b quark not from ϕ decay is required to have $p_T > 20$ GeV and $|\eta| < 5$. The decay widths of the Higgs bosons are assumed to be much smaller than the experimental resolution. The invariant mass of the two leading jets as well as b-tagging variables are used to discriminate the signal from the backgrounds. The QCD background rates and shapes are inferred from data control samples, in particular, the sample with two b tagged jets and a third, untagged jet. Separate signal hypotheses are tested and limits are placed on $\sigma(p\bar{p}\to b\bar{b}\phi)\times \mathrm{BR}(\phi\to b\bar{b})$. CDF sees a local excess of approximately 2.5σ significance in the mass range of 130-160 GeV, but DØ's search is more sensitive and sets stronger limits. The DØ result shown in Fig. 14 displays a ≈ 2 sigma local upward fluctuation in the 110 to 125 GeV mass

CDF and DØ have also performed searches for inclusive production of Higgs bosons with subsequent decays to $\tau^+\tau^-$ [230,231,232], although these limits have been superseded by the LHC searches.

In order to interpret the experimental data in terms of MSSM benchmark scenarios, it is necessary to consider carefully the effect of radiative corrections on the production and decay processes. The bounds from the $b\bar{b}\phi,\phi\to b\bar{b}$ channel depend strongly on the radiative corrections affecting the relation between the bottom quark mass and the bottom Yukawa

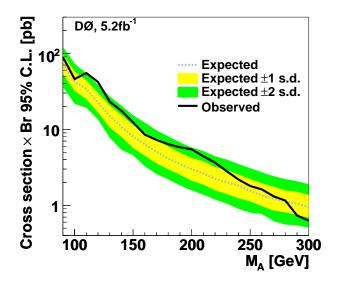

Figure 14: The 95% C.L. limits on $\sigma(p\bar{p}\to b\phi) \times \mathrm{BR}(\phi\to b\bar{b})$ from CDF and DØ. The observed limits are indicated with solid lines, and the expected limits are indicated with dashed lines. The limits are to be compared with the sum of signal predictions for Higgs bosons with similar masses.

coupling. In the channels with $\tau^+\tau^-$ final states, however, compensations occur between large corrections in the Higgs boson production and decay. The total production rates of bottom quarks and τ pairs mediated by the production of a CP-odd Higgs boson in the large $\tan\beta$ regime are approximately given by

$$\sigma_{b\overline{b}A} \times \mathrm{BR}(A \to b\overline{b}) \simeq \sigma_{b\overline{b}A}^{\mathrm{SM}} \ \frac{\tan^2 \beta}{\left(1 + \Delta_b\right)^2} \frac{9}{\left(1 + \Delta_b\right)^2 + 9},$$

and

$$\sigma_{gg \to A, b\overline{b}A} \times \text{BR}(A \to \tau^+ \tau^-) \simeq \sigma_{gg \to A, b\overline{b}A}^{\text{SM}} \ \frac{\tan^2 \beta}{\left(1 + \Delta_b\right)^2 + 9}$$

where $\sigma_{b\bar{b}A}^{\rm SM}$ and $\sigma_{gg\to A,b\bar{b}A}^{\rm SM}$ denote the values of the corresponding SM Higgs boson cross sections for a SM Higgs boson mass equal to m_A . The function Δ_b includes the dominant effects of SUSY radiative corrections for large $\tan\beta$ [170,175,187,188], and it depends strongly on $\tan\beta$ and on the SUSY mass parameters. The $b\bar{b}A$ channel is more sensitive to the value of Δ_b through the factor $1/(1+\Delta_b)^2$ than the inclusive $\tau^+\tau^-$ channel, for which this leading dependence on Δ_b cancels out. As a consequence, the limits derived from the inclusive $\tau^+\tau^-$ channel depend less on the precise MSSM scenario chosen than those of the $b\bar{b}A$ channel.

The production and decay rates of the CP-even Higgs bosons with $\tan \beta$ -enhanced couplings to down-type fermions—H (or h) for m_A larger (or smaller) than m_h^{\max} , respectively—are governed by formulas similar to the ones presented above. At high $\tan \beta$, one of the CP-even Higgs bosons and the CP-odd Higgs boson are nearly degenerate in mass, enhancing the signal

cross section by roughly a factor of two, without complicating the experimental signature except in a small mass region in which the three neutral MSSM Higgs boson masses are close together and each boson contributes to the total production rate. Detailed discussions of the impact of radiative corrections in these search modes are presented in Refs. [225] and [233].

In Fig. 15, the interpretation is shown for DØ's combination of $\phi \to b\bar{b}$ and $\phi \to \tau^+\tau^-$ searches [232] in the $(m_A, \tan\beta)$ plane for the m_h -max benchmark scenario with $\mu=200$ GeV. The neutral Higgs boson searches consider the contribution of both the CP-odd and the CP-even neutral Higgs bosons with enhanced couplings to bottom quarks. As explained above, considering other benchmark scenarios will not relevantly change the region of SUSY parameter space that can be explored via the inclusive di-tau searches, but different regions of SUSY parameter space will be probed in the case of the $b\bar{b}$ searches.

ATLAS and CMS also search for $\phi \to \tau^+\tau^-$ in pp collisions at $\sqrt{s} = 7$ TeV. ATLAS seeks tau pairs in 1.06 fb⁻¹ of data [234,235], and CMS's search uses 4.6 fb^{-1} of The searches are performed in categories data [138,139]. of the decays of the two tau leptons: $e\tau_{\rm had}$, $\mu\tau_{\rm had}$, $e\mu$, and $\mu\mu$, where $\tau_{\rm had}$ denotes a tau lepton which decays to one or more hadrons plus a tau neutrino, e denotes $\tau \to e\nu\nu$, and μ denotes $\tau \to \mu\nu\nu$. The dominant background comes from $Z \to \tau^+\tau^$ decays, although $t\bar{t}$, W+jets and Z+jets events contribute as well. Separating events into categories based on the number of b-tagged jets improves the sensitivity in the MSSM. The $b\bar{b}$ annihilation process and radiation of a Higgs boson from a bquark give rise to events in which the Higgs boson is accompanied by a $b\bar{b}$ pair in the final state, sometimes with only one b within the detector acceptance. Requiring the presence of one or more b jets reduces the background from Z+jets. Data control samples are used to constrain background rates. The rates for jets to be identified as a hadronically decaying tau lepton are measured in dijet samples, and W+jets samples provide a measurement of the rate of events that, with a fake hadronic tau, can pass the signal selection requirements. Lepton fake rates are measured using samples of unisolated lepton candidates and same-sign lepton candidates. Constraints from ATLAS's and CMS's searches for $h \to \tau^+ \tau^-$ are also shown in Fig. 15 in the m_h -max benchmark scenario, with $\mu = 200$ GeV. The neutral Higgs boson searches consider the contributions of both the CP-odd and CP-even neutral Higgs bosons with enhanced couplings to bottom quarks, as they were for the Tevatron results. As explained above, the di-tau inclusive search limits do not significantly change by considering other benchmark scenarios.

In addition to $\phi \to \tau^+ \tau^-$ at the LHC, studies indicate that with about 30 fb⁻¹ of data one can search for the non-standard neutral Higgs bosons of the MSSM in the $b\bar{b}\phi, \phi \to b\bar{b}$ channel with three b's in the final state [233]. Due to the dependence of this production and decay mode on the SUSY radiative corrections there is complementarity between the 3b channel and the inclusive tau pair channel in exploring the supersymmetric parameter space.

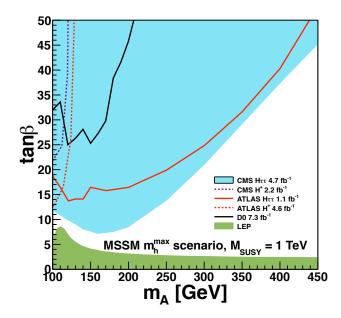

Figure 15: The 95% C.L. MSSM exclusion contours m_h -max benchmark scenario obtained by the ATLAS [234], CMS [138], and DØ [232] collaborations. The LHC collaborations contribute searches for $H \to \tau^+\tau^-$ and $H^\pm \to \tau \nu_\tau$ while DØ combines $H \to \tau^+\tau^-$ with $H \to b\bar{b}$ searches for these results. Also shown is the region excluded by LEP searches [34]. assuming a top quark mass of 174.3 GeV.

The LHC has the potential to explore a broad range of SUSY parameter space through the search for non-SM-like Higgs bosons. Nevertheless, Fig. 15 shows a broad region with intermediate $\tan \beta$ and large values of m_A that is not tested by present neutral or charged Higgs boson searches, and which might be difficult to cover completely via these searches, even with much larger data sets. In this region of parameter space it is possible that only the SM-like Higgs boson can be within the LHC's reach. If a SM-like Higgs boson is discovered, it may be challenging to determine only from the Higgs sector whether there is a supersymmetric extension of the SM in nature.

III.4. Searches for Charged MSSM Higgs Bosons

Searches for the charged Higgs bosons predicted by 2HDMs have been conducted at LEP, the Tevatron, and the LHC, and the results of these searches have been interpreted in terms of the MSSM. Due to the correlations among Higgs boson masses in the MSSM, the experimental results do not yet significantly constrain the MSSM parameter space beyond what is already obtained from the searches for neutral Higgs bosons. In the near future, however, the LHC experiments will be sensitive to charged Higgs boson decays up to ≈ 170 GeV for all values of tan β [236].

At LEP, searches were performed for pair-produced charged Higgs bosons. In the MSSM and in more general Type-II 2HDMs, for masses which are accessible at LEP energies,

the decays $H^+ \to c\overline{s}$ and $\tau^+\nu_{\tau}$ dominate. The final states $H^+H^- \to (c\overline{s})(\overline{c}s)$, $(\tau^+\nu_{\tau})(\tau^-\overline{\nu}_{\tau})$, and $(c\overline{s})(\tau^-\overline{\nu}_{\tau})+(\overline{c}s)(\tau^+\nu_{\tau})$ were considered, and the search results are usually presented as functions of BR $(H^+ \to \tau^+\nu)$. The sensitivity of the LEP searches was limited to $m_{H^\pm} < 90$ GeV, due to the background from $e^+e^- \to W^+W^-$ [237], and the kinematic limitation on the production cross section. The combined LEP data constrain $m_{H^\pm} > 78.6$ GeV independently of BR $(H^+ \to \tau^+\nu_{\tau})$ [238].

At the Tevatron, the CDF and DØ collaborations have searched for charged Higgs bosons in top quark decays with subsequent decays of the charged Higgs boson to $\tau\nu$ or to $c\bar{s}$ [239,240,241]. Assuming BR($H^+ \to c\bar{s}$) = 100%, the limits on BR($t \to H^+b$) from CDF and DØ are \approx 20% in the mass range 90 GeV < m_{H^+} < 160 GeV. Assuming BR($H^+ \to \tau^+\nu_{\tau}$) = 100%, DØ's limits on BR($t \to H^+b$) are also \approx 20% in the same mass range. These limits are valid in general 2HDMs, and they have also been interpreted in terms of the MSSM in the references.

The ATLAS collaboration has also searched for charged Higgs bosons produced in the decay of top quarks in $t\bar{t}$ events. ATLAS has searched for the decay $H^+ \to \tau^+ \nu_{\tau}$ in three final state topologies: 1) lepton+jets: with $t\overline{t} \to \overline{b}WH^+ \to$ $b\overline{b}(q\overline{q}')(\tau_{\rm lep}\nu)$, i.e., the W boson decays hadronically and the tau decays into an electron or a muon, with two neutrinos; 2) τ +lepton: with $t\bar{t} \to \bar{b}WH^+ \to b\bar{b}(l\nu)(\tau_{\rm had}\nu)$ i.e., the W boson decays leptonically (with $\ell=e,\ \mu$) and the tau decays hadronically; 3) τ +jets: $t\bar{t} \to \bar{b}WH^+ \to b\bar{b}(q\bar{q}')(\tau_{\rm had}\nu)$, i.e., both the W boson and the τ decay hadronically [242]. Assuming BR($H^+ \to \tau^+ \nu_{\tau}$) = 100%, ATLAS sets upper limits on BR $(t \to H^+ b)$ between 5% and 1% for charged Higgs boson masses between 90 GeV to 160 GeV, respectively. These limits are shown in Fig. 16. When interpreted in the context of the $m_h^{\rm max}$ scenario of the MSSM, these bounds exclude tan β values above 20 in this range of charged Higgs boson masses, but also provide sensitivity for $\tan \beta < 4$ due to the increasing predicted decay rate for $t \to H^+b$ at low tan β . The high-tan β interpretation of this result is shown in Fig. 15. ATLAS has also searched for charged Higgs bosons in top quark decays assuming BR($H^+ \rightarrow c\bar{s}$) = 100% [243], and sets limits of \approx 20% on ${\rm BR}(t \to H^+ b)$ in the 90 GeV $< m_{H^+} <$ 160 GeV mass range

The CMS collaboration has also searched for the charged Higgs boson in the decay products of top quark pairs: $t\bar{t}\to H^\pm W^\mp b\bar{b}$ and $t\bar{t}\to H^+H^-b\bar{b}$ [244]. Three types of final states with large missing transverse energy and jets originating from b-quark hadronization have been analyzed: the fully-hadronic channel with a hadronically decaying tau in association with jets, the di-lepton channel with a hadronically decaying tau in association with an electron or muon and the di-lepton channel with an electron-muon pair. Combining the results of these three analyses and assuming BR($H^\pm\to \tau\nu$)=1, the upper limits on BR($H^\pm\to H^\pm$) are less than 2% to 3% depending on the charged Higgs boson mass in the interval 80 GeV

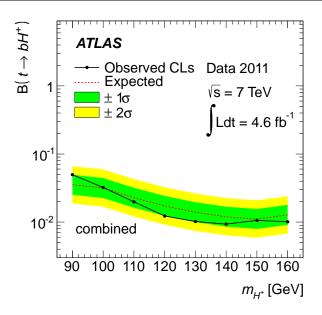

Figure 16: 95% C.L. limit on BR $(t \to H^+ b$ assuming BR $(H^+ \to \tau \nu) = 100\%$ from the AT-LAS collaboration [242].

 $< m_{H^+} < 160$ GeV. The results of this search have been translated into limits in the $(M_A, \tan \beta)$ plane for the m_h -max benchmark scenario and are shown in Fig. 15.

III.5. Effects of CP Violation on the MSSM Higgs Spectrum

In the Standard Model, CP-violation (CPV) is induced by phases in the Yukawa couplings of the quarks to the Higgs field, which results in one non-trivial phase in the CKM mixing matrix. SUSY scenarios with new CPV phases are theoretically appealing, since additional CPV beyond that observed in the K, D, and B meson systems is required to explain the observed cosmic matter-antimatter asymmetry [245,246]. the MSSM, there are additional sources of CPV from phases in the various mass parameters. In particular, the gaugino mass parameters $(M_i, i = 1, 2, 3)$, the Higgsino mass parameter, μ , the bilinear Higgs squared-mass parameter, m_{12}^2 , and the trilinear couplings of the squark and slepton fields to the Higgs fields, A_f , may carry non-trivial phases. The two parameter combinations $\arg[\mu A_f(m_{12}^2)^*]$ and $\arg[\mu M_i(m_{12}^2)^*]$ are invariant under phase redefinitions of the MSSM fields [247,248]. Therefore, if one of these quantities is non-zero, there would be new sources of CP-violation, which affects the MSSM Higgs sector through radiative corrections [182,248–253]. of the neutral CP-odd and CP-even Higgs boson states is no longer forbidden. Hence, m_A is no longer a physical parameter. However, the charged Higgs boson mass $m_{H^{\pm}}$ is still physical and can be used as an input for the computation of the neutral Higgs spectrum of the theory.

For large values of $m_{H^{\pm}}$, corresponding to the decoupling limit, the properties of the lightest neutral Higgs boson state approach those of the SM Higgs boson. That is, for $m_{H^{\pm}} \gg M_W$,

the lightest neutral Higgs boson is approximately a CP-even state, with CPV couplings that are suppressed by terms of $\mathcal{O}(m_W^2/m_{H^\pm}^2)$. In particular, the upper bound on the lightest neutral Higgs boson mass, takes the same value as in the CP-conserving case [248]. Nevertheless, there still can be significant mixing between the two heavier neutral mass eigenstates. For a detailed study of the Higgs boson mass spectrum and parametric dependence of the associated radiative corrections, see Refs. [249,252].

Major variations to the MSSM Higgs phenomenology occur in the presence of explicit CPV phases. In the CPV case, vector boson pairs couple to all three neutral Higgs boson mass eigenstates, H_i (i = 1, 2, 3), with couplings

$$g_{H_iVV} = \cos \beta \mathcal{O}_{1i} + \sin \beta \mathcal{O}_{2i}$$

$$g_{H_iH_jZ} = \mathcal{O}_{3i}(\cos\beta\mathcal{O}_{2j} - \sin\beta\mathcal{O}_{1j}) - \mathcal{O}_{3j}(\cos\beta\mathcal{O}_{2i} - \sin\beta\mathcal{O}_{1i})$$

where the g_{H_iVV} couplings are normalized to the analogous SM coupling and the $g_{H_iH_jZ}$ have been normalized to $g_Z^{\rm SM}/2$. \mathcal{O}_{ij} is the orthogonal matrix relating the weak eigenstates to the mass eigenstates. It has non-zero off-diagonal entries mixing the CP-even and CP-odd components of the weak eigenstates. The above couplings obey the relations

$$\sum_{i=1}^{3} g_{H_iZZ}^2 = 1 \quad \text{ and } \quad g_{H_kZZ} = \varepsilon_{ijk} \, g_{H_iH_jZ}$$

where ε_{ijk} is the Levi-Civita symbol.

Another consequence of CPV effects in the scalar sector is that all neutral Higgs bosons can couple to both scalar and pseudoscalar fermion bilinear densities. The couplings of the mass eigenstates H_i to fermions depend on the loop-corrected fermion Yukawa couplings (similarly to the CPC case), on $\tan \beta$ and on the \mathcal{O}_{ji} . The resulting expressions for the scalar and pseudoscalar components of the neutral Higgs boson mass eigenstates to fermions and the charged Higgs boson to fermions are given in Refs. [249,254].

The prodution processes of neutral MSSM Higgs bosons in the CPV scenario are similar to those in the CPC scenario, except for the fact that in any process, the CP eigenstates h, H, and A can be replaced by any of the three neutral Higgs mass eigenstates H_i . This is the case, since, in the presence of CP violation, the H_i 's do not have well-defined CP quantum numbers. Regarding the decay properties, the lightest mass eigenstate, H_1 , predominantly decays to $b\bar{b}$ if kinematically allowed, with a smaller fraction decaying to $\tau^+\tau^-$, similar to the CPC case. If kinematically allowed, a SM-like neutral Higgs boson, H_2 or H_3 can decay predominantly to H_1H_1 leading to many new interesting signals both at lepton and hadron colliders; otherwise it will decay preferentially to $b\bar{b}$.

III.6. Searches for Neutral Higgs Bosons in CPV Scenarios

At LEP, all three neutral Higgs eigenstates could have been produced by Higgs-strahlung, $e^+e^- \to H_iZ$, and in pairs, $e^+e^- \to Z^* \to H_iH_j$, with $i \neq j$. The production rates depend on the details of the CPV scenario. Possible cascade decays such as H_2 or $H_3 \to H_1H_1$ can lead to interesting experimental signatures in the Higgs-strahlung processes, $e^+e^- \to H_2Z$ or H_3Z , however, the searches in the CPV MSSM scenario are experimentally more difficult. The cross sections for the Higgs-strahlung and pair production processes are given in Refs [182,248,249,253].

The Higgs boson searches at LEP were interpreted [34] in a CPV benchmark scenario [182] for which the parameters were chosen so as to maximize the phenomenological differences with respect to the CPC scenario. Using the most conservative theoretical calculations available at each point in the $(m_{H_1}, \tan \beta)$ plane, parts of the region $m_{H_1} < 60$ GeV and $\tan \beta < 40$ were excluded, and values of $\tan \beta$ lower than 3 were excluded for all values of $m_{H_1} < 114$ GeV. The Tevatron CP-conserving results and projections for MSSM Higgs searches, as well as the existing projections for LHC MSSM CP-conserving searches have been reinterpreted in the framework of CP-violating MSSM Higgs in Ref. 255.

III.7. Indirect Constraints on Supersymmetric Higgs Bosons

Indirect bounds from a global fit to precision measurements of electroweak observables can be derived in terms of MSSM parameters [256] in a way similar to what was done in the SM. Given the MSSM and SM predictions for M_W as a function of m_t , and varying the Higgs boson mass and the SUSY spectrum, one finds that the MSSM overlaps with the SM when SUSY masses are large, of $\mathcal{O}(2 \text{ TeV})$, and the light SM-like Higgs boson has a mass in the experimentally preferred mass range: m_h 114-129 GeV. The MSSM Higgs boson mass expectations are compatible with the constraints provided by the measurements of m_t and M_W [257]. A global fit for m_h in the Constrained MSSM, for example, yields $m_h = 119.1^{+3.4}_{-2.9}$ GeV after including the constraints from LHC data, instead of the pre-LHC value of $m_h = 111.5^{+3.5}_{-1.2}$ GeV, improving the consistency of the model predictions with the LEP exclusion [258] ⁴. These global fit studies show that a SM-like Higgs with mass 125 GeV or larger would start to build up some tension with $g_{\mu}-2$ that may ultimately lead to exclude the CMSSM or other types of constrained SUSY scenarios for which similar results can be obtained.

Improvements in our understanding of B-physics observables put indirect constraints on MSSM scenarios in regions in which Higgs boson searches at the Tevatron and the LHC are sensitive. In particular, $BR(B_s \to \mu^+\mu^-)$, $BR(b \to s\gamma)$, and $BR(B_u \to \tau\nu)$ play an important role within minimal flavor-violating (MFV) models [259], in which flavor effects proportional to the CKM matrix elements are induced, as in the SM. For example, see Refs. [260–263]. The supersymmetric contributions to these observables come both at the tree-and loop-level, and have a different parametric dependence,

⁴ This fit does not include the direct limits on the Higgs boson mass from any collider.

but share the property that they become significant for large values of $\tan \beta$, which is also the regime in which searches for non-standard MSSM Higgs bosons at hadron colliders are the most powerful.

In the SM, the relevant contributions to the rare decay $B_s \to \mu^+\mu^-$ come through the Z-penguin and the W^\pm -box diagrams [264]. In supersymmetry with large $\tan \beta$, there are also significant contributions from Higgs-mediated neutral currents [265–268], which depend on the SUSY spectra, and grow with the sixth power of $\tan \beta$ and decrease with the fourth power of the CP-odd Higgs boson mass m_A . Therefore, the upper limits from the Tevatron and the LHC [269] put strong restrictions on possible flavor-changing neutral currents (FCNC) in the MSSM at large $\tan \beta$ [270].

Further constraints are obtained from the rare decay $b \to s\gamma$. The SM rate is known up to NNLO corrections [271,272] and is in good agreement with measurements [273]. In the Type-II 2HDM and in the absence of other sources of new physics at the electroweak scale, a bound $m_{H^\pm} > 295$ GeV has been derived [271]. Although this indirect bound appears much stronger than the results from direct charged Higgs searches, it can be invalidated by new physics contributions, such as those which can be present in the MSSM. In the minimal flavor-violating MSSM, there are new contributions from charged Higgs as well as chargino-stop and gluino-sbottom diagrams. The charged Higgs boson's contribution is enhanced for small values of its mass and can be partially canceled by the chargino and gluino contributions or by higher-order tan β -enhanced loop effects.

The branching ratio $B_u \to \tau \nu$, measured by the Belle [274,275] and BaBar [276,277] collaborations, also constrains the MSSM. The SM expectation is in slight tension with the latest experimental results [278]. In the MSSM, there is an extra tree-level contribution from the charged Higgs which interferes destructively with the SM contribution, and which increases for small values of the charged Higgs boson mass and large values of $\tan \beta$ [279]. Charged Higgs effects on $B \to D\tau\nu$ decays [280], constrain in an important way the parameter space for small values of the charged Higgs boson mass and large values of $\tan \beta$, and exclude a region that is otherwise allowed by values of $B_u \to \tau\nu$ [278,281,282]. These two observables are only mildly dependent on the SUSY spectra.

Charged Higgs bosons can play a role in explaining the evidence for CP violation in $D^0 \to \pi^+\pi^-$, K^+K^- decays recently presented by LHCb [283] and CDF [284]. In a particular minimal flavor violating 2HDM, tree-level charged Higgs insertions can give large contributions to CP violation in D^0 decays while also being consistent with stringent bounds from $D^0 - \bar{D}^0$ mixing, BR $(b \to s\gamma)$, and BR $(B_u \to \tau\nu)$, as well as direct searches such as $H \to \tau^+\tau^-$ [285].

Several studies [260-263,286,287] have shown that, in extended regions of parameter space, the combined B-physics measurements impose strong constraints on the MSSM models to which Higgs boson searches at the Tevatron and the LHC

are sensitive. Consequently, the observation of a non-SM Higgs boson at the Tevatron or the LHC would point to a rather narrow, well-defined region of MSSM parameter space [260,288] or to something beyond the minimal flavor violation framework.

Another indirect constraint on the Higgs sector comes from the search for dark matter. If dark matter particles are weakly interacting and massive, then particle physics can provide models which predict the correct relic density of the universe. In particular, the lightest supersymmetric particle, typically the lightest neutralino, is an excellent dark matter particle can-Within the MSSM, the measured relic density places constraints in the parameter space, which in turn - for specific SUSY low energy spectra- have implications for Higgs searches at colliders, and also for experiments looking for direct evidence of dark matter particles in elastic scattering with atomic nuclei. Large values of $\tan \beta$ and small m_A are relevant for the $b\overline{b}A/H$ and $A/H \to \tau^+\tau^-$ searches at the Tevatron and the LHC, and also provide a significant contribution from the CP-even Higgs H exchange to the spin-independent cross sections for direct detection experiments such as CDMS or Xenon, for example. Consequently, a signal at colliders would raise prospects for a signal in indirect detection experiments and vice-versa [286,288,290-292]. However, there are theoretical uncertainties in the calculation of dark matter scattering cross sections, and in the precise value of the local dark matter density and velocity distributions, which may dilute these model-dependent correlations.

IV. Other Model Extensions

There are many ways to extend the minimal Higgs sector of the Standard Model. In the preceding sections we have considered the phenomenology of the MSSM Higgs sector⁵, which at tree level is a constrained Type-II 2HDM (with restrictions on the Higgs boson masses and couplings). One can consider general Type-II 2HDMs [13,44,162], with no correlations between masses and couplings, or Type-I 2HDMs [163]. patterns of Higgs-fermion couplings in each case will lead to different phenomenology. It is also possible to consider models with a SM Higgs boson and one or more additional scalar SU(2) doublets that acquire no vacuum expectation value (vev) and hence play no role in the EWSB mechanism. These models are dubbed Inert Higgs Doublet Models [293]. Due to the lack of vev, the inert Higgs bosons cannot decay into a pair of gauge bosons, and imposing a Z_2 symmetry that prevents them from coupling to the fermions it follows that if the lightest inert Higgs boson is neutral it becomes a good dark matter candidate with interesting associated collider signals.

Other extensions of the Higgs sector can include [15,164] multiple copies of $SU(2)_L$ doublets, additional Higgs singlets, triplets or more complicated combinations of Higgs multiplets.

⁵ In the searches for charged Higgs bosons the results are presented for given branching ratio assumptions within a general 2HDM, and then interpreted in the MSSM.

It is also possible to enlarge the gauge symmetry beyond $SU(2)_L \times U(1)_Y$ along with the necessary Higgs structure to generate gauge boson and fermion masses. There are two main experimental constraints that govern these extensions: (i) precision measurements which constrain $\rho = m_W^2/(m_Z^2 \cos^2 \theta_W)$ to be very close to 1 and (ii) flavor changing neutral current (FCNC) effects. In electroweak models based on the SM gauge group, the tree-level value of ρ is determined by the Higgs multiplet structure. By suitable choices for the hypercharges, and in some cases the mass splitting between the charged and neutral Higgs sector or the vacuum expectation values of the Higgs fields, it is possible to obtain a richer combination of singlets, doublets, triplets and higher multiplets compatible with precision measurements [294]. Concerning the constraints coming from FCNC effects, the Glashow-Weinberg theorem [295] states that, in the presence of multiple Higgs doublets the tree-level FCNC's mediated by neutral Higgs bosons will be absent if all fermions of a given electric charge couple to no more than one Higgs doublet. The Higgs doublet models Type-I and Type-II are two different ways of satisfying this theorem. The coupling pattern of these two types can be arranged by imposing either a discrete symmetry or, in the case of Type-II, supersymmetry. The resulting phenomenology of extended Higgs sectors can differ significantly from that of the SM Higgs boson.

In supersymmetry, the most studied extensions of the MSSM have a scalar singlet and its supersymmetric partner [296-298]. These models have an extended Higgs sector with two additional neutral scalar states, one CP-even and one CP-odd, beyond those present in the MSSM. In these models, the tree-level bound on the lightest Higgs boson, considering arguments of perturbativity of the theory up to the GUT scale, is about 100 GeV. The radiative corrections to the masses are similar to those in the MSSM and yield an upper bound of about 145 GeV for the mass of the lightest neutral CP-even scalar, for stop masses in the TeV range [16,299]. plings of the Higgs bosons to the gauge bosons and fermions are weakened somewhat from mixing with the singlet and this can alter significantly the Higgs phenomenology with respect to the MSSM case.

Another extension of the MSSM which can raise the value of the lightest Higgs boson mass to a few hundred GeV is based on gauge extensions of the MSSM [17,18]. The addition of asymptotically-free gauge interactions naturally yields extra contributions to the quartic Higgs couplings. These extended gauge sector models can be combined with the presence of extra singlets or replace the singlet with a pair of triplets [19].

It is also possible that the MSSM is the low energy effective field theory of a more fundamental SUSY theory that includes additional particles with masses at or somewhat above the TeV range, and that couple significantly to the MSSM Higgs sector. A model-independent analysis of the spectrum and couplings of the MSSM Higgs fields, based on an effective theory of the MSSM degrees of freedom has been studied [18,20,21,300]. In these scenarios the tree-level mass of the lightest CP-even state

can easily be above the LEP bound of 114 GeV, thus allowing for a relatively light spectrum of superpartners, restricted only by direct searches. The Higgs spectrum and couplings can be significantly modified compared to the MSSM ones, often allowing for interesting new decay modes. It is also possible to moderately enhance the gluon fusion production cross section of the SM-like Higgs with respect to both the Standard Model and the MSSM.

Many non-SUSY solutions to the problem of electroweak symmetry breaking and the hierarchy problem are being developed. For example, Little Higgs models [25–27] propose additional sets of heavy vector-like quarks, gauge bosons, and scalar particles, with masses in the 100 GeV to a few TeV range. The couplings of the new particles are tuned in such a way that the quadratic divergences induced in the SM by the top, gauge-boson and Higgs loops are canceled at the one-loop level. If the Little Higgs mechanism successfully resolves the hierarchy problem, it should be possible to detect some of these new states at the LHC. For reviews of models and phenomenology, and a more complete list of references, see Refs. [301–303].

In Little Higgs models the production and decays of the Higgs boson are modified. For example, when the dominant production mode of the Higgs is through gluon fusion, the contribution of new fermions in the loop diagrams involved in the effective ϕqq vertex can reduce the production rate. The rate is generally suppressed relative to the SM rate due to the symmetries which protect the Higgs boson mass from quadratic divergences at the one-loop level. As a result, the branching ratio of the Higgs boson to photon pairs can be enhanced in these models [304]. By design, Little Higgs models are valid only up to a scale $\Lambda \sim 5\text{-}10$ TeV. The new physics which would enter above Λ remains unspecified, and will impact the Higgs sector. In general, it can modify Higgs couplings to third-generation fermions and gauge bosons, though these modifications are suppressed by $1/\Lambda$ [305].

Distinctive features in the Higgs phenomenology of Little Higgs models may also stem from the fact that loop-level electroweak precision bounds on models with a tree-level custodial symmetry allows for a Higgs boson heavier than the one permitted by precision electroweak fits in the SM. This looser bound follows from a cancellation of the effects on the ρ parameter of a higher mass Higgs boson and the heavy partner of the top quark. The Higgs boson can have a mass as high as 800-1000 GeV in some Little Higgs models and still be consistent with electroweak precision data [306]. Lastly, the scalar content of a Little Higgs structure is model dependent. There could be two, or even more scalar doublets in a little Higgs model, or even different representations of the electroweak gauge group [26].

Models of extra space dimensions present an alternative way of avoiding the hierarchy problem [28]. New states, known as Kaluza-Klein (KK) excitations, can appear at the TeV scale, where gravity-mediated interactions may become relevant. They share the quantum numbers of the graviton and/or SM particles. In a particular realization of these models, based on

warped extra dimensions, a light Higgs-like particle, the radion, may appear in the spectrum [307]. The mass of the radion, as well as its possible mixing with the light Higgs boson, depends strongly on the mechanism that stabilizes the extra dimension, and on the curvature-Higgs mixing.

The radion couples to the trace of the energy-momentum tensor of the SM particles, leading to effective interactions with quarks, leptons, and weak gauge bosons which are similar to the ones of the Higgs boson, although they are suppressed by the ratio of the weak scale to the characteristic mass of the new excitations. An important characteristic of the radion is its enhanced coupling to gluons. Therefore, if it is light and mixes with the Higgs boson, it may modify the standard Higgs phenomenology at lepton and hadron colliders. A search for the radion conducted by OPAL at LEP gave negative results [308]. Radion masses below 58 GeV are excluded for the mass eigenstate which becomes the Higgs boson in the no-mixing limit, for all parameters of the Randall-Sundrum model. Most recently there has been a study of the effects of radion-Higgs mixing in Higgs boson searches at the LHC [309].

In models of warped extra dimensions in which the SM particles propagate in the extra dimensions, the KK excitations of the vector-like fermions may be pair-produced at colliders and decay into combinations of two Higgs bosons and jets, or one Higgs boson, a gauge boson, and jets. KK excitations may also be singly-produced. Some of these interesting possible new signatures for SM-like Higgs bosons in association with top or bottom quarks have been studied [27,29]. Most interesting, in models with warped extra dimensions the Kaluza-Klein excitations of the quarks and leptons which can be exchanged as virtual particles in the loops, can significantly change the Higgs production via gluon fusion, as well as its decay into diphotons. These results may depend on the precise localization of the SM-like Higgs in the extra dimension as well as on the precise particle content of the models. There are many studies in the literature that address these issues and compute the effects on the Higgs phenomenology [27,310].

Models of flat extra dimensions, in which SM particles propagate in the extra dimensions, are named Universal Extra Dimensions (UED) [311]. In such models the KK particles affect the Higgs couplings at the 1-loop level. In the minimal UED model, for tree-level masses of the lowest KK particles of order 1 TeV the $gg \to h$ production rate is increased by $\approx 20\%$ while the $h \to \gamma\gamma$ decay width is decreased by a factor of $\lesssim 3\%$ [312].

It is also possible to consider a simple description of models in which electroweak symmetry breaking is triggered by a light composite Higgs, which emerges from a strongly-interacting sector as a pseudo-Goldstone boson, by utilizing an effective low-energy Lagrangian approach [31]. Recent studies of the phenomenology relevant for collider searches can be found in Ref. 313.

The Higgs boson can also be a portal to hidden sectors, in particular, the Higgs boson can decay to the particles of a low-mass hidden sector; these models are referred to as hidden valley models [314,315]. Since a light Higgs boson is a particle with a narrow width, even modest couplings to new states can give rise to a significant modification of Higgs phenomenology through exotic decays. Simple hidden valley models exist in which the Higgs boson decays to an invisible fundamental particle, which has a long lifetime to decay back to SM particles through small mixings with the SM Higgs boson; Ref. 315 describes an example. The Higgs boson may also decay to a pair of hidden valley "v-quarks," which subsequently hadronize in the hidden sector, forming "v-mesons." These mesons often prefer to decay to the heaviest state kinematically available, so that a possible signature is $h \to 4b$. Some of the v-mesons may be stable, implying a mixed missing energy plus heavy flavor final state. In other cases, the v-mesons may decay to leptons, implying the presence of low mass lepton resonances in high H_T events [316]. Other scenarios have been studied [317] in which Higgs bosons decay predominantly into light hidden sector particles, either directly, or through light SUSY states, and with subsequent cascades that increase the multiplicity of hidden sector particles. In such scenarios, the high multiplicity hidden sector particles, after decaying back into the Standard Model, appear in the detector as clusters of collimated leptons known as lepton jets.

If Higgs bosons are not discovered at the Tevatron or the LHC, other studies might be able to test alternative theories of dynamical electroweak symmetry breaking which do not involve a Higgs particle [318].

V. Searches for Higgs Bosons Beyond the MSSM

In extensions of the MSSM with one or more additional scalar singlets, limits have been set at e^+e^- and hadron colliders. The ALEPH [319] and DELPHI [320] collaborations place constraints on such models. Precise LEP 2 bounds on the Higgs boson masses depend on the couplings of the Higgs bosons to the gauge bosons and such couplings tend to be weakened somewhat from mixing with the singlet(s). At hadron colliders, searches for a light pseudoscalar boson predicted by the NMSSM have been performed by DØ [321], CDF [322], CMS [323], and ATLAS [324]. No significant excesses have been found and limits have been set on these models.

Most of the searches for the processes $e^+e^- \to hZ$ and hA, which have been discussed in the context of the CPC-MSSM, rely on the assumption that the Higgs bosons have a sizable branching ratio to $b\bar{b}$. However, for specific parameters of the MSSM [325], the general 2HDM case, or composite models [175,177,326], decays to non- $b\bar{b}$ final states may be significantly enhanced. Flavor-independent hadronically-decaying Higgs boson searches have been performed at LEP which do not require the experimental signature of a b-jet [327], and a preliminary combination of LEP data has been performed [34,328]. If Higgs bosons are produced at the SM rate and decay only to jets of hadrons, then the 95% C.L. lower limit on the mass of the Higgs boson is 112.9 GeV, independent of the fractions

of gluons and b, c, s, u and d-quarks in Higgs boson decay. In conjunction with b-flavor sensitive searches, large domains of the general Type-II 2HDM parameter space have been excluded [329].

In the Type-I 2HDM, if the CP-odd neutral Higgs boson A is light (which is not excluded in the general 2HDM case, nor in some extensions of the MSSM), the decay $H^{\pm} \to W^{\pm *}A$ may be dominant for masses accessible at LEP, a possibility that was investigated by DELPHI [330] and OPAL [331]. CDF's search for this decay chain in top quark decays [322] may also be interpreted in this scenario.

The LEP collaborations searched for Higgs bosons produced in pairs, in association with Z bosons, b quarks, and τ leptons. The decays considered are $\phi_{i,j} \to b\bar{b}, \tau^+\tau^-$, and $\phi_j \to \phi_i\phi_i$, when kinematically allowed, yielding four-b, four-b+jets, sixb and four- τ final states as well as mixed modes with bquarks and tau leptons. No evidence for a Higgs boson was found [34,224], and mass-dependent coupling limits on a variety of processes, which apply to a large class of models were, set. The limits on the cross sections of Yukawa production of Higgs bosons are typically more than 100 times larger than the SM predictions [224]. Limits on pair-produced Higgs bosons extend up to $m_{\phi_i} + m_{\phi_i}$ in the range 140- 200 GeV for fullstrength production, assuming $b\bar{b}$ and $\tau^+\tau^-$ decays. Limits on Higgs-strahlung production with subsequent decay of the Higgs into lighter Higgs pairs exclude Higgs masses of the Higgs produced in association with the Z up to 114 GeV, if the lighter Higgs bosons decay to $b\bar{b}$. Weaker limits are set if the lighter Higgs pair decays to four tau leptons, or to a mixture of tau leptons and b quarks [34].

Decays of Higgs bosons into invisible (weakly-interacting and neutral) particles may occur in many models⁶. For example, Higgs bosons might decay into pairs of Goldstone bosons or Majorons [332]. In the process $e^+e^- \to hZ$, the mass of the invisible Higgs boson can be inferred from the kinematics of the reconstructed Z boson by using the beam energy constraint. Results from the LEP experiments can be found in Refs. [219] and [333]. A preliminary combination of LEP data yields a 95% C.L. lower bound of 114.4 GeV for the mass of a Higgs boson, if it is produced with SM production rate, and if it decays exclusively into invisible final states [334].

OPAL's decay-mode independent search for $e^+e^- \to S^0Z$ [80] provides sensitivity to arbitrarily-decaying scalar particles, as only the recoiling Z boson decaying into leptons is required to be reconstructed. The energy and momentum constraints provided by the e^+e^- collisions allow the S^0 's four-vector to be reconstructed and limits placed on its production independent of its decay characteristics, allowing sensitivity for very light scalar masses. The limits obtained in this search are less than one-tenth of the SM Higgs-strahlung production rate for

1 keV< m_{S^0} < 19 GeV, and less than the SM Higgs-strahlung rate for m_{S^0} < 81 GeV.

Hidden-valley models predict a rich phenomenology of new particles, some of which can be long-lived and hadronize with SM particles to form exotic particles which decay at measurable distances in collider experiments. CDF and DØ have searched for pair-produced long-lived particles produced resonantly and which decay to $b\bar{b}$ pairs, and set limits on Higgs boson production in hidden-valley models [335,336]. The Higgs boson can also be the portal to high multiplicity hidden sector particles that may produce multiple charged leptons in the final state. A search for additional leptons in events containing a leptonically decaying W or Z boson by CDF [337] is sensitive to such models and others predicting multi-lepton final states; the results are consistent with SM expectations.

Photonic final states from the processes $e^+e^- \to Z/\gamma^* \to H\gamma$ and from $H \to \gamma\gamma$, could be significantly enhanced, over the SM loop induced effects, in models with anomalous couplings [338]. Searches for the processes $e^+e^- \to (H \to b\bar{b})\gamma$, $(H \to \gamma\gamma)q\bar{q}$, and $(H \to \gamma\gamma)\gamma$ have been used to set limits on such anomalous couplings [339]. These searches also contribute in the combinations of searches for the standard model Higgs boson, although the small predicted signal rates imply that they contribute less than other channels.

Searches with photonic final states are experimentally very appealing and they have been used to constrain fermiophobic Higgs models, in which the Higgs boson has SM-like properties except that its tree-level couplings to fermions are assumed to be absent or very small. Fermiophobic Higgs models are however quite challenging to construct; they are generally strongly fine-tuned and imply new strong dynamics at low energy scales. A Type-I fermiophobic 2HDM could predict an enhanced $h_f \to \gamma \gamma$ branching ratio, where h_f denotes a fermiophobic Higgs boson. The LEP searches are described in Ref. 340. In a preliminary combination of LEP data [341], a fermiophobic Higgs boson with mass less than 108.2 GeV (95%) C.L.) has been excluded. Fermiophobic models would also predict enhanced branching ratios for the decays $h_f \to W^*W$ and Z^*Z , a possibility that has been addressed by L3 [342] and ALEPH [343]. At hadron colliders, the process $gg \to h_f$ has a negligible rate in a fermiophobic Higgs model, but the Wh_f , Zh_f , and VBF production cross sections remain close to their SM predictions and the Higgs boson branching ratios to $\gamma\gamma$, W^+W^- , and ZZ are enhanced. A search for the SM Higgs boson at a hadron collider can not therefore be re-interpreted as a search in a fermiophobic model, even if a limit is set on the total production cross section times a specific decay branching ratio, due to the different kinematic distributions from the different production modes affecting the signal acceptance. CDF and DØ have re-optimized their $h_f \to \gamma \gamma$ searches for the fermiophobic model, and with results based on 9.7 fb⁻¹ of DØ data [344,345] and 10.0 fb^{-1} of CDF data [346,347], combined with $h_f \to W^+W^-$ and $h_f \to ZZ$ searches extend the exclusion in the fermiophobic Higgs model to 119 GeV [110,348]. Other

⁶ As discussed above, in the MSSM the Higgs can decay into pairs of lightest, stable neutralinos.

production of fermiophobic Higgs bosons, leading to a 3-photons final state, has also been searched for by DØ [349].

ATLAS and CMS search for a fermiophobic Higgs boson in $h_f \to \gamma \gamma$ searches optimized for the fermiophobic signature [350,351], and CMS combines these with searches for $h_f \to W^+W^-$ and $h_f \to ZZ$ assuming fermiophobic production and decay [10]. CMS excludes a fermiophobic Higgs boson in the range 110 GeV $< m_H < 188$ GeV at the 95% C.L.

Higgs bosons with double electric charge are predicted, for example, by models with additional triplet scalar fields or left-right symmetric models [352]. It has been emphasized that the see-saw mechanism could lead to doubly-charged Higgs bosons with masses which are accessible to current and fu-Searches were performed at LEP for the ture colliders [353]. pair-production process $e^+e^- \rightarrow H^{++}H^{--}$ with four prompt leptons in the final state [354-356]. Lower mass bounds between 95 GeV and 100 GeV were obtained for left-right symmetric models (the exact limits depend on the lepton flavors). Doubly-charged Higgs bosons were also searched for in single production [357]. Furthermore, such particles would modify the Bhabha scattering cross section and forward-backward asymmetry via t-channel exchange. The absence of a significant deviation from the SM prediction puts constraints on the Yukawa coupling of $H^{\pm\pm}$ to electrons for Higgs boson masses which reach into the TeV range [356,357].

Searches have also been carried out at the Tevatron for the pair production process $p\overline{p}\to H^{++}H^{--}$. The DØ search is performed in the $\mu^+\mu^+\mu^-\mu^-$ final state [358], while CDF also considers $e^+e^+e^-e^-$ and $e^+\mu^+e^-\mu^-$, and final states with τ leptons [359]. A search by CDF for a long-lived $H^{\pm\pm}$ boson, which would decay outside the detector, is described in [360].

CMS has searched for doubly-charged Higgs bosons which are either pair produced, $pp \to H^{++}H^{--}$ or produced in association with a singly-charged Higgs boson via s-channel W^{\pm} exchange, $pp \to H^{++}H^{-}$, assuming decays of the form $\ell^+\ell'^-$, where ℓ , ℓ' are combinations of e, μ , and τ leptons [361]. No significant excess is seen, and limits on the mass of the doubly-charged Higgs boson vary from 165 GeV to 457 GeV, depending on the production and decay mode. ATLAS has searched for doubly charged Higgs bosons in the dimuon decay [362], setting a limit on the mass of 355 GeV assuming a decay branching ratio to dimuons of 100% and coupling to left-handed fermions, and a limit on the mass of 251 GeV assuming coupling to right-handed fermions.

VI. Outlook

The Tevatron has completed its run and is finalizing its Higgs boson search results with up to 10 fb⁻¹ of data analyzed. The combination of the preliminary results from CDF and DØ's searches for the SM Higgs boson shows an excess of data events with respect to the background estimation in the mass range 115 GeV $< m_H < 135$ GeV, dominated by the $H \rightarrow b\bar{b}$ channels. The global significance for such an excess anywhere in the full mass range is 2.2 standard deviations.

In 2011, the LHC delivered approximately 5 fb⁻¹ of pp collision data at $\sqrt{s} = 7$ TeV. A variety of searches targeting the SM Higgs boson in the mass range 100 GeV $< m_H < 600$ GeV have been performed, excluding all masses except the range between 114 GeV and 129 GeV. Most of the region below 123 GeV is also excluded by the ATLAS experiment but not by other experiments. Within the allowed mass range, both ATLAS and CMS observe independent excesses of events consistent with a SM-like Higgs boson with a mass of $\approx 125 \text{ GeV}$, with global significances of 1.3σ and 2.1σ , respectively. Both experiments observe excesses of data over the corresponding background predictions in searches for Higgs bosons decaying into diphotons and Z bosons pairs. More data, at $\sqrt{s} = 8 \text{ TeV}$, being collected in 2012, are required to understand this excess. The LHC will either exclude the SM Higgs boson or confirm the existence of a SM-like Higgs particle. In the latter case, accurate measurements of the properties of the Higgs particle as well as searches for new particles will be of most relevance.

Searches at the LHC for additional Higgs bosons: charged Higgs bosons, doubly charged Higgs bosons, the neutral Higgs bosons of the MSSM, and other exotic Higgs particles, have yielded results consistent with background expectations and strong limits have been placed in significant regions of parameter space. An upgrade of the center of mass energy to 13–14 TeV is planned for the near future. This upgrade will allow the LHC to explore a wide variety of extended Higgs sectors and search for new particles expected in models beyond the SM. This upgrade will also allow for increased precision of measurements of the properties of a SM-like Higgs boson, if one exists.

A high-energy e^+e^- linear collider may be built in the future, allowing ultimate high-precision measurements of the properties of Higgs boson(s) and other particles beyond those of the SM. At a $\mu^+\mu^-$ collider, mass measurements with a precision of a few MeV would be possible, and energy scans may distinguish between signals of Higgs particles nearly degenerate in mass, as predicted in many extended Higgs models.

In the theoretical landscape, numerous models are available with novel approaches to the problem of electroweak symmetry breaking. In the next decade, the LHC's exploration of the multi-TeV energy scale will solidify our understanding of the mechanism of mass generation of the known elementary particles.

VII. Addendum

Updated July 12, 2012.

On July 4, 2012, the ATLAS and CMS collaborations simultaneously announced observation of a new particle produced in pp collision data at high energies [363–366]. The data samples used correspond to between 4.6 and 5.1 fb⁻¹ of collision data collected at $\sqrt{s}=7$ TeV in 2011, and between 5.3 and 5.9 fb⁻¹ of collisions collected at $\sqrt{s}=8$ TeV in 2012. The observed decay modes indicate that the new particle is a boson. The evidence is strong that the new particle decays to $\gamma\gamma$ and ZZ with rates consistent with those predicted for the Standard

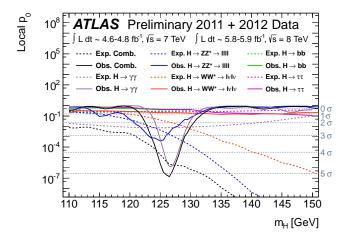

Model (SM) Higgs boson. There are indications that the new particle might also decay to W^+W^- , and decays to $b\bar{b}$ and $\tau^+\tau^-$ are being sought as well.

The ATLAS collaboration has updated its SM Higgs boson searches in the $H \to \gamma \gamma$ and $H \to ZZ \to \ell^+ \ell^- \ell'^+ \ell'^-$ [367] modes with new data collected at $\sqrt{s} = 8$ TeV and improved analysis techniques applied to both the 7 TeV and 8 TeV data. ATLAS has also finalized its $\sqrt{s} = 7$ TeV analyses in the $H \to ZZ \to \ell^+\ell^-\nu\bar{\nu}, H \to ZZ \to \ell^+\ell^-q\bar{q},$ $H \rightarrow W^+W^- \rightarrow \ell^+\nu_\ell\ell'^-\bar{\nu}_{\ell'}, \quad H \rightarrow W^+W^- \rightarrow \ell^+\nu_\ell q\bar{q'},$ $H \to \tau^+ \tau^-$, and $WH, ZH \to Wb\bar{b}, Zb\bar{b}$ channels [368], and includes them in its SM Higgs boson combined results [369,364]. ATLAS's $H \rightarrow \gamma \gamma$ search has been improved with respect to the previous version by separating events with two jets and two photons from other events, which improves the sensitivity for the vector boson fusion (VBF) process, and by improved photon identification and isolation algorithms. AT-LAS's $H \to ZZ \to \ell^+\ell^-\ell'^+\ell'^-$ search has been improved with respect to the previous results by re-optimizing the kinematic cuts, improving electron reconstruction and identification efficiency at low p_T , and improved robustness to pileup events.

The CMS collaboration has updated its SM Higgs boson searches in the $H\to\gamma\gamma$, $H\to ZZ\to\ell^+\ell^-\ell^{\prime+}\ell^{\prime-}$, $H\to ZZ\to\ell^+\ell^-\nu\bar{\nu}$, $H\to W^+W^-\to\ell^+\nu_\ell\ell^{\prime-}\bar{\nu}_{\ell^\prime}$, $H\to b\bar{b}$, and $H\to\tau^+\tau^-$ channels, all of which include 8 TeV data collected in 2012 [370]. The $t\bar{t}H\to t\bar{t}b\bar{b}$ [370] search is new and based on 2011 data. The $H\to W^+W^-\to\ell^+\nu_\ell q\bar{q}'$ [370] search is included for the first time in the combination.

CMS's $H \rightarrow \gamma \gamma$ search has been improved with respect to its earlier version by dividing the diphoton plus two jet category into two, depending on the dijet invariant mass and the jet p_T , and also by removing jets from pileup collisions. The $H \to ZZ \to \ell^+\ell^-\ell'^+\ell'^-$ search has been improved with respect to its previous version, benefiting from improved lepton identification and isolation algorithms, as well as final state radiation recovery. The discriminant variables used now to separate the expected signal from the backgrounds are twodimensional, plotting the invariant mass of the four leptons versus a matrix-element-based likelihood discriminant. CMS's $H \to W^+W^-$ search combines the results from the multivariate analysis (MVA) for the 7 TeV data with the results of a cutbased analysis on the 8 TeV data sample, which is described in Ref. 372. CMS's $VH \rightarrow Vb\bar{b}$ (with V=W or Z) search encompasses five channels: $WH \rightarrow e\nu b\bar{b}$, $WH \rightarrow \mu\nu b\bar{b}$ $ZH \rightarrow$ $e^+e^-b\bar{b}$, $ZH \to \mu^+\mu^-b\bar{b}$, and $ZH \to \nu\bar{\nu}b\bar{b}$. CMS's $H \to \tau^+\tau^$ search divides the candidate events by tau lepton decay type and subdivides the samples based on number of jets (0,1) or on VBF type. The 0 and 1 jet categories are also further subdivided according to low or high p_T of the τ .

Each experiment, ATLAS and CMS, separately combine their data to obtain independent results of their searches, computing the significance of the observation, measuring the production rates times the decay branching fractions for each

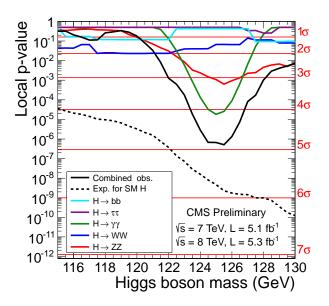

Figure 17: Local p-values for the ATLAS SM Higgs boson search (left), and the CMS SM Higgs boson search (right), separately for each decay mode. The solid lines show the observed p-values and the dashed lines show the median expected p-values, assuming a SM Higgs boson is present, computed at each value of m_H separately.

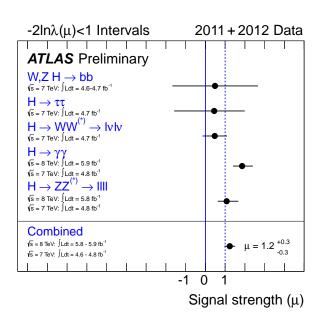

channel analyzed, and updating the mass and rate exclusions [364,366]. The separate results provide independent confirmations of the observation. The significance is quantified by a p-value, which is the probability to observe an upward fluctuation of the background which gives a result at least as signal-like as that observed in the data. A p-value of 2.87×10^{-7} corresponds to a five standard deviation excess over the background prediction. The p-values are shown for the analysis channels separately for ATLAS and CMS in Fig. 17. ATLAS observes an excess with a local significance of 5.0σ at a mass $m_H = 126.5$ GeV, with an expected significance of 4.6σ if a SM Higgs boson were present at such mass value. CMS observes

an excess with a local significance of 4.9σ at a mass $125.5~{\rm GeV}$, with an expected significance of 5.9σ , and measures the mass of the new boson as $m_H=125.3\pm0.6~{\rm GeV}$. Fig. 18 shows the best-fit cross sections times the relevant decay branching fractions for the new particle, normalized to the SM predictions for Higgs boson production and decay, assuming it has a mass of $126.5~{\rm GeV}$ (ATLAS), and $125~{\rm GeV}$ (CMS). ATLAS's combined signal strength fit, assuming SM ratios for the production and decay modes, is $\mu=\sigma/\sigma_{\rm SMH}=1.2\pm0.3$, and CMS's combined fit is $\mu=0.80\pm0.22$. Within the current experimental uncertainties, the measurements are consistent with SM predictions. Both ATLAS and CMS separately exclude SM Higgs bosons with masses outside a narrow range near the local excesses.

The Tevatron collaborations updated their Higgs boson search results on July 2, 2012 [373]. The D0 collaboration has updated its $VH \to Vb\bar{b}$ search results by improving the acceptance of the lepton selection, dividing the events into more categories based on the number an quality of b tags, and improving the MVA treatment [374]. Additional data and analysis improvements also improve the sensitivity of D0's $H \to W^+W^-$ searches by 5-10% with respect to the previous re-The CDF Higgs boson searches were updated with the full Run II data set and improved b-tagging for the Winter 2012 conferences [376]. CDF and D0 combine their results together, and, with the full suite of SM Higgs boson search analyses, see a broad excess in the range 115 GeV $< m_H < 135$ GeV, with a global signal significance of 2.5σ , and a maximum local significance of 3.0σ . Fig. 19 shows the measured cross sections times the relevant decay branching ratios normalized to those expected for a SM Higgs boson at mass $m_H = 125$ GeV for the combined CDF and D0 searches for $H \to W^+W^-, H \to \gamma\gamma$, and $VH \to Vb\bar{b}$ searches. The combined result, assuming SM ratios for the production and decay modes, is $\mu = 1.4 \pm 0.6$. In the dominant decay channel, $VH \to Vb\bar{b}$, the global significance is 2.9σ , with a maximum local significance of 3.2σ . Assuming the existence of a new particle, this provides the first strong indication for its decay into a fermion pair at a rate consistent with the SM prediction for a Higgs boson of such a mass.

In summary, a new particle has been observed at the LHC. Within the experimental uncertainties, it has characteristics consistent with those expected from the Higgs boson predicted by the Standard Model, with a mass near 125 GeV. Tevatron data also are consistent with the production and decay of a SM-like Higgs boson at this mass. However, the present experimental uncertainties still allow for a wide variety of new physics alternatives.

The LHC will continue to run until early 2013, and it is expected to deliver at least 15 fb⁻¹ more data to both ATLAS and CMS, at $\sqrt{s} = 8$ TeV. After this run, a shutdown will occur to improve the accelerator components to allow data taking at higher energies. The much larger dataset to be collected will provide the opportunity to make increasingly precise measurements of the properties of the new particle, and

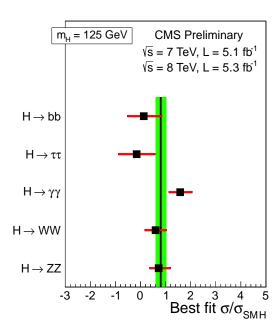

Figure 18: Best-fit production cross sections times branching ratios to $H \to \gamma\gamma$, $H \to ZZ$, $H \to W^+W^-$, $H \to b\bar{b}$, and $H \to \tau^+\tau^-$, normalized to the SM predictions for Higgs boson production and decay, assuming it has a mass of 126.5 GeV (ATLAS, left), and 125 GeV (CMS, right). The combined result, assuming SM ratios for the production and decay modes, is shown as a separate point on the ATLAS graph at $\mu = \sigma/\sigma_{\rm SMH} = 1.2 \pm 0.3$ and is shown with the shaded band on the CMS graph at $\mu = 0.80 \pm 0.22$.

test whether it is the SM Higgs boson or point the way to physics beyond the SM.

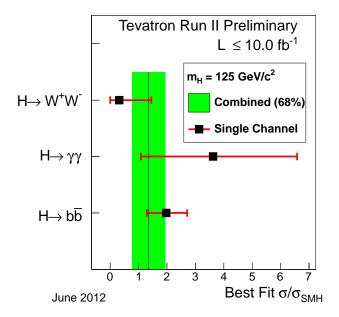

Figure 19: Best-fit cross sections times branching ratios to $H \to W^+W^-$, $H \to \gamma\gamma$ and $H \to b\bar{b}$, normalized to the SM predictions for Higgs boson production and decay, assuming it has a mass of 125 GeV, for the combined CDF and D0 search results. The combined result, assuming SM ratios for the production and decay modes, is shown with a shaded band, at $\mu = \sigma/\sigma_{\rm SMH} = 1.4 \pm 0.6$.

CONTENTS:

Standard Model H^0 (Higgs Boson) Mass Limits

- H^0 Direct Search Limits
- $-H^0$ Indirect Mass Limits from Electroweak Analysis

Mass Limits for Neutral Higgs Bosons in Supersymmetric Models

- $-H_1^0$ (Higgs Boson) Mass Limits in Supersymmetric Models
- $A^{ ilde{0}}$ (Pseudoscalar Higgs Boson) Mass Limits in Supersymmetric Models

 ${\it H}^0$ (Higgs Boson) Mass Limits in Extended Higgs Models

H[±] (Charged Higgs) Mass Limits

Mass limits for $H^{\pm\pm}$ (doubly-charged Higgs boson)

- Limits for $H^{\pm\pm}$ with $T_3=\pm 1$
- Limits for $H^{\pm\pm}$ with $T_3=0$

STANDARD MODEL H⁰ (Higgs Boson) MASS LIMITS

These limits apply to the Higgs boson of the three-generation Standard Model with the minimal Higgs sector. For a review and a bibliography, see the above review on "Higgs Bosons: Theory and Searches," where the latest unpublished results are also described.

Note: the addendum to the Higgs boson review describes the latest news reported in July 2012 on the discovery of a boson whose properties are consistent with the Standard Model Higgs boson.

H⁰ Direct Search Limits

All data that have been superseded by newer results are marked as "not used" or have been removed from this compilation, and are documented in previous editions of this Review of Particle Physics.

 $^{1}\,\mathrm{AAD}$ 12E combine data from AAD 11v, AAD 11AB, AAD 12, AAD 12D, AAD 12F. AAD 12G. The 99% CL exclusion range is 133-230 and 260-437 GeV. An excess of events over background with a local significance of 3.5 σ is observed at about $m_{H^0}=$ 126 GeV.

The GeV. 2 CHATRCHYAN 12B combine CHATRCHYAN 12E, CHATRCHYAN 12F, CHATRCHYAN 12G, CHATRCHYAN 12H, CHATRCHYAN 12I, CHATRCHYAN 12D, as well as a search in the decay mode $H^0 \to \tau \tau$. The 99% CL exclusion range is 129–525 GeV. An excess of events over background with a local significance of 3.1 σ is observed at about $m_{H^0}=$ 124 GeV.

 3 AALTONEN 10F combine searches for H^0 decaying to W^+W^- in $p\,\overline{p}$ collisions at $E_{\rm cm}$ $= 1.96 \text{ TeV with } 4.8 \text{ fb}^{-1} \text{ (CDF) and } 5.4 \text{ fb}^{-1} \text{ (DØ)}.$

4 Search for $e^+e^- \to H^0 Z$ at $E_{\rm cm} \le 209$ GeV in the final states $H^0 \to b\overline{b}$ with $Z \to \ell \ell$, $\nu \overline{\nu}$, $q\overline{q}$, $\tau^+\tau^-$ and $H^0 \to \tau^+\tau^-$ with $Z \to q\overline{q}$.

Combination of the results of all LEP experiments.

 6 A 3σ excess of candidate events compatible with m_{H^0} near 114 GeV is observed in the combined channels $q \overline{q} q \overline{q}$, $q \overline{q} \ell \overline{\ell}$, $q \overline{q} \tau^+ \tau$

⁷ AAD 12 search for H^0 production with $H \to ZZ \to \ell^+\ell^-q\overline{q}$ in 1.04 fb⁻¹ of pp collisions at $E_{\rm cm}=7$ TeV. A limit on cross section times branching ratio which is (1.7–13) times larger than the expected Standard Model cross section is given for m_{H^0} = 200-600 GeV at 95% CL. The best limit is at $m_{H^0} = 360$ GeV.

⁸ AAD 12D search for H^0 production with $H \to ZZ^{(*)} \to 4\ell$ in 4.8 fb⁻¹ of pp collisions and 12D search for H^0 production with $H \to Z Z^0 \cap A \ell$ in 4.8 ID $^-$ of pp collisions at $E_{\rm cm} = 7$ TeV in the mass range $m_{H^0} = 110$ -600 GeV. An excess of events over background with a local significance of 2.1 σ is observed at 125 GeV. AAD 12F search for H^0 production with $H \to WW^{(*)} \to \ell^+ \nu \ell^- \overline{\nu}$ in 2.05 fb⁻¹ of pp collisions at $E_{\rm cm} = 7$ TeV in the mass range $m_{H^0} = 110$ -300 GeV.

10 AAD 12g search for H^0 production with $H \rightarrow \gamma \gamma$ in 4.9 fb⁻¹ of pp collisions at $E_{\rm Cm}$ = 7 TeV in the mass range $m_{H^0} = 110$ –150 GeV. An excess of events over background with a local significance of 2.8 σ is observed at 126.5 GeV.

11 AALTONEN 12 search for $H^0 \rightarrow \gamma \gamma$ in 7.0 fb⁻¹ of $p\overline{p}$ collisions at $E_{\rm cm} = 1.96$ TeV. A limit on cross section times branching ratio which is (8.5–29) times larger than the expected Standard Model cross section is given for $m_{H^0} = 100$ –150 GeV at 95% CL.

¹²CHATRCHYAN 12C search for H^0 production with $H \to ZZ \to \ell^+\ell^-\tau^+\tau^-$ in 4.7 fb $^{-1}$ of pp collisions at $E_{\rm cm}=$ 7 TeV. A limit on cross section times branching ratio which is (4–12) times larger than the expected Standard Model cross section is given for $m_{H^0}=190$ –600 GeV at 95% CL. The best limit is at $m_{H^0}=200$ GeV.

¹³ CHATRCHYAN 12D search for H^0 production with $H \to ZZ^{(*)} \to \ell^+\ell^-q\overline{q}$ in 4.6 fb⁻¹ of pp collisions at $E_{\rm cm}=7$ TeV. A limit on cross section times branching ratio which corresponds to (1–22) times the expected Standard Model cross section is given for $m_{H^0}=130$ –164 GeV, 200–600 GeV at 95% CL. The best limit is at $m_{H^0}=230$ GeV. In the Standard Model with an additional generation of heavy quarks and leptons which receive their masses via the Higgs mechanism, m_{H^0} values in the ranges m_{H^0}

154–161 GeV and 200–470 GeV are excluded at 95% CL. 14 CHATRCHYAN 12E search for H^0 production with $H \to WW^{(*)} \to \ell^+ \nu \ell^- \overline{\nu}$ in 4.6 fb $^{-1}$ of pp collisions at $E_{\rm cm}=$ 7 TeV in the mass range $m_{H^0}=$ 110–600 GeV.

 15 CHATRCHYAN 12F search for associated H^0 W and H^0 Z production followed by W – CHAIRCH TAIL IZE SEALCH TO ASSOCIATE OF WARM 1.2 PRODUCT A $\ell^+ \ell^-$, ν^- , and $H^0 \rightarrow b \bar{b}$, in 4.7 for $^-$ of pp collisions at $E_{\rm cm} = 7$ TeV. A limit on cross section times branching ratio which is (3.1–9.0) times larger than the expected Standard Model cross section is given for $m_{H^0} = 110$ –135 GeV at 95% CL. The best limit is at $m_{\mbox{$H^0$}}=110$ GeV.

 16 CHATRCHYAN 12G search for H^0 production with $H o \gamma\gamma$ in 4.8 fb $^{-1}$ of pp collisions at $E_{\rm cm}=7$ TeV in the mass range $m_{H^0}=110$ –150 GeV. An excess of events over background with a local significance of 3.1 σ is observed at 124 GeV.

- 17 CHATRCHYAN 12 H search for H^0 production with $H\to ZZ(*)\to 4\ell$ in 4.7 fb $^{-1}$ of pp collisions at $E_{\rm CM}=7$ TeV in the mass range $m_{H^0}=110$ –600 GeV. Excesses of events over background are observed around 11 9, 12 6 and 32 0 GeV. The region $m_{H^0}=114.4$ –134 GeV remains consistent with the expectation for the production of a SM-like \cdots
- 18 CHATRCHYAN 2012I search for H^0 production with $H \to ZZ \to \ell^+\ell^- \nu \overline{\nu}$ in 4.6 fb $^{-1}$ of pp collisions at $E_{
 m cm}=$ 7 TeV in the mass range $m_{H^0}=$ 250–600 GeV.
- 19 AAD 11AB search for 40 production with 4 4 4 4 4 4 4 7 in 1.04 fb $^{-1}$ of 4 4 pcollisions at 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4
- = 240-600 GeV at 95% CL. The best limit is at m_{H^0} = 400 GeV. 20 AAD 11T search for H^0 production with $H \rightarrow Z Z^{(*)} \rightarrow 4\ell$ in 2.1 fb⁻¹ of pp collisions AAD IT! Search for n production with $n \to 22$ ~ 3 ~ 3 GeV at 95% CL. Superseded by AAD 12D.
- GeV at 93% CL. Supersected by ARD 12D. 221 AAD 11U search for H^0 production with $H^0 \to \gamma \gamma$ in 1.08 fb⁻¹ of $\rho \rho$ collisions at $E_{\rm CM}=7$ TeV. A limit on cross section times branching ratio which is (2.0-5.8) times larger than the expected Standard Model cross section is given for $m_{H^0}=110$ –150 GeV at 95% CL. Superseded by AAD 126.
- at 95% C.L. Superseded by AAD 126. 22 AAD 11v search for H^0 production with $H \to ZZ \to \ell^+\ell^-\nu\overline{\nu}$ in 1.04 fb⁻¹ of pp collisions at $E_{\rm cm}=7$ TeV. A limit on cross section times branching ratio which corresponds to (0.6–6) times the expected Standard Model cross section is given for $m_{H^0}=200$ –600 GeV at 95% CL.
- $m_{H^0} = 200$ -000 dev at 37.8 c.t. 23 AAD 11W search for Higgs boson production in the decay channels $\gamma\gamma$, $ZZ^{(*)} \rightarrow 4\ell$, $ZZ \rightarrow \ell\ell\nu\nu$, $ZZ \rightarrow \ell\ell\mu\nu$, $ZZ \rightarrow \ell\ell\mu\nu$, $ZZ \rightarrow \ell\ell\mu\nu$, $ZZ \rightarrow \ell\ell\nu$, at $ZZ \rightarrow \ell\ell\nu\nu$, $ZZ \rightarrow \ell\nu\nu$, 110-600 GeV at 95% CL. In the Standard Model with an additional generation of heavy quarks and leptons which receive their masses via the Higgs mechanism, m_{H^0} values between 140 and 185 GeV are excluded at 95% CL. The results for the Standard Model Higgs are superseded by AAD 12E.
- ²⁴ AALTONEN 11AA search in 4.0 fb⁻¹ of $p\overline{p}$ collisions at $E_{\rm cm}=1.96$ TeV for associated H^0 W and H^0 Z production followed by $W/Z \to q \, \overline{q}$, and for $p \, \overline{p} \to H^0 \, q \, \overline{q} \, X$ (vector boson fusion), both with $H^0\to b\overline{b}$. A limit on cross section times branching ratio which is (9–100) times larger than the expected Standard Model cross section is given for $m_{H^0}=100\dot{-}150$ GeV at 95% CL. The best limit is at $m_{H^0}=115$ GeV.
- 25 ABAZOV 11AB search for associated H^0W and H^0Z production followed by $H^0 \rightarrow$ ABACOV ITAB search for associated m and $m \geq p$ consists which is like-sign dilepton final states using 5.3 fb $^{-1}$ of $p\bar{p}$ collisions at $E_{\rm cm}=1.96\,{\rm TeV}$. A limit on cross section times branching ratio which is (6.4–18) times larger than the expected Standard Model cross section is given for $m_{H^0}=115$ –200 GeV at 95% CL. The best limit is for $m_{H^0}=135$ and 165 GeV.
- 26 ABAZOV 11G search for H^0 production in 5.4 fb $^{-1}$ of $p\overline{p}$ collisions at $E_{\rm cm}=1.96$ TeV in the decay mode $H^0\to WW^{(*)}\to \ell\nu q\overline{q'}$ (and processes with similar final states). A limit on cross section times branching ratio which is (3.9–37) times larger than the expected Standard Model cross section is given for $m_{H^0}=115$ –200 GeV at 95% CL. The best limit is at $m_{H^0}=160$ GeV.
- The Dest limit is at $m_{H^0}=100$ GeV. 27 ABAZOV 11J search for associated H^0 W production in 5.3 fb $^{-1}$ of $p\bar{p}$ collisions at $E_{\rm cm}=1.96$ TeV in the final state $H^0\to b\bar{b}$, $W\to\ell\nu$. A limit on cross section times branching ratio which is (2.7-30) times larger than the expected Standard Model cross section is given for $m_{H^0}=100\text{-}150$ GeV at 95% C.L. The limit at $m_{H^0}=115$ GeV is 4.5 times larger than the expected Standard Model cross section. 28 ABAZOV 11Y search for $H^0\to\gamma\gamma$ in 8.2 fb $^{-1}$ of $p\bar{p}$ collisions at $E_{\rm cm}=1.96$ TeV. A limit on cross section times branching ratio which is (10-25) times larger than the expected Standard Model cross section is given for $m_{H^0}=100\text{-}150$ GeV at 95% C.L. 29 CHATECHYAN 111 search for H^0 production with $H^0=M^{\prime\prime}$ $W^{\prime\prime}=0.00$ for $W^{\prime\prime}=0.00$.
- 29 CHATRCHYAN 11J search for H^0 production with $\stackrel{\cdots}{H} \to W^+ W^- \to \ell\ell\nu\nu$ in 36 pb $^{-1}$ of pp collisions at $E_{\rm cm}=7$ TeV. See their Fig. 6 for a limit on cross section times branching ratio for $m_{pl0}=120$ –600 GeV at 95% CL. In the Standard Model with an additional generation of heavy quarks and leptons which receive their masses via the Higgs mechanism, m_{H0} values between 144 and 207 GeV are excluded at 95% CL.
- Alt ONEN 10AD search for associated H^0Z production in 4.1 fb $^{-1}$ of $p\overline{p}$ collisions at $E_{\rm cm}=1.96$ TeV in the decay mode H^0Z production in 4.1 fb $^{-1}$ of $p\overline{p}$ collisions at $E_{\rm cm}=1.96$ TeV in the decay mode $H^0 \to b\overline{b}, Z \to \ell^+\ell^-$. A limit $\sigma \cdot {\rm B}(H^0 \to b\overline{b}) < (4.5-43) \sigma \cdot {\rm B}({\rm S}({\rm M}))$ (95% CL) is given for $m_{H^0}=100-150$ GeV. The limit for $m_{H^0}=115$ GeV is 5.9 times larger than the expected Standard Model cross section. 31 AALTONEN 10G search for H^0 production in 4.8 fb $^{-1}$ of $p\overline{p}$ collisions at $E_{\rm cm}=1.96$ TeV in the decay mode $H^0 \to WW^{(*)}$. A limit on $\sigma(H^0)$ which is (1.3-39) times larger than the expected Standard Model cross section is given for $m_{H^0}=110-200$ GeV at 95% CL. The best limit is obtained for $m_{H^0}=165$ GeV.
- at 95% CL. The best limit is obtained for $m_{H^0}=$ 165 GeV.
- 32 AALTONEN 10J search for associated H^0 W and H^0 Z production in 2.1 fb $^{-1}$ of $p\overline{p}$ collisions at $E_{\rm cm}=1.96$ TeV in the final state with (b) jets and missing p_T . A limit $\sigma<(5.8\text{--}50)\,\sigma_{\rm SM}$ (95% CL) is given for $m_{H^0}=110\text{--}150$ GeV. The limit for $m_{H^0}=115$ GeV is 6.9 times larger than the expected Standard Model cross section.
- ³³AALTONEN 10M combine searches for H^0 decaying to W^+W^- in $p\overline{p}$ collisions at $E_{\rm cm}$ = 1.96 TeV with 4.8 fb $^{-1}$ (CDF) and 5.4 fb $^{-1}$ (DØ) and derive limits $\sigma(p\overline{p}\to H^0)$ ${\sf B}(H^0 o W^+W^-) < (1.75-0.38)$ pb for $m_H=120$ -165 GeV, where H^0 is produced in gg fusion. In the Standard Model with an additional generation of heavy quarks, $m_{H^0}^{33}$ between 131 and 204 GeV is excluded at 95% CL.
- 34 ABAZOV 10B search for H^0 production in 5.4 fb $^{-1}$ of $p\overline{p}$ collisions at $E_{\rm cm}=1.96$ TeV in the decay mode $H^0 \to WW^{(*)}$. A limit on $\sigma(H^0)$ which is (1.6–21) times larger than the expected Standard Model cross section is given for $m_{H^0}=115$ –200 GeV at 95% CL. The best limit is obtained for $m_{H^0}=1$ 65 GeV.
- 35 ABAZOV 10c search for associated H^0Z and H^0W production in 5.2 fb $^{-1}$ of $p\overline{p}$ collisions at $E_{\rm cm}=1.96$ TeV in the final states $H^0\to b\overline{b}$, $Z\to \nu\overline{\nu}$, and $W\to (\ell)\nu$, where ℓ is not identified. A limit $\sigma \cdot B(H^0 \to b \, \overline{b}) < (3.4-38) \, \sigma \cdot B_{(SM)}$ (95% CL) is given for $m_{H^0}=100$ –150 GeV. The limit for $m_{H^0}=115$ GeV is 3.7 times larger than the expected Standard Model cross section.

- 36 ABAZOV $^{10 au}$ search for associated 40 Z production in 4.2 fb $^{-1}$ of 7 collisions at 2 cm = 1.96 TeV in the decay mode $H^0 \to b\overline{b}$, $Z \to \ell^+ \ell^-$. A limit $\sigma \cdot \mathrm{B}(H^0 \to b\overline{b}) \in (3.0\text{-}49)$ $\sigma \cdot \mathrm{B}_{(\mathrm{SM})}$ (95% CL) is given for $m_{H^0} = 100\text{-}150$ GeV. The limit for $m_{H^0} = 100\text{-}150$ GeV.
- 1.5 GeV is 5 (SM) (95% CL) is given for $m_{H^0} = 100$ –100 GeV. The limit for $m_{H^0} = 115$ GeV is 5 (SM) (95% CL) is given for $m_{H^0} = 100$ –100 GeV. The limit for $m_{H^0} = 10$ TeV in the decay mode $H^0 \rightarrow WW^{(*)} \rightarrow \ell^+\ell^-\nu \overline{\nu}$. A limit on $\sigma(H^0) \rightarrow B(H^0 \rightarrow WW^{(*)})$ between 0.7 and 2.5 pb (95% CL) is given for $m_{H^0} = 110$ –200 GeV, which is 1.7–45 times larger than the expected Standard Model cross section. The best limit is obtained for $m_{H^0} = 160$ GeV.
- ³⁸ AALTONEN 09AG search for associated H^0 W production in 1.9 fb $^{-1}$ of $p\overline{p}$ collisions at $E_{\rm CM}=1.96$ TeV in the decay mode $H^0\to b\overline{b}, W\to \ell\nu$. A limit on $\sigma(H^0W)$ ${\rm B}(H^0\to b\overline{b})$ (95% CL) is given for $m_{H^0}=110$ -150 GeV, which is 7.5-101.9 times $(H^0 \to b \bar{b})$ (95% CL) is given for $m_{H^0} = 110$ –150 GeV, which is 7.5–101.9 times larger than the expected Standard Model cross section. The limit for $m_{H^0} = 115$ GeV is 9.0 times larger than the expected Standard Model cross section. Superseded by AALTONEN 09AL
- 39 AALTONEN 09AI search for associated H^0 W production in 2.7 fb $^{-1}$ of $p\overline{p}$ collisions at $E_{\text{CM}}=1.96$ TeV in the decay mode $H^0\to b\overline{b}, W\to \ell\nu$. A limit on $\sigma(H^0W)$ $B(H^0^{0}\to b\overline{b})$ (95% CL) is given for $m_{H^0}=100$ –150 GeV, which is 3.3–75.5 times larger than the expected Standard Model cross section. The limit for $m_{H^0}=115\,$ GeV
- larger than the expected Standard Model cross section. The limit for $m_{H^0}=115$ GeV is 5.6 times larger than the expected Standard Model cross section. 40 AALTONEN 09Ao search for associated H^0 Z production in 2.7 fb⁻¹ of $p\overline{p}$ collisions at $E_{\rm Cm}=1.96$ TeV in the decay mode $H^0\to b\overline{b}$, $Z\to \ell^+\ell^-$. A limit on $\sigma(H^0Z)$. B($H^0\to b\overline{b}$) (95% CL) is given for $m_{H^0}=100$ –150 GeV, which is 7.0–71.3 times larger than the expected Standard Model cross section.  43 ABAZOV 09Q search for $H^0 \rightarrow \gamma \gamma$ in 2.7 fb $^{-1}$ of $p\overline{p}$ collisions at $E_{\rm cm} = 1.96$ TeV in the mass range $m_{H^0} = 100-150$ GeV. A limit (95% CL) is given for $m_{H^0} = 115-130$ GeV, which is about 20 times larger than the expected Standard Model cross section. Superseded by ABAZOV 11v Superseded by ABAZOV 11v. 44 ABAZOV 09u search for $H^0 \to \tau^+ \tau^-$ with $\tau \to$ hadrons in 1 fb⁻¹ of $p\overline{p}$ collisions at
- $E_{
 m cm}=1.96$ TeV. The production mechanisms include associated $W/Z+H^0$ production, weak boson fusion, and gluon fusion. A limit (95% CL) is given for $m_{H^0}=105-145$ GeV, which is 20-82 times larger than the expected Standard Model cross section. The limit for $m_{H^0}=115$ GeV is 29 times larger than the expected Standard Model cross
- 45 AALTONEN 08x search for associated H^0Z and H^0W production in $p\overline{p}$ collisions at $E_{\rm cm}=1.96$ TeV in the decay mode $H^0_{-}\to b\overline{b}$, $Z\to \nu\overline{\nu}$ and $W\to (\ell)\nu$, where ℓ is not detected. A limit $\sigma \cdot \mathsf{B}(H^0 \to b \, \overline{b}) < (4.7-3.3) \; \mathsf{pb} \; (95\% \; \mathsf{CL})$ is given for m_{H^0} = 110-140 GeV, which is 18-66 times larger than the expected Standard Model cross
- 47 ABAZOV 08y search for associated H^0 W production in $p\overline{p}$ collisions at $E_{\rm cm}=1.96$ TeV in the decay mode $H^0 \rightarrow b\overline{b}$, $W \rightarrow \ell \nu$. A limit $\sigma(H^0W) \cdot B(H^0 \rightarrow b\overline{b}) < (1.9-1.6)$ by (95% CL) is given for $m_{H^0} = 105-145$ GeV, which is 10-93 times larger than the expected Standard Model cross section. These results are combined with ABAZOV 06, ABAZOV 060, ABAZOV 060, and ABAZOV 07x to give cross section limits for m_{H^0}
- = 100–200 GeV which are 6–24 times larger than the Standard Model expectation. ⁴⁸ ABAZOV 07x search for associated H^0Z production in $p\overline{p}$ collisions at $E_{\rm cm}=1.96$ TeV in the final state $Z\to e^+e^-$ or $\mu^+\mu^-$; $H^0\to b\overline{b}$. A limit $\sigma(ZH^0)\to B(H^0\to b\overline{b})$ < (4.4–3.1) pb (95%CL) is given for $m_{H^0}=105$ –145 GeV, which is more than 40 times larger than the expected Standard Model cross section. Superseded by ABAZOV 10T.
- 49 ABAZOV 06 search for Higgs boson production in $p\overline{p}$ collisions at $E_{\rm cm}=1.96$ TeV with the decay chain $H^0\to WW^*\to \ell^\pm\nu\ell^{\prime\mp}\overline{\nu}$. A limit $\sigma(H^0)$ -B($H^0\to WW^*$) < (5.6–3.2) pb (95 %CL) is given for $m_{H^0}=$ 120–200 GeV, which far exceeds the expected
- Standard Model cross section. Standard Model cross section associated H^0W production in $p\overline{p}$ collisions at $E_{\rm cm}=1.96$ TeV with the decay $H^0 \to WW^*$, in the final states $\ell^\pm \ell'^\mp \nu \nu' X$ where $\ell = e$, μ . A limit $\sigma(H^0W)\cdot \mathsf{B}(H^0\to WW^*)<(3.2-2.8)\ \mathsf{pb}\ (95\ \%\mathsf{CL})\ \mathsf{is}\ \mathsf{given}\ \mathsf{for}\ m_{H^0}=$ 115-175 GeV, which far exceeds the expected Standard Model cross section.

H⁰ Indirect Mass Limits from Electroweak Analysis

For limits obtained before the direct measurement of the top quark mass, see the 1996 (Physical Review **D54** 1 (1996)) Edition of this Review. Other studies based on data available prior to 1996 can be found in the 1998 Edition (The European Physical Journal C3 1 (1998)) of this Review. For indirect limits obtained from other considerations of theoretical nature, see the Note on "Searches for Higgs Bosons."

⁵³ LEP-SLC

 $129 + 74 \\ -49$

- 51 ERLER 10A makes Standard Model fits to Z and neutral current parameters, $m_{\,t},\,m_{\,W}$ measurements available in 2009 (using also preliminary data). The quoted result is obtained from a fit that does not include the limits from the direct Higgs searches. With direct search data from LEP2 and Tevatron added to the fit, the 90% CL (99% CL) interval is 115–148 (114–197) GeV.
- ⁵² FLACHER 09 make Standard Model fits to Z and neutral current parameters, m_1 , m_{W} , and r_{W} measurements available in 2008 (using also preliminary data). The 2σ (3σ) interval is 39–155 (26–209) GeV. The quoted results are obtained from a fit that does not include the limit from the direct Higgs searches. Standard Model fits to Z parameters from LEP/SLC and m_t , m_W ,
- and Γ_W measurements available in 2005 with $\Delta\alpha_{\rm had}^{(5)}(m_Z)=0.02758\pm0.00035$. The 95% CL limit is 285 GeV.

MASS LIMITS FOR NEUTRAL HIGGS BOSONS IN SUPERSYMMETRIC MODELS

The minimal supersymmetric model has two complex doublets of Higgs bosons. The resulting physical states are two scalars $[H_1^0]$ and H_2^0 , where we define $m_{H_1^0} < m_{H_2^0}^1$, a pseudoscalar (A^0) , and a charged Higgs pair

 (H^{\pm}) . H_1^0 and H_2^0 are also called h and H in the literature. There are two free parameters in the theory which can be chosen to be $m_{\Delta0}$ and aneta= v_2/v_1 , the ratio of vacuum expectation values of the two Higgs doublets. Tree-level Higgs masses are constrained by the model to be $m_{H^0_*} \leq$

 m_Z , $m_{H_0^0} \geq m_Z$, $m_{A^0} \geq m_{H_1^0}$, and $m_{H^{\pm}} \geq m_W$. However, as described in the review on "Searches for Higgs Bosons" in this Volume these relations are violated by radiative corrections.

Unless otherwise noted, the experiments in e^+e^- collisions search for the processes $e^+e^- \to H_1^0Z^0$ in the channels used for the Standard Model Higgs searches and $e^+e^- \to H_1^0A^0$ in the final states $b\overline{b}b\overline{b}$ and $b \, \overline{b} \, \tau^+ \, \tau^-$. In $p \, \overline{p}$ collisions the experiments search for a variety of processes, as explicitly specified for each entry. Limits on the $A^{\,0}$ mass arise from these direct searches, as well as from the relations valid in the minimal supersymmetric model between m_{A^0} and $m_{H^0_1}$. As discussed in

the review on "Searches for Higgs Bosons" in this Volume, these relations depend, via potentially large radiative corrections, on the mass of the t quark and on the supersymmetric parameters, in particular those of the stop sector. The limits are weaker for larger t and \widetilde{t} masses. To include the radiative corrections to the Higgs masses, unless otherwise stated, the listed papers use theoretical predictions incorporating two-loop corrections and examine the two scenarios of no scalar top mixing and the $m_{\scriptscriptstyle L}^{\sf max}$ benchmark scenario (which gives rise to the most conservative upper bound on the mass of H_1^0 for given values of m_{A^0} and aneta), see CARENA 99B

Limits in the low-mass region of H_1^0 , as well as other by now obsolete limits from different techniques, have been removed from this compilation, and can be found in earlier editions of this Review. Unless otherwise stated, the following results assume no invisible H_1^0 or A^0 decays.

- ⁵⁴ ABDALLAH 08B give limits in eight CP-conserving benchmark scenarios and some CPviolating scenarios. See paper for excluded regions for each scenario. Supersedes AB-DALLAH 04.
- 55 SCHAEL 06B make a combined analysis of the LEP data. The quoted limit is for the $m_h^{\rm max}$ scenario with $m_t=174.3$ GeV. In the *CP*-violating CPX scenario no lower bound on $m_{H_1^0}$ can be set at 95% CL. See paper for excluded regions in various scenarios. See Figs. 2-6 and Tabs. 14–21 for limits on $\sigma(ZH^0)$ · B $(H^0 \to b\overline{b}, \tau^+\tau^-)$ and $\sigma(H^0_1H^0_2)$ ·

 $\mathsf{B}(H_1^0, H_2^0 \to b \, \overline{b}, \tau^+ \, \tau^-).$

- ⁵⁶ Search for $e^+e^- \to H_1^0 A^0$ in the final states $b\overline{b}b\overline{b}$ and $b\overline{b}\tau^+\tau^-$, and $e^+e^- \to$ $H_1^0\,Z.$ Universal scalar mass of 1 TeV, SU(2) gaugino mass of 200 GeV, and $\mu=-200$ GeV are assumed, and two-loop radiative corrections incorporated. The limits hold for $m_t{=}175$ GeV, and for the $m_h^{\rm max}$ scenario.
- 57 ABBIENDI 04M exclude 0.7 < tan/8 < 1.9, assuming $m_t=174.3$ GeV. Limits for other MSSM benchmark scenarios, as well as for CP violating cases, are also given. 58 ACHARD 02H also search for the final state $H_1^0Z \rightarrow 2A^0\,q\,\overline{q},\,A^0 \rightarrow q\,\overline{q}$. In addition, the MSSM parameter set in the "large- μ " and "no-mixing" scenarios are examined. 59 ABAZOV 12 search for production of a Higgs boson followed by the decay $H_{1,2}^0/A^0 \rightarrow$
- $\tau^+\tau^-$ in 5.4 fb $^{-1}$ of $p\overline{p}$ collisions at $E_{\rm cm}=1.96$ TeV. See their Fig. 2 for the limit on cross section times branching ratio and Fig. 3 for the excluded region in the MSSM parameter space.
- 60 AAD 11R search for production of a Higgs boson followed by the decay $H_{1.2}^0/A^0
 ightarrow$ $au^+ au^-$ in 36 pb $^{-1}$ of pp collisions at $E_{
 m cm}=$ 7 TeV. See their Fig. 3 for the limit on cross section times branching ratio and for the excluded region in the MSSM parameter
- 61 ABAZOV 11K search for associated production of a Higgs boson and a b quark, followed by the decay $H^0_{1,2}/A^0 \to b\,\overline{b}$, in 5.2 fb $^{-1}$ of $p\overline{p}$ collisions at $E_{\rm CM}=1.96$ TeV. See their Fig. 5/Table 2 for the limit on cross section times branching ratio and Fig. 6 for the excluded region in the MSSM parameter space for $\mu=-200$ GeV.
- 62 ABAZOV 11w search for associated production of a Higgs boson and a *b* quark, followed by the decay $H_{1.2}^0/A^0 \to \tau \tau$, in 7.3 fb $^{-1}$ of $p \overline{p}$ collisions at $E_{\rm cm}=1.96$ TeV. See their Fig. 2 for the limit on cross section times branching ratio and for the excluded region in the MSSM parameter space.
- G3 CHATRCHYAN 11H search for production of a Higgs boson followed by the decay $H_{1,2}^0/A^0 \to \tau^+\tau^-$ in 36 pb $^{-1}$ of pp collisions at $E_{\rm cm}=7$ TeV. See their Fig. 2 the limit on cross section times branching ratio and Fig. 3 for the excluded region in the MSSM parameter space.
- 64 ABAZOV 10D search for associated production of a Higgs boson and a b quark in 2.7 fb $^{-1}$ of $p\overline{p}$ collisions at $E_{\rm cm}=1.96$ TeV, with the decay $H_{1,2}^0/A^0 \to \ \tau^+\,\tau^-$. See their Fig. 1 for the limit on $\sigma \cdot \mathrm{B}(H_{1,2}^0/A^0 \to \tau^+\tau^-)$ (for different Higgs masses) and for the excluded region in the MSSM parameter space for $\mu=-200$ GeV. Superseded
- 65 AALTONEN 09AR search for Higgs bosons decaying to $au^+ au^-$ in two doublet models in 1.8 fb $^{-1}$ of $p\overline{p}$ collisions at $E_{
 m cm}=1.96$ TeV. See their Fig. 2 for the limit on $\sigma \cdot {\sf B}(H_{1,2}^0/{\sf A}^0 \to \ \tau^+\,\tau^-)$ for different Higgs masses, and see their Fig. 3 for the excluded region in the MSSM parameter space.
- 66 ABAZOV 09F search for associated production of a Higgs boson and a b quark in $p\overline{p}$ collisions at $E_{\rm cm}=1.96$ TeV with the decay $H_{1,2}^0/A^0\to \tau^+\tau^-$. See their Fig. 2 for the limit on $\sigma \cdot {\rm B}(H^0_{1,2}/{\it A}^0 \to \ \tau^+\tau^-)$ (for different Higgs masses) and for the excluded
- region in the MSSM parameter space for $\mu=\pm 200$ GeV. Superseded by ABAZOV 10b. 67 ABAZOV 08AJ search for associated production of a Higgs boson and a b quark in $p\overline{p}$ collisions at $E_{\rm cm}=1.96$ TeV with the decay $H_{1,2}^0/A^0\to b\overline{b}$. See their Tab. 3 for the limit on $\sigma \cdot {\sf B}(H^0_{1,2}/{\sf A}^0 \to b \, \overline{b})$ for different Higgs masses, and see their Fig. 3 for the excluded region in the MSSM parameter space for $\mu=\pm 200$ GeV. Superseded by
- ⁶⁸ ABAZOV 08W search for Higgs boson production in $p\overline{p}$ collisions at $E_{\rm cm}=1.96$ TeV with the decay $H_{1,2}^0/A^0 \to \tau^+\tau^-$. See their Fig. 3 for the limit on $\sigma \cdot {\rm B}(H_{1,2}^0/A^0 \to \tau^+\tau^-)$ $\tau^+\,\tau^-)$ for different Higgs masses, and see their Fig. 4 for the excluded region in the MSSM parameter space. Superseded by ABAZOV 12.
- 69 This limit applies also in the no-mixing scenario. Furthermore, ABDALLAH 04 excludes the range $0.54 < \tan \beta < 2.36$. The limit improves in the region $\tan \beta < 6$ (see Fig. 28). Limits for $\mu = 1$ TeV are given in Fig. 30. 70 ABBIENDI 03G search for $e^+e^- \rightarrow H_1^0Z$ followed by $H_1^0 \rightarrow A^0A^0$, $A^0 \rightarrow c\overline{c}$, gg,
- or $\tau^+\tau^-$. In the no-mixing scenario, the region $m_{H_1^0}=45$ -85 GeV and $m_{A^0}=2$ -9.5 GeV is excluded at 95% CL.
- 71 HEISTER 02 excludes the range 0.7 <tan β < 2.3. A wider range is excluded with different stop mixing assumptions. Updates BARATE 01c.

- 83 ABAZOV 10D search for associated production of a Higgs boson and a b quark in $2.7 \, \mathrm{fb}^{-1}$ of $p \overline{p}$ collisions at $E_{\mathrm{Cm}} = 1.96$ TeV, with the decay $H_{1,2}^0/A^0 \to \tau^+ \tau^-$. See their Fig. 1 for the limit on $\sigma \cdot \mathsf{B}(H_{1,2}^0/A^0 \to \tau^+\tau^-)$ (for different Higgs masses) and for the excluded region in the MSSM parameter space for $\mu=-200$ GeV. Superseded
- ⁸⁴ AALTONEN 09AR search for Higgs bosons decaying to $\tau^+\tau^-$ in two doublet models in 1.8 fb⁻¹ of $p\overline{p}$ collisions at $E_{\rm cm}=1.96$ TeV. See their Fig. 2 for the limit on $\sigma \cdot \mathsf{B}(H^0_{1,2}/\mathsf{A}^0 \to \tau^+\tau^-)$ for different Higgs masses, and see their Fig. 3 for the excluded region in the MSSM parameter space.
- 85 ABAZOV 09F search for associated production of a Higgs boson and a b quark in $p\overline{p}$ collisions at $E_{\rm cm}=1.96$ TeV with the decay $H_{1,2}^0/A^0\to \tau^+\tau^-$. See their Fig. 2 for the limit on $\sigma \cdot \mathrm{B}(H_{1,2}^0/\mathrm{A}^0 \to \tau^+ \, \tau^-)$ (for different Higgs masses) and for the excluded region in the MSSM parameter space for $\mu=\pm 200$ GeV. Superseded by ABAZOV 10D.
- ⁸⁶ ABAZOV 08AJ search for associated production of a Higgs boson and a b quark in $p\overline{p}$ collisions at $E_{\rm cm}=1.96$ TeV with the decay $H_{1,2}^0/A^0\to b\overline{b}$. See their Tab. 3 for the limit on $\sigma \cdot \mathsf{B}(H^0_{1,2}/\mathsf{A}^0 \to b\,\overline{b})$ for different Higgs masses, and see their Fig. 3 for the excluded region in the MSSM parameter space for $\mu=\pm 200$ GeV. Superseded by
- 87 ABAZOV 08W search for Higgs boson production in $p\overline{p}$ collisions at $E_{\text{cm}} = 1.96 \text{ TeV}$ with the decay $H_{1,2}^0/A^0 \to \tau^+\tau^-$. See their Fig. 3 for the limit on $\sigma \cdot {\rm B}(H_{1,2}^0/A^0 \to T^+\tau^-)$ $\tau^+\,\tau^-)$ for different Higgs masses, and see their Fig. 4 for the excluded region in the MSSM parameter space. Superseded by ABAZOV 12.

- ⁸⁸ ACOSTA 05Q search for $H_{1,2}^0/A^0$ production in $p\overline{p}$ collisions at $E_{
 m cm}=1.8$ TeV with $H^0_{1,2}/A^0
 ightarrow \ au^+ \, au^-$ At $m_{A^0}=$ 100 GeV, the obtained cross section upper limit is above theoretical expectation.
- 89 This limit applies also in the no-mixing scenario. Furthermore, ABDALLAH 04 excludes the range 0.54 < tan β < 2.36. The limit improves in the region tan β < 6 (see Fig. 28). Limits for μ = 1 TeV are given in Fig. 30.
- 90 ABBIENDI 03G search for $e^+\,e^- \to H_1^0\,Z$ followed by $H_1^0 \to A^0\,A^0$, $A^0 \to c\,\overline{c}$, gg, or $au^+ au^-$. In the no-mixing scenario, the region $m_{H_1^0}=$ 45-85 GeV and $m_{A^0}=$ 2-9.5
- GeV is excluded at 95% CL. 91 AKEROYD 02 examine the possibility of a light A^0 with $\tan\beta$ <1. Electroweak measurements are found to be inconsistent with such a scenario.

H^0 (Higgs Boson) MASS LIMITS in Extended Higgs Models

This Section covers models which do not fit into either the Standard Model or its simplest minimal Supersymmetric extension (MSSM), leading to anomalous production rates, or nonstandard final states and branching ratios. In particular, this Section covers limits which may apply to generic two-Higgs-doublet models (2HDM), or to special regions of the MSSM parameter space where decays to invisible particles or to photon pairs are dominant (see the Note on 'Searches for Higgs Bosons' at the beginning of this Chapter). See the footnotes or the comment lines for details on the nature of the models to which the limits apply.

- 92 AALTONEN 12 search for $H^0\to\gamma\gamma$ in 7.0 fb $^{-1}$ of $p\overline{p}$ collisions at $E_{\rm CM}=1.96$ TeV in the mass range $m_{H^0}=100$ –150 GeV. The limit assumes that all fermion Yukawa couplings vanish.
- 93 AALTONEN 11P search in 2.7 fb $^{-1}$ of $p \overline{p}$ collisions at $E_{\rm CM}=1.96$ TeV for the decay chain $t \rightarrow bH^+$, $H^+ \rightarrow W^+A^0$, $A^0 \rightarrow \tau^+\tau^-$ with m_{A^0} between 4 and 9 GeV. See their Fig. 4 for limits on B($t
 ightarrow b \, H^+$) for 90 < $m_{H^+} <$ 160 GeV.
- 94 ABAZOV 11Y search for $H^0\to\gamma\gamma$ in 8.2 fb $^{-1}$ of $p\overline{p}$ collisions at $E_{\rm cm}=1.96$ TeV in the mass range $m_{H^0}=100$ –150 GeV. The limit assumes that all fermion Yukawa couplings vanish couplings vanish.
- 95 The limit applies at $m_{A^0}=214.3$ MeV, motivated by PARK 05.
- 96 DEL-AMO-SANCHEZ 11J search for the process $\varUpsilon(2S) \to \varUpsilon(1S) \pi^+ \pi^- \to$ $A^0\gamma\gamma^+\pi^-$ with A^0 decaying to invisible final states. They give limits on B($\Upsilon(1S)\to A^0\gamma$)-B($A^0\to$ invisible) in the range $(1.9-4.5)\times 10^{-6}$ (90% CL) for $0\le m_{A^0}\le 10^{-6}$ 8.0 GeV, and (2.7–37) \times 10⁻⁶ for 8.0 $\leq m_{A^0} \leq$ 9.2 GeV.
- 8. GeV, and $(2.7-37) \times 10^{-9}$ for 8.0 $\leq m_{A0} \leq 9.2$ GeV.

 97 LEES 11H search for the process $\Upsilon(2S,3S) \to A^0 \gamma$ with A^0 decaying hadronically and give limits on B($\Upsilon(2S,3S) \to A^0 \gamma$)-B($A^0 \to$ hadrons) in the range $1 \times 10^{-6} 8 \times 10^{-5}$ (90% CL) for $0.3 < m_{A^0} < 7$ GeV. The decay rates for $\Upsilon(2S)$ and $\Upsilon(3S)$ are assumed to be equal up to the phase space factor.

 98 ABBIENDI 10 earch for $e^+e^- \to H^0 Z$ with H^0 decaying invisibly. The limit assumes SM production cross section and B($H^0 \to$ invisible) = 1.

 99 ABBIENDI 10 search for $e^+e^- \to Z^0$ with the decay chain $H^0 \to \widetilde{\chi}_1^0 \widetilde{\chi}_2^0$, $\widetilde{\chi}_2^0 \to 0$
- $\widetilde{\chi}_1^0$ + $(\gamma$ or $Z^*)$, when $\widetilde{\chi}_1^0$ and $\widetilde{\chi}_2^0$ are nearly degenerate. For a mass difference of 2 (4) GeV, a lower limit on m_{H^0} of 108.4 (107.0) GeV (95% CL) is obtained for SM ZH^0 cross section and B($H^0 \xrightarrow{i} \widetilde{\chi}_1^0 \widetilde{\chi}_2^0$) = 1.
- $100\,\mathrm{A}\,\mathrm{NDREAS}$ 10 analyze various rare decays and find $m_{A0}>210\,\mathrm{MeV}$ or that its couplings to fermions are 4 orders of magnitude below those of the standard Higgs.
- 101 The limit applies at $m_{A0}=214.3$ MeV, motivated by PARK 05. HYUN 10 summarize mass-dependent limits in their Table I.
- 102 SCHAEL 10 search for the process $e^+e^- \rightarrow H^0$ Z followed by the decay chain H^0 A⁰ $A^0 \rightarrow \tau^+ \tau^- \tau^+ \tau^-$ with $Z \rightarrow \ell^+ \ell^-$, $\nu \overline{\nu}$ at $E_{\rm cm}=$ 183–209 GeV. For a H^0 Z Z coupling equal to the SM value, B($H^0 \rightarrow A^0 A^0$) = B($A^0 \rightarrow \tau^+ \tau^-$) = 1, and M_{A^0} = 4–10 GeV, m_{H^0} up to 107 GeV is excluded at 95% CL.
- 103 AALTONEN 09AB search for $H^0 \to \gamma \gamma$ in 3.0 fb $^{-1}$ of $\rho \overline{\rho}$ collisions at $E_{\rm cm}=1.96$ TeV in the mass range $m_{H^0}=70$ -150 GeV. Associated H^0W , H^0Z production and WW, ZZ fusion are considered. The limit assumes that all fermion Yukawa couplings vanish. 104 AALTONEN, 09AR search for Higgs bosons decaying to $\tau^+\tau^-$ in two doublet models
- in 1.8 fb $^{-1}$ of $p\overline{p}$ collisions at $E_{\rm cm}=$ 1.96 TeV. See their Fig. 2 for the limit on $\sigma \cdot \mathrm{B}(H_{1,2}^0/A^0 \to \tau^+\tau^-)$ for different Higgs masses, and see their Fig. 3 for the excluded region in the MSSM parameter space.
- 105 ABAZOV 090 search for $H^0 \to \gamma \gamma$ in 2.7 fb $^{-1}$ of $p \overline{p}$ collisions at $E_{\rm CM}=1.96$ TeV in the mass range $m_{H^0}=100$ –150 GeV. The limit assumes that all fermion Yukawa couplings vanish. Superseded by ABAZOV 11Y.
- couplings vanish. Superseded by ABAZOV 11Y. 106 ABAZOV 09V search for H^0 production followed by the decay chain $H^0 \rightarrow A^0 A^0 \rightarrow \mu^+ \mu^- \mu^+ \mu^-$ or $\mu^+ \mu^- + \tau^-$ in 4.2 fb $^{-1}$ of $p \bar{p}$ collisions at $E_{\rm CM}=1.96$ TeV. See their Fig. 3 for limits on $\sigma(H^0)$ -B $(H^0 \rightarrow A^0 A^0)$ for $m_{A^0}=3.6$ -19 GeV. 107 AUBERT 09P search for the process $\Upsilon(3S) \rightarrow A^0 \gamma$ with $A^0 \rightarrow \tau^+ \tau^-$ for $4.03 < m_{A^0} < 9.52$ and $9.61 < m_{A^0} < 10.10$ GeV, and give limits on $B(\Upsilon(3S) \rightarrow A^0 \gamma)$ by $A^0 \rightarrow A^0 \gamma$ with $A^0 \rightarrow A^0 \gamma$ by $A^0 \rightarrow A^0 \gamma$ by
- $A^{0}\gamma$)·B($A^{0} \rightarrow \tau^{+}\tau^{-}$) in the range (1.5–16) \times 10⁻⁵ (90% CL).
- 108 AUBERT 09z search for the process $\Upsilon(2S) \rightarrow A^0 \gamma$ with $A^0 \rightarrow \mu^+ \mu^-$ for 0.212 $< m_{A^0} < 9.3$ GeV and give limits on B($\Upsilon(2S) \rightarrow A^0 \gamma$).B($A^0 \rightarrow \mu^+ \mu^-$) in the range $(0.3-8) \times 10^{-6} (90\% \text{ CL}).$
- 109 AUBERT 09z search for the process $\Upsilon(3S) \rightarrow A^0 \gamma$ with $A^0 \rightarrow \mu^+ \mu^-$ for 0.212 $< m_{A^0} < 9.3$ GeV and give limits on B($\Upsilon(3S) \rightarrow A^0 \gamma$)·B($A^0 \rightarrow \mu^+ \mu^-$) in the range $(0.3-5) \times 10^{-6} (90\% \text{ CL}).$
- 110 The limit applies at $m_{A0}=214.3$ MeV, motivated by PARK 05. TUNG 09 show mass-dependent limits in their Fig. 5.
 111 ABAZOV 08u search for $H^0 \to \gamma \gamma$ in $\rho \overline{\rho}$ collisions at $E_{\rm cm}=1.96$ TeV in the mass
- range $m_{H^0} = 70$ –150 GeV. Associated H^0 W, H^0 Z production and WW, ZZ fusion are considered. See their Tab. 1 for the limit on $\sigma \cdot B(H^0 \to \gamma \gamma)$, and see their Fig. 3 for the excluded region in the m_{H^0} — $\mathrm{B}(H^0 o \gamma \gamma)$ plane.
- $^{112} \text{LOVE 08 search for the process} \stackrel{\prime\prime}{\varUpsilon} (1\text{S}) \rightarrow ~A^0 \gamma \text{ with } A^0 \rightarrow ~\mu^+ \,\mu^- \text{ (for } m_{A^0} < 2m_{\tau})$ and $A^0 \to \tau^+ \tau^-$. Limits on B($\Upsilon(1S) \to A^0 \gamma$) \cdot B($A^0 \to \ell^+ \ell^-$) in the range 10⁻⁶-10⁻⁴ (90% CL) are given.
- ¹¹³ ABBIENDI 07 search for $e^+e^- \rightarrow H^0Z$ with $Z \rightarrow q \overline{q}$ and H^0 decaying to invisible final states. The H^0 width is varied between 1 GeV and 3 TeV. A limit $\sigma \cdot \mathsf{B}(H^0 \to \mathsf{invisible})$ < (0.07–0.57) pb (95%CL) is obtained at $E_{
 m cm}=$ 206 GeV for $m_{H^0}\stackrel{.}{=}$ 60–114 GeV.

- $^{114}\, \rm BESSON$ 07 give a limit B($\Upsilon(1S) \to~\eta_b\, \gamma) \,\cdot\, {\rm B}(\eta_b \to~\tau^+\,\tau^-) <$ 0.27% (95% CL), which constrains a possible A^0 exchange contribution to the η_b decay.
- 115 SCHAEL 07 search for Higgs bosons in association with a fermion pair and decaying to WW*. The limit is from this search and HEISTER 02L for a H⁰ with SM production
- cross section and B($H^0 \to f\overline{f}$) = 0 for all fermions f. 116 ABBIENDI 05A search for $e^+e^- \to H_1^0A^0$ in general Type-II two-doublet models, with
- decays H_1^0 , $A^0 \to q\overline{q}$, gg, $\tau^+\tau^-$, and $H_1^0 \to A^0A^0$. 117 ABDALLAH 050 search for $e^+e^- \to H^0Z$ and H^0A^0 with H^0 , A^0 decaying to two jets of any flavor including gg. The limit is for SM H^0Z production cross section with $B(H^0 \to jj) = 1.$
- 118 Search for $e^+e^- \to H^0\,Z$ with H^0 decaying invisibly. The limit assumes SM production cross section and B $(H^0 \to {\rm invisible})=1$.
- ¹¹⁹PARK 05 found three candidate events for $\Sigma^+ \to p \mu^+ \mu^-$ in the HyperCP experiment. Due to a narrow spread in dimuon mass, they hypothesize the events as a possible signal of a new boson. It can be interpreted as a neutral particle with $m_{A^0}=214.3\pm0.5$ MeV and the branching fraction B($\Sigma^+ \to \ \rho \, A^0) \times$ B($A^0 \to \ \mu^+ \, \mu^-) = (3.1 \, \frac{+ \, 2.4}{-1.9} \, \pm \, 1.5) \times 10^{-8}$.
- ¹²⁰ ABBIENDI 04κ search for $e^+e^- \rightarrow H^0Z$ with H^0 decaying to two jets of any flavor including gg. The limit is for SM production cross section with B($H^0 \rightarrow jj$) = 1.
- 121 ABDALLAH 04 consider the full combined LEP and LEP2 datasets to set limits on the Higgs coupling to W or Z bosons, assuming SM decays of the Higgs. Results in Fig. 26.
- 122 Search for associated production of a $\gamma\gamma$ resonance with a Z boson, followed by Z ightarrow $q\overline{q}$, $\ell^+\ell^-$, or $\nu\overline{\nu}$, at $E_{\rm cm} \leq$ 209 GeV. The limit is for a H^0 with SM production cross section and B($H^0 \rightarrow f\overline{f})=0$ for all fermions f.
- 123 Updates ABREU 01F.
- 124 ABDALLAH 040 search for $Z\to b\overline{b}H^0$, $b\overline{b}A^0$, $\tau^+\tau^-H^0$ and $\tau^+\tau^-A^0$ in the final states 4b, $b\overline{b}\tau^+\tau^-$, and 4 τ . See paper for limits on Yukawa couplings. 125 ABDALLAH 040 search for $e^+e^-\to H^0Z$ and H^0A^0 , with H^0 , A^0 decaying to $b\overline{b}$,
- $au^+ \, au^-$, or $H^0 o A^0 A^0$ at $E_{
 m cm} = 1$ 89–208 GeV. See paper for limits on couplings.
- ¹²⁶ ACHARD 04B search for $e^+e^-\to H^0Z$ with H^0 decaying to $b\,\overline{b},\,c\,\overline{c},\,$ or $g\,g.$ The limit is for SM production cross section with $B(H^0 \rightarrow jj) = 1$.
- 127 ACHARD 04F search for H^0 with anomalous coupling to gauge boson pairs in the processes $e^+e^- o H^0\gamma$, $e^+e^-H^0$, H^0Z with decays $H^0 o f\overline{f}$, $\gamma\gamma$, $Z\gamma$, and W^*W at $E_{\rm cm}=189$ –209 GeV. See paper for limits.
- 128 ABBIENDI 03F search for $H^0 \to \text{anything in } e^+e^- \to H^0 Z$, using the recoil mass spectrum of $Z \to e^+e^-$ or $\mu^+\mu^-$. In addition, it searched for $Z \to \nu\overline{\nu}$ and $H^0 \to e^+e^$ e^+e^- or photons. Scenarios with large width or continuum H^0 mass distribution are considered. See their Figs. 11–14 for the results.
- 129 ABBIENDI 03G search for $e^+e^- \rightarrow H_1^0$ Z followed by $H_1^0 \rightarrow A^0A^0$, $A^0 \rightarrow c\overline{c}$, gg, or $au^+ au^-$ in the region $m_{H_1^0} =$ 45-86 GeV and $m_{A^0} =$ 2-11 GeV. See their Fig. 7 for
- 130 ACHARD 03c search for $e^+e^- \rightarrow ZH^0$ followed by $H^0 \rightarrow WW^*$ or ZZ^* at $E_{cm}=$ 200-209 GeV and combine with the ACHARD 02c result. The limit is for a H^0 with SM production cross section and B($H^0 \to f \bar{f}$) = 0 for all f. For B($H^0 \to WW^*$) + $\mathsf{B}(H^0 \to ZZ^*) = 1$, $\mathsf{m}_{H^0} > 108.1$ GeV is obtained. See fig. 6 for the limits under different BR assumptions.
- 131 ABBIENDI 02D search for $Z \to b\overline{b}H_1^0$ and $b\overline{b}A^0$ with $H_1^0/A^0 \to \tau^+\tau^-$, in the range $4 < m_H < 12$ GeV. See their Fig. 8 for limits on the Yukawa coupling.
- ¹³² For B($H^0 \rightarrow \gamma \gamma$)=1, m_{H^0} >117 GeV is obtained.
- 133 ACHARD 02c search for associated production of a $\gamma\gamma$ resonance with a Z boson, followed by $Z \to q \overline{q}$, $\ell^+ \ell^-$, or $\nu \overline{\nu}$, at $E_{\rm cm} \leq 209$ GeV. The limit is for a H^0 with SM production cross section and B($H^0 \to f \overline{f}$)=0 for all fermions f. For B($H^0 \to \gamma \gamma$)=1, $m_{H^0} > 114 \text{ GeV}$ is obtained.
- $^{134}\,\mathrm{For}\;\mathrm{B}(H^0\,\rightarrow\,\gamma\gamma){=}1,\,m_{H^0}>113.1~\mathrm{GeV}$ is obtained.
- ¹³⁵ HEISTER 02M search for $e^+e^- \rightarrow H^0 Z$, assuming that H^0 decays to $q \overline{q}$, g g, or $^+ au^-$ only. The limit assumes SM production cross section.
- $^{136} ABBIENDI$ 01E search for neutral Higgs bosons in general Type-II two-doublet models, at $E_{\rm cm} \leq$ 189 GeV. In addition to usual final states, the decays H_1^0 , $A^0 \to q \, \overline{q}$, $g \, g$ are searched for. See their Figs. 15,16 for excluded regions.
- AFFOLDER 01H search for associated production of a $\gamma\gamma$ resonance and a W or Z (tagged by two jets, an isolated lepton, or missing E_T). The limit assumes Standard Model values for the production cross section and for the couplings of the H^0 to W and Z bosons. See their Fig. 11 for limits with B($H^0 \to \gamma \gamma$) < 1. ACCIARRI 00M search for $e^+e^- \to ZH^0$ with H^0 decaying invisibly at
- 138 ACCIARRI 00M search for $e^+e^- o ZH^0$ with H^0 decaying invisibly at $E_{\rm cm} = 183-189\,{\rm GeV}$. The limit assumes SM production cross section and ${\rm B}(H^0 o {\rm invisible}) = 1$. See their Fig. 6 for limits for smaller branching ratios.
- 139 ACCIARRI 00R search for $e^+e^- \to H^0\gamma$ with $H^0 \to b \, \overline{b}$, $Z\gamma$, or $\gamma\gamma$. See their Fig. 3 for limits on σ -B. Explicit limits within an effective interaction framework are also given, for which the Standard Model Higgs search results are used in addition.
- Acciarki our search for the two-photon type processes $e^+e^- \to e^+e^-H^0$ with $H^0 \to b\,\overline{b}$ or $\gamma\gamma$. See their Fig. 4 for limits on $\Gamma(H^0 \to \gamma\gamma)\cdot \mathrm{B}(H^0 \to \gamma\gamma$ or $b\,\overline{b})$ for m_{H^0} =70–170 GeV. 140 ACCIARRI 00R search for the two-photon type processes e^+e^-
- 141 ACCIARRI 00s search for associated production of a $\gamma\gamma$ resonance with a $q\overline{q}$, $\nu\overline{\nu}$, or $\ell^+\ell^-$ pair in e^+e^- collisions at $E_{\rm cm}=189$ GeV. The limit is for a H^0 with SM production cross section and B($H^0\to f\bar T$)=0 for all fermions f. For B($H^0\to \gamma\gamma$)=1, $m_{H^0} >$ 98 GeV is obtained. See their Fig. 5 for limits on B($H
 ightarrow \gamma \gamma$) $\cdot \sigma(e^+e^-
 ightarrow$ $Hf\overline{f})/\sigma(e^+e^- \rightarrow Hf\overline{f})$ (SM).
- 142 BARATE 00L search for associated production of a $\gamma\gamma$ resonance with a $q\overline{q}$, $\nu\overline{\nu}$, or $\ell^+\ell^-$ pair in e^+e^- collisions at $E_{\rm cm}=$ 88–202 GeV. The limit is for a H^0 with SM production cross section and B($H^0\to f\overline{t}$)=0 for all fermions f. For B($H^0\to \gamma\gamma$)=1, $m_{H^0} >$ 109 GeV is obtained. See their Fig. 3 for limits on B($H \to \gamma \gamma$) $\sigma(e^+ e^- \to e^-)$ $Hf\overline{f})/\sigma(e^+e^- \rightarrow Hf\overline{f})$ (SM).

- 143 ABBIENDI 99E search for $e^+\,e^-\to H^0\,A^0$ and $H^0\,Z$ at $E_{\rm Cm}=183$ GeV. The limit is with $m_H{=}m_A$ in general two Higgs-doublet models. See their Fig. 18 for the exclusion limit in the $m_H{-}m_A$ plane. Updates the results of ACKERSTAFF 98s.
- 144 ABBIENDI 990 search for associated production of a $\gamma\gamma$ resonance with a $q\overline{q}, \nu\overline{\nu}$, or $\ell^+\ell^-$ pair in e^+e^- collisions at 189 GeV. The limit is for a H^0 with SM production
- $\ell^+\ell^-$ pair in e^+e^- collisions at 189 GeV. The limit is for a H^o with SM production cross section and $B(H^0 \to f\overline{T}) = 0$, for all fermions f. See their Fig. 4 for limits on $\sigma(e^+e^- \to H^0Z^0) \times B(H^0 \to \gamma\gamma) \times B(X^0 \to f\overline{T})$ for various masses. Updates the results of ACKERSTAFF 98Y.

 145 ABBOTT 99s search for associated production of a $\gamma\gamma$ resonance and a dijet pair. The limit assumes Standard Model values for the production cross section and for the couplings of the H^0 to W and Z bosons. Limits in the range of $\sigma(H^0 + Z/W) \cdot B(H^0 \to \gamma\gamma) = 0.80 0.34$ pb are obtained in the mass range $m_{H^0} = 65 150$ GeV.

 146 ABREU 99 search for $e^+e^- \to H^0\gamma$ with $H^0 \to b\overline{b}$ or $\gamma\gamma$, and $e^+e^- \to H^0q\overline{q}$ with $H^0 \to \infty$. See their Fig. A for limits on $\sigma \times B$. Explicit limits within an effective
- with $H^0 \to \gamma \gamma$. See their Fig. 4 for limits on $\sigma \times B$. Explicit limits within an effective interaction framework are also given. 147 GONZALEZ-GARCIA 98b use DØ limit for $\gamma \gamma$ events with missing E_T in $p\overline{p}$ collisions (ABBOTT 98) to constrain possible ZH or WH production followed by unconventional $H \to \gamma \gamma$ decay which is induced by higher-dimensional operators. See their Figs. 1 and 2 for limit on the acceptance of the convention of the second of for limits on the anomalous couplings.
- 148 KRAWCZYK 97 analyse the muon anomalous magnetic moment in a two-doublet Higgs model (with type II Yukawa couplings) assuming no H_1^0 Z Z coupling and obtain $m_{H_1^0}\gtrsim$
 - 5 GeV or $m_{A0}\gtrsim$ 5 GeV for $\tan\beta>$ 50. Other Higgs bosons are assumed to be much
- 149 heavier. ALEXANDER 96H give B(Z \rightarrow H $^0\gamma$)×B(H 0 \rightarrow $q\overline{q}$) < 1-4 × 10 $^{-5}$ (95%CL) and $B(Z \to H^0 \gamma) \times B(H^0 \to b \overline{b}) < 0.7 - 2 \times 10^{-5} \text{ (95 \%CL) in the range 20 } < m_{H^0} < 80$
- $^{150}\,{\rm GeV}.$ See Fig. 4 of ABREU 95H for the excluded region in the $m_{\Breve{H}^0}-m_{\Breve{A}^0}$ plane for general two-doublet models. For $\tan\beta>$ 1, the region $m_{H^0}+m_{A^0}\lesssim$ 87 GeV, $m_{H^0}<$ 47 GeV is
- 151 excluded at 95% CL, with m_{H^0} <2 m_μ in general two-doublet models. Excluded regions in the space of mass-mixing angles from LEP, beam dump, and π^\pm , η rare decays are shown in Figs. 3,4. The considered mass region is not totally excluded.

H[±] (Charged Higgs) MASS LIMITS

Unless otherwise stated, the limits below assume B($H^+ \to \tau^+ \nu$)+B($H^+ \to c \overline{s}$)=1, and hold for all values of B($H^+ o au^+
u_ au$), and assume H^+ weak isospin of T_3 =+1/2. In the following, $tan \beta$ is the ratio of the two vacuum expectation values in two-doublet

The limits are also applicable to point-like technipions. For a discussion of techniparticles, see the Review of Dynamical Electroweak Symmetry Breaking in this Review.

For limits obtained in hadronic collisions before the observation of the top quark, and based on the top mass values inconsistent with the current measurements, see the 1996 (Physical Review D54 1 (1996)) Edition of this Review.

Searches in $e^+\,e^-$ collisions at and above the $\it Z$ pole have conclusively ruled out the existence of a charged Higgs in the region $m_{H^+}\!\lesssim$ 45 GeV, and are now superseded by the most recent searches in higher energy $e^+\,e^-$ collisions at LEP. Results by now obsolete are therefore not included in this compilation, and can be found in the previous Edition (The European Physical Journal C15 1 (2000)) of this Review.

In the following, and unless otherwise stated, results from the LEP experiments (ALEPH, DELPHI, L3, and OPAL) are assumed to derive from the study of the $e^+e^ightarrow~H^+H^-$ process. Limits from $b
ightarrow~s\gamma$ decays are usually stronger in generic 2HDM models than in Supersymmetric models.

- 152 AALTONEN 11P search in 2.7 fb $^{-1}$ of $p\,\overline{p}$ collisions at $E_{\rm cm}=$ 1.96 TeV for the decay chain $t\to b\,H^+$, $H^+\to W^+A^0$, $A^0\to \tau^+\tau^-$ with $m_{A^0}^{--}$ between 4 and 9 GeV. See their Fig. 4 for limits on B($t
 ightarrow b\,H^+)$ for 90 $< m_{H^+}^{} <$ 160 GeV.
- 153 DESCHAMPS 10 make Type II two Higgs doublet model fits to weak leptonic and semileptonic decays, $b \to s \gamma$, B, B_s mixings, and $Z \to b \bar{b}$. The limit holds irrespective
- ¹⁵⁴ AALTONEN 09AJ search for $t \to bH^+$, $H^+ \to c\overline{s}$ in $t\overline{t}$ events in 2.2 fb⁻¹ of $p\overline{p}$ collisions at $E_{
 m cm}=1.96$ TeV. Upper limits on B(t
 ightarrow bH^+) between 0.08 and 0.32 (95% CL) are given for $m_{H^+}=$ 60–150 GeV and B($H^+\to c\, \overline{s})=1.$
- 155 ABAZOV 09AC search for $t \to bH^+$, $H^+ \to \tau^+ \nu$ in $t \overline{t}$ events in 0.9 fb $^{-1}$ of $p \overline{p}$ collisions at $E_{\rm cm}=1.96$ TeV. Upper limits on B($t o bH^+$) between 0.19 and 0.25 (95% CL) are given for m_{H^+} = 80–155 GeV and B $(H^+ \to \tau^+ \nu)$ = 1. See their Fig. 4 for an excluded region in a MSSM scenario.
- 156 ABAZOV 09AG measure $t\overline{t}$ cross sections in final states with ℓ + jets (ℓ = e, μ), $\ell\ell$, and $au\ell$ in 1 fb $^{-1}$ of $p\,\overline{p}$ collisions at $E_{
 m cm}=1.96$ TeV, which constrains possible t bH^+ branching fractions. Upper limits (95% CL) on B($t \rightarrow bH^+$) between 0.15 and 0.40 (0.48 and 0.57) are given for B($H^+ \to \tau^+ \nu$) = 1 (B($H^+ \to c \overline{s}$) = 1) for m_{H^+} 80-155 GeV.
- 157 = 80-155 GeV.

 157 ABAZOV 09AI search for $t \to bH^+$ in $t\,\overline{t}$ events in 1 fb $^{-1}$ of $\rho\overline{\rho}$ collisions at $E_{\rm CM}=1.96$ TeV. Final states with $\ell+$ jets ($\ell=e,\mu$), $\ell\ell$, and $\tau\ell$ are examined. Upper limits on B(t ightarrow $b\,H^+$) (95% CL) between 0.15 and 0.19 (0.19 and 0.22) are given for B(H^+ ightarrow $\tau^+ \,
 u) = 1 \, (B(H^+ \to c \, \overline{s}) = 1) \, \text{for} \, m_{H^+} = 80 \text{--} 155 \, \text{GeV. For} \, B(H^+ \to \tau^+ \,
 u) = 1 \, (B(H^+ \to c \, \overline{s}) = 1) \, \text{for} \, m_{H^+} = 80 \text{--} 155 \, \text{GeV.}$ also a simultaneous extraction of B($t \to bH^+$) and the $t\bar{t}$ cross section is performed, yielding a limit on B($t
 ightarrow bH^+$) between 0.12 and 0.26 for $m_{H^+} =$ 80–155 GeV. See
- their Figs. 5–8 for excluded regions in several MSSM scenarios. 158 ABAZOV 09P search for H^+ production by $q \, \overline{q}^\prime$ annihilation followed by $H^+ \to t \, \overline{b}$ ABACOV 697 sealer for $p_{\overline{p}}$ collisions at $E_{\rm cm}=1.96$ TeV. Cross section limits in several two-doublet models are given for $m_{H^+}=180$ –300 GeV. A region with $20\lesssim \tan\beta\lesssim 70$ is excluded (95% CL) for 180 GeV $\lesssim m_{H^+}\lesssim 184$ GeV in type-I models.
- 159 FLACHER 09 make Type II two Higgs doublet model fits to weak leptonic and semileptonic decays, $b\to s\gamma$, and $Z\to b\,\bar{b}$. The limit holds irrespective of $\tan\beta$. 160 ABULENCIA 06E search for associated H^0 W production in $\rho\overline{\rho}$ collisions at $E_{\rm CM}=1.96$
- TeV. A fit is made for $t\overline{t}$ production processes in dilepton, lepton + jets, and lepton + aufinal states, with the decays $t \to W^+ b$ and $t \to H^+ b$ followed by $H^+ \to \tau^+ \nu$, $c \, \overline{s}$, $t^*\overline{b}$, or W^+H^0 . Within the MSSM the search is sensitive to the region $\tan \beta < 1$ or > 30 in the mass range $m_{H^+}=$ 80–160 GeV. See Fig. 2 for the excluded region in a
- certain MSSM scenario. H⁺
 161 ABDALLAH 04I search for $e^+e^- \rightarrow H^+H^-$ with H^\pm decaying to $\tau\nu$, cs, or W^*A^0 in Type-I two-Higgs-doublet models.
- $_{
 m 162\,ABBIENDI~03}$ give a limit $m_{H^+}>1.28{
 m tan}eta$ GeV (95%CL) in Type II two-doublet
- 163 ABAZOV 02B search for a charged Higgs boson in top decays with $H^+
 ightarrow ~ au^+
 u$ at $E_{
 m cm}=$ 1.8 TeV. For $m_{H^+}=$ 75 GeV, the region aneta> 32.0 is excluded at 95%CL. The
- excluded mass region extends to over 140 GeV for $\tan \beta$ values above 100. 164 BORZUMATI 02 point out that the decay modes such as $b\overline{b}$ W, A^0 W, and supersymmetric ones can have substantial branching fractions in the mass range explored at LEP II
- and Tevatron. 165 ABBIENDI 01Q give a limit $\tan\beta/m_{H^+} <$ 0.53 GeV $^{-1}$ (95%CL) in Type II two-doublet
- models. 166 BARATE 01E give a limit $\tan\beta/m_{H^+} <$ 0.40 GeV $^{-1}$ (90% CL) in Type II two-doublet models. An independent measurement of $B o au
 u_ au$ X gives $aneta/m_{H^+} < 0.49~ ext{GeV}^{-1}$ (90% CL)
- 167 GAMBINO 01 use the world average data in the summer of 2001 B($b
 ightarrow s \gamma$)= (3.23 \pm $0.42) \times 10^{-4}$. The limit applies for Type-II two-doublet models.
- 168 AFFOLDER (0) search for a charged Higgs boson in top decays with $H^+ \to \tau^+ \nu$ in $p\overline{p}$ collisions at $E_{\rm cm} = 1.8$ TeV. The excluded mass region extends to over 120 GeV for $\tan eta$ values above 100 and B(au
 u)=1. If B $(t o bH^+) \gtrsim$ 0.6, m_{H^+} up to 160 GeV is excluded. Updates ABE 97L.
- 169 ABBOTT 99E search for a charged Higgs boson in top decays in $\rho \overline{\rho}$ collisions at $E_{\rm CM} = 1.8$ TeV, by comparing the observed $t\overline{t}$ cross section (extracted from the data assuming the dominant decay $t\to b\,W^+)$ with theoretical expectation. The search is sensitive to regions of the domains $\tan\!\beta\!\lesssim\!1$, $50<\!m_{H^+}({\rm GeV})\lesssim\!120$ and $\tan\!\beta\!\lesssim\!40$, $50<\!m_{H^+}$
- (GeV) \lesssim 160. See Fig. 3 for the details of the excluded region. $170~{\sf ACKERSTAFF}$ 99D measure the Michel parameters ρ , ξ , η , and $\xi\delta$ in leptonic τ decays from $Z \to \tau \tau$. Assuming $e - \mu$ universality, the limit $m_{H^+} > 0.97 \, {\rm tan} \beta$ GeV (95%CL) is obtained for two-doublet models in which only one doublet couples to leptons.
- 171 ACCIARRI 97F give a limit $m_{H^+}>2.6$ tan β GeV (90% CL) from their limit on the exclusive $B\to \tau \nu_T$ branching ratio.
- $172\,\mathrm{A\,MMAR}$ 97B measure the Michel parameter ho from au o $e\,
 u\,
 u$ decays and assumes e/μ universality to extract the Michel η parameter from $\tau \to \mu \nu \nu$ decays. The measurement is translated to a lower limit on m_{H^+} in a two-doublet model $m_{H^+} > 0.97$ tan β GeV
- 173 COARASA 97 reanalyzed the constraint on the $(m_{H^\pm}, \tan\beta)$ plane derived from the inclusive $B \to \tau \nu_{\tau} X$ branching ratio in GROSSMAN 95B and BUSKULIC 95. They show that the constraint is quite sensitive to supersymmetric one-loop effects.
- 174 GUCHAIT 97 studies the constraints on m_{H^+} set by Tevatron data on ℓau final states in
- $t\overline{t} o (Wb)(Hb), W o \ell
 u, H o au_{
 u}^{H^+}$. See Fig. 2 for the excluded region. 175 MANGANO 97 reconsiders the limit in ACCIARRI 97F including the effect of the potentially large $B_C o au
 u_{
 u}^{T}$ background to $B_U o au
 u_{
 u}^{T}$ decays. Stronger limits are obtained.
- $^{176}\,\mathrm{STAHL}$ 97 fit τ lifetime, leptonic branching ratios, and the Michel parameters and derive limit $m_{H^+}>1.5~{
 m tan}eta~{
 m GeV}$ (90% CL) for a two-doublet model. See also STAHL 94.
- 177 ALAM 95 measure the inclusive $b o s \gamma$ branching ratio at $\varUpsilon(4S)$ and give B(b $s\gamma$) < 4.2 × 10⁻⁴ (95% CL), which translates to the limit m_{H^+} >[244 + 63/(tan β) $^{1.3}$] GeV in the Type II two-doublet model. Light supersymmetric particles can invalidate this
- 178 BUSKULIC 95 give a limit $m_{H^+}>1.9~{
 m tan}eta$ GeV (90% CL) for Type-II models from $b \to \tau \nu_{\tau} X$ branching ratio, as proposed in GROSSMAN 94.

Gauge & Higgs Boson Particle Listings

Higgs Bosons — H^0 and H^{\pm}

– MASS LIMITS for $H^{\pm\pm}$ (doubly-charged Higgs boson) \cdot

This section covers searches for a doubly-charged Higgs boson with couplings to lepton pairs. Its weak isospin T_3 is thus restricted to two possibilities depending on lepton chiralities: $T_3(H^{\pm\pm})=\pm 1$, with the coupling $g_{\ell\ell}$ to $\ell_L^-\ell_L^{\prime-}$ and $\ell_R^+\ell_R^{\prime+}$ ("left-handed") and $T_3(H^{\pm\pm})=0$, with the coupling to $\ell_R^-\ell_L'^-$ and $\ell_L^+\ell_L'^+$ ("right-handed"). These Higgs bosons appear in some left-right symmetric models based on the gauge group $\mathrm{SU}(2)_L \times \mathrm{SU}(2)_R \times \mathrm{U}(1).$ These two cases are listed separately in the following lowing. Unless noted, one of the lepton flavor combinations is assumed to be dominant in the decay.

LIMITS for $H^{\pm\pm}$ with $T_3=\pm1$

- 179 ABAZOV 12A search for $H^{++}H^{--}$ production in 7.0 fb $^{-1}$ of $p\overline{p}$ collisions at $E_{\rm cm}=$
- ¹⁸⁰ AALTONEN 11AF search for $H^{++}H^{--}$ production in 6.1 fb⁻¹ of $p\overline{p}$ collisions at E_{cm}
- 181 AALT ONEN 08AA search for $H^{++}H^{--}$ production in $p\overline{p}$ collisions at $E_{cm}=1.96$ TeV.
- The limit assumes 100% branching ratio to the specified final state. 182 ABAZOV 08v search for $H^{++}H^{--}$ production in $p\overline{p}$ collisions at $E_{\rm Cm}=1.96$ TeV. The limit is for B($H\to\mu\mu$) = 1. The limit is updated in ABAZOV 12A.
- 183 ABDALLAH 03 search for $^{\prime\prime}H^{++}H^{--}$ pair production either followed by $^{\prime\prime}H^{++}$ $^{\prime\prime}$ au^+ , or decaying outside the detector.
- 184 ABBIENDI 02c searches for pair production of $H^{++}H^{--}$, with $H^{\pm\pm} \to \ell^{\pm}\ell^{\pm}$ (ℓ,ℓ' $=e,\mu, au$). The limit holds for $\ell{=}\ell'{=} au$, and becomes stronger for other combinations of leptonic final states. To ensure the decay within the detector, the limit only applies for $g(H\ell\ell)\gtrsim 10^{-7}$.
- 185 AKTAS 06 A search for single $H^{\pm\pm}$ production in ep collisions at HERA. Assuming that H^{++} only couples to $e^+\mu^+$ with $g_{e\,\mu}=$ 0.3 (electromagnetic strength), a limit $m_{H^{++}} >$ 141 GeV (95% CL) is derived. For the case where H^{++} couples to e au only the limit is 112 GeV.
- ¹⁸⁶ ACOSTA 05L search for $H^{++}H^{--}$ pair production in $p\overline{p}$ collisions. The limit is valid for $g_{\ell\ell'} < 10^{-8}$ so that the Higgs decays outside the detector.
- 187 ABAZOV 04E search for $H^{++}H^{--}$ pair production in $H^{\pm\pm}\to~\mu^\pm\,\mu^\pm$. The limit is valid for $g_{\mu\mu}\gtrsim 10^{-7}$.
- $^{9\mu\mu}\sim$ 188 ACOSTA 04c search for $H^{++}H^{--}$ pair production in $p\overline{p}$ collisions with muon and electron final states.The limit holds for $\mu\mu$. For $e\,e$ and $e\,\mu$ modes, the limits are 133 and 115 GeV, respectively. The limits are valid for $g_{\ell\ell'}\gtrsim 10^{-5}$. Superseded by AALTONEN 11AF.
- 189 ABBIENDI 03Q searches for single $H^{\pm\pm}$ via direct production in $e^+e^- \rightarrow e^\mp e^\mp H^{\pm\pm}$, ABBIENDI USQ searches for single H^{++} via direct production in $e^+e^- \to e^+e^-$, and via t-channel exchange in $e^+e^- \to e^+e^-$. In the direct case, and assuming $\mathsf{B}(H^{\pm\pm}\to\ell^\pm\ell^\pm)=1$, a 95% CL limit on $h_{ee}<0.071$ is set for $m_{H^{\pm\pm}}<160$ GeV (see Fig. 6). In the second case, indirect limits on h_{ee} are set for $m_{H^{\pm\pm}} <$ 2 TeV (see
- 190 GORDEEV 97 search for muonium-antimuonium conversion and find $G_{M\overline{M}}/G_F < 0.14$ (90% CL), where $G_{M\overline{M}}$ is the lepton-flavor violating effective four-fermion coupling. This limit may be converted to $m_{H^{++}}>$ 210 GeV if the Yukawa couplings of H^{++} to ee and $\mu\mu$ are as large as the weak gauge coupling. For similar limits on muonium-antimuonium conversion, see the muon Particle Listings.
- 191 ASAKA 95 point out that H^{++} decays dominantly to four fermions in a large region of parameter space where the limit of ACTON 92M from the search of dilepton modes does
- 192 ACTON 92M limit assumes $H^{\pm\pm}\to \ell^\pm\ell^\pm$ or $H^{\pm\pm}$ does not decay in the detector. Thus the region $g_{\ell\ell}\approx 10^{-7}$ is not excluded.
- 193 ACTON 92M from $\Delta\Gamma_Z$ <40 MeV. 194 SWARTZ 90 assume $H^{\pm\pm} \to \ell^{\pm}\ell^{\pm}$ (any flavor). The limits are valid for the Higgslepton coupling $g(H\ell\ell) \gtrsim 7.4 \times 10^{-7}/[m_H/\text{GeV}]^{1/2}$. The limits improve somewhat for ee and $\mu\mu$ decay modes.

- 195 ABAZOV 12A search for $H^{++}H^{--}$ production in 7.0 fb $^{-1}$ of $p\,\overline{p}$ collisions at $E_{\rm cm}=$
- 196 AALTONEN 11AF search for $H^{++}H^{--}$ production in 6.1 fb⁻¹ of $p\overline{p}$ collisions at $E_{\rm cm}$ = 1.96 TeV.
- 197 a BAZOV 08v search for $H^{++}H^{--}$ production in $\rho\overline{p}$ collisions at $E_{\rm cm}=1.96$ TeV. The limit is for B($H\to\mu\mu$) = 1. The limit is updated in ABAZOV 12A. 198 ABDALLAH 03 search for $H^{++}H^{--}$ pair production either followed by $H^{++}\to 1.00$
- $au^+ au^+$, or decaying outside the detector.
- 199 ACHARD 03F search for $e^+e^- \to H^{++}H^{--}$ with $H^{\pm\pm} \to \ell^\pm\ell'^\pm$. The limit holds for $\ell=\ell'=\tau$, and slightly different limits apply for other flavor combinations. The limit is valid for $g_{\ell\ell'}\gtrsim 10^{-7}$.
- ²⁰⁰ ABBIENDI 02c searches for pair production of $H^{++}H^{--}$, with $H^{\pm\pm}\to \ell^\pm\ell^\pm$ (ℓ,ℓ' $=e,\mu, au$). the limit holds for $\ell=\ell'= au$, and becomes stronger for other combinations of leptonic final states. To ensure the decay within the detector, the limit only applies for $g(H\ell\ell) \gtrsim 10^{-7}$
- 201 AKTAS 06 A search for single $^{\pm\pm}$ production in ep collisions at HERA. Assuming that H^{++} only couples to $e^+\mu^+$ with $g_{e\,\mu}=$ 0.3 (electromagnetic strength), a limit $m_{H^{++}}~>141$ GeV (95% CL) is derived. For the case where H^{++} couples to $e\tau$ only the limit is 112 GeV.
- 202 ACOSTA 05L search for $H^{++}H^{--}$ pair production in $p\overline{p}$ collisions. The limit is valid for $g_{pp'} < 10^{-8}$ so that the Higgs decays outside the detector.
- 203 ABAZOV 04E search for $H^{++}H^{--}$ pair production in $H^{\pm\pm}\to \mu^{\pm}\mu^{\pm}$. The limit is valid for $g_{\mu\mu}\gtrsim 10^{-7}$
- 204 ACOSTA 04G search for $H^{++}H^{--}$ pair production in $p\bar{p}$ collisions with muon and
- ACOSIA 046 Search for H^+H^- pair production in pp collisions with muon and electron final states. The limit holds for $\mu\mu$. Superseded by AALTONEN 11AF. 205 ABBIENDI 030 searches for single $H^{\pm\pm}$ via direct production in $e^+e^- \rightarrow e^+e^+H^{\pm\pm}$, and via t-channel exchange in $e^+e^- \rightarrow e^+e^-$. In the direct case, and assuming $B(H^{\pm\pm} \rightarrow \ell^{\pm}\ell^{\pm}) = 1$, a 95% CL limit on $h_{ee} < 0.071$ is set for $m_{H^{\pm\pm}} < 160$ GeV (see Fig. 6). In the second case, indirect limits on h_{ee} are set for $m_{H^{\pm\pm}}^{~~11}$ < 2 TeV (see
- 206 GORDEEV 97 search for muonium-antimuonium conversion and find $G_{M\overline{M}}/G_F < 0.14$ (90% CL), where $G_{\overline{MM}}$ is the lepton-flavor violating effective four-fermion coupling. This limit may be converted to $m_{H^{++}} > 210$ GeV if the Yukawa couplings of H^{++} to ee and $\mu\mu$ are as large as the weak gauge coupling. For similar limits on muonium-antimuonium conversion, see the muon Particle Listings. 2^{07} ACTON 92M limit assumes $H^{\pm\pm} \rightarrow \ell^{\pm}\ell^{\pm}$ or $H^{\pm\pm}$ does not decay in the detector.
- Thus the region $g_{\ell\ell} \approx 10^{-7}$ is not excluded.
- 208 ACTON 92M from $\Delta\Gamma_Z$ <40 MeV. 209 SWARTZ 90 assume $H^{\pm\pm}\to \ell^\pm\ell^\pm$ (any flavor). The limits are valid for the Higgslepton coupling $g(H\ell\ell)\gtrsim 7.4\times 10^{-7}/[m_H/\text{GeV}]^{1/2}$. The limits improve somewhat for ee and $\mu\mu$ decay modes.

W'-BOSON SEARCHES

Revised May 2012 by G. Brooijmans (Columbia University), M.-C. Chen (UC Irvine) and B.A. Dobrescu (Fermilab).

The W^\prime boson is a hypothetical massive particle of electric charge ± 1 and spin 1, which is predicted in various extensions of the Standard Model.

W' couplings to quarks and leptons. The Lagrangian terms describing couplings of a W'^+ boson to fermions are given by

$$\frac{W_{\mu}^{\prime+}}{\sqrt{2}}\Big[\overline{u}_{i}\Big(\!C_{q_{ij}}^{\rm R}P_{R}+C_{q_{ij}}^{\rm L}P_{L}\!\Big)\gamma^{\mu}d_{j}+\overline{\nu}_{i}\Big(\!C_{l_{ij}}^{\rm R}P_{R}+C_{l_{ij}}^{\rm L}P_{L}\!\Big)\gamma^{\mu}e_{j}\Big]\;. \eqno(1)$$

Here u, d, ν and e are the Standard Model fermions in the mass eigenstate basis, i, j = 1, 2, 3 label the fermion generation,

and $P_{R,L}=(1\pm\gamma_5)/2$. The coefficients $C^{\mathbf{t}}_{q_{ij}},\ C^{\mathbf{r}}_{q_{ij}},\ C^{\mathbf{t}}_{l_{ij}},\ C^{\mathbf{r}}_{l_{ij}}$ are complex dimensionless parameters. If $C^{\mathbf{r}}_{l_{ij}}\neq 0$, then the ith generation includes a right-handed neutrino. Using this notation, the Standard Model W couplings are $C^{\mathbf{t}}_{q}=gV_{\mathrm{CKM}},$ $C^{\mathbf{t}}_{l}=g$ and $C^{\mathbf{r}}_{q}=C^{\mathbf{r}}_{l}=0$.

Unitarity considerations imply that the W' is a gauge boson associated with a spontaneously-broken gauge symmetry. This is true even when it is a composite particle (e.g., techni- ρ^{\pm} in technicolor theories [1]) if its mass is much smaller than the compositeness scale, or a Kaluza-Klein mode in theories where the W boson propagates in extra dimensions [2]. The simplest extension of the electroweak gauge group that includes a W' boson is $SU(2)_1 \times SU(2)_2 \times U(1)$, but larger groups are encountered in some theories. A generic property of these gauge theories is that they also include a Z' boson; whether the W' boson can be discovered first depends on theoretical details.

The renormalizable photon-W' coupling is fixed by electromagnetic gauge invariance. By contrast, the W'WZ and W'W'Z couplings as well as the W' boson couplings to Z' or Higgs bosons are model-dependent.

A tree-level mass mixing may be induced between the electrically-charged gauge bosons. Upon diagonalization of their mass matrix, the W-Z mass ratio and the couplings of the observed W boson are shifted from the Standard Model values. Given that these are well measured, the W-W' mixing angle must be smaller than about 10^{-2} . Similarly, a Z-Z' mixing is induced in generic theories, leading to even tighter constraints. There are, however, theories in which these mixings are negligible (e.g., due to a new parity [3]), even when the W' and Z' masses are below the electroweak scale.

A popular model [4] is based on the "left-right symmetric" gauge group, $SU(2)_L \times SU(2)_R \times U(1)_{B-L}$, with the Standard Model fermions that couple to the W boson transforming as doublets under $SU(2)_L$, and the other ones transforming as doublets under $SU(2)_R$. In this model the W' boson couples primarily to the right-handed fermions, and its coupling to left-handed fermions arises solely due to W-W' mixing. As a result, C_q^t is proportional to the CKM matrix, and its elements are much smaller than the diagonal elements of C_q^R .

There are many other models based on the $SU(2)_1 \times SU(2)_2 \times U(1)$ gauge symmetry. In the "alternate left-right" model [5], all the couplings shown in Eq. (1) vanish, but there are some new fermions such that the W' boson couples to pairs involving a Standard Model fermion and a new fermion. In the "ununified Standard Model" [6], the left-handed quarks are doublets under one SU(2), and the left-handed leptons are doublets under a different SU(2), leading to a mostly leptophobic W' boson: $C^t_{lij} \ll C^t_{qij}$ and $C^R_{qij} = C^R_{lij} = 0$. Fermions of different generations may also transform as doublets under different SU(2) gauge groups [7]. In particular, the couplings to third generation quarks may be enhanced [8].

The W' couplings to Standard Model fermions may be highly suppressed if the quarks and leptons are singlets under one SU(2) [9], or if there are some vectorlike fermions that

mix with the Standard Model ones [10]. Gauge groups that embed the electroweak symmetry, such as $SU(3)_W \times U(1)$ or $SU(4)_W \times U(1)$, also include one or more W' bosons [11].

Collider searches. At LEP-II, W' bosons could have been produced in pairs via their photon and Z couplings. The production cross section depends only on the W' mass, and is large enough to rule out $M_{W'} \leq \sqrt{s}/2 \approx 105$ GeV for most patterns of decay modes.

At hadron colliders, W' bosons can be detected through resonant pair production of fermions or electroweak bosons. Assuming that the W' width is much smaller than its mass, the contribution of the s-channel W' boson exchange to the total rate for $pp \to f\bar{f}'X$, where f and f' are fermions whose electric charges differ by ± 1 , and X is any final state, may be approximated by the branching fraction $B(W' \to f\bar{f}')$ times the production cross section

$$\sigma(pp \to W'X) \simeq \frac{\pi}{48 s} \sum_{i,j} \left[(C_{q_{ij}}^{l})^{2} + (C_{q_{ij}}^{R})^{2} \right] w_{ij} \left(M_{W'}^{2} / s, M_{W'} \right).$$
(2)

The functions w_{ij} include the information about proton structure, and are given to leading order in α_s by

$$w_{ij}(z,\mu) = \int_{z}^{1} \frac{dx}{x} \left[u_{i}(x,\mu) \, \overline{d}_{j}\left(\frac{z}{x},\mu\right) + \overline{u}_{i}(x,\mu) \, d_{j}\left(\frac{z}{x},\mu\right) \right], \quad (3)$$

where $u_i(x,\mu)$ and $d_i(x,\mu)$ are the parton distributions inside the proton at the factorization scale μ for the up- and downtype quark of the *i*th generation, respectively. QCD corrections to W' production are sizable (they also include quark-gluon initial states), but preserve the above factorization of couplings at next-to-leading order [12].

The most commonly studied W' signal consists of a highenergy electron or muon and large missing transverse energy, with the transverse mass distribution forming a Jacobian peak with its endpoint at $M_{W'}$ (see Fig. 1 of Ref. 13) Given that the branching fractions for $W' \to e\nu$ and $W' \to \mu\nu$ could be very different, these channels should be analyzed separately. Searches in these channels often assume that the left-handed couplings vanish (no interference between W and W'), and that the right-handed neutrino of the first generation is light compared to $M_{W'}$ and escapes the detector. However, if a W'boson were discovered and the final state fermions have lefthanded helicity, then the effects of W-W' interference could be observed [14], providing useful information about the W'couplings.

In the $e\nu$ channel, the 95% CL limit set by the ATLAS Collaboration [13] with 1 fb⁻¹ of data on the cross section (at $\sqrt{s}=7$ TeV) times branching fraction is shown in Fig. 1. The CMS limit based on 5 fb⁻¹ of data in this channel [15], for $M_{W'}$ in the 0.5-3 TeV range, varies between 70 and 2.6 fb. For $M_{W'}$ in the 500-600 GeV range, the strongest limits on W' couplings are set by CDF [16] with 5.3 fb⁻¹ (for a comparison, see Fig. 3 of Ref. 13). The limits are much weaker for $M_{W'}$ in the 200-500 GeV range because these were obtained using only

The $t\bar{b}$ channel is particularly important because a W' boson that couples only to right-handed fermions cannot decay to leptons when the right-handed neutrinos are heavier than $M_{W'}$ (additional motivations are provided by a W' boson with enhanced couplings to the third generation [8], and by a leptophobic W' boson). The usual signal consists of a leptonically decaying W boson and two b-jets. The upper limits on the W' couplings to left- and right-handed quarks normalized to the Standard Model W boson couplings, set by DØ with 2.3 fb⁻¹ [21] and by CDF with 1.9 fb⁻¹ [22], respectively, are shown in Fig. 2. LHC searches in this channel have set cross section limits for $M_{W'}$ in the 0.5 – 2.1 TeV range [23].

For $M_{W'}\gg m_t$, one could also use hadronic W boson decays to search for $W'\to t\bar{b}$ with a boosted top quark. If W' couplings to left-handed quarks are large, then interference effects modify the Standard Model s-channel single-top production [24].

Searches for dijet resonances may be used to set limits on $W' \to q\bar{q}'$ [18]. In the 105-200 GeV mass range the limits are rather weak, as they have been set so far only by the UA2 Collaboration; even in the 200-700 GeV range only small data sets from the Tevatron and the LHC have been used so far.

In some theories [3], the W' couplings to Standard Model fermions are suppressed by discrete symmetries. W' production then occurs in pairs, through a photon or Z boson. The decay modes are model-dependent and often involve other new particles. The ensuing collider signals arise from cascade decays and typically include missing transverse energy.

A fermiophobic W' boson which couples to WZ may be produced at hadron colliders in association with a Z boson, or via WZ fusion. This would give rise to (WZ)Z and (WZ)jj final states, where the parentheses represent a resonance [25]. The study of these processes is important for understanding the origin of electroweak symmetry-breaking. The DØ [26] and CDF [27] Collaborations have set limits on $\sigma(p\bar{p}\to W'X)\times B(W'\to WZ)$ for $M_{W'}$ in the 180 – 1000 GeV range, while searches [28] at the 7 TeV LHC have set cross-section limits for $M_{W'}$ in the 200 – 1500 GeV range.

Low-energy constraints. The properties of W' bosons are also constrained by measurements of processes at energies much below $M_{W'}$. The bounds on W-W' mixing [18] are mostly due to the change in the properties of the W boson compared to the Standard Model. Limits on the deviation in the ZWW coupling provide a leading constraint for fermiophobic W' bosons [10].

Constraints arising from low-energy effects of W' exchange are strongly model-dependent. If the W' couplings to quarks are not suppressed, then box diagrams involving a W and a W' boson contribute to neutral meson-mixing. In the case of W' couplings to right-handed quarks as in the left-right symmetric model, the limit from $K_L - K_s$ mixing is severe: $M_{W'} > 2.5 \text{ TeV } [29]$. However, if no correlation between $C_{q_{ij}}^{R}$ and $C_{l_{ij}}^{R}$ is assumed, then the limit on $M_{W'}$ may be significantly relaxed [30].

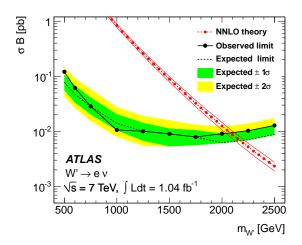

Figure 1: 95% CL limit on $\sigma(pp \to W'X) \times B(W' \to e\nu)$ from ATLAS [13]. The theoretical prediction (dash-dotted line) is for $C_q^{\mathsf{R}} = gV_{\mathrm{CKM}},$ $C_l^{\mathsf{R}} = g, C_q^{\mathsf{L}} = 0.$

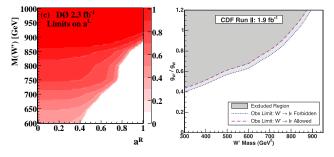

Figure 2: 95% CL upper limits on W' couplings using the $t\bar{b}$ and $\bar{t}b$ final states, assuming that the diagonal couplings are generation independent. Left panel: DØ [21] limit on $C_{q_{11}}^{\ell}/g$ as contours in the $C_{q_{11}}^{R}/g - M_{W'}$ plane. Right panel: CDF [22] limit on $C_{q_{11}}^{R}/g$.

0.2 fb⁻¹ of Tevatron data [17], while the 105 – 200 GeV range

 0.2 fb^{-1} of Tevatron data [17], while the 105 - 200 GeV range has been even less explored (see the UA1 and UA2 references in Ref. 18).

In the $\mu\nu$ channel, the most stringent limit in the 0.5-3 TeV range, set by CMS [15] with 5 fb⁻¹, varies between 39 and 2.7 fb. The ATLAS $\mu\nu$ limit [13] is higher by about 50% compared to that shown in Fig. 1. For $M_{W'}$ in the 200 – 500 GeV range there are only weak limits on the W' couplings from the Tevatron Run I [19]. There are no direct limits on $W' \to \mu\nu$ for $M_{W'}$ in the 105 – 200 GeV range.

Dedicated searches for the $W' \to \tau \nu$ decay have not yet been performed, but limits can be derived from some searches in the $\ell + E_T$ channel as well as from charged-Higgs searches such as $pp \to t\bar{b} \tau \nu X$.

The W' decay into a lepton and a right-handed neutrino, ν_R , may also be followed by the ν_R decay through a virtual W' boson into a lepton and two quark jets. The ATLAS search [20] with 2.1 fb⁻¹ sets cross-section limits in the $\ell^+\ell^-jj$ channel decreasing from 20 fb to 3 fb for $M_{W'}$ in the 1 – 2.7 TeV range.

W' exchange also contributes at tree level to various lowenergy processes. In particular, it would impact the measurement of the Fermi constant G_F in muon decay, which in turn would change the predictions of many other electroweak processes. A recent test of parity violation in polarized muon decay [31] has set limits of about 600 GeV on $M_{W'}$, assuming W' couplings to right-handed leptons as in left-right symmetric models. There are also W' contributions to the neutron electric dipole moment, β decays, and other processes [18].

If right-handed neutrinos have Majorana masses, then there are tree-level contributions to neutrinoless double-beta decay, and a limit on $M_{W'}$ versus the ν_R mass may be derived [32]. For ν_R masses below a few GeV, the W' boson contributes to leptonic and semileptonic B meson decays, so that limits may be placed on various combinations of W' parameters [30]. For ν_R masses below ~ 30 MeV, most stringent constraints on $M_{W'}$ are due to the limits on ν_R emission from supernova.

MASS LIMITS for W' (Heavy Charged Vector Boson Other Than W) in Hadron Collider Experiments

Couplings of W' to quarks and leptons are taken to be identical with those of W. The following limits are obtained from $\rho \overline{\rho} \to W' X$ with W' decaying to the mode indicated in the comments. New decay channels (e.g., $W' \to WZ$) are assumed to be suppressed. The most recent preliminary results can be found in the "W'-boson searches" review above. $E(gev) \qquad CLS \qquad DOCUMENT ID \qquad TECN \qquad COMMENT$

 $^1\,\mathrm{The}$ quoted limit is obtained assuming $\,\mathit{W'}\,\mathit{WZ}$ coupling strength is the same as the ordinary $\,\mathit{W}\,\mathit{WZ}$ coupling strength in the Standard Model.

 2 ABAZOV 11L limit is for W^\prime with SM-like coupling which interferes with the SM W boson. For W^\prime with right-handed coupling, the bound becomes >885 GeV (>890 GeV) if W^\prime decays to both leptons and quarks (only to quarks). If both left- and right-handed couplings present, the limit becomes >916 GeV.

 3 The quoted limit assumes $g_{W'\,W\,Z}/g_{W\,W\,Z}=(\,M_W/\,M_{W'})^2$. See their Fig. 4 for limits in mass-coupling plane.

 4 The quoted limit assumes $g_{W'\,W\,Z}/g_{W\,W\,Z}=(M_W/M_{W'})^2.$ See their Fig. 3 for limits in mass-coupling plane.

- 5 The AALTONEN 09AA quoted limit is for a right-handed W^\prime with SM-like coupling allowing $W' \to \ell \nu$ decays.
- ⁶ AALTONEN 09AC search for new particle decaying to dijets.
- 7 The ABAZOV 08P quoted limit is for W^\prime with SM-like coupling which interferes with the SM W boson. For W' with right-handed coupling, the bound becomes >739 GeV (>768 GeV) if W' decays to both leptons and quarks (only to quarks).
- 8 The ABAZOV 06N quoted limit is for W^\prime with SM-like coupling which interferes with the SM W boson. For W^\prime with right-handed coupling, M_{W^\prime} between 200 and 630 (670) GeV is excluded for ${\it M}_{\nu_R} \ll \ \bar{\it M}_{W'} \ ({\it M}_{\nu_R} \ > {\it M}_{W'}).$
- $^9\,{\rm The}$ ACOSTA 03B quoted limit is for $M_{W'}\gg M_{\nu_R}.$ For $M_{W'}<\! M_{\nu_R}$, $M_{W'}$ between
- 225 and 566 GeV is excluded. 10 The quoted limit is obtained assuming W'WZ coupling strength is the same as the ordinary WWZ coupling strength in the Standard Model. See their Fig. 2 for the limits on the production cross sections as a function of the W^\prime width.
- 11 AFFOLDER 01: combine a new bound on $W'\to e\nu$ of 754 GeV with the bound of ABE 00 on $W'\to \mu\nu$ to obtain quoted bound.
- $^{12}\mathsf{ABE}$ 00 assume that the neutrino from W' decay is stable and has a mass significantly less than $m_{W'}$
- $^{13}\,\mathrm{ABE}$ 97G search for new particle decaying to dijets.
- $^{14}\,\mathrm{For}$ bounds on W_{R} with nonzero right-handed mass, see Fig. 5 from ABACHI 96c.
- 15 ABACHI 95E assume that the decay $W'
 ightarrow \ W \, Z$ is suppressed and that the neutrino from W^\prime decay is stable and has a mass significantly less m_{W^\prime}
- 16 ABE 95M assume that the decay $W'\to WZ$ is suppressed and the (right-handed) neutrino is light, noninteracting, and stable. If $m_{\nu}{=}60$ GeV, for example, the effect on the mass limit is negligible.
- 17 RiZZO 93 analyses CDF limit on possible two-jet resonances. The limit is sensitive to the inclusion of the assumed $\, K$ factor.

WR (Right-Handed W Boson) MASS LIMITS

Assuming a light right-handed neutrino, except for BEALL 82, LANGACKER 89B, and COLANGELO 91. $g_R=g_L$ assumed. [Limits in the section MASS LIMITS for W' below are also valid for W_R if $m_{\nu_R} \ll m_{W_R}$.] Some limits assume manifest left-right symmetry, i.e., the equality of left- and right Cabibbo-Kobayashi-Maskawa matrices. For a comprehensive review, see LA NGACKER 89B. Limits on the W_L - W_R mixing angle ζ are found in the next section. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

- 18 CZAKON 99 perform a simultaneous fit to charged and neutral sectors.
- 19 WAUTERS $^{\dot{}}$ 0 limit is from a measurement of the asymmetry parameter of polarized $^{60}{
 m Co}~eta$ decays. The listed limit assumes no mixing.
- 20 MELCONIAN 07 measure the neutrino angular asymmetry in eta^+ -decays of polarized $^{37}\mathrm{K}$, stored in a magneto-optical trap. Result is consistent with SM prediction and does not constrain the $\widetilde{W_L}-W_R$ mixing angle appreciably.
- 21 SCHUMANN 07 limit is from measurements of the asymmetry $\langle \vec{p}_{\nu} \cdot \sigma_{n} \rangle$ in the β decay of polarized neutrons. Zero mixing is assumed.
- 22 CYBURT 05 limit follows by requiring that three light u_R 's decouple when $T_{dec}>140$ MeV. For different T_{dec} , the bound becomes $M_{W_R} >$ 3.3 TeV (T_{dec} / 140 MeV) $^{3/4}$.
- 23 THOMAS 01 limit is from measurement of eta^+ polarization in decay of polarized 12 N. The listed limit assumes no mixing.
- 24 ACKERSTAFF 99D limit is from $ilde{ au}$ decay parameters. Limit increase to 145 GeV for zero

- 25 BARENBOIM 98 assumes minimal left-right model with Higgs of ${\rm SU}(2)_R$ in ${\rm SU}(2)_L$ doublet. For Higgs in ${\rm SU}(2)_L$ triplet, $m_{W_R}>$ 1100 GeV. Bound calculated from effect of corresponding Z_{LR} on electroweak data through Z- Z_{LR} mixing.
- 26 The quoted limit is from μ decay parameters. BARENBOIM 97 also evaluate limit from K_L - K_S mass difference.
- $27\,\mbox{STAHL}$ 97 limit is from fit to $\tau\mbox{-decay}$ parameters.
- 28 ALLET 96 measured polarization-asymmetry correlation in 12 N eta^+ decay. The listed limit assumes zero L-R mixing.
- 29 KUZNETSOV 95 limit is from measurements of the asymmetry $\langle \vec{p}_{\mu} \cdot \sigma_{\eta} \rangle$ in the β decay of polarized neutrons. Zero mixing assumed. See also KUZNETSOV 94B.
- ³⁰ KUZNETSOV 94B limit is from measurements of the asymmetry $\langle \vec{p}_{\nu} \cdot \sigma_{n} \rangle$ in the β decay
- of polarized neutrons. Zero mixing assumed. 31 BHATTACHARYYA 93 uses Z-Z' mixing limit from LEP '90 data, assuming a specific Higgs sector of $SU(2)_L \times SU(2)_R \times U(1)$ gauge model. The limit is for m_t =200 GeV and slightly improves for smaller m_t .
- $^{32}\,\mathrm{SEVERIJNS}$ 93 measured polarization-asymmetry correlation in $^{107}\mathrm{ln}~\beta^+$ decay. The listed limit assumes zero L-R mixing. Value quoted here is from SEVERIJNS 94 erratum.
- 33 IMAZATO 92 measure positron asymmetry in $^{K^+}$ ightarrow $\mu^+
 u_\mu$ decay and obtain $\xi P_{\mu} >$ 0.990 (90% CL). If W_{R} couples to $u\overline{s}$ with full weak strength ($V_{n\,s}^{R}\!=\!1$), the result corresponds to $m_{W_R} > 653$ GeV. See their Fig. 4 for m_{W_R} limits for general
- $|V_{us}^R|^2=1-|V_{ud}^R|^2$. 34 POLAK 92B limit is from fit to muon decay parameters and is essentially determined by JODIDIO 86 data assuming ζ =0. Supersedes POLAK 91.
- 35 AQUINO 91 limits obtained from neutron lifetime and asymmetries together with uni-tarity of the CKM matrix. Manifest left-right symmetry assumed. Stronger of the two limits also includes muon decay results.
- 36 COLANGELO 91 limit uses hadronic matrix elements evaluated by QCD sum rule and is less restrictive than BEALL 82 limit which uses vacuum saturation approximation. Manifest left-right symmetry assumed.
- ³⁷ POLAK 91 limit is from fit to muon decay parameters and is essentially determined by JODIDIO 86 data assuming $\zeta{=}0$. Superseded by POLAK 92B.
- $^{38}\,\mathrm{BARBIERI}$ 89B limit holds for $m_{\nu_R} \leq 10$ MeV.
- 39 LANGACKER 89B limit is for any ν_R mass (either Dirac or Majorana) and for a general class of right-handed quark mixing matrices.
- 40 BALKE 88 limit is for $m_{\nu_e R}=0$ and $m_{\nu_\mu R}\leq 50$ MeV. Limits come from precise measurements of the muon decay asymmetry as a function of the positron energy.
- 41 JODIDIO 86 is the same TRIUMF experiment as STOKER 85 (and CARR 83); however, it uses a different technique. The results given here are combined results of the two techniques. The technique here involves precise measurement of the end-point e^{+} spectrum in the decay of the highly polarized μ^+
- 42 STOKER 85 is same TRIUMF experiment as CARR 83. Here they measure the decay e^+ spectrum asymmetry above 46 MeV/c using a muon-spin-rotation technique. Assumed a light right-handed neutrino. Quoted limits are from combining with CARR 83.
- 43 BERGSMA 83 set limit $m_{W_2}/m_{W_1}~>1.9$ at CL =90%
- 44 CARR 83 is TRIUMF experiment with a highly polarized μ^+ beam. Looked for deviation from V-A at the high momentum end of the decay e^+ energy spectrum. Limit from previous world-average muon polarization parameter is $m_{W_R} >$ 240 GeV. Assumes a light right-handed neutrino.
- ⁴⁵ BEALL 82 limit is obtained assuming that W_R contribution to $K_I^0 K_S^0$ mass difference is smaller than the standard one, neglecting the top quark contributions. Manifest left-right symmetry assumed.

I

Limit on W_L - W_R **Mixing Angle** ζ Lighter mass eigenstate $W_1 = W_L \cos \zeta - W_R \sin \zeta$. Light ν_R assumed unless noted. Values in brackets are from cosmological and astrophysical considerations.

- ACKERSTAFF 99D limit is from τ decay parameters.
- 47 CZAKON 99 perform a simultaneous fit to charged and neutral sectors.
- 48 The quoted limit is from μ decay parameters. BARENBOIM 97 also evaluate limit from K_L - K_S mass difference.
- ⁴⁹ MISHRA 92 limit is from the absence of extra large-x, large-y $\overline{
 u}_\mu$ N ightarrow $\overline{
 u}_\mu$ X events at Tevatron, assuming left-handed u and right-handed $\overline{
 u}$ in the neutrino beam. The result gives $\zeta^2(1-2m_{W_1}^2/m_{W_2}^2)$ < 0.0015. The limit is independent of u_R mass
- 50 AQUINO 91 limits obtained from neutron lifetime and asymmetries together with unitarity of the CKM matrix. Manifest left-right asymmetry is assumed.
- $^{51}\,\mathrm{BARBIERI}$ 89B limit holds for $m_{\nu_R} \leq 10\,$ MeV.
- 52 First JODIDIO 86 result assumes $m_{W_R} = \infty$, second is for unconstrained m_{W_R}

Z'-BOSON SEARCHES

Revised May 2012 by G. Brooijmans (Columbia University), M.-C. Chen (UC Irvine), and B.A. Dobrescu (Fermilab).

The Z' boson is a hypothetical massive, electrically-neutral and color-singlet particle of spin 1. This particle is predicted

in many extensions of the Standard Model, and has been the object of extensive phenomenological studies [1].

Z' boson couplings to quarks and leptons. The couplings of a Z' boson to the first-generation fermions are given by

$$Z'_{\mu} \left(f_u \overline{u}_L \gamma^{\mu} u_L + f_d \overline{d}_L \gamma^{\mu} d_L + g_u^R \overline{u}_R \gamma^{\mu} u_R + g_d^R \overline{d}_R \gamma^{\mu} d_R \right. \\ + \left. g_{\nu} \overline{\nu}_L \gamma^{\mu} \nu_L + g_e^I \overline{e}_L \gamma^{\mu} e_L + g_e^R \overline{e}_R \gamma^{\mu} e_R \right) , \tag{1}$$

where u,d,ν and e are the quark and lepton fields in the mass eigenstate basis, and the coefficients f_u , f_d , f_u , f_d , f_u , f_d , f_v , f_d ,

These parameters describing the Z' boson interactions with quarks and leptons are subject to some theoretical constraints. Quantum field theories that include a heavy spin-1 particle are well behaved at high energies only if that particle is a gauge boson associated with a spontaneously broken gauge symmetry. Quantum effects preserve the gauge symmetry only if the couplings of the gauge boson to fermions satisfy anomaly cancellation conditions. Furthermore, the fermion charges under the new gauge symmetry are constrained by the requirement that the quarks and leptons get masses from gauge-invariant interactions with Higgs doublets or whatever else breaks the electroweak symmetry.

The relation between the couplings displayed in Eq. (1) and the gauge charges $z_{fi}^{\!\! L}$ and $z_{fi}^{\!\! R}$ of the fermions $f=u,d,\nu,e$ involves the unitary 3×3 matrices V_f^L and V_f^R that transform the gauge eigenstate fermions f_L^i and f_R^i , respectively, into the mass eigenstates. In addition, the Z' couplings are modified if the new gauge boson in the gauge eigenstate basis (\tilde{Z}'_{μ}) has a kinetic mixing $(-\chi/2)B^{\mu\nu}\tilde{Z}'_{\mu\nu}$ with the hypercharge gauge boson B^{μ} (due to a dimension-4 or 6 operator, depending on whether the new gauge symmetry is Abelian or not), or a mass mixing $\delta M^2 \tilde{Z}^{\mu} \tilde{Z}'_{\mu}$ with the linear combination (\tilde{Z}_{μ}) of neutral bosons which has same couplings as the Standard Model Z^0 [2]. Both the kinetic and mass mixings shift the mass and couplings of the Z boson, such that the electroweak measurements impose upper limits on χ and $\delta M^2/(M_{Z'}^2-M_Z^2)$ of the order of 10^{-3} [3]. Keeping only linear terms in these two small quantities, the couplings of the mass-eigenstate Z' boson are given by

$$g_{f\,ij}^L = g_z V_{fii'}^L \, z_{f\,i'}^L \left(V_f^L\right)_{i'j}^\dagger + \frac{e}{c_{\mathrm{W}}} \Bigg(\frac{s_{\mathrm{W}} \chi M_{Z'}^2 + \delta M^2}{2s_{\mathrm{W}} \left(M_{Z'}^2 - M_Z^2\right)} \sigma_f^3 - \epsilon \, Q_f \Bigg) \quad , \label{eq:gfij}$$

$$g_{fij}^{R} = g_z V_{fii'}^{R} z_{fi'}^{R} (V_f^{R})_{i'j}^{\dagger} - \frac{e}{c_W} \epsilon Q_f ,$$
 (2)

where g_z is the new gauge coupling, Q_f is the electric charge of f, e is the electromagnetic gauge coupling, s_W and c_W are the

Table 1: Examples of generation-independent U(1)' charges for quarks and leptons. The parameter x is an arbitrary rational number. Anomaly cancellation requires certain new fermions [4].

| fermion | $U(1)_{B-xL}$ | $U(1)_{10+x\bar{5}}$ | $U(1)_{d-xu}$ | $U(1)_{q+xu}$ |

sine and cosine of the weak mixing angle, $\sigma_f^3=+1$ for $f=u,\nu$ and $\sigma_f^3=-1$ for f=d,e, and

$$\epsilon = \frac{\chi \left(M_{Z'}^2 - c_W^2 M_Z^2 \right) + s_W \delta M^2}{M_{Z'}^2 - M_Z^2} \ . \tag{3}$$

U(1) gauge groups. A simple origin of a Z' boson is a new U(1)' gauge symmetry. In that case, the matricial equalities $z_u^l = z_d^l$ and $z_\nu^l = z_e^l$ are required by the $SU(2)_W$ gauge symmetry. Given that the U(1)' interaction is not asymptotically free, the theory may be well-behaved at high energies (for example, by embedding U(1)' in a non-Abelian gauge group) only if the Z' couplings are commensurate numbers, i.e. any ratio of couplings is a rational number. Satisfying the anomaly cancellation conditions (which include an equation cubic in charges) with rational numbers is highly nontrivial, and in general new fermions charged under U(1)' are necessary.

Consider first the case where the couplings are generationindependent (the V_f matrices then disappear from Eq. (2)), so that there are five commensurate couplings: g_q^L , g_u^R , g_d^R , g_l^R , g_e^R . Four sets of charges are displayed in Table 1, each of them spanned by one free parameter, x [4]. The first set, labelled B-xL, has charges proportional to the baryon number minus x times the lepton number. These charges allow all Standard Model Yukawa couplings to a Higgs doublet which is neutral under $U(1)_{B-xL}$, so that there is no tree-level $\tilde{Z}-\tilde{Z}'$ mixing. For x=1 one recovers the $U(1)_{B-L}$ group, which is non-anomalous in the presence of one "right-handed neutrino" (a chiral fermion that is a singlet under the Standard Model gauge group) per generation. For $x \neq 1$, it is necessary to include some fermions that are vector-like (i.e. their mass terms are gauge invariant) with respect to the electroweak gauge group and chiral with respect to $U(1)_{B-xL}$. In the particular cases x=0 or $x\gg 1$ the Z' is leptophobic or quark-phobic, respectively.

The second set, $U(1)_{10+x\bar{5}}$, has charges that commute with the representations of the SU(5) grand unified group. Here x is related to the mixing angle between the two U(1) bosons encountered in the $E_6 \to SU(5) \times U(1) \times U(1)$ symmetry breaking patterns of grand unified theories [1,6]. This set leads to $\tilde{Z} - \tilde{Z}'$ mass mixing at tree level, such that for a Z' mass close to the electroweak scale, the measurements at

the Z-pole require some fine tuning between the charges and VEVs of the two Higgs doublets. Vector-like fermions charged under the electroweak gauge group and also carrying color are required (except for x=-3) to make this set anomaly free. The particular cases x=-3,1,-1/2 are usually labelled $U(1)_\chi$, $U(1)_\psi$, and $U(1)_\eta$, respectively. Under the third set, $U(1)_{d-xu}$, the weak-doublet quarks are neutral, and the ratio of u_R and d_R charges is -x. For x=1 this is the "right-handed" group $U(1)_R$. For x=0, the charges are those of the E_6 -inspired $U(1)_I$ group, which requires new quarks and leptons. Other generation-independent sets of U(1)' charges are given in [5].

Table 2: Lepton-flavor dependent charges under various U(1) gauge groups. No new fermions other than right-handed neutrinos are required.

| fermion | $B - xL_e - yL_{\mu}$ | 2+1 leptocratic |
|-----------------------------|-----------------------|-----------------|
| $q_{1_L}, q_{2_L}, q_{3_L}$ | 1/3 | 1/3 |
| u_R, c_R, t_R | 1/3 | x/3 |
| d_R, s_R, b_R | 1/3 | (2-x)/3 |
| (u_L^e, e_L) | -x | -1 - 2y |
| (u^μ_L,μ_L) | -y | -1 + y |
| $(u_L^	au,	au_L)$ | x+y-3 | -1 + y |
| e_R | -x | -(2+x)/3 - 2y |
| μ_R | -y | -(2+x)/3+y |
| $	au_R$ | x+y-3 | -(2+x)/3+y |

In the absence of new fermions charged under the Standard Model group, the most general generation-independent charge assignment is $U(1)_{q+xu}$, which is a linear combination of hypercharge and B-L. Many other anomaly-free solutions exist if generation-dependent charges are allowed. Table 2 shows such solutions that depend on two free parameters, x and y, with generation dependence only in the lepton sector, which includes one right-handed neutrino per generation. The charged-lepton masses may be generated by Yukawa couplings to a single Higgs doublet. These are forced to be flavor diagonal by the generation-dependent U(1)' charges, so that there are no tree-level flavor-changing neutral current (FCNC) processes involving electrically-charged leptons. For the "leptocratic" set, neutrino masses are induced by operators of high dimensionality that may explain their smallness [7].

If the $SU(2)_W$ -doublet quarks have generation-dependent U(1)' charges, then the mass eigenstate quarks have flavor off-diagonal couplings to the Z' boson (see Eq. (1), and note that $V_u^t \left(V_d^t\right)^{\dagger}$ is the CKM matrix). These are severely constrained by measurements of FCNC processes, which in this case are mediated at tree-level by Z' boson exchange [8]. The constraints are relaxed if the first and second generation charges are the same, although they are increasingly tightened by the measurements of B meson properties. If only the $SU(2)_W$ -singlet quarks have generation-dependent U(1)' charges, there is more

freedom in adjusting the flavor off-diagonal couplings because the $V_{n,d}^R$ matrices are not observable in the Standard Model.

The anomaly cancellation conditions for U(1)' could be relaxed only if at scales above $\sim 4\pi M_{Z'}/g_z$ there is an axion which has certain dimension-5 couplings to the gauge bosons. However, such a scenario violates unitarity unless the quantum field theory description breaks down at a scale near $M_{Z'}$ [9].

Other models. Z' bosons may also arise from larger gauge groups. These may be orthogonal to the electroweak group, as in $SU(2)_W \times U(1)_Y \times SU(2)'$, or may embed the electroweak group, as in $SU(3)_W \times U(1)$ [10]. If the larger group is spontaneously broken down to $SU(2)_W \times U(1)_Y \times U(1)'$ at a scale $v_* \gg M_{Z'}/g_z$, then the above discussion applies up to corrections of order $M_{Z'}^2/(g_zv_*)^2$. For $v_* \sim M_{Z'}/g_z$, additional gauge bosons have masses comparable to $M_{Z'}$, including at least a W' boson [10]. If the larger gauge group breaks together with the electroweak symmetry directly to the electromagnetic $U(1)_{\rm em}$, then the left-handed fermion charges are no longer correlated $(z_u^l \neq z_d^l, z_\nu^l \neq z_e^l)$ and a $Z'W^+W^-$ coupling is induced.

If the electroweak gauge bosons propagate in extra dimensions, then their Kaluza-Klein excitations include a series of Z' boson pairs. Each of these pairs can be associated with a different $SU(2) \times U(1)$ gauge group in four dimensions. The properties of the Kaluza-Klein particles depend strongly on the extra-dimensional theory [11]. For example, in universal extra dimensions there is a parity that forces all couplings of Eq. (1) to vanish in the case of the lightest Kaluza-Klein bosons, while allowing couplings to pairs of fermions involving a Standard Model one and a heavy vector-like fermion. There are also 4-dimensional gauge theories (e.g., little Higgs with T parity) with Z' bosons exhibiting similar properties. By contrast, in a warped extra dimension, the couplings of Eq. (1) may be sizable even when Standard Model fields propagate along the extra dimension.

Z' bosons may also be composite particles. For example, in technicolor theories [12], the techni- ρ is a spin-1 boson that may be interpreted as arising from a spontaneously broken gauge symmetry [13].

Resonances versus cascade decays. In the presence of the couplings shown in Eq. (1), the Z' boson may be produced in the s-channel at colliders, and would decay to pairs of fermions. The decay width into a pair of electrons is given by

$$\Gamma\left(Z' \to e^+ e^-\right) \simeq \left[\left(g_e^L\right)^2 + \left(g_e^R\right)^2\right] \frac{M_{Z'}}{24\pi} ,$$
 (4)

where small corrections from electroweak loops are not included. The decay width into $q\bar{q}$ is similar, except for an additional color factor of 3, QCD radiative corrections, and fermion mass corrections. Thus, one may compute the Z' branching fractions in terms of the couplings of Eq. (1). However, other decay channels, such as WW or a pair of new particles, could have large widths and need to be added to the total decay width.

As mentioned above, there are theories in which the Z' couplings are controlled by a discrete symmetry which does not allow its decay into a pair of Standard Model particles. Typically, such theories involve several new particles, which may be produced only in pairs and undergo cascade decays through Z' bosons, leading to signals involving some missing (transverse) energy. Given that the cascade decays depend on the properties of new particles other than Z', this case is not discussed further here.

LEP-II limits. The Z' contribution to the cross sections for $e^+e^- \to f\bar{f}$ proceeds through an s-channel Z' exchange (when f=e, there are also t- and u-channel exchanges). For $M_{Z'} < \sqrt{s}$, the Z' appears as an $f\bar{f}$ resonance in the radiative return process where photon emission tunes the effective center-of-mass energy to $M_{Z'}$. The agreement between the LEP-II measurements and the Standard Model predictions implies that either the Z' couplings are smaller than or of order 10^{-2} , or else $M_{Z'}$ is above 209 GeV, the maximum energy of LEP-II. In the latter case, the Z' effects may be approximated up to corrections of order $s/M_{Z'}^2$ by the contact interactions

$$\frac{g_z^2}{M_{Z'}^2 - s} \left[\bar{e} \gamma_\mu \left(z_e^L P_L + z_e^R P_R \right) e \right] \left[\bar{f} \gamma^\mu \left(z_f^L P_L + z_f^R P_R \right) f \right] , \quad (5)$$

where $P_{L,R}$ are chirality projection operators, and the relation between Z' couplings and charges (see Eq. (2) in the limit where the mass and kinetic mixings are neglected) was used assuming generation-independent charges. The four LEP collaborations have set limits on the coefficients of such operators for all possible chiral structures and for various combinations of fermions [14]. Thus, one may derive bounds on $(M_{Z'}/g_z)|z_e^lz_f^l|^{-1/2}$ and the analogous combinations of LR, RL and RR charges, which are typically on the order of a few TeV. LEP-II limits were derived in Ref. [4] on the four sets of charges shown in Table 1.

Somewhat stronger bounds could be set on $M_{Z'}/g_z$ for specific sets of Z' couplings if the effects of several operators from Eq. (5) are combined. Dedicated analyses by the LEP collaborations have set limits on Z' bosons for particular values of the gauge coupling (see section 3.5.2 of [14]).

Searches at hadron colliders. Z' bosons with couplings to quarks (see Eq. (1)) may be produced at hadron colliders in the s channel, and would show up as resonances in the invariant mass distribution of the decay products. The cross section for producing a Z' boson at the LHC which then decays to some $f\bar{f}$ final state takes the form

$$\sigma\left(pp \to Z'X \to f\bar{f}X\right) \simeq \frac{\pi}{48\,s}\,\sum_{q} c_{q}^{f}\,w_{q}\!\left(s,M_{Z'}^{2}\right) \qquad (6)$$

for flavor-diagonal couplings to quarks. Here we have neglected the interference with the Standard Model contribution to $f\bar{f}$ production, which is a good approximation for a narrow Z' resonance. The coefficients

$$c_q^f = \left[\left(g_q^L \right)^2 + \left(g_q^R \right)^2 \right] B(Z' \to f\bar{f}) \tag{7}$$

contain all the dependence on the Z' couplings, while the functions w_q include all the information about parton distributions and QCD corrections [4,5]. This factorization holds exactly to NLO, and the deviations from it induced at NNLO are very small. Note that the w_u and w_d functions are substantially larger than the w_q functions for the other quarks. Eq. (6) also applies to the Tevatron, except for changing the pp initial state to $p\bar{p}$, which implies that the $w_q(s, M_{Z'}^2)$ functions are replaced by some other functions $\bar{w}_q((1.96 \text{ TeV})^2, M_{Z'}^2)$.

It is common to present results of Z' searches as limits on the cross section versus $M_{Z'}$ (e.g., see Fig. 1). An alternative is to plot exclusion curves for fixed $M_{Z'}$ values in the $c_u^f - c_d^f$ planes, allowing a simple derivation of the mass limit within any Z' model. LHC limits in the $c_u^\ell - c_d^\ell$ plane ($\ell = e$ or μ) for different $M_{Z'}$ are shown in Fig. 2 (for Tevatron limits, see [15]).

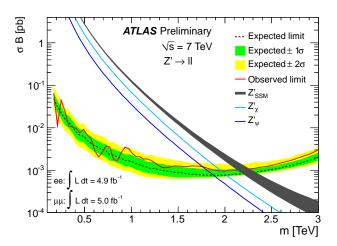

Figure 1: Upper limit on $\sigma(pp \to Z'X \to \ell^+\ell^-X)$ with $\ell = e$ or μ as a function of $M_{Z'}$ [27], assuming equal couplings for electrons and muons. The lines labelled by Z'_{ψ} and Z'_{χ} are theoretical predictions for the $U(1)_{10+x5}$ models in Table 1 with x = -3 and x = +1, respectively, for g_z fixed by an E_6 unification condition. The $Z'_{\rm SSM}$ line corresponds to Z' couplings equal to those of the Z boson.

The observation of a dilepton resonance at the LHC would determine the Z' mass and width. A measurement of the total cross section would define a band in the $c_u^\ell - c_d^\ell$ plane. Angular distributions can be used to measure several combinations of Z' parameters (an example of how angular distributions improve the Tevatron sensitivity is given in [16]). Even though the original quark direction in a pp collider is unknown, the leptonic forward-backward asymmetry $A_{\rm FB}^\ell$ can be extracted from the kinematics of the dilepton system, and is sensitive to parity-violating couplings. A fit to the Z' rapidity distribution can distinguish between the couplings to up and down quarks. These measurements, combined with off-peak observables, have the potential to differentiate among various Z' models [17]. For example, the couplings of a Z' boson with mass below 1.5 TeV

can be well determined with 100 fb⁻¹ of data at $\sqrt{s} = 14$ TeV. With this amount of data, the spin of the Z' boson may be determined for $M_{Z'} \leq 3$ TeV [18], and the expected sensitivity extends to $M_{Z'} \sim 5-6$ TeV for many models [19].

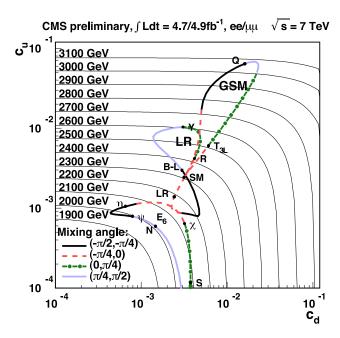

Figure 2: CMS results from Ref. 35. Limits in the $c_u^\ell - c_d^\ell$ plane ($\ell = e$ or μ) are shown as thin lines for certain $M_{Z'}$ values. For specific sets of charges (described in Ref. 5), parametrized by a mixing angle, the mass limit is given by the intersection of the thick and thin lines.

The Z' decays into e^+e^- and $\mu^+\mu^-$ are useful due to relatively good mass resolution and large acceptance. The Z' decays into $e\mu$ and $\tau^+\tau^-$, along with $t\bar{t}$, $b\bar{b}$ and jj which suffer from larger backgrounds, are also important as they probe various combinations of Z' couplings to fermions.

Z' searches at the Tevatron have been performed by the CDF and DØ Collaborations in the e^+e^- [20], $\mu^+\mu^-$ [21], $e\mu$ [22], $\tau^+\tau^-$ [23], $t\bar{t}$ [24], jj [25] and WW [26] final states. At the 7 TeV LHC, the ATLAS and CMS Collaborations have searched for Z' bosons in the e^+e^- and $\mu^+\mu^-$ channels [27,28], as well as in the $e\mu$ [29], $\tau^+\tau^-$ [30], $t\bar{t}$ [31] and jj [32] final states. The $pp \to Z'X \to W^+W^-X$ process may also be explored at the LHC, and is important for disentangling the origin of electroweak symmetry breaking. The Z' boson may be produced in this process through its couplings to either quarks [33] or W bosons [34].

Low-energy constraints. Z' boson properties are also constrained by a variety of low-energy experiments [36]. Polarized electron-nucleon scattering and atomic parity violation are sensitive to electron-quark contact interactions, which get contributions from Z' exchange that can be expressed in terms of the couplings introduced in Eq. (1) and M'_Z . Further corrections to the electron-quark contact interactions are induced in

the presence of $\tilde{Z}-\tilde{Z}'$ mixing because of the shifts in the Z couplings to quarks and leptons [2]. Deep-inelastic neutrinonucleon scattering is similarly affected by Z' bosons. Other low-energy observables are discussed in [3]. Interestingly, due to the $\tilde{Z}-\tilde{Z}'$ mixing, the global fit in Z' models often prefers a higher Higgs mass than in the Standard Model [37]. In some models, the lower limits on $M_{Z'}$ set by the low energy data are above 1 TeV [3].

Although the LHC data are most constraining for many Z' models, one should be careful in assessing the relative reach of various experiments given the freedom in Z' couplings. For example, a Z' associated with the $U(1)_{B-xL_e-yL_\mu}$ model (see Table 2) for x=0 and $y\gg 1$ couples only to leptons of the second and third generations, with implications for the muon g-2, neutrino oscillations or τ decays, and would be hard to see in processes involving first-generation fermions. Moreover, the combination of LHC searches and low-energy measurements could allow a precise determination of the Z' parameters [38].

MASS LIMITS for Z' (Heavy Neutral Vector Boson Other Than Z)

Limits for Z'_{SM}

 Z'_{SM} is assumed to have couplings with quarks and leptons which are identical to those of Z, and decays only to known fermions. The most recent preliminary results can be found in the "Z'-boson searches" review above.

- 53 AAD 11AD search for resonances decaying to e^+e^- , $\mu^+\mu^-$ in $p\,p$ collisions at $\sqrt{s}=7$
- 54 CHEUNG 01B limit is derived from bounds on contact interactions in a global electroweak analysis.
- 55 AAD 11J search for resonances decaying to $e^+\,e^-$ or $\mu^+\,\mu^-$ in pp collisions at $\sqrt{s}=7$ TeV.
- 56 AALTONEN 111 search for resonances decaying to $\mu^+\mu^-$ in $p\overline{p}$ collisions at $\sqrt{s}=1.96$
- 57 ABAZOV 11A, AALTONEN 09T, AALTONEN 07H, and ABULENCIA 06L search for resonances decaying to e^+e^- in $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV.
- Solvance Caying to e^+e^- im pp consists at $\sqrt{s}=1$ 30 feV. e^+e^- or $\mu^+\mu^-$ in pp collisions at $\sqrt{s}=7$ TeV
- ⁵⁹ The quoted limit assumes $g_{WWZ'}/g_{WWZ} = (M_W/M_{Z'})^2$. See their Fig. 4 for limits in mass-coupling plane.
- 60 AALTONEN 09AC search for new particle decaying to dijets.
- ⁶¹ AALTONEN 09v search for resonances decaying to $\mu^+\mu^-$ in $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV.
- 62 ERLER 09 give 95% CL limit on the Z-Z' mixing $-0.0026 < \theta < 0.0006$.
- 63 ABDALLAH 06C use data $\sqrt{s}=130$ –207 GeV.
- ⁶⁴ ABULENCIA 05A search for resonances decaying to electron or muon pairs in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV.
- 65 ACOSTA 05R search for resonances decaying to tau lepton pairs in $\overline{\rho}p$ collisions at \sqrt{s} ... = 1.96 TeV.
- 66 ABBIENDI 04G give 95% CL limit on Z-Z' mixing $-0.00422 < \theta < 0.00091$. $\sqrt{s} = 91$ to 207 GeV
- 67 (BAZOV 01B search for resonances in $p\overline{p}\to e^+e^-$ at \sqrt{s} =1.8 TeV. They find σ · B($Z'\to ee$) < 0.06 pb for $M_{Z'}$ > 500 GeV.
- ⁶⁸ ABREU 00s uses LEP data at \sqrt{s} =90 to 189 GeV.
- ⁶⁹ BARATE 00I search for deviations in cross section and asymmetries in $e^+e^- \rightarrow$ fermions at \sqrt{s} =90 to 183 GeV. Assume θ =0. Bounds in the mass-mixing plane are shown in their Figure 18.
- 70 ERLER 99 give 90%CL limit on the Z-Z' mixing $-0.0041 < \theta < 0.0003$. $\rho_0{=}1$ is assumed
- 71 ABE 97s find $\sigma(Z') \times B(e^+e^-, \mu^+\mu^-) <$ 40 fb for $m_{Z'} >$ 600 GeV at $\sqrt{s} = 1.8$ TeV.
- $^{72}\,\mathrm{VILAIN}$ 94B assume $m_{\,t}=$ 150 GeV.
- 73 ALITTI 93 search for resonances in the two-jet invariant mass. The limit assumes B($Z'
 ightarrow q\overline{q}$)=0.7. See their Fig. 5 for limits in the $m_{Z'}$ -B($q\overline{q}$) plane.
- ⁷⁴ RIZZO 93 analyses CDF limit on possible two-jet resonances.
- 75 ABE 90r use data for R, $R_{\ell\ell}$, and $A_{\ell\ell}$. They fix $m_W=80.49\pm0.43\pm0.24$ GeV and $m_Z=91.13\pm0.03$ GeV.

Limits for Z_{LR}

 Z_{LR} is the extra neutral boson in left-right symmetric models. $g_L = g_R$ is assumed unless noted. Values in parentheses assume stronger constraint on the Higgs sector, usually motivated by specific left-right symmetric models (see the Note on the W'). Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino. Direct search bounds assume decays to Standard Model fermions only, unless noted.

- $^{76}_{--}$ DEL-AGUILA 10 give 95% CL limit on the Z-Z' mixing $-0.0012 < \theta < 0.0004$
- 77 ABE 97s find $\sigma(Z') \times B(e^+e^-, \mu^+\mu^-) <$ 40 fb for $m_{Z'} >$ 600 GeV at $\sqrt{s} = 1.8$ TeV.
- 78 ERLER 09 give 95% CL limit on the Z-Z' mixing $-0.0013 < \theta < 0.0006$.
- 79 ABDALLAH 06c give 95% CL limit | heta| < 0.0028. See their Fig. 14 for limit contours in the mass-mixing plane.
- 80 ABBIENDI 04G give 95% CL limit on Z-Z' mixing $-0.00098 < \theta < 0.00190$. See their Fig. 20 for the limit contour in the mass-mixing plane. $\sqrt{s} = 91$ to 207 GeV.
- 81 CHEUNG 01 B limit is derived from bounds on contact interactions in a global electroweak
- 82 ABREU 00s give 95% CL limit on Z-Z' mixing $|\theta| < 0.0018$. See their Fig. 6 for the limit contour in the mass-mixing plane. \sqrt{s} =90 to 189 GeV.
- 83 BARATE 001 search for deviations in cross section and asymmetries in $e^+e^-
 ightarrow$ fermions The sum of the various increases section and asymmetries in $e^+e^- \to \text{refmions}$ at $\sqrt{s} = 90$ to 183 GeV. Assume $\theta = 0$. Bounds in the mass-mixing plane are shown in their Figure 18.
- 84 CHAY 00 also find $-0.0003 < \theta <$ 0.0019. For g_R free, $m_{Z^{\prime}} >$ 430 GeV.
- $^{85}\,{\sf ERLER}$ 00 discuss the possibility that a discrepancy between the observed and predicted values of $Q_{W}(\mathsf{Cs})$ is due to the exchange of Z' . The data are better described in a certain class of the Z' models including Z_{LR} and Z_{χ} .
- 86 CASALBUONI 99 discuss the discrepancy between the observed and predicted values of $Q_{W}(\mathrm{Cs}).$ It is shown that the data are better described in a class of models including the Z_{LR} model.
- $87\,\text{CZAKON}$ 99 perform a simultaneous fit to charged and neutral sectors. Assumes manifest left-right symmetric model. Finds $|\theta| < 0.0042$.
- 88 ERLER 99 give 90% CL limit on the Z-Z' mixing -0.0009 < heta < 0.0017.
- 89 ERLER 99 assumes 2 Higgs doublets, transforming as 10 of SO(10), embedded in E_6 .
- 90 BARENBOIM 98 also gives 68% CL limits on the $\it Z-Z'$ mixing $-0.0005 < \theta < 0.0033$. Assumes Higgs sector of minimal left-right model.
- 91 CONRAD 98 limit is from measurements at CCFR, assuming no Z- Z^\prime mixing.
- 92 VILAIN 94 B assume $m_{\,t}\,=\,15\,0$ GeV and $heta{=}0$. See Fig. 2 for limit contours in the mass-mixing plane.
- 93 RIZZO 93 analyses CDF limit on possible two-jet resonances.
- 94 GRIFOLS 90 limit holds for $m_{\nu_R} \lesssim 1$ MeV. A specific Higgs sector is assumed. See also GRIFOLS 90D, RIZZO 91.
- 95 BARBIERI 89B limit holds for $m_{
 u_R} \le 10$ MeV. Bounds depend on assumed supernova core temperature.

Limits for Z_χ Z_χ is the extra neutral boson in SO(10) \to SU(5) \times U(1) χ . $g_\chi = e/\cos\theta_W$ is assumed unless otherwise stated. We list limits with the assumption $\rho=1$ but with no further constraints on the Higgs sector. Values in parentheses assume stronger constraint on the Higgs sector motivated by superstring models. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

- 177 Search for Z' decaying to dijets at \sqrt{s} =1.8 TeV. For Z' with electromagnetic strength coupling, no bound is obtained.

Indirect Constraints on Kaluza-Klein Gauge Bosons

Bounds on a Kaluza-Klein excitation of the \overline{Z} boson or photon in d=1 extra dimension. These bounds can also be interpreted as a lower bound on 1/R, the size of the extra dimension. Unless otherwise stated, bounds assume all fermions live on a single brane and all gauge fields occupy the 4+d-dimensional bulk. See also the section on "Extra Dimensions" in the "Searches" Listings in this Review.

- $^{178}\,\mathrm{MUECK}$ 02 limit is 2σ and is from global electroweak fit ignoring correlations among observables. Higgs is assumed to be confined on the brane and its mass is fixed. For scenarios of bulk Higgs, of brane-SU(2)_L, bulk-U(1)_Y, and of bulk-SU(2)_L, brane-U(1)_Y, the corresponding limits are > 4.6 TeV, > 4.3 TeV and > 3.0 TeV, respectively.
- 179 Bound is derived from limits on $e \, \nu \, q \, q'$ contact interaction, using data from HERA and
- the Tevatron. 180 Bound holds only if first two generations of quarks lives on separate branes. If quark mixing is not complex, then bound lowers to 400 TeV from Δm_K . $^{181}\,\mathrm{See}$ Figs. 1 and 2 of DELGADO 00 for several model variations. Special boundary con-

ditions can be found which permit KK states down to 950 GeV and that agree with the

measurement of $Q_W({\rm Cs})$. Quoted bound assumes all Higgs bosons confined to brane; placing one Higgs doublet in the bulk lowers bound to 2.3 TeV. 182 Bound is derived from global electroweak analysis assuming the Higgs field is trapped on the matter brane. If the Higgs propagates in the bulk, the bound increases to 3.8 TeV. 183 Bound is derived from global electroweak analysis but considering only presence of the KK W bosons.

184 Global electroweak analysis used to obtain bound independent of position of Higgs on brane or in bulk

185 Bounds from effect of KK states on G_F , α , M_W , and M_Z . Hard cutoff at string scale determined using gauge coupling unification. Limits for d=2,3,4 rise to 3.5, 5.7, and 7.8

¹⁸⁶Bound obtained for Higgs confined to the matter brane with m_H =500 GeV. For Higgs in the bulk, the bound increases to 3.5 TeV.

LEPTOQUARKS

Updated May 2012 by S. Rolli (US Department of Energy) and M. Tanabashi (Nagoya Univ.).

Leptoquarks are hypothetical particles carrying both baryon number (B) and lepton number (L). The possible quantum numbers of leptoquark states can be restricted by assuming that their direct interactions with the ordinary SM fermions are dimensionless and invariant under the standard model (SM) gauge group. Table 1 shows the list of all possible quantum numbers with this assumption [1]. The columns of $SU(3)_C$, $SU(2)_W$, and $U(1)_Y$ in Table 1 indicate the QCD representation, the weak isospin representation, and the weak hypercharge, respectively. The spin of a leptoquark state is taken to be 1 (vector leptoquark) or 0 (scalar leptoquark).

Table 1: Possible leptoquarks and their quantum numbers.

| Spin | 3B + L | $SU(3)_c$ | $SU(2)_W$ | $U(1)_Y$ | Allowed coupling |
|------|--------|-----------|-----------|----------|-----------------------------------------------------------------|
| 0 | -2 | $\bar{3}$ | 1 | 1/3 | $\bar{q}_L^c \ell_L \text{ or } \bar{u}_R^c e_R$ |
| 0 | -2 | $\bar{3}$ | 1 | 4/3 | $ar{d}_R^c e_R$ |
| 0 | -2 | $\bar{3}$ | 3 | 1/3 | $ar{q}^c_L \ell_L$ |
| 1 | -2 | $\bar{3}$ | 2 | 5/6 | $\bar{q}_L^c \gamma^\mu e_R$ or $\bar{d}_R^c \gamma^\mu \ell_L$ |
| 1 | -2 | $\bar{3}$ | 2 | -1/6 | $\bar{u}_R^c \gamma^\mu \ell_L$ |
| 0 | 0 | 3 | 2 | 7/6 | $\bar{q}_L e_R$ or $\bar{u}_R \ell_L$ |
| 0 | 0 | 3 | 2 | 1/6 | $ar{d}_R\ell_L$ |
| 1 | 0 | 3 | 1 | 2/3 | $\bar{q}_L \gamma^\mu \ell_L$ or $\bar{d}_R \gamma^\mu e_R$ |
| 1 | 0 | 3 | 1 | 5/3 | $\bar{u}_R \gamma^\mu e_R$ |
| 1 | 0 | 3 | 3 | 2/3 | $ar{q}_L \gamma^\mu \ell_L$ |

If we do not require leptoquark states to couple directly with SM fermions, different assignments of quantum numbers become possible [2,3].

Leptoquark states are expected to exist in various extensions of SM. The Pati-Salam model [4] is an example predicting the existence of a leptoquark state. Vector leptoquark states also exist in grand unification theories based on SU(5) [5], SO(10) [6], which includes Pati-Salam color SU(4), and larger gauge groups. Scalar quarks in supersymmetric models with R-parity violation may also have leptoquark-type Yukawa couplings. The bounds on the leptoquark states can therefore be applied to constrain R-parity-violating supersymmetric models. Scalar leptoquarks are expected to exist at TeV scale in extended technicolor models [7,8] where leptoquark states appear as the bound states of techni-fermions. Compositeness of quarks

and leptons also provides examples of models which may have light leptoquark states [9].

Bounds on leptoquark states are obtained both directly and indirectly. Direct limits are from their production cross sections at colliders, while indirect limits are calculated from the bounds on the leptoquark-induced four-fermion interactions, which are obtained from low-energy experiments, or from collider experiments below threshold.

If a leptoquark couples to fermions belonging to more than a single generation in the mass eigenbasis of the SM fermions, it can induce four-fermion interactions causing flavor-changing neutral currents and lepton-family-number violations. The quantum number assignment of Table 1 allows several leptoquark states to couple to both left- and right-handed quarks simultaneously. Such leptoquark states are called non-chiral and may cause four-fermion interactions affecting the $(\pi \to e\nu)/(\pi \to \mu\nu)$ ratio [10]. Non-chiral scalar leptoquarks also contribute to the muon anomalous magnetic moment [11,12]. Since indirect limits provide more stringent constraints on these types of leptoquarks, it is often assumed that a leptoquark state couples only to a single generation in a chiral interaction, for which indirect limits become much weaker. Additionally, this assumption gives strong constraints on concrete models of leptoquarks.

Leptoquark states which couple only to left- or righthanded quarks are called chiral leptoquarks. Leptoquark states which couple only to the first (second, third) generation are referred as the first- (second-, third-) generation leptoquarks. Refs. [13,14] give extensive lists of the bounds on the leptoquark-induced four-fermion interactions. For the isoscalar and vector leptoquarks S_0 and V_0 , for example, which couple with the first- (second-) generation left-handed quark, and the first-generation left-handed lepton, the bounds of Ref. 13 read $\lambda^2 < 0.03 \times (M_{LO}/300 \text{ GeV})^2$ for S_0 , and $\lambda^2 < 0.02 \times (M_{\rm LQ}/300~{\rm GeV})^2$ for $V_0~(\lambda^2 < 5 \times (M_{\rm LQ}/300~{\rm GeV})^2$ for S_0 , and $\lambda^2 < 3 \times (M_{LQ}/300 \text{ GeV})^2$ for V_0) with λ being the leptoquark coupling strength. The e^+e^- experiments are sensitive to the indirect effects coming from t- and uchannel exchanges of leptoquarks in the $e^+e^- \rightarrow q\bar{q}$ process. The HERA experiments give bounds on the leptoquark-induced four-fermion interaction. For detailed bounds obtained in this way, see the Boson Particle Listings for "Indirect Limits for Leptoquarks" and its references.

Collider experiments provide direct limits on the leptoquark states through limits on the pair- and single-production cross sections. The leading-order cross sections of the parton processes

$$q + \bar{q} \rightarrow LQ + \overline{LQ}$$

 $g + g \rightarrow LQ + \overline{LQ}$
 $e + q \rightarrow LQ$ (1)

may be written as [15]

$$\begin{split} \hat{\sigma}_{\text{LO}} \left[q \bar{q} \to \text{LQ} + \overline{\text{LQ}} \right] &= \frac{2\alpha_s^2 \pi}{27 \hat{s}} \beta^3, \\ \hat{\sigma}_{\text{LO}} \left[g g \to \text{LQ} + \overline{\text{LQ}} \right] &= \frac{\alpha_s^2 \pi}{96 \hat{s}} \\ &\times \left[\beta (41 - 31 \beta^2) + (18 \beta^2 - \beta^4 - 17) \log \frac{1 + \beta}{1 - \beta} \right], \\ \hat{\sigma}_{\text{LO}} \left[e q \to \text{LQ} \right] &= \frac{\pi \lambda^2}{4} \delta (\hat{s} - M_{\text{LQ}}^2) \end{split} \tag{2}$$

for a scalar leptoquark. Here $\sqrt{\hat{s}}$ is the invariant energy of the parton subprocess, and $\beta \equiv \sqrt{1-4M_{\rm LQ}^2/\hat{s}}$. The leptoquark Yukawa coupling is given by λ . Leptoquarks are also produced singly at hadron colliders through $g+q\to LQ+\ell$ [16], which allows extending to higher masses the collider reach in the leptoquark search [17], depending on the leptoquark Yukawa coupling.

The LHC, Tevatron and LEP experiments search for pair production of the leptoquark states, which arises from the leptoquark gauge interaction. The searches are carried on in signatures including high P_T leptons, E_T jets and large missing transverse energy, due to the typical decay of the leptoquark. The gauge couplings of a scalar leptoquark are determined uniquely according to its quantum numbers in Table 1. Since all of the leptoquark states belong to color-triplet representation, the scalar leptoquark pair-production cross section at the Tevatron and LHC can be determined solely as a function of the leptoquark mass without making further assumptions. This is in contrast to the indirect or single-production limits, which give constraints in the leptoquark mass-coupling plane. For the first- and second-generation scalar leptoquark states with decaying branching fraction $\beta = B(eq) = 1$ and $\beta = B(\mu q) = 1$, the CDF and DØ experiments obtain the lower bounds on the leptoquark mass > 236 GeV (first generation, CDF) [18], > 299 GeV (first generation, DØ) [19], > 226 GeV (second generation, CDF) [20], and > 316 GeV (second generation, DØ) [21] at 95% CL. Third generation leptoquark mass bounds come from the DØ experiment [22] which sets a limit at 247 GeV for a charge -1/3 third generation scalar leptoquark, at 95% C.L.

Recent results from the LHC proton-proton collider, running at a center of mass energy of 7 TeV, extend previous Tevatron mass limits for scalar leptoquarks to > 384 GeV (first generation, CMS, $\beta=1$) [23] and > 339 GeV(first generation, CMS, $\beta=0.5$) [24]; > 660 GeV (first generation, ATLAS, $\beta=1$) and > 607 GeV (first generation, ATLAS, $\beta=1$) and > 523 GeV (second generation, CMS, $\beta=1$) [26] and > 523 GeV (second generation, CMS, $\beta=0.5$) [26] and; > 685 GeV (second generation, ATLAS, $\beta=1$) and > 594 GeV (second generation, ATLAS, $\beta=0.5$) [27]. All limits at 95% C.L. Finally a new measurement performed by the CMS experiment [28] extends the mass limit to 350 GeV for a charge -1/3 third generation scalar leptoquark, at 95% C.L.

The magnetic-dipole-type and the electric-quadrupole-type interactions of a vector leptoquark are not determined even if we fix its gauge quantum numbers as listed in the Table [29]. The production of vector leptoquarks depends in general on additional assumptions that the leptoquark couplings and their pair-production cross sections are enhanced relative to the scalar leptoquark contributions. At the Tevatron for instance, since the acceptance for vector and scalar leptoquark detection is similar, limits on the vector leptoquark mass will be more stringent (see for example [35,19]). The leptoquark pair-production cross sections in e^+e^- collisions depend on the leptoquark $SU(2)\times U(1)$ quantum numbers and Yukawa coupling with electron [30]. The OPAL experiment sets mass bounds on various leptoquark states from the pair-production cross sections [31]. For a second-generation weak-isosinglet weak-hypercharge -4/3scalar-leptoquark state, for example, the OPAL pair-production bound is $M_{\rm LO} > 100~{\rm Ge/c^2V}$ at 95% C.L. The LEP experiments also searched for the single production of the leptoquark states from the process $e\gamma \to LQ + q$.

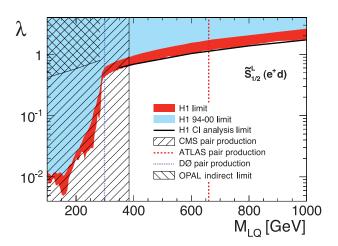

The most stringent searches for the leptoquark single production are performed by the HERA experiments. Since the leptoquark single-production cross section depends on its Yukawa coupling, the leptoquark mass limits from HERA are usually displayed in the mass-coupling plane. For leptoquark Yukawa coupling $\lambda=0.1$, the ZEUS bounds on the first-generation leptoquarks range from 248 to 290 GeV, depending on the leptoquark species [32]. Recently the H1 Collaboration released a comprehensive summary of searches for first generation leptoquarks using the full data sample collected in ep collisions at HERA (446 pb⁻¹). No evidence of production of leptoquarks is observed in final states with a large transverse momentum electron or large missing transverse momentum. For a coupling strength $\lambda=0.3$, first generation leptoquarks with masses up to 800 GeV are excluded at 95% C.L. [34]

Fig. 1 summarizes ATLAS, CMS, DØ, LEP, and H1 limits on two typical first-generation scalar-leptoquark states in the mass-coupling plane [34].

The search for LQ will be continued with more LHC data. Early feasability studies by the LHC experiments ATLAS [36] and CMS [37] indicate that clear signals can be established for masses up to about M(LQ) 1.3 to 1.4 TeV for first- and second-generation scalar LQ, with a likely final reach 1.5 TeV, for collisions at 14 TeV in the center of mass.

- 187 AAD 12H search for scalar leptoquarks using eejj and $e\nu jj$ events in pp collisions at $E_{\rm CM}=7$ TeV. The limit above assumes B(e q)=1. For B(e q)=0.5, the limit becomes 100 GeV.
- 188 AAD 11D search for scalar leptoquarks using $\mu\mu jj$ and $\mu\nu jj$ events in pp collisions at $E_{\rm CM}=7$ TeV. The limit above assumes B(μq) = 1. For B(μq) = 0.5, the limit becomes 362 GeV.
- 189 ABAZOV 10L search for pair productions of scalar leptoquark state decaying to νb in $p\overline{p}$ collisions at $E_{\rm CM}=1.96$ TeV. The limit above assumes ${\rm B}(\nu b)=1$.
- 190 AAD 11D search for scalar leptoquarks using eejj and $e\nu jj$ events in pp collisions at $E_{\rm CM}=7$ TeV. The limit above assumes ${\sf B}(eq)=1$. For ${\sf B}(eq)=0.5$, the limit becomes 319 GeV.
- 1913ABAZOV 11v search for scalar leptoquarks using $e\nu jj$ events in $p\overline{p}$ collisions at $E_{\rm cm}=1.96$ TeV. The limit above assumes ${\rm B}(eq)=0.5$.
- 192 CHATRCHYAN 11N search for scalar leptoquarks using $e\nu jj$ events in pp collisions at $E_{\rm CM}=7$ TeV. The limit above assumes B(eq)=0.5.
- 193 KHACHATRYAN 11 D search for scalar leptoquarks using eejj events in pp collisions at $E_{\rm cm}=7$ TeV. The limit above assumes B(eq)=1.
- 194 KHACHATRYAN 11E search for scalar leptoquarks using $\mu\mu jj$ events in pp collisions at $E_{cm}=$ 7 TeV. The limit above assumes $B(\mu q)=1$.
- 195 ABAZOV 09 search for scalar leptoquarks using $\mu\mu jj$ and $\mu\nu jj$ events in $p\overline{p}$ collisions at $E_{\rm CM}=1.96$ TeV. The limit above assumes ${\rm B}(\mu q)=1$. For ${\rm B}(\mu q)=0.5$, the limit becomes 270 GeV.
- becomes 270 GeV. 196 ABAZOV 09AF search for scalar leptoquarks using eejj and $e\nu jj$ events in $p\overline{p}$ collisions at $E_{cm}=1.96$ TeV. The limit above assumes B(eq)=1. For B(eq)=0.5 the bound becomes 284 GeV. 197 AALTONEN 08P search for vector leptoquarks using $\tau^+\tau^-b\overline{b}$ events in $p\overline{p}$ collisions
- at $E_{\rm CM}=1.96$ TeV. Assuming Yang-Mills (minimal) couplings, the mass limit is >317 GeV (251 GeV) at 95% CL for B(τb) = 1.
- 198 Search for pair production of scalar leptoquark state decaying to τb in $p\overline{p}$ collisions at $E_{\rm cm} = 1.96$ TeV. The limit above assumes $B(\tau b) = 1.06$
- 199 Search for scalar leptoquarks using $\nu\nu jj$ events in $\overline{p}p$ collisions at $E_{\rm cm}=1.96$ TeV. The limit above assumes $B(\nu q) = 1$.
- 200 ABAZOV 07; search for pair productions of scalar leptoquark state decaying to νb in $p\overline{p}$ collisions at $E_{\rm cm}=1.96$ TeV. The limit above assumes ${\rm B}(\nu b)=1$.
- 201 ABAZOV 06A search for scalar leptoquarks using $\mu\mu jj$ events in $p\overline{p}$ collisions at $E_{\rm CM}=1.8$ TeV and 1.96 TeV. The limit above assumes $B(\mu q)=1$. For $B(\mu q)=0.5$, the limit becomes 204 GeV. 202 ABAZOV 06L search for scalar leptoquarks using $\nu\nu jj$ events in $p\overline{p}$ collisions at $E_{\rm cm}=$
- 1.8 TeV and at 1.96 TeV. The limit above assumes $\tilde{\mathsf{B}}(\nu\,q)=1$.
- 1.8 FeV and at 1.90 FeV. The lithit above assumes $B(\nu q) = 1$. 203 ABULENCIA 06T search for scalar leptoquarks using $\mu\mu jj$, $\mu\nu jj$, and $\nu\nu jj$ events in $\rho \overline{\rho}$ collisions at $E_{\rm cm}=1.96$ TeV. The quoted limit assumes $B(\mu q)=1$. For $B(\mu q)=0.5$ or 0.1, the bound becomes 208 GeV or 143 GeV, respectively. See their Fig. 4 for the exclusion limit as a function of $B(\mu q)$.
- 204 ABAZOV 05H search for scalar leptoquarks using eejj and $e \nu j j$ events in $\overline{p} p$ collisions at $E_{\rm CM}=1.8$ TeV and 1.96 TeV. The limit above assumes B(e q) =1. For B(e q) =0.5 the bound becomes 234 GeV.
- 205 ACOSTA 05P search for scalar leptoquarks using eejj, $e\nu jj$ events in $\overline{p}p$ collisions at $E_{\rm CM}=1.96{\rm TeV}$. The limit above assumes ${\rm B}(eq)=1$. For ${\rm B}(eq)=0.5$ and 0.1, the bound becomes 205 GeV and 145 GeV, respectively.
- 206 ABBIENDI 03R search for scalar/vector leptoquarks in e^+e^- collisions at $\sqrt{s}=189$ –209 GeV. The quoted limits are for charge -4/3 isospin 0 scalar-leptoquark with $\mathsf{B}(\ell q)=1$. ee their table 12 for other cases.
- 207 ABAZOV 02 search for scalar leptoquarks using $\nu\nu jj$ events in $\overline{p}p$ collisions at $E_{\rm CM}=1.8$ TeV. The bound holds for all leptoquark generations. Vector leptoquarks are likewise
- constrained to lie above 200 GeV. 208 ABAZOV 01D search for scalar leptoquarks using $e\nu jj$, eejj, and $\nu\nu jj$ events in $p\overline{p}$ collisions at $E_{\rm cm}=1.8$ TeV. The limit above assumes B(eq)=1. For B(eq)=0.5 and 0, the bound becomes 204 and 79 GeV, respectively. Bounds for vector leptoquarks are also
- given. Supersedes ABBOTT 98E. 209 ABBIENDI 00M search for scalar /vector leptoquarks in e^+e^- collisions at \sqrt{s} =183 GeV. The quoted limits are for charge -4/3 isospin 0 scalar-leptoquarks with B(ℓq)=1. See their Table 8 and Figs. 6–9 for other cases.
- ²¹⁰ABBOTT 00c search for scalar leptoquarks using $\mu\mu jj$, $\mu\nu jj$, and $\nu\nu jj$ events in $p\overline{p}$ collisions at $E_{\rm cm} = 1.8$ TeV. The limit above assumes $B(\mu q) = 1$. For $B(\mu q) = 0.5$ and 0,

- the bound becomes 180 and 79 GeV respectively. Bounds for vector leptoquarks are also
- given. 211 AFFOLDER 00k search for scalar leptoquark using $\nu\nu cc$ events in $\rho \overline{\rho}$ collisions at $E_{\rm cm} = 1.8$ TeV. The quoted limit assumes B(νc)=1. Bounds for vector leptoquarks are also given.
- 212 AFFOLDER 00K search for scalar leptoquark using $\nu\nu bb$ events in $p\overline{p}$ collisions at $E_{\rm Cm} = 1.8$ TeV. The quoted limit assumes B(νb)=1. Bounds for vector leptoquarks are also given.
- 213 ABBOTT 991 search for leptoquarks using $\mu\nu jj$ events in $p\overline{p}$ collisions at $E_{\rm cm}=1.8{\rm TeV}$. The quoted limit is for a scalar leptoquark with ${\rm B}(\mu q)={\rm B}(\nu q)=0.5$. Limits on vector leptoquarks range from 240 to 290 GeV.
- 214 ABBOTT 98E search for scalar leptoquarks using $e\nu jj$, eejj, and $\nu\nu jj$ events in $p\overline{p}$ collisions at $E_{\rm cm}=1.8$ TeV. The limit above assumes ${\rm B}(eq)=1$. For ${\rm B}(eq)=0.5$ and 0, the bound becomes 204 and 79 GeV, respectively.
- 215 ABBOTT 98) search for charge -1/3 third generation scalar and vector leptoquarks in $p\overline{p}$ collisions at $E_{\rm cm}=1.8$ TeV. The quoted limit is for scalar leptoquark with B(νb)=1.
- 216 ABE 98s search for scalar leptoquarks using $\mu\mu jj$ events in $p\overline{p}$ collisions at $E_{\rm CM}=1.8\,{\rm TeV}$. The limit is for B(μq)= 1. For B(μq)=B(νq)=0.5, the limit is > 160 GeV. 217 GROSS-PILCHER 98 is the combined limit of the CDF and DØ Collaborations as determined.
- mined by a joint CDF/DØ working group and reported in this FNAL Technical Memo. Original data published in ABE 97x and ABBOTT 98E. ²¹⁸ABE 97F search for third generation scalar and vector leptoquarks in $p\overline{p}$ collisions at
- $E_{\rm cm}=1.8$ TeV. The quoted limit is for scalar leptoquark with B(au b)=1. 219 ABE 97x search for scalar leptoquarks using eejj events in $p\overline{p}$ collisions at $E_{cm}=1.8$ TeV. The limit is for B(eq)=1.
- $220\,\text{Limit}$ is for charge -1/3 isospin-0 leptoquark with $B(\ell \, q)\,=\,2/3$
- $221\,\mathrm{First}$ and second generation leptoquarks are assumed to be degenerate. The limit is slightly lower for each generation.
- 222 Limits are for charge -1/3, isospin-0 scalar leptoquarks decaying to ℓ^-q or νq with any branching ratio. See paper for limits for other charge-isospin assignments of leptoquarks.
- 223 KIM 90 assume pair production of charge 2/3 scalar-leptoquark via photon exchange. The decay of the first (second) generation leptoquark is assumed to be any mixture of $d\,e^+$ and $u\,\overline{
 u}\,(s\,\mu^+$ and $c\,\overline{
 u}).$ See paper for limits for specific branching ratios.
- $^{224}\,\text{BARTEL}$ 87B limit is valid when a pair of charge 2/3 spinless leptoquarks X is produced with point coupling, and when they decay under the constraint $B(X \to c\overline{\nu}_{\mu}) + B(X \to c\overline{\nu}_{\mu})$
- 225 BEHREND 86B assumed that a charge 2/3 spinless leptoquark, χ , decays either into $s\mu^+$ or $c\overline{\nu}$: $\mathrm{B}(\chi \to s\mu^+) + \mathrm{B}(\chi \to c\overline{\nu}) = 1$.

MASS LIMITS for Leptoquarks from Single Production

95

VALUE (GeV)

>298

These limits depend on the $q\text{-}\ell\text{-leptoquark}$ coupling $g_{L\,Q}$. It is often assumed that $g_{LQ}^2/4\pi$ =1/137. Limits shown are for a scalar, weak isoscalar, charge -1/3 leptoguark.

- 93 ZEUS First generation $^{226}\,\mathrm{CHEKA\,NOV}$ 03B limit is for a scalar, weak isoscalar, charge -1/3 leptoquark coupled with e_R . See their Figs. 11–12 and Table 5 for limits on states with different quantum numbers.
- 227 Limit from single production in Z decay. The limit is for a leptoquark coupling of electromagnetic strength and assumes $\mathrm{B}(\ell q)=2/3$. The limit is 77 GeV if first and second leptoquarks are degenerate.
- $228\,\mathrm{AARON}\ 11\mathrm{A}$ search for various leptoquarks with lepton-flavor violating couplings. See their Figs. 2–3 and Tables 1–4 for detailed limits.
- The quoted limit is for a scalar, weak isoscalar, charge -1/3 leptoquark coupled with e_R . See their Figs. 3-5 for limits on states with different quantum numbers.
- 230 ABAZOV 07E search for leptoquark single production through qg fusion process in $p\overline{p}$ collisions. See their Fig. 4 for exclusion plot in mass-coupling plane.
- 231 AKTAS 05B limit is for a scalar, weak isoscalar, charge -1/3 leptoquark coupled with e_R . See their Fig. 3 for limits on states with different quantum numbers.
- 232 CHEKANOV 05 search for various leptoquarks with lepton-flavor violating couplings. See their Figs.6–10 and Tables 1–8 for detailed limits.
- 233 For limits on states with different quantum numbers and the limits in the mass-coupling plane, see their Fig. 4 and Fig. 5.
- $^{234}\textsc{CHEKANOV}$ 02 search for various leptoquarks with lepton-flavor violating couplings. See their Figs. 6–7 and Tables 5–6 for detailed limits
- 235 For limits on states with different quantum numbers and the limits in the mass-coupling plane, see their Fig. 3.
- 236 See their Fig. 14 for limits in the mass-coupling plane.
- 237 BREITWEG 00E search for $^{F=0}$ leptoquarks in ^{e+}p collisions. For limits in masscoupling plane, see their Fig. 11.
- 238 ABREU 996 limit obtained from process $e\gamma \to LQ+q$. For limits on vector and scalar states with different quantum numbers and the limits in the coupling-mass plane, see their Fig. 4 and Table 2

- $^{239}\mbox{For limits on states}$ with different quantum numbers and the limits in the mass-coupling plane, see their Fig. 13 and Fig. 14. ADLOFF 99 also search for leptoquarks with lepton-flavor violating couplings. ADLOFF 99 supersedes AID 96B.
- 240 DERRICK 97 search for various leptoquarks with lepton-flavor violating couplings. See
- their Figs. 5–8 and Table 1 for detailed limits.

 241 DERRICK 93 search for single leptoquark production in *ep* collisions with the decay *eq* and νq . The limit is for leptoquark coupling of electromagnetic strength and assumes $B(e\,q)=B(\nu\,q)=1/2$. The limit for $B(e\,q)=1$ is 176 GeV. For limits on states with different quantum numbers, see their Table 3.

- ²⁴²AARON 11C limit is for weak isotriplet spin-0 leptoquark at strong coupling $\lambda=\sqrt{4\pi}$. For the limits of leptoquarks with different quantum numbers, see their Table 3. Limits are derived from bounds of eq contact intereractions.
- ²⁴³DORSNER 11 give bounds on scalar, weak singlet, charge 4/3 leptoquark from K, B, audecays, meson mixings, LFV, g-2 and $Z \rightarrow b\overline{b}$.
- 244 AKTAS 07A search for lepton-flavor violation in ep collision. See their Tables 4–7 for limits on lepton-flavor violating four-fermion interactions induced by various leptoquarks.
- 245 SCHAEL 07A limit is for the weak-isoscalar spin-0 left-handed leptoquark with the coupling of electromagnetic strength. For the limits of leptoquarks with different quantum numbers, see their Table 35.
- 246 SMIRNOV 07 obtains mass limits for the vector and scalar chiral leptoquark states from $\rightarrow e \mu$, $B \rightarrow e \tau$ decays.
- 247 CHEKA NOV 05 search for various leptoquarks with lepton-flavor violating couplings. See their Figs. 6–10 and Tables 1–8 for detailed limits.
- 248 ADLOFF 03 limit is for the weak isotriplet spin-0 leptoquark at strong coupling $\lambda = \sqrt{4\pi}$. For the limits of leptoquarks with different quantum numbers, see their Table 3. Limits are derived from bounds on $e^\pm q$ contact interactions. 249 The bound is derived from B($B^0 \to e^\pm \mu^\mp$) < 1.7 × 10⁻⁷.
- ²⁵⁰ CHEKA NOV 02 search for lepton-flavor violation in *ep* collisions. See their Tables 1–4 for limits on lepton-flavor violating and four-fermion interactions induced by various eptoquarks
- 251 CHEUNG 018 quoted limit is for a scalar, weak isoscalar, charge -1/3 leptoquark with a coupling of electromagnetic strength. The limit is derived from bounds on contact interactions in a global electroweak analysis. For the limits of leptoquarks with different quantum numbers, see Table 5.
- $^{252}\mathsf{ACCIARRI}$ 00P limit is for the weak isoscalar spin-0 leptoquark with the coupling of electromagnetic strength. For the limits of leptoquarks with different quantum numbers, see their Table 4.
- 253 ADLOFF 00 limit is for the weak isotriplet spin-0 leptoquark at strong coupling, $\lambda = \sqrt{4\pi}$. For the limits of leptoquarks with different quantum numbers, see their Table 2. ADLOFF 00 limits are from the Q^2 spectrum measurement of $e^+ p \rightarrow e^+ X$.
- 254 BARATE 001 search for deviations in cross section and jet-charge asymmetry in $e^+\,e^ \overline{q}q$ due to *t*-channel exchange of a leptoquark at \sqrt{s} =130 to 183 GeV. Limits for other scalar and vector leptoquarks are also given in their Table 22.
- ²⁵⁵ BARGER 00 explain the deviation of atomic parity violation in cesium atoms from prediction is explained by scalar leptoquark exchange.
- 256 GABRIELLI 00 calculate various process with lepton flavor violation in leptoquark models.
- 257 ZARNECKI 00 limit is derived from data of HERA, LEP, and Tevatron and from various low-energy data including atomic parity violation. Leptoquark coupling with electromagnetic strength is assumed.
- ²⁵⁸ABBIENDI 99 limits are from $e^+e^- \rightarrow q\overline{q}$ cross section at 130–136, 161–172, 183 GeV. See their Fig. 8 and Fig. 9 for limits in mass-coupling plane.

- 259 ABE 98v quoted limit is from B($B_S \to e^{\pm} \mu^{\mp}$)< 8.2 imes 10 $^{-6}$. ABE 98v also obtain a similar limit on $\it M_{LQ}$ > 20.4 TeV from B($\it B_d$ ightarrow $e^{\pm}\,\mu^{\mp}$)< 4.5 imes 10 $^{-6}$ Both bounds assume the non-canonical association of the b quark with electrons or muons
- 260 ACCIARRI 98J limit is from $e^+e^-\to q\overline{q}$ cross section at $\sqrt{s}=130$ –172 GeV which can be affected by the t- and u-channel exchanges of leptoquarks. See their Fig. 4 and Fig. 5 for limits in the mass-coupling plane.
- 261 ACKERSTAFF 98V limits are from $e^+\,e^-
 ightarrow$ $q\,\overline{q}$ and $e^+\,e^- o b\,\overline{b}$ cross sections at \sqrt{s} = 130–172 GeV, which can be affected by the t- and u-channel exchanges of leptoquarks. See their Fig. 21 and Fig. 22 for limits of leptoquarks in mass-coupling plane.
- 262 DEANDREA 97 limit is for \bar{R}_2 leptoquark obtained from atomic parity violation (APV). The coupling of leptoquark is assumed to be electromagnetic strength. See Table 2 for limits of the four-fermion interactions induced by various scalar leptoquark exchange. DEANDREA 97 combines APV limit and limits from Tevatron and HERA. See Fig. 1–4 for combined limits of leptoquark in mass-coupling plane
- 263 DERRICK 97 search for lepton-flavor violation in *ep* collision. See their Tables 2–5 for limits on lepton-flavor violating four-fermion interactions induced by various leptoquarks.
- 264 GROSSMAN 97 estimate the upper bounds on the branching fraction $B \to \tau^+\tau^-({\rm X})$ from the absence of the B decay with large missing energy. These bounds can be used to constrain leptoquark induced four-fermion interactions.
- 265 JADACH 97 limit is from $e^+e^- \to q\overline{q}$ cross section at \sqrt{s} =172.3 GeV which can be affected by the t- and u-channel exchanges of leptoquarks. See their Fig. 1 for limits on vector leptoquarks in mass-coupling plane.
- 266 KUZNETSOV 95B use π , K, B, au decays and μe conversion and give a list of bounds on the leptoquark mass and the fermion mixing matrix in the Pati-Salam model. The quoted limit is from $K_L \to \mu e$ decay assuming zero mixing.
- 267 MIZUKOSHI 95 calculate the one-loop radiative correction to the $\it Z$ -physics parameters in various scalar leptoquark models. See their Fig. 4 for the exclusion plot of third generation leptoquark models in mass-coupling plane.
- 268 BHATTACHARYYA 94 limit is from one-loop radiative correction to the leptonic decay width of the Z. m_H =250 GeV, $\alpha_s(m_Z)$ =0.12, m_r =180 GeV, and the electroweak strength of leptoquark coupling are assumed. For leptoquark coupled to \overline{e}_L t_R , $\overline{\mu}t$, and $\overline{\tau}t$, see Fig. 2 in BHATTACHARYYA 94B erratum and Fig. 3.
- 269 DAVIDSON 94 gives an extensive list of the bounds on leptoquark-induced four-fermion interactions from π , K, D, B, μ , τ decays and meson mixings, etc. See Table 15 of DAVIDSON 94 for detail.
- 270 KUZNETSOV 94 gives mixing independent bound of the Pati-Salam leptoquark from the cosmological limit on $\pi^0 o \overline{
 u}
 u$
- 271 LEURER 94, LEURER 94B limits are obtained from atomic parity violation and apply to any chiral leptoquark which couples to the first generation with electromagnetic strength. For a nonchiral leptoquark, universality in $\pi_{\ell 2}$ decay provides a much more stringent bound.
- 272 MAHANTA 94 gives bounds of P- and T-violating scalar-leptoquark couplings from atomic and molecular experiments.
- $273\,{\rm From}~(\pi\to~e\nu)/(\pi\to~\mu\nu)$ ratio. SHANKER 82 assumes the leptoquark induced four-fermion coupling 4g^2/M² (\overline{v}_{eL} u_R) (\overline{d}_L e_R) with g=0.004 for spin-0 leptoquark and g^2/M^2 $(\overline{\nu}_{eL} \ \gamma_{\mu} u_L) \ (\overline{d}_R \ \gamma^{\mu} e_R)$ with $g \simeq 0.6$ for spin-1 leptoquark.

- $^{279}\mathrm{CHATRCHYAN}$ 11Y search for new resonance decaying to dijets in pp collisions at
- 280 AALTONEN 10L search for massive color octet non-chiral vector particle decaying into $t\overline{t}$ pair with mass in the range 400 GeV < M < 800 GeV. See their Fig. 6 for limit in the mass-coupling plane.
- 281 KHACHATRYAN 10 search for new resonance decaying to dijets in pp collisions at
- 282 AALTONEN 09AC search for new narrow resonance decaying to dijets.
- ²⁸³ CHOUDHURY 07 limit is from the $t\overline{t}$ production cross section measured at CDF.
- 284 DONCHESKI 98 compare α_S derived from low-energy data and that from $\Gamma(Z\to {\rm hadrons})/\Gamma(Z\to {\rm leptons})$.
- 285 ABE 97G search for new particle decaying to dijets.
- 286 ABE 95N assume axigluons decaying to quarks in the Standard Model only.
- ²⁸⁷ABE 93G assume $\Gamma(g_A)=N\alpha_S m_{g_A}/6$ with N=10.
- $^{288}\text{CUYPERS}$ 91 compare α_{S} measured in \varUpsilon decay and that from R at PEP/PETRA
- energies. 289 ABE 90H assumes $\Gamma(g_A)=N\alpha_S m_{g_A}/6$ with N=5 ($\Gamma(g_A)=0.09m_{g_A}$). For N=10, the excluded region is reduced to 120–150 GeV.
- 290 ROBINETT 89 result demands partial-wave unitarity of J=0 $t\overline{t} \rightarrow t\overline{t}$ scattering amplitude and derives a limit $m_{g_A} > 0.5 \; m_{\;t}$. Assumes $m_{\;t} > 56$ GeV.
- ²⁹¹ ALBAJAR 88B result is from the nonobservation of a peak in two-jet invariant mass distribution. $\Gamma(g_A) < 0.4~m_{g_A}$ assumed. See also BAGGER 88.
- 292 CUYPERS 88 requires $\Gamma(\varUpsilon \to gg_A) < \Gamma(\varUpsilon \to ggg)$. A similar result is obtained by
- 293 DONCHESKI 88. Pequires $\Gamma(T \to g q \overline{q})/\Gamma(T \to g g g) < 0.25$, where the former decay proceeds via axigluon exchange. A more conservative estimate of < 0.5 leads to

X^0 (Heavy Boson) Searches in Z Decays

Searches for radiative transition of Z to a lighter spin-0 state X^0 decaying to hadrons, a lepton pair, a photon pair, or invisible particles as shown in the comments. The limits are for the product of branching ratios.

- 304 ODAKA 89 looked for a narrow or wide scalar resonance in $e^+\,e^ightarrow$ hadrons at $E_{
 m cm}$
- $_{
 m 305}$ DERRICK 86 found no deviation from the Standard Model Bhabha scattering at $E_{
 m cm} =$ 29 GeV and set limits on the possible scalar boson e^+e^- coupling. See their figure 4 for excluded region in the $\Gamma(X^0 \to e^+ e^-)$ - m_{X^0} plane. Electronic chiral invariance requires a parity doublet of X^0 , in which case the limit applies for $\Gamma(X^0 \to e^+e^-) =$
- 306 ADEVA 85 first limit is from 2γ , $\mu^+\mu^-$, hadrons assuming X^0 is a scalar. Second limit is from e^+e^- channel. $E_{\rm cm}=40$ –47 GeV. Supersedes ADEVA 84.
- 307 BERGER 85B looked for effect of spin-0 boson exchange in $e^+\,e^ightarrow\,e^+\,e^-$ and $\mu^+\,\mu^$ at $E_{
 m cm}=$ 34.7 GeV. See Fig. 5 for excluded region in the $m_{\chi^0}-\Gamma(\chi^0)$ plane.
- 308 ADEVA 84 and BEHREND 84c have $E_{
 m cm}=39.8$ –45.5 GeV. MARK-J searched 0 in $e^+e^- o$ hadrons, 2γ , $\mu^+\mu^-$, e^+e^- and CELLO in the same channels plus au pair. No narrow or broad X^0 is found in the energy range. They also searched for the effect of X^0 with $m_{X} > E_{
 m cm}$. The second limits are from Bhabha data and for spin-0 singlet. The same limits apply for $\Gamma(X^0 \to e^+e^-) = 2$ MeV if X^0 is a spin-0 doublet. The second limit of BEHREND 84c was read off from their figure 2. The original papers also list limits in other channels.

Search for X^0 Resonance in e^+e^- Collisions

The limit is for $\Gamma(X^0 \to e^+e^-) \cdot \mathsf{B}(X^0 \to f)$, where f is the specified final state. Spin 0 is assumed for X^0 .

| | ³²⁴ ABAZOV | 11ı D0 | $X^0 \rightarrow jj$ | |
| | ³²⁵ ABE | 97w CDF | $X^0 \rightarrow b \overline{b}$ | |

324 ABAZOV 111 search for X^0 production associated with W in $p\overline{p}$ collisions at $E_{\rm CM}=1.96$ TeV. The 95% CL upper limit on the cross section ranges from 2.57 to 1.28 pb for X^0 mass between 110 and 170 GeV. 325 ABE 97% search for X^0 production associated with W in $p\overline{p}$ collisions at $E_{\rm CM}=1.8$ TeV. The 95% CL upper limit on the production cross section times the branching ratio for $X^0 \to b\overline{b}$ ranges from 14 to 19 pb for X^0 mass between 70 and 120 GeV. See their Fig. 3 for upper limits of the production cross section as a function of m_{X^0} .

Heavy Particle Production in Quarkonium Decays

Limits are for branching ratios to modes shown.

|-----|---------------------------------------|---------|----------------------|--------|---------|------------------------------------------------------------------------------------------------------|
| • • | • We do not use the | followi | ng data for averages | , fits | limits, | etc. • • • |
| <1 | $.5 \times 10^{-5}$ | 90 | 326 BALEST | 95 | CLE2 | $\Upsilon(1S) \to X^0 \gamma$ |
| < 3 | $3 \times 10^{-5} - 6 \times 10^{-3}$ | | 327 BALEST | 95 | CLE2 | $m_{X^0} < 5 \text{ GeV}$ $\Upsilon(1S) \rightarrow X^0 \overline{X}^0 \gamma$, |
| <5 | 6.6×10^{-5} | 90 | 328 ANTREASYAN | 90c | CBAL | $m_{X^0}^{'} < 3.9 \text{ GeV}^{'}$ $r(1S) \rightarrow X^0 \gamma$, $m_{X^0}^{'} < 7.2 \text{ GeV}$ |
| | | | 329 ALBRECHT | 89 | ARG | χ., . |

 $^{326}\,\mathrm{BALEST}$ 95 two-body limit is for pseudoscalar $\mathrm{\textit{X}}^{\,0}$. The limit becomes $< 10^{-4}$ for m_{χ^0} < 7.7 GeV

327 BALEST 95 three-body limit is for phase-space photon energy distribution and angular distribution same as for $\mathcal{T} \to gg\gamma$.

328 ANTREASYAN 90c assume that X^0 does not decay in the detector.

329 ALBRECHT 89 give limits for $B(\mathcal{T}(1S),\mathcal{T}(2S)\to X^0\gamma)$ - $B(X^0\to \pi^+\pi^-,K^+K^-,p\overline{p})$ for $m_{X^0}<3.5$ GeV.

Axions (A^0) and Other Very Light Bosons, Searches for

AXIONS AND OTHER SIMILAR PARTICLES

Revised March 2012 by G.G. Raffelt (MPI Physics, Munich) and L.J. Rosenberg (U. of Washington).

Introduction

In this section, we list coupling-strength and mass limits for light neutral scalar or pseudoscalar bosons that couple weakly to normal matter and radiation. Such bosons may arise from a global spontaneously broken U(1) symmetry, resulting in a massless Nambu-Goldstone (NG) boson. If there is a small explicit symmetry breaking, either already in the Lagrangian or

due to quantum effects such as anomalies, the boson acquires a mass and is called a pseudo-NG boson. Typical examples are axions (A^0) [1,2], familons [3] and Majorons [4], associated, respectively, with a spontaneously broken Peccei-Quinn, family and lepton-number symmetry.

A common characteristic among these light bosons ϕ is that their coupling to Standard-Model particles is suppressed by the energy scale that characterizes the symmetry breaking, *i.e.*, the decay constant f. The interaction Lagrangian is

$$\mathcal{L} = f^{-1}J^{\mu}\partial_{\mu}\phi\,,\tag{1}$$

where J^{μ} is the Noether current of the spontaneously broken global symmetry. If f is very large, these new particles interact very weakly. Detecting them would provide a window to physics far beyond what can be probed at accelerators.

Axions remain of particular interest because the Peccei-Quinn (PQ) mechanism remains perhaps the most credible scheme to preserve CP in QCD. Moreover, the cold dark matter of the universe may well consist of axions and they are searched for in dedicated experiments with a realistic chance of discovery.

Originally it was assumed that the PQ scale f_A was related to the electroweak symmetry-breaking scale $v_{\rm weak} = (\sqrt{2}G_{\rm F})^{-1/2} = 247$ GeV. However, the associated "standard" and "variant" axions were quickly excluded—we refer to the Listings for detailed limits. Here we focus on "invisible axions" with $f_A \gg v_{\rm weak}$ as the main possibility.

Axions have a characteristic two-photon vertex, inherited from their mixing with π^0 and η . It allows for the main search strategy based on axion-photon conversion in external magnetic fields [5], an effect that also can be of astrophysical interest. While for axions the product " $A\gamma\gamma$ interaction strength × mass" is essentially fixed by the corresponding π^0 properties, one may consider more general axion-like particles (ALPs) where the two parameters are independent. Several experiments have recently explored this more general parameter space.

I. THEORY

I.1 Peccei-Quinn mechanism and axions

The QCD Lagrangian includes a CP-violating term $\mathcal{L}_{\Theta} = \bar{\Theta} (\alpha_s/8\pi) \, G^{\mu\nu a} \tilde{G}^a_{\mu\nu}$, where $-\pi \leq \bar{\Theta} \leq +\pi$ is the effective Θ parameter after diagonalizing quark masses, G is the color field strength tensor, and \tilde{G} its dual. Limits on the neutron electric dipole moment [6] imply $|\bar{\Theta}| \lesssim 10^{-10}$ even though $\bar{\Theta} = \mathcal{O}(1)$ is otherwise completely satisfactory. The spontaneously broken global Peccei-Quinn symmetry $\mathrm{U}(1)_{\mathrm{PQ}}$ was introduced to solve this "strong CP problem" [1], an axion being the pseudo-NG boson of $\mathrm{U}(1)_{\mathrm{PQ}}$ [2]. This symmetry is broken due to the axion's anomalous triangle coupling to gluons,

$$\mathcal{L} = \left(\bar{\Theta} - \frac{\phi_A}{f_A}\right) \frac{\alpha_s}{8\pi} G^{\mu\nu a} \tilde{G}^a_{\mu\nu} \,, \tag{2}$$

where ϕ_A is the axion field and f_A the axion decay constant. Color anomaly factors have been absorbed in the normalization of f_A which is defined by this Lagrangian. Thus normalized, f_A

Gauge & Higgs Boson Particle Listings Axions (A⁰) and Other Very Light Bosons

is the quantity that enters all low-energy phenomena [7]. Non-perturbative effects induce a potential for ϕ_A whose minimum is at $\phi_A = \bar{\Theta} f_A$, thereby canceling the $\bar{\Theta}$ term in the QCD Lagrangian and thus restoring CP symmetry.

The resulting axion mass is given by $m_A f_A \approx m_\pi f_\pi$ where $m_\pi = 135$ MeV and $f_\pi \approx 92$ MeV. In more detail one finds

$$m_A = \frac{z^{1/2}}{1+z} \frac{f_\pi m_\pi}{f_A} = \frac{0.60 \text{ meV}}{f_A/10^{10} \text{ GeV}},$$
 (3)

where $z = m_u/m_d$. We have used the canonical value z = 0.56 [8], although the range z = 0.35-0.60 is plausible [9].

Originally one assumed $f_A \sim v_{\rm weak}$ [1,2]. Tree-level flavor conservation fixes the axion properties in terms of a single parameter $\tan \beta$, the ratio of the vacuum expectation values of two Higgs fields that appear as a minimal ingredient. This "standard axion" is excluded after extensive searches [10]. A narrow peak structure observed in positron spectra from heavy ion collisions [11] suggested an axion-like particle of mass 1.8 MeV that decays into e^+e^- , but extensive follow-up searches were negative. "Variant axion models" were proposed which keep $f_A \sim v_{\rm weak}$ while dropping the constraint of tree-level flavor conservation [12], but these models are also excluded [13].

Axions with $f_A \gg v_{\rm weak}$ evade all current experimental limits. One generic class of models invokes "hadronic axions" where new heavy quarks carry U(1)_{PQ} charges, leaving ordinary quarks and leptons without tree-level axion couplings. The prototype is the KSVZ model [14], where in addition the heavy quarks are electrically neutral. Another generic class requires at least two Higgs doublets and ordinary quarks and leptons carry PQ charges, the prototype being the DFSZ model [15]. All of these models contain at least one electroweak singlet scalar that acquires a vacuum expectation value and thereby breaks the PQ symmetry. The KSVZ and DFSZ models are frequently used as generic examples, but other models exist where both heavy quarks and Higgs doublets carry PQ charges.

I.2 Model-dependent axion couplings

Although the generic axion interactions scale approximately with f_{π}/f_A from the corresponding π^0 couplings, there are non-negligible model-dependent factors and uncertainties. The axion's two-photon interaction plays a key role for many searches,

$$\mathcal{L}_{A\gamma\gamma} = \frac{G_{A\gamma\gamma}}{4} F_{\mu\nu} \tilde{F}^{\mu\nu} \phi_A = -G_{A\gamma\gamma} \mathbf{E} \cdot \mathbf{B} \phi_A, \qquad (4)$$

where F is the electromagnetic field-strength tensor and \tilde{F} its dual. The coupling constant is

$$G_{A\gamma\gamma} = \frac{\alpha}{2\pi f_A} \left(\frac{E}{N} - \frac{2}{3} \frac{4+z}{1+z} \right)$$

$$= \frac{\alpha}{2\pi} \left(\frac{E}{N} - \frac{2}{3} \frac{4+z}{1+z} \right) \frac{1+z}{z^{1/2}} \frac{m_A}{m_\pi f_\pi},$$
(5)

where E and N are the electromagnetic and color anomalies of the axial current associated with the axion. In grand unified models, and notably for DFSZ [15], E/N=8/3, whereas for KSVZ [14] E/N=0 if the electric charge of the new heavy

quark is taken to vanish. In general, a broad range of E/N values is possible [16]. The two-photon decay width is

$$\Gamma_{A \to \gamma \gamma} = \frac{G_{A \gamma \gamma}^2 m_A^3}{64 \, \pi} = 1.1 \times 10^{-24} \text{ s}^{-1} \left(\frac{m_A}{\text{eV}}\right)^5.$$
(6)

The second expression uses Eq. (5) with z = 0.56 and E/N = 0. Axions decay faster than the age of the universe if $m_A \gtrsim 20\,$ eV.

The interaction with fermions f has derivative form and is invariant under a shift $\phi_A \rightarrow \phi_A + \phi_0$ as behooves a NG boson,

$$\mathcal{L}_{Aff} = \frac{C_f}{2f_A} \bar{\Psi}_f \gamma^\mu \gamma_5 \Psi_f \partial_\mu \phi_A . \tag{7}$$

Here, Ψ_f is the fermion field, m_f its mass, and C_f a model-dependent coefficient. The dimensionless combination $g_{Aff} \equiv C_f m_f/f_A$ plays the role of a Yukawa coupling and $\alpha_{Aff} \equiv g_{Aff}^2/4\pi$ of a "fine-structure constant." The oftenused pseudoscalar form $\mathcal{L}_{Aff} = -\mathrm{i} \left(C_f m_f/f_A \right) \bar{\Psi}_f \gamma_5 \Psi_f \phi_A$ need not be equivalent to the appropriate derivative structure, for example when two NG bosons are attached to one fermion line as in axion emission by nucleon bremsstrahlung [17].

In the DFSZ model [15], the tree-level coupling coefficient to electrons is

$$C_e = \frac{\cos^2 \beta}{3},\tag{8}$$

where $\tan\beta$ is the ratio of two Higgs vacuum expectation values that are generic to this and similar models.

For nucleons, $C_{n,p}$ are related to axial-vector current matrix elements by generalized Goldberger-Treiman relations,

$$C_p = (C_u - \eta)\Delta u + (C_d - \eta z)\Delta d + (C_s - \eta w)\Delta s,$$

$$C_n = (C_u - \eta)\Delta d + (C_d - \eta z)\Delta u + (C_s - \eta w)\Delta s.$$
(9)

Here, $\eta = (1+z+w)^{-1}$ with $z = m_u/m_d$ and $w = m_u/m_s \ll z$ and the Δq are given by the axial vector current matrix element $\Delta q S_{\mu} = \langle p | \bar{q} \gamma_{\mu} \gamma_5 q | p \rangle$ with S_{μ} the proton spin.

Neutron beta decay and strong isospin symmetry considerations imply $\Delta u - \Delta d = F + D = 1.269 \pm 0.003$, whereas hyperon decays and flavor SU(3) symmetry imply $\Delta u + \Delta d - 2\Delta s = 3F - D = 0.586 \pm 0.031$ [19]. The strange-quark contribution is $\Delta s = -0.08 \pm 0.01_{\rm stat} \pm 0.05_{\rm syst}$ from the COMPASS experiment [18], and $\Delta s = -0.085 \pm 0.008_{\rm exp} \pm 0.013_{\rm theor} \pm 0.009_{\rm evol}$ from HERMES [19], in agreement with each other and with an early estimate of $\Delta s = -0.11 \pm 0.03$ [20]. We thus adopt $\Delta u = 0.84 \pm 0.02$, $\Delta d = -0.43 \pm 0.02$ and $\Delta s = -0.09 \pm 0.02$, very similar to what was used in the axion literature.

The uncertainty of the axion-nucleon couplings is dominated by the uncertainty $z=m_u/m_d=0.35$ –0.60 that we mentioned earlier. For hadronic axions $C_{u,d,s}=0$ so that $-0.51 < C_p < -0.36$ and $0.10 > C_n > -0.05$. Therefore it is well possible that $C_n=0$ whereas C_p does not vanish within the plausible z range. In the DFSZ model, $C_u=\frac{1}{3}\sin^2\beta$ and $C_d=\frac{1}{3}\cos^2\beta$ and C_n and C_p as functions of β and z do not vanish simultaneously.

The axion-pion interaction is given by the Lagrangian [21]

$$\mathcal{L}_{A\pi} = \frac{C_{A\pi}}{f_{\pi}f_{A}} \left(\pi^{0}\pi^{+}\partial_{\mu}\pi^{-} + \pi^{0}\pi^{-}\partial_{\mu}\pi^{+} - 2\pi^{+}\pi^{-}\partial_{\mu}\pi^{0} \right) \partial_{\mu}\phi_{A},$$
(10)

Gauge & Higgs Boson Particle Listings Axions (A^0) and Other Very Light Bosons

where $C_{A\pi} = (1-z)/[3(1+z)]$ in hadronic models. The chiral symmetry-breaking Lagrangian provides an additional term $\mathcal{L}'_{A\pi} \propto (m_{\pi}^2/f_{\pi}f_A) (\pi^0\pi^0 + 2\pi^-\pi^+) \pi^0\phi_A$. For hadronic axions it vanishes identically, in contrast to the DFSZ model (Roberto Peccei, private communication).

II. LABORATORY SEARCHES

II.1 Photon regeneration

Searching for "invisible axions" is extremely challenging. The most promising approaches rely on the axion-two-photon vertex, allowing for axion-photon conversion in external electric or magnetic fields [5]. For the Coulomb field of a charged particle, the conversion is best viewed as a scattering process, $\gamma + Ze \leftrightarrow Ze + A$, called Primakoff effect [22]. In the other extreme of a macroscopic field, usually a large-scale B-field, the momentum transfer is small, the interaction coherent over a large distance, and the conversion is best viewed as an axion-photon oscillation phenomenon in analogy to neutrino flavor oscillations [23].

Photons propagating through a transverse magnetic field, with incident \mathbf{E}_{γ} and magnet \mathbf{B} parallel, may convert into axions. For $m_A^2 L/2\omega \ll 2\pi$, where L is the length of the B field region and ω the photon energy, the resultant axion beam is coherent with the incident photon beam and the conversion probability is $\Pi \sim (1/4)(G_{A\gamma\gamma}BL)^2$. A practical realization uses a laser beam propagating down the bore of a superconducting dipole magnet (like the bending magnets in high-energy accelerators). If another magnet is in line with the first, but shielded by an optical barrier, then photons may be regenerated from the pure axion beam [24]. The overall probability $P(\gamma \to A \to \gamma) = \Pi^2$.

The first such experiment utilized two magnets of length $L=4.4~\mathrm{m}$ and $B=3.7~\mathrm{T}$ and found $G_{A\gamma\gamma}<6.7\times10^{-7}~\mathrm{GeV}^{-1}$ at 95% CL for $m_A<1~\mathrm{meV}$ [25]. More recently, several such experiments were performed (see Listings), improving the limit to $G_{A\gamma\gamma}<0.7\times10^{-7}~\mathrm{GeV}^{-1}$ at 95% CL for $m_A\lesssim0.5~\mathrm{meV}$ [26]. Some of these experiments have also reported limits for scalar bosons where the photon \mathbf{E}_{γ} must be chosen perpendicular to the magnet \mathbf{B} .

The concept of resonantly enhanced photon regeneration may open unexplored regions of coupling strength [27]. In this scheme, both the production and detection magnets are within Fabry-Perot optical cavities and actively locked in frequency. The $\gamma \to A \to \gamma$ rate is enhanced by a factor $2\mathcal{F}\mathcal{F}'/\pi^2$ relative to a single-pass experiment, where \mathcal{F} and \mathcal{F}' are the finesses of the two cavities. The resonant enhancement could be of order $10^{(10-12)}$, improving the $G_{A\gamma\gamma}$ sensitivity by $10^{(2.5-3)}$.

Another new concept involves axion absorption and emission between electromagnetic fields within a high finesse optical cavity [28]. A signal appears as resonant sidebands on the carrier. This technique could be sensitive in the mass range 10^{-6} – 10^{-4} eV and reach the KSVZ line after one year of operation.

II.2 Photon polarization

An alternative to regenerating the lost photons is to use the beam itself to detect conversion: the polarization of light propagating through a transverse B field suffers dichroism and birefrigence [29]. Dichroism: The E_{\parallel} component, but not E_{\perp} , is depleted by axion production, causing a small rotation of linearly polarized light. For $m_A^2 L/2\omega \ll 2\pi$ the effect is independent of m_A , for heavier axions it oscillates and diminishes as m_A increases, and it vanishes for $m_A > \omega$. Birefringence: This rotation occurs because there is mixing of virtual axions in the E_{\parallel} state, but not for E_{\perp} . Hence, linearly polarized light will develop elliptical polarization. Higher-order QED also induces vacuum birefringence. A search for these effects was performed on the same dipole magnets in the early experiment above [30]. The dichroic rotation gave a stronger limit than the ellipticity rotation: $G_{A\gamma\gamma} < 3.6 \times 10^{-7} \text{ GeV}^{-1}$ at 95% CL for $m_A < 5 \times 10^{-4}$ eV. The ellipticity limits are better at higher masses, as they fall off smoothly and do not terminate at m_A .

In 2006 the PVLAS collaboration reported a signature of magnetically induced vacuum dichroism that could be interpreted as the effect of a pseudoscalar with $m_A = 1$ –1.5 meV and $G_{A\gamma\gamma} = (1.6-5) \times 10^{-6}~{\rm GeV}^{-1}$ [31]. Since then, these findings are attributed to instrumental artifacts [32]. This particle interpretation is also excluded by the above photon regeneration searches that were perhaps inspired by the original PVLAS result.

II.3 Long-range forces

New bosons would mediate long-range forces, which are severely constrained by "fifth force" experiments [33]. Those looking for new mass-spin couplings provide significant constraints on pseudoscalar bosons [34]. However, they do not yet cover realistic parameters for invisible axion models because they are only sensitive for small m_A . The corresponding coupling strengths scale with $f_A^{-1} \approx m_A/m_\pi f_\pi$ and are too small to be detected. Still, these efforts provide constraints on more general low-mass bosons.

III. AXIONS FROM ASTROPHYSICAL SOURCES

III.1 Stellar energy-loss limits:

Low-mass weakly-interacting particles (neutrinos, gravitons, axions, baryonic or leptonic gauge bosons, etc.) are produced in hot astrophysical plasmas, and can thus transport energy out of stars. The coupling strength of these particles with normal matter and radiation is bounded by the constraint that stellar lifetimes or energy-loss rates not conflict with observation [35–37].

We begin this discussion with our Sun and concentrate on hadronic axions. They are produced predominantly by the Primakoff process $\gamma + Ze \rightarrow Ze + A$. Integrating over a standard solar model yields the axion luminosity [51]

$$L_A = G_{10}^2 \, 1.85 \times 10^{-3} \, L_{\odot} \,, \tag{11}$$

where $G_{10} = G_{A\gamma\gamma} \times 10^{10}$ GeV. The maximum of the spectrum is at 3.0 keV, the average at 4.2 keV, and the number flux at Earth is G_{10}^2 3.75 × 10¹¹ cm⁻² s⁻¹. The solar photon luminosity is fixed, so axion losses require enhanced nuclear energy production and thus enhanced neutrino fluxes. The all-flavor measurements by SNO together with a standard solar model imply $L_A \lesssim 0.10 L_{\odot}$, corresponding to $G_{10} \lesssim 7$ [38], mildly superseding a similar limit from helioseismology [39].

A more restrictive limit derives from globular-cluster (GC) stars that allow for detailed tests of stellar-evolution theory. The stars on the horizontal branch (HB) in the color-magnitude diagram have reached helium burning with a core-averaged energy release of about 80 erg g⁻¹ s⁻¹, compared to Primakoff axion losses of G_{10}^2 30 erg g⁻¹ s⁻¹. The accelerated consumption of helium reduces the HB lifetime by about $80/(80+30\,G_{10}^2)$. Number counts of HB stars in 15 GCs compared with the number of red giants (that are not much affected by Primakoff losses) reveal agreement with expectations within 20–40% in any one GC and overall on the 10% level [36]. Therefore, a reasonably conservative limit is

$$G_{A\gamma\gamma} \lesssim 1 \times 10^{-10} \text{ GeV}^{-1},$$
 (12)

although a detailed error budget is not available.

We translate this constraint on $G_{A\gamma\gamma}$ to $f_A > 2.3 \times 10^7~{\rm GeV}$ ($m_A < 0.3~{\rm eV}$), using z = 0.56 and E/N = 0 as in the KSVZ model, and show the excluded range in Figure 1. For the DFSZ model with E/N = 8/3, the corresponding limits are slightly less restrictive, $f_A > 0.8 \times 10^7~{\rm GeV}$ ($m_A < 0.7~{\rm eV}$). The exact high-mass end of the exclusion range has not been determined. The relevant temperature is around 10 keV and the average photon energy is therefore around 30 keV. The excluded m_A range thus certainly extends beyond the shown 100 keV.

If axions couple directly to electrons, the dominant emission processes are $\gamma + e^- \rightarrow e^- + A$ and $e^- + Ze \rightarrow Ze + e^- + A$. Moreover, bremsstrahlung is efficient in white dwarfs (WDs), where the Primakoff and Compton processes are suppressed by the large plasma frequency. The enhanced energy losses would delay helium ignition in GC stars, implying $\alpha_{Aee} \lesssim 0.5 \times 10^{-26}$ [40]. Enhanced WD cooling led to a similar limit from the WD luminosity function [41]. Based on much better data and detailed WD cooling treatment, today it appears that the WD luminosity function fits better with a new energy-loss channel that can be interpreted in terms of axion losses corresponding to $\alpha_{Aee} \sim 10^{-27}$ [42]. For pulsationally unstable WDs (ZZ Ceti stars), the period decrease \dot{P}/P is a measure of the cooling speed. A well-studied case is the star G117-B15A, where the measured P/P also implies additional cooling that can be interpreted in terms of similar axion losses [43]. moment we prefer to interpret these results as an upper limit $\alpha_{Aee} \lesssim 10^{-27}$ shown in Figure 1.

Similar constraints derive from the measured duration of the neutrino signal of the supernova SN 1987A. Numerical simulations for a variety of cases, including axions and Kaluza-Klein gravitons, reveal that the energy-loss rate of a nuclear medium

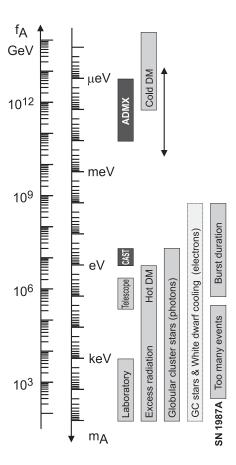

Figure 1: Exclusion ranges as described in the text. The dark intervals are the approximate CAST and ADMX search ranges. Limits on coupling strengths are translated into limits on m_A and f_A using z=0.56 and the KSVZ values for the coupling strengths. The "Laboratory" bar is a rough representation of the exclusion range for standard or variant axions. The "GC stars and white-dwarf cooling" range uses the DFSZ model with an axion-electron coupling corresponding to $\cos^2\beta=1/2$. The Cold Dark Matter exclusion range is particularly uncertain. We show the benchmark case from the misalignment mechanism.

at the density $3 \times 10^{14}\,$ g cm⁻³ and temperature 30 MeV should not exceed about $1 \times 10^{19}\,$ erg g⁻¹ s⁻¹ [36]. The energy-loss rate from nucleon bremsstrahlung, $N+N\to N+N+A$, is $(C_N/2f_A)^2(T^4/\pi^2m_N)\,F$. Here F is a numerical factor that represents an integral over the dynamical spin-density structure function because axions couple to the nucleon spin. For realistic conditions, even after considerable effort, one is limited to a heuristic estimate leading to $F\approx 1$ [37].

The SN 1987A limits are of particular interest for hadronic axions where the bounds on α_{Aee} are moot. Within uncertainties of $z=m_u/m_d$ a reasonable choice for the coupling constants is then $C_p=-0.4$ and $C_n=0$. Using a proton fraction of 0.3, F=1, and T=30 MeV one finds [37]

$$f_A \gtrsim 4 \times 10^8 \text{ GeV}$$
 and $m_A \lesssim 16 \text{ meV}$. (13)

Gauge & Higgs Boson Particle Listings Axions (A^0) and Other Very Light Bosons

If axions interact sufficiently strongly they are trapped. Only about three orders of magnitude in g_{ANN} or m_A are excluded, a range shown somewhat schematically in Figure 1. For even larger couplings, the axion flux would have been negligible, yet it would have triggered additional events in the detectors, excluding a further range [44]. A possible gap between these two SN 1987A arguments was discussed as the "hadronic axion window" under the assumption that $G_{A\gamma\gamma}$ was anomalously small [45]. This range is now excluded by hot dark matter bounds (see below).

The very tentative indication for additional WD cooling by axion emission described above is not in conflict with SN 1987A bounds. Still, if the WD interpretation were correct, SNe would lose a large fraction of their energy as axions. This would lead to a diffuse SN axion background (DSAB) in the universe with an energy density comparable to the extra-galactic background light [46]. However, there is no apparent way of detecting it or the axion burst from the next nearby SN.

III.2 Searches for solar axions

Instead of using stellar energy losses to derive axion limits, one can also search directly for these fluxes, notably from the Sun. The main focus has been on axion-like particles with a two-photon vertex. They are produced by the Primakoff process with a flux given by Equation 11 and can be detected at Earth with the reverse process in a macroscopic B-field ("axion helioscope") [5]. The average energy of solar axions of 4.2 keV implies a photon-axion oscillation length in vacuum of $2\pi \left(2\omega/m_A^2\right) \sim \mathcal{O}(1 \text{ mm})$, precluding the vacuum mixing from achieving its theoretical maximum in any practical magnet. However, one can endow the photon with an effective mass in a gas, $m_{\gamma} = \omega_{\text{plas}}$, thus matching the axion and photon dispersion relations [47].

An early implementation of these ideas used a conventional dipole magnet, with a conversion volume of variable-pressure gas with a xenon proportional chamber as x-ray detector [48]. The conversion magnet was fixed in orientation and collected data for about 1000 s/day. Axions were excluded for $G_{A\gamma\gamma} < 3.6 \times 10^{-9} \text{ GeV}^{-1}$ for $m_A < 0.03 \text{ eV}$, and $G_{A\gamma\gamma} < 7.7 \times 10^{-9} \text{ GeV}^{-1}$ for $0.03 < m_A < 0.11 \text{ eV}$ at 95% CL.

Later, the Tokyo axion helioscope used a superconducting magnet on a tracking mount, viewing the Sun continuously. They reported $G_{A\gamma\gamma} < 6 \times 10^{-10} \text{ GeV}^{-1}$ for $m_A < 0.3 \text{ eV}$ [49]. Recently this experiment was recommissioned and a similar limit for masses around 1 eV was reported [50]. These exclusion ranges are shown in Figure 2.

The most recent helioscope CAST (CERN Axion Solar Telescope) uses a decommissioned LHC dipole magnet on a tracking mount. The hardware includes grazing-incidence x-ray optics with solid-state x-ray detectors, as well as a novel x-ray Micromegas position-sensitive gaseous detector. CAST has established a 95% CL limit $G_{A\gamma\gamma} < 8.8 \times 10^{-11}~{\rm GeV}^{-1}$ for $m_A < 0.02~{\rm eV}$ [51]. To cover larger masses, the magnet bores are filled with a gas at varying pressure. The runs with

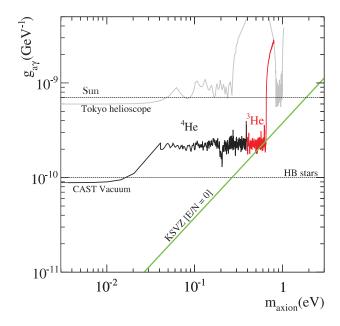

Figure 2: Solar exclusion plot for axion-like particles (adapted from [53]). The green solid line corresponds to KSVZ axions.

⁴He cover masses up to about 0.4 eV [52], providing the ⁴He limits shown in Figure 2. To cover yet larger masses to about 1.15 eV, ³He was used to achieve a larger pressure at cryogenic temperatures. First limits up to 0.64 eV were recently published [53], allowing CAST to "cross the axion line" for the KSVZ model (Figure 2).

Going to yet larger masses in a helioscope search is not well motivated because of the cosmic hot dark matter bound of $m_A \lesssim 0.7 \text{ eV}$ (see below). Sensitivity to significantly smaller values of $G_{A\gamma\gamma}$ can be achieved with a next-generation axion helioscope with a much larger magnetic-field cross section. Realistic design options for this "International Axion Observatory" (IAXO) have been studied in some detail [54].

Other Primakoff searches for solar axions have been carried out using crystal detectors, exploiting the coherent conversion of axions into photons when the axion angle of incidence satisfies a Bragg condition with a crystal plane [55]. However, none of these limits is more restrictive than the one derived from solar neutrinos that was discussed earlier.

Another idea is to look at the Sun with an x-ray satellite when the Earth is in between. Solar axions would convert in the Earth magnetic field on the far side and could be detected [56]. The sensitivity to $G_{A\gamma\gamma}$ could be comparable to CAST, but only for much smaller m_A . Deep solar x-ray measurements with existing satellites, using the solar magnetosphere as conversion region, have reported preliminary limits on $G_{A\gamma\gamma}$ [57].

III.3 Conversion of astrophysical photon fluxes

Large-scale B fields exist in astrophysics that can induce axion-photon oscillations. In practical cases, B is much smaller than in the laboratory, whereas the conversion region L is much

Gauge & Higgs Boson Particle Listings Axions (A^0) and Other Very Light Bosons

larger. Therefore, while the product BL can be large, realistic sensitivities are usually restricted to very low-mass particles, far away from the "axion line" in a plot like Figure 2.

One example is SN 1987A, which would have emitted a burst of axion-like particles due to the Primakoff production in its core. They would have partially converted into γ -rays in the galactic B-field. The absence of a γ -ray burst in coincidence with SN 1987A neutrinos provides a limit $G_{A\gamma\gamma} \lesssim 1 \times 10^{-11} \text{ GeV}^{-1}$ for $m_A \lesssim 10^{-9} \text{ eV}$ [58], the most restrictive limit for very small m_A . Axion-like particles from other stars (e.g. magnetic white dwarfs or neutron stars) can be converted to photons, but no tangible new limits or signatures seem to have appeared, except perhaps from solar x-ray observations (see above).

Magnetically induced oscillations between photons and axion-like particles (ALPs) can modify the photon fluxes from distant sources in various ways: (i) Frequency-dependent dimming. (ii) Modified polarization. (iii) Avoiding absorption by propagation in the form of axions. For example, dimming of SNe Ia could influence the interpretation in terms of cosmic acceleration [59], although it has become clear that photon-ALP conversion could only be a subdominant effect [60]. More recently, it appears that the universe could be too transparent to TeV γ -rays that should be absorbed by pair production on the extra-galactic background light [61]. The situation is not conclusive at present, but the possible role of photon-ALP oscillations in TeV γ -ray astronomy is tantalizing [62].

IV. COSMIC AXIONS

IV.1 Cosmic axion populations

In the early universe, axions are produced by processes involving quarks and gluons [63]. After color confinement, the dominant thermalization process is $\pi + \pi \leftrightarrow \pi + A$ [21]. The resulting axion population would contribute a hot dark matter component in analogy to massive neutrinos. Cosmological precision data provide restrictive constraints on a possible hot dark-matter fraction that translate into $m_A < 0.7$ eV at the 95% statistical CL [64], but in detail depend on the used data set and assumed cosmological model.

For $m_A \gtrsim 20$ eV, axions decay fast on a cosmic time scale, removing the axion population while injecting photons. This excess radiation provides additional limits up to very large axion masses [65]. An anomalously small $G_{A\gamma\gamma}$ provides no loophole because suppressing decays leads to thermal axions overdominating the mass density of the universe.

The main cosmological interest in axions derives from their possible role as cold dark matter (CDM). In addition to thermal processes, axions are abundantly produced by the "misalignment mechanism" [66]. After the breakdown of the PQ symmetry, the axion field relaxes somewhere in the "bottom of the wine bottle" potential. Near the QCD epoch, instanton effects explicitly break the PQ symmetry, the very effect that causes dynamical PQ symmetry restoration. This "tilting of the wine

bottle" drives the axion field toward the CP-conserving minimum, thereby exciting coherent oscillations of the axion field that ultimately represent a condensate of CDM. The cosmic mass density in this homogeneous field mode is [67]

$$\Omega_A h^2 \approx 0.7 \left(\frac{f_A}{10^{12} \text{ GeV}}\right)^{7/6} \left(\frac{\bar{\Theta}_i}{\pi}\right)^2,$$
 (14)

where h is the present-day Hubble expansion parameter in units of 100 km s⁻¹ Mpc⁻¹, and $-\pi \leq \bar{\Theta}_{\rm i} \leq \pi$ is the initial "misalignment angle" relative to the CP-conserving position. If the PQ symmetry breakdown takes place after inflation, $\bar{\Theta}_{\rm i}$ will take on different values in different patches of the universe. The average contribution is [67]

$$\Omega_A h^2 \approx 0.3 \left(\frac{f_A}{10^{12} \text{ GeV}}\right)^{7/6}$$
 (15)

Comparing with the measured CDM density of $\Omega_{\rm CDM}h^2 \approx 0.13$ implies that axions with $m_A \approx 10~\mu {\rm eV}$ provide the dark matter, whereas smaller masses are excluded (Figure 1).

This density sets only a rough scale for the expected m_A . The mass of CDM axions could be significantly smaller or larger than 10 μ eV. Apart from the overall particle physics uncertainties, the cosmological sequence of events is crucial. Assuming axions make up CDM, much smaller masses are possible if inflation took place after the PQ transition and the initial value $\bar{\Theta}_i$ was small ("anthropic axion window" [68]). The oscillating galactic dark matter axion field induces extremely small oscillating nuclear electric dipole moments. Conceivably, these could be measured by extremely tiny energy shifts in cold molecules [69].

Conversely, if the PQ transition took place after inflation, there are additional sources for nonthermal axions, notably the decay of cosmic strings and domain walls. According to Sikivie and collaborators, these populations are comparable to the misalignment contribution [67]. Other groups find a significantly enhanced axion density [70] or rather, a larger m_A value for axions providing CDM. Moreover, the spatial axion density variations are large at the QCD transition and they are not erased by free streaming. When matter begins to dominate the universe, gravitationally bound "axion miniculsters" form promptly [71]. A significant fraction of CDM axions can reside in these bound objects.

If the reheat temperature after inflation is too small to restore PQ symmetry, the axion field is present during inflation. It is subject to quantum fluctuations, leading to isocurvature fluctuations that are severely constrained [72].

IV.2 Telescope searches

The two-photon decay is extremely slow for axions with masses in the CDM regime, but could be detectable for eV masses. The signature would be a quasi-monochromatic emission line from galaxies and galaxy clusters. The expected optical line intensity for DFSZ axions is similar to the continuum night emission. An early search in three rich Abell clusters [73],

Gauge & Higgs Boson Particle Listings Axions (A^0) and Other Very Light Bosons

and a recent search in two rich Abell clusters [74], exclude the "Telescope" range in Figure 1 unless the axion-photon coupling is strongly suppressed. Of course, axions in this mass range would anyway provide an excessive hot DM contribution.

Very low-mass axions in halos produce a weak quasi-monochromatic radio line. Virial velocities in undisrupted dwarf galaxies are very low, and the axion decay line would therefore be extremely narrow. A search with the Haystack radio telescope on three nearby dwarf galaxies provided a limit $G_{A\gamma\gamma} < 1.0 \times 10^{-9} \ {\rm GeV}^{-1}$ at 96% CL for $298 < m_A < 363 \ \mu {\rm eV}$ [75]. However, this combination of m_A and $G_{A\gamma\gamma}$ does not exclude plausible axion models.

IV.3 Microwave cavity experiments

The limits of Figure 1 suggest that axions, if they exist, provide a significant fraction or even perhaps all of the cosmic CDM. In a broad range of the plausible m_A range for CDM, galactic halo axions may be detected by their resonant conversion into a quasi-monochromatic microwave signal in a high-Q electromagnetic cavity permeated by a strong static B field [5,76]. The cavity frequency is tunable, and the signal is maximized when the frequency is the total axion energy, rest mass plus kinetic energy, of $\nu = (m_A/2\pi) \left[1 + \mathcal{O}(10^{-6})\right]$, the width above the rest mass representing the virial distribution in the galaxy. The frequency spectrum may also contain finer structure from axions more recently fallen into the galactic potential and not yet completely virialized [77].

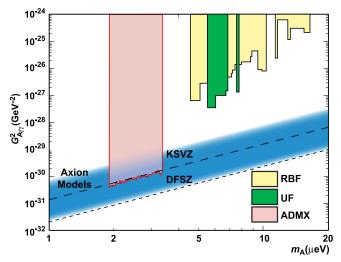

Figure 3: Exclusion region reported from the microwave cavity experiments RBF and UF [78] and ADMX [79]. A local dark-matter density of 450 MeV cm⁻³ is assumed.

The feasibility of this technique was established in early experiments of relatively small sensitive volume, $\mathcal{O}(1 \text{ liter})$, with HFET-based amplifiers, setting limits in the range $4.5 < m_A < 16.3 \ \mu\text{eV}$ [78], but lacking by 2–3 orders of magnitude the sensitivity required to detect realistic axions.

Later, ADMX ($B \sim 8$ T, $V \sim 200$ liters) has achieved sensitivity to KSVZ axions, assuming they saturate the local dark matter density and are well virialized, over the mass range 1.9–3.3 μ eV [79]. Should halo axions have a component not yet virialized, ADMX is sensitive to DFSZ axions [80]. responding 90% CL exclusion regions shown in Figure 3 are normalized to an assumed local CDM density of 7.5×10^{-25} g cm⁻³ $(450 \text{ MeV cm}^{-3})$. More recently the ADMX experiment commissioned an upgrade [81] that replaces the microwave HFET amplifiers by near quantum-limited low-noise dc SQUID microwave amplifiers [82], allowing for a significantly improved sensitivity [83]. This apparatus is also sensitive to other hypothetical light bosons over a limited parameter space [84]. Alternatively, a Rydberg atom single-photon detector [85] can in principle evade the standard quantum limit for coherent photon detection.

Conclusions

Experimental, astrophysical, and cosmological limits have been refined and indicate that axions, if they exist, very likely have very low mass, $m_A \lesssim 10$ meV, suggesting that axions are a non-negligible fraction of the cosmic CDM. The upgraded versions of the ADMX experiment will ultimately cover the range 1–100 μ eV with a sensitivity allowing one to detect such axions, unless the local DM density is unexpectedly small or the axion-photon coupling anomalously weak. Other experimental techniques remain of interest to search for axion-like particles, although at present no method besides the DM search is known that could detect realistic axions obeying the astrophysical and cosmological limits, and fulfilling the QCD-implied relationship between mass and coupling strength.

 3 This limit applies for a mass near 180 MeV. For other masses in the range $m_{_{\mathbf{V}0}}=$ 150-250 MeV the limit is less restrictive, but still improves ADLER 02c and ATIYA 93B. $^4\,\mathrm{A\,NISIM\,OVSKY}$ 04 bound is for $m_{\chi^0}\!=\!0.$

 5 ADLER 02C bound is for $m_{\chi^{0}}$ <60 MeV. See Fig. 2 for limits at higher masses.

⁶ The quoted limit is for $m_{X^0} = 0$ -80 MeV. See their Fig. 5 for the limit at higher mass. The branching fraction limit assumes pure phase space decay distributions. ⁷ ALTEGOER 98 looked for X^0 from π^0 decay which penetrate the shielding and convert

to π^0 in the external Coulomb field of a nucleus. 8 KITCHING 97 limit is for B($K^+\to \pi^+ X^0$)·B($X^0\to \gamma\gamma$) and applies for $m_{X^0}\simeq$ 50

MeV, $au_{X^0} < 10^{-10}\,\mathrm{s}$. Limits are provided for $0 < m_{X^0} < 100$ MeV, $au_{X^0} < 10^{-8}\,\mathrm{s}$.

⁹ ADLER 96 looked for a peak in missing-mass distribution. This work is an update of ATIYA 93. The limit is for massless stable χ^0 particles and extends to $m_{\chi 0} = 80$ MeV at the same level. See paper for dependence on finite lifetime.

 $^{
m 10}$ AMSLER 94B and AMSLER 96B looked for a peak in missing-mass distribution

 11 The MEIJERDREES 94 limit is based on inclusive photon spectrum and is independent of X^0 decay modes. It applies to $\tau(X^0)\!>\!10^{-23}\,{\rm sec}.$

 $^{12}\mathrm{ATIYA}$ 93B looked for a peak in missing mass distribution. The bound applies for stable X^0 of m_{X^0} = 150 - 250 MeV, and the limit becomes stronger (10⁻⁸) for m_{X^0} = 180 - 240

13 NG 93 studied the production of X^0 via $\gamma\gamma\to\pi^0\to\gamma X^0$ in the early universe at $T\simeq 1$ MeV. The bound on extra neutrinos from nucleosynthesis $\Delta N_{\nu} < 0.3$ (WALKER 91) is employed. It applies to $m_{\chi 0} \ll 1$ MeV in order to be relativistic down to nucleosynthesis temperature. See paper for heavier X^0 .

 14 ALLIEGRO 92 limit applies for $m_{\chi^0} = 150$ –340 MeV and is the branching ratio times the decay probability. Limit is $<1.5\stackrel{\frown}{\times}10^{-8}$ at 99%CL.

The limit applies to $m_{\chi^0} = 0$ -130 MeV in the narrow resonance limit. See paper for the dependence on

If MEI JERDREES 92 limit applies for $\tau_{X0}=10^{-23}$ - 10^{-11} sec. Limits between 2×10^{-4} and 4 imes 10 $^{-6}$ are obtained for $m_{\chi^0}=$ 25–120 MeV. Angular momentum conservation requires that X^0 has spin ≥ 1 .

17 ATIYA 90B limit is for B($K^+ \to \pi^+ X^0$)·B($X^0 \to \gamma \gamma$) and applies for $m_{X^0} =$ 50 MeV, $au_{\chi 0}~<~10^{-10}$ s. Limits are also provided for 0 < $m_{\chi 0}~<$ 100 MeV, $au_{\chi 0}^{++}~<~10^{-8}$ s. 18 KORENCHENKO 87 limit assumes $m_{A^0}=1.7$ MeV, $\tau_{A^0}\lesssim 10^{-12}$ s, and ${\rm B}(A^0\to$ $e^+e^-)=1.$

07 CNTR $A^0 \rightarrow e^+e^-$

Gauge & Higgs Boson Particle Listings Axions (A^0) and Other Very Light Bosons

37 JAIN

- 19 EICHLER 86 looked for $\pi^+ \rightarrow e^+ \nu A^0$ followed by $A^0 \rightarrow$ e^+e^- . Limits on the branching fraction depend on the mass and and lifetime of A^0 . The quoted limits are valid when $au(A^0) \gtrsim 3. imes 10^{-10} ext{s}$ if the decays are kinematically allowed.
- ²⁰ YAMAZAKI 84 looked for a discrete line in $K^+ \to \pi^+ X$. Sensitive to wide mass range (5–300 MeV), independent of whether X decays promptly or not.
- ²¹ ASANO 82 at KEK set limits for B($K^+
 ightarrow \pi^+ X^0$) for m_{X^0} <100 MeV as BR ASANO 81B is KEK experiment. Set B(K' > X') is $m \chi_0$
 1. × 10⁻⁹ s, BR < 1.4 × 10⁻⁶ for τ < 1. × 10⁻⁹s.
 22 ASANO 81B is KEK experiment. Set B(K' $\rightarrow \pi^+ X^0$) < 3.8 × 10⁻⁸ at CL = 90%.
- 23 ZHIT NITSKII 79 argue that a heavy axion predicted by YANG 78 (3 < m <40 MeV) contradicts experimental muon anomalous magnetic moments.

A⁰ (Axion) Searches in Quarkonium Decays

Decay or transition of quarkonium. Limits are for branching ratio.

⁶⁸ MICELMAC... 78 69 VYSOTSKII 78 37 JAIN 07 claims evidence for $A^0 \rightarrow e^+ e^-$ produced in 207 Pb collision on nuclear emulsion (Ag/Br) for $\mathit{m}(A^0) = 7 \pm 1$ or 19 ± 1 MeV and $\tau(A^0) \leq 10^{-13}$ s.

38 AHMAD 97 reports a result of APEX Collaboration which studied positron production in $^{238}\mathrm{U} + ^{232}\mathrm{Ta}$ and $^{238}\mathrm{U} + ^{181}\mathrm{Ta}$ collisions, without requiring a coincident electron. No narrow lines were found for $250 < E_{
ho+} < 750 \ {\rm keV}.$

 39 LEINBERGER 97 (ORANGE Collaboration) at GSI looked for a narrow sum-energy e^+e^- -line at ~ 635 keV in 238 U $_+^{181}$ Ta collision. Limits on the production probability for a narrow sum-energy e^+e^- line are set. See their Table 2.

 40 GANZ 96 (EPos II Collaboration) has placed upper bounds on the production cross section of e^+e^- pairs from 238 U+ 181 Ta and 238 U+ 232 Th collisions at GSI. See Table 2 for limits both for back-to-back and isotropic configurations of $e^+\,e^-$ pairs. These limits rule out the existence of peaks in the $e^+\,e^-$ sum-energy distribution, reported by an

 41 KAMEL 96 looked for $^{e+}e^-$ pairs from the collision of 32 S (200 GeV/nucleon) and emulsion. No evidence of mass peaks is found in the region of sensitivity $m_{e\,e} > 2$ MeV.

emulsion. No evidence of mass peaks is round in the region of sensitivity $m_{ee} > 2$ knev. 42 BLUEMLEIN 92 is a proton beam dump experiment at Serpukhov with a secondary target to induce Bethe-Heitler production of e^+e^- or $\mu^+\mu^-$ from the produce A^0 . See Fig. 5 for the excluded region in m_{A^0} -x plane. For the standard axion, 0.3 < x < 25 is excluded at 95 % C.L. If combined with BLUEMLEIN 91, 0.008 < x < 32 is excluded. 43 MEIJERDREES 92 give $\Gamma(\pi^-p \to nA^0)$ -B($A^0 \to e^+e^-$)/ $\Gamma(\pi^-p \to all) < 10^-5$ (90% CL) for $m_{A^0} = 100$ MeV, $\tau_{A^0} = 10^{-11}$ - 10^{-23} sec. Limits ranging from 2.5×10^{-3} to 10^{-7} are given for $m_{A^0} = 25$ -136 MeV. 44 BLITEMIFIN 91 is a proton beam dump experiment at Serpukhov. No candidate event

44 BLUEMLEIN 91 is a proton beam dump experiment at Serpukhov. No candidate event for $A^0
ightarrow e^+e^-$, 2γ are found. Fig. 6 gives the excluded region in m_{A^0} -x plane (x = $aneta = v_2/v_1$). Standard axion is excluded for 0.2 $< m_{A^0} < 3.2\,{\rm MeV}$ for most

x>1, 0.2–11 MeV for most x<1. 45 FAISSNER 89 searched for $A^0\to e^+e^-$ in a proton beam dump experiment at SIN. No excess of events was observed over the background. A standard axion with mass $2m_e$ –20 MeV is excluded. Lower limit on f_{A^0} of $\simeq \bar{1}\,^{04}$ GeV is given for $m_{A^0}=2m_e$ -20 MeV.

 46 DEBOER 88 reanalyze EL-NADI 88 data and claim evidence for three distinct states with mass $\sim 1.1,\,\sim 2.1,\,$ and $\sim 9\,$ MeV, lifetimes $10^{-1}6^{-}10^{-15}\,$ s decaying to e^+e^- and note the similarity of the data with those of a cosmic-ray experiment by Bristol group (B.M. Anand, Proc. of the Royal Society of London, Section A A22 183 (1953)). For a criticism see PERKINS 89, who suggests that the events are compatible with π^0 Dalitz decay. DEBOER 89B is a reply which contests the criticism.

 47 EL-NADI 88 claim the existence of a neutral particle decaying into e^+e^- with mass 1.60 \pm 0.59 MeV, lifetime (0.15 \pm 0.01) \times 10⁻¹⁴s, which is produced in heavy ion interactions with emulsion nuclei at \sim 4 GeV/c/nucleon.

 $^{
m 48}$ FAISSNER 88 is a proton beam dump experiment at SIN. They found no candidate event for $A^0 \to \gamma \gamma$. A standard axion decaying to 2γ is excluded except for a region $x{\simeq}$ 1. Lower limit on f_{A^0} of 10^2 – 10^3 GeV is given for $m_{A^0}=0.1$ –1 MeV.

Gauge & Higgs Boson Particle Listings Axions (A^0) and Other Very Light Bosons

- 49 BADIER 86 did not find long-lived A^0 in 300 GeV π^- Beam Dump Experiment that decays into e^+e^- in the mass range $m_{A^0}=(20$ –200) MeV, which excludes the A^0 decay constant $f(A^0)$ in the interval (60–600) GeV. See their figure 6 for excluded region on $f(A^0)$ - m_{A^0} plane.
- 50 BERGSMA 85 look for $A^0\to 2\gamma,\,e^+e^-,\,\mu^+\mu^-.$ First limit above is for $m_{A^0}=1$ MeV; second is for 200 MeV. See their figure 4 for excluded region on $f_{A^0} - m_{A^0}$ plane, where t_{A0} is A^0 decay constant. For Peccei-Quinn PECCEI 77 A^0 , m_{A0} <180 keV and au >0.037 s. (CL = 90%). For the axion of FAISSNER 81B at 250 keV, BERGSMA 85 expect 15 events but observe zero.
- 51 FAISSNER 83 observed 19 1- γ and 12 2- γ events where a background of 4.8 and 2.3 respectively is expected. A small-angle peak is observed even if iron wall is set in front of the decay region.
- 52 FAISSNER 838 extrapolate SIN γ signal to LAMPF ν experimental condition. Resulting 370 γ 's are not at variance with LAMPF upper limit of 450 γ 's. Derived from LAMPF limit that $\left[d\sigma(A^0)/\omega$ at $90^\circ\right]m_{A^0}/\tau_{A^0}<14\times10^{-35}$ cm² sr $^{-1}$ MeV ms $^{-1}$. See comment on FRANK 83B.
- 55 FRANK 838 stress the importance of LAMPF data bins with negative net signal. By statistical analysis say that LAMPF and SIN-AO are at variance when extrapolation by phase-space model is done. They find LAMPF upper limit is 248 not 450 γ 's. See comment on FAISSNER 83B.
- 54 HOFFMAN 83 set CL = 90% limit $d\sigma/dt$ B(e^+e^-) $< 3.5 \times 10^{-32}$ cm 2 /GeV 2 for 140 $< m_{A^0}$ <160 MeV. Limit assumes $\tau(A^0)$ $< 10^{-9}$ s.
- 55 FETSCHER 82 reanalyzes SIN beam-dump data of FAISSNER 81. Claims no evidence for axion since 2γ peak rate remarkably decreases if iron wall is set in front of the decay
- 56 FAISSNER 81 see excess μe events. Suggest axion interactions.
- 57 FAISSNER 81 B is SIN 590 MeV proton beam dump. Observed $^{14.5}$ \pm $^{5.0}$ events of $^{2}\gamma$ decay of long-lived neutral penetrating particle with $m_{2\gamma} \lesssim$ 1 MeV. Axion interpretation with η -A 0 mixing gives $m_{A^0}=250\pm25$ keV, $au_{(2\gamma)}=(7.3\pm3.7)\times10^{-3}\,\mathrm{s}$ from above rate. See critical remarks below in comments of FETSCHER 82, FAISSNER 83, FAISSNER 83B, FRANK 83B, and BERGSMA 85. Also see in the next subsection ALEK-
- SEEV 82B, CAVAIGNAC 83, and ANANEV 85. 58 KIM 81 analyzed 8 candidates for $A^0\to~2\gamma$ obtained by Aachen-Padova experiment at CERN with 26 GeV protons on Be. Estimated axion mass is about 300 keV and lifetime is $(0.86 \sim 5.6) \times 10^{-3} \, \mathrm{s}$ depending on models. Faissner (private communication), says axion production underestimated and mass overestimated. Correct value around 200
- 59 FAIS-SNER 80 is SIN beam dump experiment with 590 MeV protons looking for 40 \rightarrow $e^+\,e^-$ decay. Assuming $A^0/\pi^0=5.5\times 10^{-7}$, obtained decay rate limit $20/(A^0$ mass) MeV/s (CL = 90%), which is about 10^{-7} below theory and interpreted as upper limit to $m_{\Delta^0} < 2m_{\rho^-}$
- 60 JACQUES 80 is a BNL beam dump experiment. First limit above comes from nonobservation of excess neutral-current-type events $[\sigma(\text{production})\sigma(\text{interaction}) < 7. \times 10^{-68}]$ cm 4 , CL = 90%]. Second limit is from nonobservation of axion decays into 2γ 's or $e^+\,e^-$, and for axion mass a few MeV.
- 61 SOUKAS 80 at BNL observed no excess of neutral-current-type events in beam dump.
- $^{62}\mathrm{BECHIS}$ 79 looked for the axion production in low energy electron Bremsstrahlung and the subsequent decay into either 2γ or e^+e^- . No signal found. CL = 90% limits for model parameter(s) are given.
- ⁶³COTEUS 79 is a beam dump experiment at BNL.
- 64 DISHAW 79 is a calorimetric experiment and looks for low energy tail of energy distributions due to energy lost to weakly interacting particles.
- 65 BELLOTTI 78 first value comes from search for $A^0 \to e^+e^-$. Second value comes from search for $A^0 \to 2\gamma$, assuming mass $<\!2m_{e^-}$. For any mass satisfying this, limit is above value $\times ({\rm mass}^{-4})$. Third value uses data of PL 60B 401 and quotes $\sigma({\rm production})\sigma({\rm interaction}) < 10^{-67}~{\rm cm}^4$.
- $^{66}_{-}$ BOSETTI 78B quotes $\sigma({
 m production})\sigma({
 m interaction}) < 2. imes 10^{-67}~{
 m cm}^4$.
- 67 DONNELLY 78 examines data from reactor neutrino experiments of REINES 76 and GURR 74 as well as SLAC beam dump experiment. Evidence is negative.
- 68 MICELMACHER 78 finds no evidence of axion existence in reactor experiments of REINES 76 and GURR 74. (See reference under DONNELLY 78 below)
- 69 YYSOTSKII 78 derived lower limit for the axion mass 25 keV from luminosity of the sun and 200 keV from red supergiants.

A⁰ (Axion) Searches in Reactor Experiments

| VALUE | DO CUMENT ID | | I E CN | COMMENT |

| • • • We do not use the follo | owing data for averag | es, fits | , limits, | etc. • • • |
| | ⁷⁰ CHANG | 07 | | Primakoff or Compton |
| | | | | Reactor; $A^0 \rightarrow e^+ e^-$ |
| | ⁷² KETOV | | | Reactor, $A^0 	o \gamma \gamma$ |
| | ⁷³ косн | 86 | SPEC | Reactor; $A^0 \rightarrow \gamma \gamma$ |
| | ⁷⁴ DATAR | | | Light water reactor |
| | ⁷⁵ VUILLEUMIE | R 81 | CNTR | Reactor, $A^0 	o 2\gamma$ |

- $^{70}\,\mathrm{CHANG}$ 07 looked for monochromatic photons from Primakoff or Compton conversion of axions from the Kuo-Sheng reactor due to axion coupling to photon or electron, respectively. The search places model-independent limits on the products ${\it G_{A\gamma\gamma}G_{ANN}}$ and $G_{A\,e\,e}\,G_{A\,N\,N}$ for $m(A^0)$ less than the MeV range.
- 71 ALTMANN 95 looked for A0 decaying into $e^+\,e^-$ from the Bugey 5 nuclear reactor. They obtain an upper limit on the A^0 production rate of $\omega(A^{\bar{0}})/\omega(\gamma) \times B(A^0 \to 0)$ $e^+\,e^-)$ < 10^{-16} for $m_{A^0}=1.5$ MeV at 90% CL. The limit is weaker for heavier A^0 . In the case of a standard axion, this limit excludes a mass in the range $2m_e < m_{A^0} < 4.8$ MeV at 90% CL. See Fig. 5 of their paper for exclusion limits of axion-like resonances Z^0 in the (m_{X^0}, f_{X^0}) plane.
- 72 KETOV 86 searched for A^0 at the Rovno nuclear power plant. They found an upper limit on the A^0 production probability of 0.8 $[100~{
 m keV}/m_{A^0}]^6~ imes 10^{-6}$ per fission. In

- the standard axion model, this corresponds to $m_{A^0} >$ 150 keV. Not valid for $m_{A^0} \gtrsim$
- 1 MeV. 73 KOCH 86 searched for $A^0 \to \gamma \gamma$ at nuclear power reactor Biblis A. They found an upper limit on the A^0 production rate of $\omega(A^0)/\omega(\gamma(M1)) < 1.5 \times 10^{-10}$ (CL=95%). Standard axion with $m_{A^0} = 250$ keV gives 10^{-5} for the ratio. Not valid for $m_{A^0} > 1022$
- 74 DATAR 82 looked for $A^0 \rightarrow 2\gamma$ in neutron capture $(np \rightarrow dA^0)$ at Tarapur 500 MW reactor. Sensitive to sum of I=0 and I=1 amplitudes. With ZEHNDER 81 [(I=0)]- (I = 1)] result, assert nonexistence of standard A^0 .
- 75 VUILLEUMIER 81 is at Grenoble reactor. Set limit $m_{A^0}~<$ 280 keV.

A^0 (Axion) and Other Light Boson (X^0) Searches in Nuclear Transitions Limits are for branching ratio

- 76 DERBIN 02 looked for the axion emission in an M1 transition in ^{125}m Te decay. They looked for a possible presence of a shifted energy spectrum in gamma rays due to the undetected axion.
- $^{77}\mathsf{DEBOER}$ 97c reanalyzed the existent data on Nuclear M1 transitions and find that a 9 MeV boson decaying into e^+e^- would explain the excess of events with large opening angles. See also DEBOER 01 for follow-up experiments.
- ⁷⁸TSUNODA 95 looked for axion emission when ²⁵²Cf undergoes a spontaneous fission, with the axion decaying into $e^+\,e^-$. The bound is for $m_{A^0} =$ 40 MeV. It improves to 2.5×10^{-5} for $m_{\ensuremath{A^0}}\!=\!200$ MeV.
- 79 MINOWA 93 studied chain process, 139 Ce \rightarrow 139 La* by electron capture and M1 transition of 139 La* to the ground state. It does not assume decay modes of A^0 . The bound applies for m_{A^0} < 166 keV.
- $^{80}\,\mathrm{HICKS}$ 92 bound is applicable for $\tau_{X^0}~<\mathrm{4}\times\mathrm{10}^{-11}~\mathrm{sec.}$
- 81 The ASANUMA 90 limit is for the branching fraction of X^0 emission per $^{241}{\rm Am}\,\alpha$ decay and valid for $\tau_{X^0}~<~3\times 10^{-11}~{\rm s}.$
- ⁸² The DEBOER 90 limit is for the branching ratio $^8\mathrm{Be}^*$ (18.15 MeV, $^{1+}$) \to $^8\mathrm{Be}A^0$, $A^0
 ightarrow e^+ \, e^-$ for the mass range $m_{A^0} =$ 4–15 MeV.
- ⁸³ The BINI 89 limit is for the branching fraction of 16 O*(6.05 MeV, 0⁺) \rightarrow 16 O X^0 , $X^0
 ightarrow e^+e^-$ for $m_{X}=1.5$ –3.1 MeV. $au_{X^0}\lesssim 10^{-11}$ s is assumed. The spin-parity
- of X is restricted to 0^+ or 1^- .

 84 AVIGNONE 88 looked for the 1115 keV transition $C^* \rightarrow CuA^0$, either from $A^0 \rightarrow CuA^0$. 2γ in-flight decay or from the secondary A^0 interactions by Compton and by Primakoff processes. Limits for axion parameters are obtained for $m_{A^0} < 1.1$ MeV.
- 85 DATAR 88 rule out light pseudoscalar particle emission through its decay $A^0 \rightarrow e^+e^-$ in the mass range 1.02–2.5 MeV and lifetime range 10^{-13} – 10^{-8} s. The above limit is for $\tau=5\times10^{-13}$ s and m=1.7 MeV; see the paper for the τ -m dependence of the
- ⁸⁶The limit is for the branching fraction of $^{16}{\rm O}^*(6.05~{\rm MeV},\,0^+) \rightarrow ^{16}{\rm O}\,X^0$, $X^0 \rightarrow$ $e^+\,e^-$ against internal pair conversion for $m_{\chi^0}=1.7$ MeV and $au_{\chi^0}~<~10^{-11}\,\mathrm{s}.$ Similar limits are obtained for $m_{\chi^0}=1.3$ –3.2 MeV. The spin parity of χ^0 must be either 0+ or 1-. The limit at 1.7 MeV is translated into a limit for the X^0 -nucleon coupling constant: $g_{X^0NN}^2/4\pi < 2.3 \times 10^{-9}$.
- 87 The DOEHNER 88 limit is for $m_{A^0}=1.7\,$ MeV, $au(A^0)<10^{-10}\,$ s. Limits less than
- 10^{-4} are obtained for $m_{A^0}=1.2^{-2}.2$ MeV. 88 SAVAGE 88 looked for A^0 that decays into $e^+\,e^-$ in the decay of the 9.17 MeV J^P 2^+ state in 14 N, 17.64 MeV state $J^P=1^+$ in $^8{\rm Be},$ and the 18.15 MeV state J^P

Gauge & Higgs Boson Particle Listings Axions (A^0) and Other Very Light Bosons

- 1^+ in $^8{
 m Be}$. This experiment constrains the isovector coupling of A^0 to hadrons, if m_{A^0} = (1.1 $\,\rightarrow\,$ 2.2) MeV and the isoscalar coupling of ${\it A}^{\,0}$ to hadrons, if ${\it m}_{{\it A}^{\,0}}$ = (1.1 $\,\rightarrow\,$ 2.6) MeV. Both limits are valid only if $au(A^0) \lesssim 1 imes 10^{-11}\,$ s.
- 89 Limits are for $\Gamma(A^0(1.8~{
 m MeV}))/\Gamma(\pi{
 m M1});$ i.e., for 1.8 MeV axion emission normalized to the rate for internal emission of $e^+\,e^-$ pairs. Valid for $au_{A^0}~<~2 imes 10^{-11} {
 m s.}~^{6}{
 m Li}$ isovector decay data strongly disfavor PECCEI 86 model I, whereas the $^{10}\mathrm{B}$ and $^{14}\mathrm{N}$
- isoscalar decay data strongly reject PECCEI 86 model II and III. 90 SAVAGE 86B looked for A^0 that decays into $e^+\,e^-$ in the decay of the 9.17 MeV $J^P=$ 2^+ state in 14 N. Limit on the branching fraction is valid if $\tau_{A^0}\lesssim 1.\times 10^{-11}{\rm s}$ for m_{A^0} = (1.1-1.7) MeV. This experiment constrains the iso-vector coupling of A^0 to hadrons.
- 91 A NA NEV 85 with IBR-2 pulsed reactor exclude standard 40 at CL = 95% masses below 470 keV (Li* decay) and below $2m_{\it e}$ for deuteron* decay.
- 92 CAVAIGNAC 83 at Bugey reactor exclude axion at any $m_{^{97}}{
 m Nb^*decay}$ and axion with m_{A^0} between 275 and 288 keV (deuteron* decay).
- 93 ALEKSEEV 82 with IBR-2 pulsed reactor exclude standard 0 at CL = 95% mass-ranges m_{A^0} <400 keV (Li* decay) and 330 keV < m_{A^0} <2.2 MeV. (deuteron* decay).
- ⁹⁴ LEHMANN 82 obtained $A^0 \rightarrow 2\gamma$ rate $< 6.2 \times 10^{-5} / \text{s}$ (CL = 95%) excluding m_{A^0}
- 95 between 100 and 1000 keV. 95 ZEHNDER 82 used Gosgen 2.8GW light-water reactor to check A^0 production. No 2γ peak in Li*, Nb* decay (both single p transition) nor in n capture (combined with previous Ba* negative result) rules out standard A^0 . Set limit $m_{\Delta 0} <$ 60 keV for any
- 96 ZEHNDER 81 looked for Ba* \rightarrow A^0 Ba transition with A^0 \rightarrow 2γ . Obtained 2γ coincidence rate $<2.2\times10^{-5}/\mathrm{s}$ (CL = 95%) excluding m_{A^0} >160 keV (or 200 keV in the constant of the depending on Higgs mixing). However, see BARROSO 81.
- 97 CALAPRICE 79 saw no axion emission from excited states of carbon. Sensitive to axion mass between 1 and 15 MeV.

- $(A^0 \rightarrow e e)$ 98 The listed BROSS 91 limit is for $m_{A^0}\,=\,1.14$ MeV. B($A^0\,\rightarrow\,\,e^+\,e^-)\,=1$ assumed. Excluded domain in the au_{A^0} - m_{A^0} plane extends up to $m_{A^0} \approx$ 7 MeV (see Fig. 5). Combining with electron g-2 constraint, axions coupling only to e^+e^- ruled out for $m_{A^0} <$ 4.8 MeV (90% CL).
- $^{99}\,{}^{60}{}^{00}$ 90 use the same apparatus as BROWN 86 and improve the previous limit in the shorter lifetime region. Combined with g-2 constraint, axions coupling only to e^+e^- are ruled out for m_{A^0} < 2.7 MeV (90% CL).
- $^{A^{-}}$ BJORKEN 88 reports limits on axion parameters ($f_{A},\,m_{A},\,\tau_{A}$) for $m_{A^{0}}\,<$ 200 MeV from electron beam-dump experiment with production via Primakoff photoproduction, bremsstrahlung from electrons, and resonant annihilation of positrons on atomic elec-
- $101\,\mathrm{BLINOV}$ 88 assume zero spin, $m=1.8\,\mathrm{MeV}$ and lifetime $<~5\times10^{-12}\,\mathrm{s}$ and find
- $\Gamma(A^0\to\gamma\gamma) {\rm B}(A^0\to e^+e^-) < 2~{\rm eV}~({\rm CL=90\%}).$ 102 Assumes $A^0\gamma\gamma$ coupling is small and hence Primakoff production is small. Their figure 2 shows limits on axions for $m_{A^0}<15~{\rm MeV}.$
- $^{103}\mathrm{Uses}$ electrons in hadronic showers from an incident 800 GeV proton beam. Limits for $m_{A^0} <$ 15 MeV are shown in their figure 3.
- $^{104}\,m_{A^0}^{A}=1.8$ MeV assumed. The excluded domain in the $\tau_{A^0}-m_{A^0}$ plane extends up to $m_{A^0}^{\prime\prime} \approx$ 14 MeV, see their figure 4.
- 105 The limits are obtained from their figure 3. Also given is the limit on the ${\it A^0}\,\gamma\gamma - {\it A^0}\,e^+\,e^-$ coupling plane by assuming Primakoff production.

 106 HALLIN 92 quote limits on lifetime, 8×10^{-14} – 5×10^{-13} sec depending on mass, assuming B(A $^0
ightarrow e^+e^-) = 100\%$. They say that TSERTOS 91 overstated their sensitivity by a factor of 3.

 107 HENDERSON 92c exclude axion with lifetime $\tau_{A^0}{=}1.4\times10^{-12}$ – 4.0 $\times10^{-10}$ s, assuming $B(A^0)$ \rightarrow $e^+e^-)=100\%$. HENDERSON 92c also exclude a vector boson with $r = 1.4 \times 10^{-12} - 6.0 \times 10^{-10} \text{ s.}$

 108 WU 92 quote limits on lifetime $> 3.3 \times 10^{-13}$ s assuming B(A⁰ $\rightarrow e^+e^-$)=100%. They say that TSERTOS 89 overestimate the limit by a factor of $\pi/2$. WU 92 also quote a bound for vector boson, $\tau > 8.2 \times 10^{-13} \, \mathrm{s}$.

 109 WIDMANN 91 bound applies exclusively to the case B($A^0
ightarrow e^+ \, e^-$)=1, since the detection efficiency varies substantially as $\Gamma(A^0)_{total}$ changes. See their Fig. 6.

 110 JUDGE 90 excludes an elastic pseudoscalar $e^+\,e^-$ resonance for 4.5 $imes 10^{-13}$ s $<~ au(A^0)$ $<~7.5 imes10^{-12}\,\mathrm{s}$ (95% CL) at $m_{A^0}=1.832$ MeV. Comparable limits can be set for $m_{A^0} = 1.776 - 1.856 \text{ MeV}.$

- 111 See also TSERTOS 88B in references
- 112 The upper limit listed in TSERTOS 88 is too large by a factor of 4. See TSERTOS 88B,
- 113 VA NKLINKEN 88 looked for relatively long-lived resonance ($au=10^{-10}$ – 10^{-12} s). The
- sensitivity is not sufficient to exclude such a narrow resonance. 114 MAIER 87 obtained limits $R\Gamma\lesssim 60$ eV (100 eV) at $m_{A^0}\simeq 1.64$ MeV (1.83 MeV) for energy resolution $\Delta E_{\rm CM}\simeq 3$ keV, where R is the resonance cross section normalized to that of Bhabha scattering, and $\Gamma=\Gamma_{e\,e}^2/\Gamma_{total}.$ For a discussion implying that $\Delta E_{
 m cm} \simeq 10$ keV, see TSERTOS 89.
- 115 VONWIMMERSPERG 87 measured Bhabha scattering for $E_{\rm CM}=1.37$ –1.86 MeV and found a possible peak at 1.73 with $\int \sigma dE_{\rm CM}=14.5\pm6.8$ keV-b. For a comment and a reply, see VANKLINKEN 88B and VONWIMMERSPERG 88. Also see CONNELL 88.

Search for A^0 (Axion) Resonance in $e^+e^- \rightarrow \gamma\gamma$

The limit is for $\Gamma(A^0 \rightarrow e^+ e^-) \cdot \Gamma(A^0 \rightarrow \gamma \gamma) / \Gamma_{\text{total}}$

- ¹²⁸LESSA 07 consider decays of the form Meson $\rightarrow \ell \nu$ Majoron and $\ell \rightarrow \ell' \nu \overline{\nu}$ Majoron and use existing data to derive limits on the neutrino-Majoron Yukawa couplings $g_{lphaeta}$ $(\alpha,\beta\!=\!e,\mu, au)$. Their best limits are $|g_{e\,\alpha}|^2<5.5 imes10^{-6}$, $|g_{\mu\,\alpha}|^2<4.5 imes10^{-5}$, $|g_{\tau\alpha}|^2 < 5.5 \times 10^{-2}$ at CL = 90%
- 129 DIAZ 98 studied models of spontaneously broken lepton number with both singlet and triplet Higgses. They obtain limits on the parameter space from invisible decay $Z \rightarrow H^0A^0 \rightarrow X^0X^0X^0X^0X^0$ and $e^+e^- \rightarrow ZH^0$ with $H^0 \rightarrow X^0X^0$.
- 130 BOBRAKOV 91 searched for anomalous magnetic interactions between polarized electrons expected from the exchange of a massless pseudoscalar boson (arion). A limit $x_e^2 < 2 imes 10^{-4}$ (95%CL) is found for the effective anomalous magneton parametrized as $x_e (G_F / 8\pi \sqrt{2})^{1/2}$.
- 131 ALBRECHT 90E limits are for B($au o \ell X^0$)/B($au o \ell
 u \overline{
 u}$). Valid for $m_{\chi^0} < 100$
- MeV. The limits rise to 7.1% (for μ), 5.0% (for e) for $m_{\chi^0}=$ 500 MeV. 132 ATIYA 90 limit is for $m_{\chi^0}=$ 0. The limit B $<1\times10^{-8}$ holds for $m_{\chi^0}<$ 95 MeV. For the reduction of the limit due to finite lifetime of X^0 , see their Fig. 3
- $133\,\mathrm{BOLTON}$ 88 limit corresponds to $F>3.1 imes10^9$ GeV, which does not depend on the chirality property of the coupling.
- 134 CHANDA 88 find v_T < 10 MeV for the weak-triplet Higgs vacuum expectation value in Gelmini-Roncadelli model, and $\nu_S~>~5.8\times 10^6$ GeV in the singlet Majoron model.
- 135 CHOI 88 used the observed neutrino flux from the supernova SN1987A to exclude the neutrino Majoron Yukawa coupling h in the range 2×10^{-5} $< h < 3\times 10^{-4}$ for the interaction $L_{
 m int}=rac{1}{2}i\hbar\overline{\psi}^c_
 u\gamma_5\psi_
 u\phi_{
 m X}$. For several families of neutrinos, the limit applies for
- $^{136}\,\mathrm{PIC}\dot{\mathrm{CIOTTO}}$ 88 limit applies when $m_{\chi^0}~<$ 55 MeV and $\tau_{\chi^0}~>$ 2ns, and it decreases to 4 $\times\,10^{-7}$ at $m_{\chi\,0}\,=\,125\,$ MeV, beyond which no limit is obtained.
- 137 GOLD MAN 87 limit corresponds to $F > 2.9 \times 10^9$ GeV for the family symmetry breaking scale from the Lagrangian $L_{\rm int}=(1/F)\overline{\psi}_{\mu}\gamma^{\mu}~(a+b\gamma_5)~\psi_e\partial_{\mu}\phi_{X^0}$ with $a^2+b^2=1$. This is not as sensitive as the limit $F>9.9 imes10^9$ GeV derived from the search for $\mu^+ o$ $e^+\,X^0$ by JODIDIO 86, but does not depend on the chirality property of the coupling.

- 138 Limits are for $\Gamma(\mu \to e X^0)/\Gamma(\mu \to e \nu \overline{\nu})$. Valid when $m_{X^0}=$ 0-93.4, 98.1-103.5
- MeV. 139 EICHLER 86 looked for $\mu^+ \to e^+ X^0$ followed by $X^0 \to e^+ e^-$. Limits on the branching fraction depend on the mass and and lifetime of X^0 . The quoted limits are valid when $\tau_{X^0} \lesssim 3. \times 10^{-10} \, \mathrm{s}$ if the decays are kinematically allowed.
- 140 JODIDIO 86 corresponds to $F>9.9\times10^9$ GeV for the family symmetry breaking scale with the parity-conserving effective Lagrangian $L_{\rm int}=(1/{\it F})~\overline{\psi}_{\mu}\gamma^{\mu}\psi_{e}\partial^{\mu}\phi_{X^0}$
- 141 BALTRUSAITIS 85 search for light Goldstone boson(X^0) of broken U(1). CL = 95% limits are B($au o \mu^+ X^0$)/B($au o \mu^+ \nu
 u$) <0.125 and B($au o e^+ X^0$)/B($au o e^+ \nu
 u$) <0.04. Inferred limit for the symmetry breaking scale is $m ext{>} 3000$ TeV.
- 142 The primordial heavy neutrino must decay into ν and familon, f_A , early so that the red-shifted decay products are below critical density, see their table. In addition, $K \rightarrow 5$ πf_A and $\mu
 ightarrow e f_A$ are unseen. Combining these excludes $m_{
 m heavy}
 u$ between 5 imes 10 $^{-5}$ and 5 \times 10 $^{-4}$ MeV (μ decay) and $m_{
 m heavy}
 u$ between 5 \times 10 $^{-5}$ and 0.1 MeV (K-decay).

Majoron Searches in Neutrinoless Double β Decay

Limits are for the half-life of neutrinoless $\beta\beta$ decay with a Majoron emission. No experiment currently claims any such evidence. Only the best or comparable limits for each isotope are reported. Also see the reviews ZUBER 98 and FAESSLER 98B.

- 143 BERNATOWICZ 92 studied double-eta decays of 128 Te and 130 Te, and found the ratio $au(^{130}{
 m Te})/ au(^{128}{
 m Te}) = (3.52\,\pm\,0.11) imes 10^{-4}$ in agreement with relatively stable theoretical predictions. The bound is based on the requirement that Majoron-emitting decay cannot be larger than the observed double-beta rate of $^{128}{\rm Te}$ of $(7.7\pm0.4)\times10^{24}$ year. We calculated 90% CL limit as $(7.7\text{--}1.28 \times 0.4\text{=-}7.2) \times 10^{24}$
- $^{144}\,\mathrm{AR}\,\mathrm{NOLD}\,11$ use the NEMO-3 detector to obtain the reported limit on Majoron emission. $< 0.6-1.6 \times 10^{-4}$ depending on the nuclear It implies that the coupling constant $g_{\nu\chi} < 0.6$ –1 matrix element used. Supercedes ARNABOLDI 03.
- $^{145}\,\mathrm{ARGYRIADES}$ 10 use the NEMO-3 tracking detector and $^{96}\mathrm{Zr}$ to derive the reported
- limit. No limit for the Majoron electron coupling is given. $^{146} \, \text{ARGYRIADES} \,\, 09 \,\, \text{use} \,\, ^{150} \, \text{Nd} \,\, \text{data} \,\, \text{taken} \,\, \text{with} \,\, \text{the NEMO-3 tracking detector.} \quad \text{The}$ reported limit corresponds to $\langle g_{\nu\chi} \rangle < 1.7^{-3.0} \times 10^{-4}$ using a range of nuclear matrix elements that include the effect of nuclear deformation. 147 ARNOLD 06 use 100 Mo data taken with the NEMO-3 tracking detector. The reported
- limit corresponds to $\langle g_{\nu\,\chi} \rangle < (0.4$ –1.8) $\times\,10^{-4}$ using a range of matrix element calculations. Supersedes ARNOLD 04.
- 148 NEMO-3 tracking calorimeter is used in ARNOLD 06 . Reported half-life limit for 82 Se corresponds to $\langle g_{\nu\gamma} \rangle < (0.66-1.9) \times 10^{-4}$ using a range of matrix element calculations. Supersedes ARNOLD 04.
- $^{149} \rm ARNOLD$ 04 use the NEMO-3 tracking detector. The limit corresponds to $\langle g_{\nu\chi} \rangle~<$ (0.5-0.9)10-4 using the matrix elements of SIMKOVIC 99, STOICA 01 and CIV-ÎTARESÉ 03
- 150 ARNOLD 04 use the NEMO-3 tracking detector. The limit corresponds to $\langle g_{\nu\chi} \rangle~<$ $(0.7 - 1.6)10^{-4}$ using the matrix elements of SIMKOVIC 99, STOICA 01 and CIV-ITARESE 03.
- 151 Supersedes ALESSANDRELLO 00. Array of TeO $_2$ crystals in high resolution cryogenic calorimeter. Some enriched in 130 Te. Derive $\langle g_{\nu\chi} \rangle~<~17$ –33 $\times~10^{-5}$ depending on
- matrix element.

 152 Supersedes ALESSANDRELLO 00. Cryogenic calorimeter search.
- 153 Limit for the $0
 u\chi$ decay with Majoron emission of 116 Cd using enriched CdWO $_4$ scintillators. $\langle g_{\nu\chi} \rangle <$ 4.6–8.1 \times 10⁻⁵ depending on the matrix element. Supersedes DANEVICH 00.
- 154 Limit for the $0\nu2\chi$ decay of 116 Cd. Supersedes DANEVICH 00.
- 155 BERNABEI 02D obtain limit for 0 $u\chi$ decay with Majoron emission of 136 Xe using liquid Xe scintillation detector. They derive $\langle g_{
 u\chi}
 angle <$ 2.0–3.0 imes 10⁻⁵ with several nuclear

Gauge & Higgs Boson Particle Listings Axions (A^0) and Other Very Light Bosons

- 156 Replaces TANAKA 93. FUSHIMI 02 derive half-life limit for the $0 \nu \chi$ decay by means of tracking calorimeter ELEGANT V. Considering various matrix element calculations, a range of limits for the Majoron-neutrino coupling is given: $\langle g_{\nu\chi} \rangle < (6.3-360) \times 10^{-5}$.
- 157 ASHITKOV 01 result for 0 $u\chi$ of 100 Mo is less stringent than ARNOLD 00.
- 158 DANEVICH 01 obtain limit for the $0
 u\chi$ decay with Majoron emission of 160 Gd using Gd₂SiO₅:Ce crystal scintillators.
- 159 DANEVICH 01 obtain limit for the 0ν 2χ decay with 2 Majoron emission of 160 Gd.
- 160 ARNOLD 00 reports limit for the $0
 u\chi$ decay with Majoron emission derived from tracking calorimeter NEMO 2. Using $^{82}{\rm Se}$ source: $\langle g_{\nu\chi}\rangle < 1.6\times 10^{-4}$. Matrix element from GUENTHER 96. 161 Using $^{96}{\rm Zr}$ source: $\langle g_{\nu\chi} \rangle < 2.6 \times 10^{-4}$. Matrix element from ARNOLD 99.
- 162 ARNOLD 00 reports limit for the $0\nu2\chi$ decay with two Majoron emission derived from tracking calorimeter NEMO 2.
- $^{163} \text{ARNOLD}$ 98 determine the limit for $0 \nu_{\chi}$ decay with Majoron emission of $^{82} \text{Se}$ using the NEMO-2 tracking detector. They derive $\langle g_{\nu_\chi} \rangle <$ 2.3–4.3 \times 10⁻⁴ with several nuclear
- matrix elements. 164 LUESCHER 98 report a limit for the 0ν decay with Majoron emission of 136 Xe using Xe TPC. This result is more stringent than BARABASH 89. Using the matrix elements of ENGEL 88, they obtain a limit on $\langle g_{\nu\chi} \rangle$ of 2.0×10^{-4} .
- $^{165}\,\mathrm{See}$ Table 1 in GUENTHER 96 for limits on the Majoron coupling in different models.

Invisible A⁰ (Axion) MASS LIMITS from Astrophysics and Cosmology

 $v_1=v_2$ is usually assumed ($v_i=v_1$ vacuum expectation values). For a review of these limits, see RAFFELT 91 and TURNER 90. In the comment lines below, D and K refer

- 166 CADAMURO 11 use the deuterium abundance to show that the $\,m_{A^0}\,$ range 0.7 eV -300 keV is excluded for axions, complementing HANNESTAD 10.
- 167 DERBIN 11A look for solar axions produced by Compton and bremsstrahlung processes, in the resonant excitation of ¹⁶⁹Tm, constraining the axion-electron × axion nucleon
- 168 A NDRIA MONJE 10 search for solar axions produced from 7 Li (478 keV) and D $(p,\gamma)^{3}$ He (5.5 MeV) nuclear transitions. They show limits on the axion-photon coupling for two reference values of the axion-nucleon coupling for $m_A < 100$ eV.
- 169 This is an update of HANNESTAD 08 including 7 years of WMAP data.
- 170 ANDRIAMONJE 09 look for solar axions produced from the thermally excited 14.4 keV level of 57 Fe. They show limits on the axion-nucleon imes axion-photon coupling assuming $m_A < 0.03 \text{ eV}$
- $171\,\mathrm{DERBIN}$ 09A look for Primakoff-produced solar axions in the resonant excitation of $^{169}\text{Tm}\text{,}$ constraining the axion-photon \times axion-nucleon couplings.
- $^{172}\,\mathrm{KEKEZ}$ 09 look at axio-electric effect of solar axions in HPGe detectors. The one-loop axion-electron coupling for hadronic axions is used.
- 173 This is an update of HANNESTAD 07 including 5 years of WMAP data.
- 174 This is an update of HANNESTAD 05A with new cosmological data, notably WMAP (3 years) and baryon acoustic oscillations (BAO). Lyman-lpha data are left out, in contrast to HANNESTAD 05A and MELCHIORRI 07A, because it is argued that systematic errors are large. It uses Bayesian statistics and marginalizes over a possible neutrino hot dark matter component.
- 175 MELCHIORRI 07A is analogous to HANNESTAD 05A, with updated cosmological data, notably WMAP (3 years). Uses Bayesian statistics and marginalizes over a possible neutrino hot dark matter component. Leaving out Lyman-α data, a conservative limit is
- 176 HANNESTAD 05A puts an upper limit on the mass of hadronic axion because in this mass range it would have been thermalized and contribute to the hot dark matter component of the universe. The limit is based on the CMB anisotropy from WMAP, SDSS large scale structure, Lyman lpha, and the prior Hubble parameter from HST Key Project. A χ^2
- statistic is used. Neutrinos are assumed not to contribute to hot dark matter.

 177 MOROI 98 points out that a KSVZ axion of this mass range (see CHANG 93) can be a viable hot dark matter of Universe, as long as the model-dependent $g_{A\gamma}$ is accidentally small enough as originally emphasized by KAPLAN 85; see Fig. 1.
- small enough as originally emphasized by KAPLAN 85; see Fig. 1. $178\, {\rm BORISOV}\,97\, {\rm bound}\, {\rm is}\, {\rm on}\, {\rm the}\, {\rm axion-electron}\, {\rm coupling}\, g_{ae} < 1\times 10^{-13}\, {\rm from}\, {\rm the}\, {\rm photoproduction}\, {\rm of}\, {\rm axions}\, {\rm off}\, {\rm magnetic}\, {\rm fields}\, {\rm in}\, {\rm the}\, {\rm outer}\, {\rm layers}\, {\rm of}\, {\rm neutron}\, {\rm stars}.$ $179\, {\rm KACHELRIESS}\, 97\, {\rm bound}\, {\rm is}\, {\rm on}\, {\rm the}\, {\rm axion-electron}\, {\rm coupling}\, g_{ae}^2 < 1\times 10^{-10}\, {\rm from}\, {\rm the}\, {\rm production}\, {\rm of}\, {\rm axions}\, {\rm in}\, {\rm strongly}\, {\rm magnetic}\, {\rm deutron}\, {\rm stars}\, .$
 The authors also quote a stronger limit, $g_{ae}^2 < 9\times 10^{-13}\, {\rm which}\, {\rm is}\, {\rm strongly}\, {\rm dependent}\, {\rm on}\, {\rm the}\, {\rm strength}\, {\rm of}\, {\rm nucleons}\, {\rm axiongly}\, {\rm strongly}\, {\rm otherwise}\, {\rm otherwise}\, {\rm axiongly}\, {\rm otherwise}\,
- $180\,\mathrm{KEIL}$ 97 uses new measurements of the axial-vector coupling strength of nucleons, as well as a reanalysis of many-body effects and pion-emission processes in the core of the neutron star, to update limits on the invisible-axion mass.
- $^{181}\,\mathrm{RAFFELT}$ 95 reexamined the constraints on axion emission from red giants due to the axion-electron coupling. They improve on DEARBORN 86 by taking into proper account degeneracy effects in the bremsstrahlung rate. The limit comes from requiring the red giant core mass at helium ignition not to exceed its standard value by more than 5% (0.025 solar masses).
- $^{182}\text{ALTHERR}$ 94 bound is on the axion-electron coupling $\textit{g}_{\textit{ae}} < 1.5 \times 10^{-13}$, from energy
- loss via axion emission.

 183 CHANG 93 updates ENGEL 90 bound with the Kaplan-Manohar ambiguity in $z=m_u/m_d$ (see the Note on the Quark Masses in the Quark Particle Listings). It leaves the window $f_{A} = 3 \times 10^{5} - 3 \times 10^{6}$ GeV open. The constraint from Big-Bang Nucleosynthesis is satisfied this window as well.
- $^{184}\, \mathrm{BERSHADY}$ 91 searched for a line at wave length from 3100–8300 Å expected from 2γ decays of relic thermal axions in intergalactic light of three rich clusters of galaxies.
- 185 KIM 91c argues that the bound from the mass density of the universe will change drastically for the supersymmetric models due to the entropy production of saxion (scalar component in the axionic chiral multiplet) decay. Note that it is an upperbound rather han a lowerbound.
- 186 RAFFELT 91B argue that previous SN 1987A bounds must be relaxed due to corrections to nucleon bremsstrahlung processes.
- 188 ENGEL 90 rule out $10^{-10} \lesssim g_{AN} \lesssim 10^{-3}$, which for a hadronic axion with EMC motivated axion-nucleon couplings corresponds to $2.5 \times 10^{-3} \, {\rm eV} \lesssim m_{A^0} \lesssim 2.5 \times 10^{-3} \, {\rm eV}$ 10^4 eV. The constraint is loose in the middle of the range, i.e. for $g_{AN} \sim 10^{-6}$.
- 189 RAFFELT 90D is a re-analysis of DEARBORN 86. 190 The region $m_{A^0}\gtrsim 2$ eV is also allowed.
- 191 ERICSON 89 considered various nuclear corrections to axion emission in a supernova core, and found a reduction of the previous limit (MAYLE 88) by a large factor.
- 192 MAYLE 89 limit based on naive quark model couplings of axion to nucleons. Limit based on couplings motivated by EMC measurements is 2–4 times weaker. The limit from axion-electron coupling is weak: see HATSUDA 88B.
- $^{193}\,\mathrm{RAFFELT}$ 88B derives a limit for the energy generation rate by exotic processes in heliumburning stars $\epsilon <$ 100 erg g $^{-1}$ s $^{-1}$, which gives a firmer basis for the axion limits based on red giant cooling.
- $^{194}\,\mathrm{RAFFELT}$ 87 also gives a limit $g_{A\gamma}~<~1\times10^{-10}~\mathrm{GeV}^{-1}$
- 195 DEARBORN 86 also gives a limit $g_{A\gamma} < 1.4 imes 10^{-11}~{
 m GeV}^{-1}$.
- 196 RAFFELT 86 gives a limit $g_{A\gamma} < 1.1 \times 10^{-10}~{\rm GeV}^{-1}$ from red giants and $< 2.4 \times 10^{-9}$ ${
 m GeV}^{-1}$ from the sun.
- 197 KAPLAN 85 says $m_{A^0} <$ 23 eV is allowed for a special choice of model parameters.
- $^{198}\,\mathrm{FU\,KUGITA}$ 82 gives a limit $g_{A\gamma}~<~2.3\times10^{-10}~\mathrm{GeV}^{-1}$

Search for Relic Invisible Axions

Limits are for $[G_{A\gamma\gamma}/m_{A^0}]^2
ho_A$ where $G_{A\gamma\gamma}$ denotes the axion two-photon coupling, $L_{\rm int}=rac{G_{A\gamma\gamma}}{4}\phi_AF_{\mu
u}\widetilde{F}^{\mu
u}=G_{A\gamma\gamma}\phi_A{f E}\cdot{f B},$ and ho_A is the axion energy density near the earth.

- $^{199} \mathrm{HOSKINS} \ 11$ is analogous to DUFFY 06. See Fig. 4 for the mass-dependent limit in terms of the local density.
- $200\,\mathrm{ASZTALOS}$ 10 used the upgraded detector of ASZTALOS 04 to search for halo axions. See their Fig. 5 for the $m_{\ensuremath{A^0}}$ dependence of the limit.
- 201 DUFFY 06 used the upgraded detector of ASZTALOS 04, while assuming a smaller velocity dispersion than the isothermal model as in Eq. (8) of their paper. See Fig. 10 of their paper on the axion mass dependence of the limit.
- $^{202} \text{ASZTALOS}$ 04 looked for a conversion of halo axions to microwave photons in magnetic field. At 90% CL, the KSVZ axion cannot have a local halo density more than 0.45 $\,$ GeV/cm 3 in the quoted mass range. See Fig. 7 of their paper on the axion mass dependence of the limit.
- 203 KIM 98 calculated the axion-to-photon couplings for various axion models and compared them to the HAGMANN 90 bounds. This analysis demonstrates a strong model dependence of ${\it G}_{A\,\gamma\gamma}$ and hence the bound from relic axion search.
- 204 HAGMANN 90 experiment is based on the proposal of SIKIVIE 83.
- 205 WUENSCH 89 looks for condensed axions near the earth that could be converted to photons in the presence of an intense electromagnetic field via the Primakoff effect, following the proposal of SIKIVIE 83. The theoretical prediction with $[G_{A\gamma\gamma}/m_{\Delta0}]^2=$ $2\times 10^{-14}~{\rm MeV^{-4}}$ (the three generation DFSZ model) and $\rho_A=300~{\rm MeV/cm^3}$ that makes up galactic halos gives $(G_A\gamma\gamma/m_{A^0})^2~\rho_A=4\times 10^{-44}$. Note that our definition of $G_A\gamma\gamma$ is $(1/4\pi)$ smaller than that of WUENSCH 89.

Invisible A⁰ (Axion) Limits from Photon Coupling

Limits are for the axion-two-photon coupling $G_{A\gamma\gamma}$ defined by $L=G_{A\gamma\gamma}\phi_A {f E}{\cdot}{f B}$. For scalars S^0 the limit is on the coupling constant in $L = G_{S\gamma\gamma}\phi_S(\mathbf{E}^2 - \mathbf{B}^2)$.

- $^{206}\,\text{ARIK}$ 11 search for solar axions using ^{3}He buffer gas in CAST, continuing from the ^{4}He version of ARIK 09. See Fig. 2 for the exact mass-dependent limits.
- 207 ALPS is a photon regeneration experiment. See their Fig. 4 for mass-dependent limits on scalar and pseudoscalar bosons.
- $^{208}\,\mathrm{AH\,MED}$ 09A is analogous to AVIGNONE 98.
- 209 ARIK 09 is the ⁴He filling version of the CAST axion helioscope in analogy to INOUE 02 and INOUE 08. See their Fig. 7 for mass-dependent limits.
- 210 CHOU 09 use the GammeV apparatus in the afterglow mode to search for chameleons, (pseudo)scalar bosons with a mass depending on the environment. For pseudoscalars they exclude at 3σ the range $2.6\times 10^{-7}~{\rm GeV}^{-1}< G_{A\gamma\gamma}<4.2\times 10^{-6}~{\rm GeV}^{-1}$ for vacuum m_{A^0} roughly below 6 meV for density scaling index exceeding 0.8.
- $^{211}\,\mathrm{GONDOLO}$ 09 use the all-flavor measured solar neutrino flux to constrain solar interior temperature and thus energy losses

- 212 LIPSS photon regeneration experiment, assuming scalar particle S^0 . See Fig. 4 for mass-
- 213 CHOU 08 perform a variable-baseline photon regeneration experiment. See their Fig. 3 for mass-dependent limits. Excludes the PVLAS result of ZAVATTINI 06.
- 214 FOUCHE 08 is an update of ROBILLIARD 07. See their Fig. 12 for mass-dependent
- 215 | NOUE 08 is an extension of INOUE 02 to larger axion masses, using the Tokyo axion
- helioscope. See their Fig. 4 for mass-dependent limits.

 216 ZAVATTINI 08 is an upgrade of ZAVATTINI 06, see their Fig. 8 for mass-dependent limits. They now exclude the parameter range where ZAVATTINI 06 had seen a positive ignature.
- 217 ANDRIAMONJE 07 looked for Primakoff conversion of solar axions in 9T superconducting magnet into X-rays. Supersedes ZIOUTAS 05.
- 218 ROBILLIARD 07 perform a photon regeneration experiment with a pulsed laser and pulsed magnetic field. See their Fig. 4 for mass-dependent limits. Excludes the PVLAS result of ZAVATTINI 06 with a CL exceeding 99.9%.
- 219 ZAVATTINI 06 propagate a laser beam in a magnetic field and observe dichroism and birefringence effects that could be attributed to an axion-like particle. This result is now excluded by ROBILLIARD 07, ZAVATTINI 08, and CHOU 08.
- 220 I NOUE 02 looked for Primakoff conversion of solar axions in 4T superconducting magnet
- 221 MORALES 02B looked for the coherent conversion of solar axions to photons via the Primakoff effect in Germanium detector.
- 222 BERNABEI 01B looked for Primakoff coherent conversion of solar axions into photons via Bragg scattering in Nal crystal in DAMA dark matter detector.
- 223 ASTIER 00B looked for production of axions from the interaction of high-energy photons with the horn magnetic field and their subsequent re-conversion to photons via the interaction with the NOMAD dipole magnetic field.
- 224 MASSO 00 studied limits on axion-proton coupling using the induced axion-photon coupling through the proton loop and CAMERON 93 bound on the axion-photon coupling using optical rotation. They obtained the bound $s_p^2/4\pi < 1.7 \times 10^{-9}$ for the coupling $g_p \overline{p} \gamma_5 p \phi_A$
- 225 AVIGNONE 98 result is based on the coherent conversion of solar axions to photons via the Primakoff effect in a single crystal germanium detector.
- $\frac{226}{1-2}$ Based on the conversion of solar axions to X-rays in a strong laboratory magnetic field.
- 227 Experiment based on proposal by MAIANI 86.
- 228 Experiment based on proposal by VANBIBBER 87.
- $^{229} \, \mathsf{LAZARUS} \,\, \mathsf{92} \,\, \mathsf{experiment}$ is based on proposal found in VANBIBBER 89.
- $^{230}\,\text{RUOSO}$ 92 experiment is based on the proposal by VANBIBBER 87.
- $231\, \text{SEMERTZIDIS}$ 90 experiment is based on the proposal of MAIANI 86. The limit is obtained by taking the noise amplitude as the upper limit. Limits extend to $m_{A0}=$ $4 imes 10^{-3}$ where $\textit{G}_{A \, \gamma \, \gamma} \, < \, 1 imes 10^{-4} \, \, \mathrm{GeV}^{-1}$.

Limit on Invisible A^0 (Axion) Electron Coupling

The limit is for ${\it G_{Aee}}\partial_{\mu}\phi_{A}\overline{e}\gamma^{\mu}\gamma_{5}e$ in ${\it GeV}^{-1}$, or equivalently, the dipole-dipole potential $\frac{G_{Aee}^2}{4\pi} ((\boldsymbol{\sigma}_1 \cdot \boldsymbol{\sigma}_2) - 3(\boldsymbol{\sigma}_1 \cdot \boldsymbol{n}) (\boldsymbol{\sigma}_2 \cdot \boldsymbol{n}))/r^3$ where $\boldsymbol{n} = \boldsymbol{r}/r$.

- 232 AALSETH 11 assume keV-mass pseudoscalars are the local dark matter and constrain the axio-electric effect in the CoGeNT detector. See their Fig. 4 for mass-dependent
- 233 AHMED 09A is analogous to AALSETH 08, using the CDMS detector. See their Fig. 5 for mass-dependent limits.
- $^{234}_{--}$ DAVOUDIASL 09 use geophysical constraints on Earth cooling by axion emission.
- 235 These experiments measured induced magnetization of a bulk material by the spin-dependent potential generated from other bulk material with aligned electron spins, where the magnetic field is shielded with superconductor.
- $236\,\mathrm{These}$ experiments used a torsion pendulum to measure the potential between two bulk matter objects where the spins are polarized but without a net magnetic field in either
- 237 WINELAND 91 looked for an effect of bulk matter with aligned electron spins on atomic hyperfine splitting using nuclear magnetic resonance

Invisible A⁰ (Axion) Limits from Nucleon Coupling

Limits are for the axion mass in eV

Gauge & Higgs Boson Particle Listings Axions (A^0) and Other Very Light Bosons

- ²³⁸ DERBIN 11 looked for solar axions emitted by the M1 transition of thermally excited 57 Fe nuclei in the Sun, using their possible resonant capture on 57 Fe in the laboratory. The mass bound assumes $m_u/m_d=0.56$ and the flavor-singlet axial vector matrix element $S=3F-D\simeq0.5$.
- 239 BELLI 08A is analogous to KRCMAR 01 and DERBIN 05.
- 240 BELLINI 08 consider solar axions emitted in the M1 transition of 7 Li* (478 keV) and bellin to consider solar axions entire in the wint transition of $El^{-}(476 \text{ keV})$ and look for a peak at 478 keV in the energy spectra of the Counting Test Facility (CTF), a Borexino prototype. For $m_{A^0} < 450$ keV they find mass-dependent limits on products of axion couplings to photons, electrons, and nucleons.
- ²⁴¹ ADELBERGER 07 use precision tests of Newton's law to constrain a force contribution from the exchange of two pseudoscalars. See their Fig. 5 for limits on the pseudoscalar coupling to nucleons, relevant for m_{A^0} below about 1 meV.
- $^{242}\,\mathrm{DERBIN}$ 05 bound is based on the same principle as KRCMAR 01.
- ²⁴³LJUBICIC 04 looked for ejection of K-shell electrons by the axioelectric effect of 14.4 keV solar axions in a Germanium detector. The limit assumes the hadronic axion model and the same solar axion flux as in KRCMAR 98 and KRCMAR 01. 244 KRCMAR 01 looked for solar axions emitted by the M1 transition of ⁷Li after the electron
- capture by ${}^{7}\mathrm{Be}$ and the emission of 384 keV line neutrino, using their resonant capture on $^7\mathrm{Li}$ in the laboratory. The mass bound assumes $m_u/m_d =$ 0.56 and the flavor-singlet axial-vector matrix element S=0.4.

Axion Limits from T-violating Medium-Range Forces

V

The limit is for the coupling $g=g_{
m p}\,\,g_{
m S}$ in a $ar{T}$ -violating potential between nucleons or nucleon and electron of the form $V=rac{g\hbar^2}{8\pi m_p}(\pmb{\sigma}\cdot \pmb{\hat{r}})~(rac{1}{r^2}+rac{1}{\lambda r})~e^{-r/\lambda}$, where $g_{\rm p}$ and $g_{\rm S}$ are dimensionless scalar and pseudoscalar coupling constants and $\lambda=\hbar/(m_Ac)$ is the range of the force.

- $^{245}\,\mathrm{HOEDL}$ 11 use a novel torsion pendulum to study the force by the polarized electrons of an external magnet. In their Fig. 3 they show restrictive limits on g in the approximate m_{A^0} range 0.03–10 meV.
- 246 PETUKHOV 10 use spin relaxation of polarized 3 He and find $g<3\times10^{-23}~(\text{cm}/\lambda)^2$ at 95% CL for the force range $\lambda=10^{-4}$ -1 cm. 247 SEREBROV 10 use spin precession of ultracold neutrons close to bulk matter and find $g<2\times10^{-21}~(\text{cm}/\lambda)^2$ at 95% CL for the force range $\lambda=10^{-4}$ -1 cm.
- 248 IGNATOVICH 09 use data on depolarization of ultracold neutrons in material traps. They show λ -dependent limits in their Fig. 1.
- 249 SEREBROV 09 uses data on depolarization of ultracold neutrons stored in material traps and finds $g < 2.96 \times 10^{-21} \ (\text{cm}/\lambda)^2$ for the force range $\lambda = 10^{-3} 1$ cm and $g < 3.9 \times 10^{-22} \ (\text{cm}/\lambda)^2$ for $\lambda = 10^{-4} 10^{-3}$ cm, each time at 95% CL, significantly improving on BAESSLER 07.
- $250\,\mathrm{BAESSLER}$ 07 use the observation of quantum states of ultracold neutrons in the Earth's gravitational field to constrain g for an interaction range 1 μ m-a few mm. See their Fig. 3
- 251 HECKEL 06 studied the influence of unpolarized bulk matter, including the laboratory's surroundings or the Sun, on a torsion pendulum containing about 9×10^{22} polarized electrons. See their Fig. 4 for limits on g as a function of interaction range.
- $^{252}\,\mathrm{Nl}$ 99 searched for a T-violating medium-range force acting on paramagnetic Tb F $_3$ salt. See their Fig. 1 for the result.
- 253 POSPELOV 98 studied the possible contribution of *T*-violating Medium-Range Force to the neutron electric dipole moment, which is possible when axion interactions violate *CP*. The size of the force among nucleons must be smaller than gravity by a factor of $2 imes 10^{-10}~(1~{
 m cm}/\lambda_A)$, where $\lambda_A = \hbar/m_A c$.
- 254 YOUDIN 96 compared the precession frequencies of atomic ¹⁹⁹Hg and Cs when a large mass is positioned near the cells, relative to an applied magnetic field. See Fig. 3 for
- 255 RITTER 93 studied the influence of bulk mass with polarized electrons on an unpolarized torsion pendulum, providing limits in the interaction range from 1 to 100 cm
- 256 VENEMA 92 looked for an effect of Earth's gravity on nuclear spin-precession frequencies of $^{199}\mathrm{Hg}$ and $^{201}\mathrm{Hg}$ atoms.
- 257 WINELAND 91 looked for an effect of bulk matter with aligned electron spins on atomic hyperfine resonances in stored ${}^9{\rm Be}^+$ ions using nuclear magnetic resonance

e MASS (atomic mass units u)

The primary determination of an electron's mass comes from measuring the ratio of the mass to that of a nucleus, so that the result is obtained in u (atomic mass units). The conversion factor to MeV is more uncertain than the mass of the electron in u; indeed, the recent improvements in the mass determination are not evident when the result is given in MeV. In this datablock we give the result in u, and in the following datablock in MeV.

 $^{^1}$ BEIER 02 compares Larmor frequency of the electron bound in a $^{12}{\rm C}^{5+}$ ion with the cyclotron frequency of a single trapped $^{12}{\rm C}^{5+}$ ion.

e MASS

2010 CODATA (MOHR 12) gives the conversion factor from u (atomic mass units, see the above datablock) to MeV as 931.494 061 (21). Earlier values use the then-current conversion factor. The conversion error dominates the uncertainty of the masses given below.

e- MEAN LIFE / BRANCHING FRACTION

A test of charge conservation. See the "Note on Testing Charge Conservation and the Pauli Exclusion Principle" following this section in our 1992 edition (Physical Review **D45** S1 (1992), p. VI.10).

Most of these experiments are one of three kinds: Attempts to observe (a) the 255.5 keV gamma ray produced in $e^- \to \nu_e \gamma$, (b) the (K) shell x ray produced when an electron decays without additional energy deposit, e.g., $e^- \to \nu_e \overline{\nu}_e \nu_e$ ("disappearance" experiments), and (c) nuclear deexcitation gamma rays after the electron disappears from an atomic shell and the nucleus is left in an excited state. The last can include both weak boson and photon mediating processes. We use the best $e^- \to \nu_e \gamma$ limit for the Summary Tables.

Note that we use the mean life rather than the half life, which is often reported. $% \left(1\right) =\left(1\right) \left(1\right$

¹⁶ The authors of A. Derbin et al, arXiv:0704.2047v1 argue that this limit is overestimated by at least a factor of 5.

 $^{^2}$ FARNHAM 95 compares cyclotron frequency of trapped electrons with that of a single trapped 12 C $^{6+}$ ion.

 $^{^4}$ BEIER 02 compares Larmor frequency of the electron bound in a $^{12}\mathrm{C}^{5+}$ ion with the cyclotron frequency of a single trapped $^{12}\mathrm{C}^{5+}$ ion.

 $^{^{5}\,\}text{FARNHAM}$ 95 compares cyclotron frequency of trapped electrons with that of a single trapped $^{12}\text{C}^{6+}$ ion.

⁸ SCHAEFER 95 removes model dependency of MUELLER 92.

⁹ MUELLER 92 argues that an inequality of the charge magnitudes would, through higherorder vacuum polarization, contribute to the net charge of atoms.

¹¹ Superseded by HANNEKE 08 per private communication with Gerald Gabrielse.

¹⁵ ABDULLAH 90, COMMINS 94, and REGAN 02 use the relativistic enhancement of a valence electron's electric dipole moment in a high-Z atom.

 $^{^{17}}$ ORITO 85 assumes that electromagnetic forces extend out to large enough distances and that the age of our galaxy is 10^{10} years.

μ MASS (atomic mass units u)

The muon's mass is obtained from the muon-electron mass ratio as determined from the measurement of Zeeman transition frequencies in muonium $(\mu^+e^-$ atom). Since the electron's mass is most accurately known in u, the muon's mass is also most accurately known in u. The conversion factor to MeV has approximately the same relative uncertainty as the mass of the muon in u. In this datablock we give the result in u, and in the following datablock in MeV.

μ MASS

2010 CODATA (MOHR 12) gives the conversion factor from u (atomic mass units, see the above datablock) to MeV as 931.494.061 (21). Earlier values use the then-current conversion factor. The conversion error contributes significantly to the uncertainty of the masses given below.

μ/p MAGNETIC MOMENT RATIO

This ratio is used to obtain a precise value of the muon mass and to reduce experimental muon Larmor frequency measurements to the muon magnetic moment anomaly. Measurements with an error > 0.00001 have been omitted. By convention, the minus sign on this ratio is omitted. CODATA values were fitted using their selection of data, plus other data from multiparameter fits.

THE MUON ANOMALOUS MAGNETIC MOMENT

Updated July 2011 by A. Hoecker (CERN), and W.J. Marciano (BNL).

The Dirac equation predicts a muon magnetic moment, $\vec{M} = g_{\mu} \frac{e}{2m_{\mu}} \vec{S}$, with gyromagnetic ratio $g_{\mu} = 2$. Quantum loop effects lead to a small calculable deviation from $g_{\mu} = 2$, parameterized by the anomalous magnetic moment

$$a_{\mu} \equiv \frac{g_{\mu} - 2}{2} \ . \tag{1}$$

That quantity can be accurately measured and, within the Standard Model (SM) framework, precisely predicted. Hence, comparison of experiment and theory tests the SM at its quantum loop level. A deviation in $a_{\mu}^{\rm exp}$ from the SM expectation would signal effects of new physics, with current sensitivity reaching up to mass scales of $\mathcal{O}(\text{TeV})$ [1,2]. For recent and very thorough muon g-2 reviews, see Refs. [3,4].

The E821 experiment at Brookhaven National Lab (BNL) studied the precession of μ^+ and μ^- in a constant external magnetic field as they circulated in a confining storage ring. It found [6] ¹

$$\begin{split} a_{\mu+}^{\rm exp} &= 11\,659\,204(6)(5)\times 10^{-10}\,,\\ a_{\mu-}^{\rm exp} &= 11\,659\,215(8)(3)\times 10^{-10}\,, \end{split} \tag{2}$$

where the first errors are statistical and the second systematic. Assuming CPT invariance and taking into account correlations between systematic errors, one finds for their average [6]

$$a_{\mu}^{\text{exp}} = 11659208.9(5.4)(3.3) \times 10^{-10}$$
 . (3)

These results represent about a factor of 14 improvement over the classic CERN experiments of the 1970's [7]. Improvement of the measurement in Eq. (3) by a factor of four by moving the E821 storage ring to Fermilab, and utilizing a cleaner and more intense muon beam has been proposed.

The SM prediction for a_{μ}^{SM} is generally divided into three parts (see Fig. 1 for representative Feynman diagrams)

$$a_{\mu}^{\text{SM}} = a_{\mu}^{\text{QED}} + a_{\mu}^{\text{EW}} + a_{\mu}^{\text{Had}} . \tag{4}$$

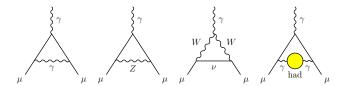

Figure 1: Representative diagrams contributing to $a_{\mu}^{\rm SM}$. From left to right: first order QED (Schwinger term), lowest-order weak, lowest-order hadronic.

The QED part includes all photonic and leptonic (e, μ, τ) loops starting with the classic $\alpha/2\pi$ Schwinger contribution. It has been computed through 4 loops and estimated at the 5-loop level [8]

$$a_{\mu}^{\text{QED}} = \frac{\alpha}{2\pi} + 0.765857410(27) \left(\frac{\alpha}{\pi}\right)^2 + 24.05050964(43) \left(\frac{\alpha}{\pi}\right)^3 + 130.8055(80) \left(\frac{\alpha}{\pi}\right)^4 + 663(20) \left(\frac{\alpha}{\pi}\right)^5 + \cdots$$
 (5

Employing $\alpha^{-1} = 137.035999084(51)$, determined [8,9] from the electron a_e measurement, leads to

$$a_{\mu}^{\rm QED} = 116\,584\,718.09(0.15) \times 10^{-11}\,,$$
 (6)

where the error results from uncertainties in the coefficients of Eq. (5) and in α .

Loop contributions involving heavy W^{\pm}, Z or Higgs particles are collectively labeled as a_{μ}^{EW} . They are suppressed by at

least a factor of
$$\frac{\alpha}{\pi} \frac{m_{\mu}^2}{m_W^2} \simeq 4 \times 10^{-9}$$
. At 1-loop order [10]

$$a_{\mu}^{\text{EW}}[1\text{-loop}] = \frac{G_{\mu}m_{\mu}^{2}}{8\sqrt{2}\pi^{2}} \left[\frac{5}{3} + \frac{1}{3} \left(1 - 4\sin^{2}\theta_{\text{W}} \right)^{2} + \mathcal{O}\left(\frac{m_{\mu}^{2}}{M_{W}^{2}} \right) + \mathcal{O}\left(\frac{m_{\mu}^{2}}{m_{H}^{2}} \right) \right],$$

$$= 194.8 \times 10^{-11}, \tag{7}$$

for $\sin^2\theta_{\rm W} \equiv 1-M_W^2/M_Z^2 \simeq 0.223$, and where $G_{\mu} \simeq 1.166 \times 10^{-5} \ {\rm GeV^{-2}}$ is the Fermi coupling constant. Two-loop corrections are relatively large and negative [11]

$$a_{\mu}^{\text{EW}}[2\text{-loop}] = -40.7(1.0)(1.8) \times 10^{-11},$$
 (8)

where the errors stem from quark triangle loops and the assumed Higgs mass range between 100 and 500 GeV. The 3-loop leading logarithms are negligible [11,12], $\mathcal{O}(10^{-12})$, implying in total

$$a_{\mu}^{\text{EW}} = 154(1)(2) \times 10^{-11} \ . \tag{9}$$

Hadronic (quark and gluon) loop contributions to $a_{\mu}^{\rm SM}$ give rise to its main theoretical uncertainties. At present, those effects

¹ The original results reported by the experiment have been updated in Eqs. (2) and (3) to the newest value for the absolute muon-to-proton magnetic ratio $\lambda = 3.183345137(85)$ [5]. The change induced in $a_{\mu}^{\rm exp}$ with respect to the value of $\lambda = 3.18334539(10)$ used in Ref. 6 amounts to $+0.92 \times 10^{-10}$.

are not calculable from first principles, but such an approach, at least partially, may become possible as lattice QCD matures. Instead, one currently relies on a dispersion relation approach to evaluate the lowest-order (i.e., $\mathcal{O}(\alpha^2)$) hadronic vacuum polarization contribution $a_{\mu}^{\mathrm{Had}}[\mathrm{LO}]$ from corresponding cross section measurements [13]

$$a_{\mu}^{\text{Had}}[\text{LO}] = \frac{1}{3} \left(\frac{\alpha}{\pi}\right)^{2} \int_{m^{2}}^{\infty} ds \, \frac{K(s)}{s} R^{(0)}(s) \,,$$
 (10)

where K(s) is a QED kernel function [14], and where $R^{(0)}(s)$ denotes the ratio of the bare² cross section for e^+e^- annihilation into hadrons to the pointlike muon-pair cross section at center-of-mass energy \sqrt{s} . The function $K(s) \sim 1/s$ in Eq. (10) gives a strong weight to the low-energy part of the integral. Hence, $a_{\mu}^{\text{Had}}[\text{LO}]$ is dominated by the $\rho(770)$ resonance.

Currently, the available $\sigma(e^+e^- \to \text{hadrons})$ data give a leading-order hadronic vacuum polarization (representative) contribution of [15]

$$a_{\mu}^{\text{Had}}[\text{LO}] = 6\,923(42)(3) \times 10^{-11},$$
 (11)

where the first error is experimental (dominated by systematic uncertainties), and the second due to perturbative QCD, which is used at intermediate and large energies to predict the contribution from the quark-antiquark continuum. New multi-hadron data from the BABAR experiment have increased the constraints on unmeasured exclusive final states and led to a small reduction in the hadronic contribution compared to the 2009 PDG value.

Alternatively, one can use precise vector spectral functions from $\tau \to \nu_{\tau}$ + hadrons decays [16] that can be related to isovector $e^+e^- \to \text{hadrons}$ cross sections by isospin symmetry. Replacing e^+e^- data in the two-pion and four-pion channels by the corresponding isospin-transformed τ data, and applying isospin-violating corrections (from QED and $m_d - m_u \neq 0$), one finds [15]

$$a_{\mu}^{\text{Had}}[\text{LO}] = 7015(42)(19)(3) \times 10^{-11} (\tau),$$
 (12)

where the first error is experimental, the second estimates the uncertainty in the isospin-breaking corrections applied to the τ data, and the third error is due to perturbative QCD. The current discrepancy between the e^+e^- and τ -based determinations of $a_{\mu}^{\rm Had}[{\rm LO}]$ has been reduced to 1.8 σ with respect to earlier evaluations. New e^+e^- and τ data from the *B*-factory experiments BABAR and Belle have increased the experimental information. Reevaluated isospin-breaking corrections have also contributed to this improvement [17]. BABAR recently

reported good agreement with the τ data in the most important two-pion channel [18]. The remaining discrepancy with the older e^+e^- and τ datasets may be indicative of problems with one or both data sets. It may also suggest the need for additional isospin-violating corrections to the τ data.

Higher order, $\mathcal{O}(\alpha^3)$, hadronic contributions are obtained from dispersion relations using the same $e^+e^- \to \text{hadrons}$ data [16,19,22], giving $a_\mu^{\text{Had,Disp}}[\text{NLO}] = (-98.4 \pm 0.6) \times 10^{-11}$, along with model-dependent estimates of the hadronic light-by-light scattering contribution, $a_\mu^{\text{Had,LBL}}[\text{NLO}]$, motivated by large- N_C QCD [23–29]. § Following [27], one finds for the sum of the two terms

$$a_{\mu}^{\text{Had}}[\text{NLO}] = 7(26) \times 10^{-11},$$
 (13)

where the error is dominated by hadronic light-by-light uncertainties.

Adding Eqs. (6), (9), (11) and (13) gives the representative e^+e^- data based SM prediction

$$a_{\mu}^{\text{SM}} = 116591802(2)(42)(26) \times 10^{-11},$$
 (14)

where the errors are due to the electroweak, lowest-order hadronic, and higher-order hadronic contributions, respectively. The difference between experiment and theory

$$\Delta a_{\mu} = a_{\mu}^{\text{exp}} - a_{\mu}^{\text{SM}} = 287(63)(49) \times 10^{-11},$$
 (15)

(with all errors combined in quadrature) represents an interesting but not yet conclusive discrepancy of 3.6 times the estimated 1σ error. All the recent estimates for the hadronic contribution compiled in Fig. 2 exhibit similar discrepancies. Switching to τ data reduces the discrepancy to 2.4σ , assuming the isospin-violating corrections are under control within the estimated uncertainties.

An alternate interpretation is that Δa_{μ} may be a new physics signal with supersymmetric particle loops as the leading candidate explanation. Such a scenario is quite natural, since generically, supersymmetric models predict [1] an additional contribution to $a_{\nu}^{\rm SM}$

$$a_{\mu}^{\rm SUSY} \simeq \pm 130 \times 10^{-11} \cdot \left(\frac{100 \text{ GeV}}{m_{\rm SUSY}}\right)^2 \tan\beta,$$
 (16)

where $m_{\rm SUSY}$ is a representative supersymmetric mass scale, and $\tan\beta \simeq 3\text{--}40$ is a potential enhancement factor. Supersymmetric particles in the mass range 100–500 GeV could be the source of the deviation Δa_{μ} . If so, those particles could be directly observed at the next generation of high energy colliders.

New physics effects [1] other than supersymmetry could also explain a non-vanishing Δa_{μ} . A recent popular scenario involves the "dark photon", a relatively light hypothetical vector boson from the dark matter sector that couples to our world of particle

² The bare cross section is defined as the measured cross section corrected for initial-state radiation, electron-vertex loop contributions and vacuum-polarization effects in the photon propagator. However, QED effects in the hadron vertex and final state, as photon radiation, are included.

³ Some representative recent estimates of the hadronic light-by-light scattering contribution, $a_{\mu}^{\rm Had,LBL}[\rm NLO]$, that followed after the sign correction of [25], are: $105(26) \times 10^{-11}$ [27], $110(40) \times 10^{-11}$ [23], $136(25) \times 10^{-11}$ [24].

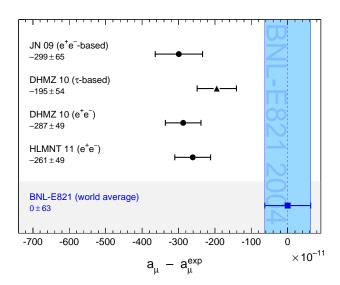

Figure 2: Compilation of recently published results for a_{μ} (in units of 10^{-11}), subtracted by the central value of the experimental average (3). The shaded band indicates the experimental error. The SM predictions are taken from: JN [4], DHMZ [15], and HMNT [19]. Note that the quoted errors do not include the uncertainty on the subtracted experimental value. To obtain for each theory calculation a result equivalent to Eq. (15), the errors from theory and experiment must be added in quadrature.

physics through mixing with the ordinary photon [30,31]. As a result, it couples to ordinary charged particles with strength $\varepsilon \cdot e$ and gives rise to an additional muon anomalous magnetic moment contribution

$$a_{\mu}^{\mathrm{dark \ photon}} = \frac{\alpha}{2\pi} \varepsilon^2 F(m_V/m_{\mu}) \,,$$
 (17)

where $F(x) = \int_0^1 2z(1-z)^2/[(1-z)^2+x^2z]\,dz$. For values of $\varepsilon \sim 1$ –2·10⁻³ and $m_V \sim 10$ –100 MeV, the dark photon, which was originally motivated by cosmology, can provide a viable solution to the muon g-2 discrepancy. Searches for the dark photon in that mass range are currently underway at Jefferson Lab, USA, and MAMI in Mainz, Germany.

μ MAGNETIC MOMENT ANOMALY

The parity-violating decay of muons in a storage ring is observed. The difference frequency ω_a between the muon spin precision and the orbital angular frequency $(e/m_\mu c)\langle B\rangle$ is measured, as is the free proton NMR frequency ω_p , thus determining the ratio $R\!=\!\omega_a/\omega_p$. Given the magnetic moment ratio $\lambda\!=\!\mu_\mu/\mu_p$ (from hyperfine structure in muonium), $(g\!-\!2)/2=R/(\lambda\!-\!R)$.

$\mu_{\mu}/(e\hbar/2m_{\mu})-1=(g_{\mu}-2)/2$

 7 BENNETT 06 reports $(g_\mu-2)/2=(1165\,9208.0\,\pm\,5.4\,\pm\,3.3)\,\times\,10^{-10}$. We rescaled this value using μ/p magnetic moment ratio of 3.183345137(85) from MOHR 08.

 8 BAILEY 79 values recalculated by HUGHES 99 using the COHEN 87 μ/p magnetic moment. The improved MOHR 99 value does not change the result.

$(g_{\mu^+} - g_{\mu^-}) / g_{\text{average}}$

 11 MEYER 00 measure the 1s–2s muonium interval, and then interpret the result in terms of muon-electron charge ratio q_{μ^+}/q_{e^-} .

μ^- DECAY MODES

 μ^+ modes are charge conjugates of the modes below.

| | Mode | Fraction (Γ _i /Γ) | Confidence level |
|-----------------------|-----------------------------------------|------------------------------------|------------------|
| $\overline{\Gamma_1}$ | $e^- \overline{\nu}_e \nu_\mu$ | ≈ 100% | |
| Γ_2 | $e^-\overline{ u}_e^{} u_\mu\gamma$ | [a] (1.4 ± 0.4) % | |
| Γ_3 | $e^- \overline{ u}_e u_\mu e^+ e^-$ | [b] $(3.4 \pm 0.4) \times 10^{-5}$ | |

Lepton Family number (LF) violating modes

| Γ_4 | $e^- \nu_e \overline{\nu}_\mu$ | LF | [c] < 1.2 | % | 90% |
|------------|--------------------------------|----|-----------|-------------------|-----|
| Γ_5 | $e^-\gamma$ | LF | < 2.4 | $\times 10^{-12}$ | 90% |
| Γ_6 | $e^-e^+e^-$ | LF | < 1.0 | $\times 10^{-12}$ | 90% |
| Γ_7 | $e^-2\gamma$ | LF | < 7.2 | $\times 10^{-11}$ | 90% |

- [a] This only includes events with the γ energy > 10 MeV. Since the $e^-\overline{\nu}_e\,\nu_\mu$ and $e^-\overline{\nu}_e\,\nu_\mu\gamma$ modes cannot be clearly separated, we regard the latter mode as a subset of the former.
- [b] See the Particle Listings below for the energy limits used in this measurement.
- $\left[c\right]$ A test of additive vs. multiplicative lepton family number conservation.

 16 FREEDMAN 93 limit on $\overline{
u}_e$ observation is here interpreted as a limit on lepton family

number violation. The BERGSMA 83 gives a limit on the inverse muon decay cross-section ratio $\sigma(\overline{\nu}_{\mu}e^{-}\rightarrow \mu^{-}\overline{\nu}_{e})/\sigma(\nu_{\mu}e^{-}\rightarrow \mu^{-}\nu_{e})$, which is essentially equivalent to $\Gamma(e^{-}\nu_{e}\overline{\nu}_{\mu})/\Gamma_{\rm total}$ for small values like that quoted.

 $\Gamma(e^-\gamma)/\Gamma_{total}$ Forbidden by lepton family number conservation.

MUON DECAY PARAMETERS

Revised January 2012 by W. Fetscher and H.-J. Gerber (ETH Zürich).

Introduction: All measurements in direct muon decay, $\mu^- \to e^- + 2$ neutrals, and its inverse, $\nu_\mu + e^- \to \mu^- + \text{neutral}$, are successfully described by the "V-A interaction," which is a particular case of a local, derivative-free, lepton-number-conserving, four-fermion interaction [1]. As shown below, within this framework, the Standard Model assumptions, such as the V-A form and the nature of the neutrals $(\nu_\mu \text{ and } \bar{\nu}_e)$, and hence the doublet assignments $(\nu_e \ e^-)_L$ and $(\nu_\mu \ \mu^-)_L$, have been determined from experiments [2,3]. All considerations on muon decay are valid for the leptonic tau decays $\tau \to \ell + \nu_\tau + \bar{\nu}_e$ with the replacements $m_\mu \to m_\tau$, $m_e \to m_\ell$.

Parameters: The differential decay probability to obtain an e^{\pm} with (reduced) energy between x and x + dx, emitted in the direction \hat{x}_3 at an angle between ϑ and $\vartheta + d\vartheta$ with respect to the muon polarization vector \mathbf{P}_{μ} , and with its spin parallel to the arbitrary direction $\hat{\zeta}$, neglecting radiative corrections, is given by

$$\begin{split} \frac{\mathrm{d}^{2}\Gamma}{\mathrm{d}x \, \mathrm{d}\cos\vartheta} &= \frac{m_{\mu}}{4\pi^{3}} \, W_{e\mu}^{4} \, G_{\mathrm{F}}^{2} \, \sqrt{x^{2} - x_{0}^{2}} \\ &\times (F_{\mathrm{IS}}(x) \pm P_{\mu}\cos\vartheta \, F_{\mathrm{AS}}(x)) \\ &\times \left[1 + \hat{\boldsymbol{\zeta}} \cdot \boldsymbol{P}_{e}(x,\vartheta) \right] \, . \end{split} \tag{1}$$

Here, $W_{e\mu} = \max(E_e) = (m_{\mu}^2 + m_e^2)/2m_{\mu}$ is the maximum e^{\pm} energy, $x = E_e/W_{e\mu}$ is the reduced energy, $x_0 = m_e/W_{e\mu} = 9.67 \times 10^{-3}$, and $P_{\mu} = |\mathbf{P}_{\mu}|$ is the degree of muon polarization. $\hat{\boldsymbol{\zeta}}$ is the direction in which a perfect polarization-sensitive electron detector is most sensitive. The isotropic part of the spectrum, $F_{\rm IS}(x)$, the anisotropic part $F_{\rm AS}(x)$, and the electron polarization, $\mathbf{P}_e(x,\vartheta)$, may be parametrized by the Michel parameter ρ [1], by η [4], by ξ and δ [5,6], etc. These are bilinear combinations of the coupling constants $g_{\varepsilon\mu}^{\gamma}$, which occur in the matrix element (given below).

 μ

If the masses of the neutrinos as well as x_0^2 are neglected, the energy and angular distribution of the electron in the rest frame of a muon (μ^{\pm}) measured by a polarization insensitive detector, is given by

$$\frac{\mathrm{d}^2 \Gamma}{\mathrm{d}x \, \mathrm{d} \cos \vartheta} \sim x^2 \cdot \left\{ 3(1-x) + \frac{2\rho}{3} (4x-3) + 3\eta \, x_0 (1-x) / x \right.$$

$$\pm P_\mu \cdot \xi \cdot \cos \vartheta \left[1 - x + \frac{2\delta}{3} (4x-3) \right] \right\} . \tag{2}$$

Here, ϑ is the angle between the electron momentum and the muon spin, and $x \equiv 2E_e/m_\mu$. For the Standard Model coupling, we obtain $\rho = \xi \delta = 3/4$, $\xi = 1$, $\eta = 0$ and the differential decay rate is

$$\frac{\mathrm{d}^2 \Gamma}{\mathrm{d}x \, \mathrm{d} \cos \vartheta} = \frac{G_{\mathrm{F}}^2 m_{\mu}^5}{192\pi^3} \left[3 - 2x \pm P_{\mu} \cos \vartheta (2x - 1) \right] x^2 \quad . \quad (3)$$

The coefficient in front of the square bracket is the total decay rate.

If only the neutrino masses are neglected, and if the e^{\pm} polarization is detected, then the functions in Eq. (1) become

$$F_{\rm IS}(x) = x(1-x) + \frac{2}{9} \rho(4x^2 - 3x - x_0^2) + \eta \cdot x_0(1-x)$$

$$F_{\rm AS}(x) = \frac{1}{3}\xi \sqrt{x^2 - x_0^2}$$

$$\times \left[1 - x + \frac{2}{3}\delta(4x - 3 + (\sqrt{1 - x_0^2} - 1))\right]$$

$$\mathbf{P}_e(x, \vartheta) = P_{\rm T_1} \cdot \hat{\mathbf{x}}_1 + P_{\rm T_2} \cdot \hat{\mathbf{x}}_2 + P_L \cdot \hat{\mathbf{x}}_3 . \tag{4}$$

Here $\hat{\boldsymbol{x}}_1,~\hat{\boldsymbol{x}}_2,$ and $\hat{\boldsymbol{x}}_3$ are orthogonal unit vectors defined as follows:

$$\begin{split} \widehat{\boldsymbol{x}}_3 & \text{ is along the } e \text{ momentum } \boldsymbol{p}_e \\ \frac{\widehat{\boldsymbol{x}}_3 \times \boldsymbol{P}_{\mu}}{|\widehat{\boldsymbol{x}}_2 \times \boldsymbol{P}_{\mu}|} = \widehat{\boldsymbol{x}}_2 & \text{ is transverse to } \boldsymbol{p}_e \text{ and perpendicular} \\ & \text{ to the "decay plane"} \\ \widehat{\boldsymbol{x}}_2 \times \widehat{\boldsymbol{x}}_3 = \widehat{\boldsymbol{x}}_1 & \text{ is transverse to the } \boldsymbol{p}_e \text{ and in the} \\ & \text{"decay plane."} \end{split}$$

The components of P_e then are given by

$$\begin{split} P_{\mathrm{T}_{1}}(x,\vartheta) &= P_{\mu}\sin\vartheta \cdot F_{\mathrm{T}_{1}}(x)/\left(F_{\mathrm{IS}}(x) \pm P_{\mu}\cos\vartheta \cdot F_{\mathrm{AS}}(x)\right) \\ P_{\mathrm{T}_{2}}(x,\vartheta) &= P_{\mu}\sin\vartheta \cdot F_{\mathrm{T}_{2}}(x)/\left(F_{\mathrm{IS}}(x) \pm P_{\mu}\cos\vartheta \cdot F_{\mathrm{AS}}(x)\right) \\ P_{L}(x,\vartheta) &= \left(\pm F_{\mathrm{IP}}(x) + P_{\mu}\cos\vartheta \\ &\quad \times F_{\mathrm{AP}}(x)\right)/\left(F_{\mathrm{IS}}(x) \pm P_{\mu}\cos\vartheta \cdot F_{\mathrm{AS}}(x)\right) \;, \end{split}$$

where

$$F_{\text{T}_{1}}(x) = \frac{1}{12} \left\{ -2 \left[\xi'' + 12(\rho - \frac{3}{4}) \right] (1 - x) x_{0} -3\eta(x^{2} - x_{0}^{2}) + \eta''(-3x^{2} + 4x - x_{0}^{2}) \right\}$$

$$F_{\text{T}_{2}}(x) = \frac{1}{3} \sqrt{x^{2} - x_{0}^{2}} \left\{ 3 \frac{\alpha'}{A} (1 - x) + 2 \frac{\beta'}{A} \sqrt{1 - x_{0}^{2}} \right\}$$

$$F_{\text{IP}}(x) = \frac{1}{54} \sqrt{x^{2} - x_{0}^{2}} \left\{ 9 \xi' \left(-2x + 2 + \sqrt{1 - x_{0}^{2}} \right) + 4 \xi (\delta - \frac{3}{4}) (4x - 4 + \sqrt{1 - x_{0}^{2}}) \right\}$$

$$F_{\text{AP}}(x) = \frac{1}{6} \left\{ \xi''(2x^{2} - x - x_{0}^{2}) + 4(\rho - \frac{3}{4}) (4x^{2} - 3x - x_{0}^{2}) + 2\eta''(1 - x) x_{0} \right\} . \tag{5}$$

For the experimental values of the parameters ρ , ξ , ξ' , ξ'' , δ , η , η'' , α/A , β/A , α'/A , β'/A , which are not all independent, see the Data Listings below. Experiments in the past have also been analyzed using the parameters a, b, c, a', b', c', α/A , β/A , α'/A , β'/A (and $\eta = (\alpha - 2\beta)/2A$), as defined by Kinoshita and Sirlin [5,6]. They serve as a model-independent summary of all possible measurements on the decay electron (see Listings below). The relations between the two sets of parameters are

$$\begin{split} \rho - \frac{3}{4} &= \frac{3}{4}(-a+2c)/A \;, \\ \eta &= (\alpha - 2\beta)/A \;, \\ \eta'' &= (3\alpha + 2\beta)/A \;, \\ \delta - \frac{3}{4} &= \frac{9}{4} \; \cdot \; \frac{(a'-2c')/A}{1 - [a+3a'+4(b+b')+6c-14c']/A} \;, \\ 1 - \xi \frac{\delta}{\rho} &= 4 \; \frac{[(b+b')+2(c-c')]/A}{1 - (a-2c)/A} \;, \\ 1 - \xi' &= \; [(a+a')+4(b+b')+6(c+c')]/A \;, \\ 1 - \xi'' &= \; (-2a+20c)/A \;, \end{split}$$

where

$$A = a + 4b + 6c. (6)$$

The differential decay probability to obtain a left-handed ν_e with (reduced) energy between y and y+dy, neglecting radiative corrections as well as the masses of the electron and of the neutrinos, is given by [7]

$$\frac{\mathrm{d}\Gamma}{\mathrm{d}y} = \frac{m_{\mu}^5 G_F^2}{16\pi^3} \cdot Q_L^{\nu_e} \cdot y^2 \left\{ (1-y) - \omega_L \cdot (y - \frac{3}{4}) \right\}. \tag{7}$$

Here, y=2 E_{ν_e}/m_{μ} . $Q_L^{\nu_e}$ and ω_L are parameters. ω_L is the neutrino analog of the spectral shape parameter ρ of Michel. Since in the Standard Model, $Q_L^{\nu_e}=1$, $\omega_L=0$, the measurement of $d\Gamma/dy$ has allowed a null-test of the Standard Model (see Listings below).

Matrix element: All results in direct muon decay (energy spectra of the electron and of the neutrinos, polarizations, and angular distributions), and in inverse muon decay (the reaction cross section) at energies well below $m_W c^2$, may be parametrized in terms of amplitudes $g_{\varepsilon\mu}^{\gamma}$ and the Fermi coupling constant G_F , using the matrix element

$$\frac{4G_F}{\sqrt{2}} \sum_{\substack{\gamma = S, V, T \\ \varepsilon \mid \mu = R, L}} g_{\varepsilon\mu}^{\gamma} \langle \bar{e}_{\varepsilon} | \Gamma^{\gamma} | (\nu_e)_n \rangle \langle (\bar{\nu}_{\mu})_m | \Gamma_{\gamma} | \mu_{\mu} \rangle. \tag{8}$$

We use the notation of Fetscher et al. [2], who in turn use the sign conventions and definitions of Scheck [8]. Here, $\gamma = S, V, T$ indicates a scalar, vector, or tensor interaction; and $\varepsilon, \mu = R, L$ indicate a right- or left-handed chirality of the electron or muon. The chiralities n and m of the ν_e and $\bar{\nu}_{\mu}$ are then determined by the values of γ, ε , and μ . The particles are represented by fields of definite chirality [9].

As shown by Langacker and London [10], explicit leptonnumber nonconservation still leads to a matrix element equivalent to Eq. (8). They conclude that it is not possible, even in principle, to test lepton-number conservation in (leptonic) muon decay if the final neutrinos are massless and are not observed.

The ten complex amplitudes $g_{\varepsilon\mu}^{\gamma}$ (g_{RR}^{T} and g_{LL}^{T} are identically zero) and G_{F} constitute 19 independent (real) parameters to be determined by experiment. The Standard Model interaction corresponds to one single amplitude g_{LL}^{V} being unity and all the others being zero.

The (direct) muon decay experiments are compatible with an arbitrary mix of the scalar and vector amplitudes g_{LL}^S and g_{LL}^V – in the extreme even with purely scalar $g_{LL}^S = 2$, $g_{LL}^V = 0$. The decision in favour of the Standard Model comes from the quantitative observation of inverse muon decay, which would be forbidden for pure g_{LL}^S [2].

Experimental determination of V-A: In order to determine the amplitudes $g_{\varepsilon\mu}^{\gamma}$ uniquely from experiment, the following set of equations, where the left-hand sides represent experimental results, has to be solved.

 $a = 16(|g_{RL}^V|^2 + |g_{LR}^V|^2) + |g_{RL}^S + 6g_{RL}^T|^2 + |g_{LR}^S + 6g_{LR}^T|^2$

 $a' = 16(|g_{RL}^V|^2 - |g_{LR}^V|^2) + |g_{RL}^S + 6g_{RL}^T|^2 - |g_{LR}^S + 6g_{LR}^T|^2$

$$\begin{split} \alpha &= 8 \mathrm{Re} \left\{ g_{RL}^V(g_{LR}^{S*} + 6g_{LR}^{T*}) + g_{LR}^V(g_{RL}^{S*} + 6g_{RL}^{T*}) \right\} \\ \alpha' &= 8 \mathrm{Im} \left\{ g_{LR}^V(g_{RL}^{S*} + 6g_{RL}^{T*}) - g_{RL}^V(g_{LR}^{S*} + 6g_{LR}^{T*}) \right\} \\ b &= 4 (|g_{RR}^V|^2 + |g_{LL}^V|^2) + |g_{RR}^S|^2 + |g_{LL}^S|^2 \\ b' &= 4 (|g_{RR}^V|^2 - |g_{LL}^V|^2) + |g_{RR}^S|^2 - |g_{LL}^S|^2 \\ \beta &= -4 \mathrm{Re} \left\{ g_{RR}^V g_{LL}^{S*} + g_{LL}^V g_{RR}^{S*} \right\} \\ \beta' &= 4 \mathrm{Im} \left\{ g_{RR}^V g_{LL}^{S*} + g_{LL}^V g_{RR}^{S*} \right\} \\ c &= \frac{1}{2} \left\{ |g_{RL}^S - 2g_{RL}^T|^2 + |g_{LR}^S - 2g_{LR}^T|^2 \right\} \\ c' &= \frac{1}{2} \left\{ |g_{RL}^S - 2g_{RL}^T|^2 - |g_{LR}^S - 2g_{LR}^T|^2 \right\} \\ \mathrm{nd} \\ Q_L^{\nu_e} &= 1 - \left\{ \frac{1}{4} |g_{LR}^S|^2 + \frac{1}{4} |g_{LL}^S|^2 + |g_{RR}^V|^2 + |g_{RL}^V|^2 + 3|g_{LR}^T|^2 \right\} \\ \omega_L &= \frac{3}{4} \frac{\left\{ |g_{RR}^S|^2 + 4|g_{LR}^V|^2 + |g_{RL}^S|^2 + 12|g_{RL}^T|^2 \right\}}{|g_{RR}^S|^2 + |g_{RR}^S|^2 + 4|g_{LL}^V|^2 + 4|g_{LR}^V|^2 + 12|g_{RL}^T|^2} \,. \end{split}$$

It has been noted earlier by C. Jarlskog [11], that certain experiments observing the decay electron are especially informative if they yield the V-A values. The complete solution is now found as follows. Fetscher et al. [2] introduced four probabilities $Q_{\varepsilon\mu}(\varepsilon,\mu=R,L)$ for the decay of a μ -handed muon into an ε -handed electron, and showed that there exist upper bounds on Q_{RR} , Q_{LR} , and Q_{RL} , and a lower bound on Q_{LL} . These probabilities are given in terms of the $g_{\varepsilon\mu}^{\gamma}$'s by

$$Q_{\varepsilon\mu} = \frac{1}{4} |g_{\varepsilon\mu}^S|^2 + |g_{\varepsilon\mu}^V|^2 + 3(1 - \delta_{\varepsilon\mu})|g_{\varepsilon\mu}^T|^2 , \qquad (9)$$

where $\delta_{\varepsilon\mu} = 1$ for $\varepsilon = \mu$, and $\delta_{\varepsilon\mu} = 0$ for $\varepsilon \neq \mu$. They are related to the parameters a, b, c, a', b', and c' by

$$Q_{RR} = 2(b+b')/A ,$$

$$Q_{LR} = [(a-a') + 6(c-c')]/2A ,$$

$$Q_{RL} = [(a+a') + 6(c+c')]/2A ,$$

$$Q_{LL} = 2(b-b')/A ,$$
(10)

with A = 16. In the Standard Model, $Q_{LL} = 1$ and the others are zero.

Since the upper bounds on Q_{RR} , Q_{LR} , and Q_{RL} are found to be small, and since the helicity of the ν_{μ} in pion decay is known from experiment [12,13] to very high precision to be -1 [14], the cross section S of *inverse* muon decay, normalized to the V-A value, yields [2]

$$|g_{LL}^S|^2 \le 4(1-S) \tag{11}$$

and

$$|g_{LL}^V|^2 = S. (12)$$

Thus the Standard Model assumption of a pure V-A leptonic charged weak interaction of e and μ is derived (within errors) from experiments at energies far below mass of the W^{\pm} : Eq. (12) gives a lower limit for V-A, and Eqs. (9) and (11) give upper limits for the other four-fermion interactions. The existence of such upper limits may also be seen from $Q_{RR}+Q_{RL}=(1-\xi')/2$ and $Q_{RR}+Q_{LR}=\frac{1}{2}(1+\xi/3-16\ \xi\delta/9)$. Table 1 gives the current experimental limits on the magnitudes of the $g_{E\mu}^{\gamma}$'s. More stringent limits on the six coupling constants g_{LR}^{S} , g_{LR}^{V} , g_{LR}^{T} , g_{RL}^{S} , g_{RL}^{V} , and g_{RL}^{T} have been derived from upper limits on the neutrino mass [18]. Limits on the "charge retention" coordinates, as used in the older literature (e.g., Ref. 19), are given by Burkard et al. [20].

Table 1. Coupling constants $g_{\varepsilon\mu}^{\gamma}$ and some combinations of them. Ninety-percent confidence level experimental limits. The limits on $|g_{LL}^S|$ and $|g_{LL}^V|$ are from Ref. 15, and the others from a general analysis of muon decay measurements. Top two rows: Ref. 22, next two rows: Ref. 16, bottom three rows: Ref. 17, last row: Ref. 21. The experimental uncertainty on the muon polarization in pion decay is included. Note that, by definition, $|g_{\varepsilon\mu}^S| \leq 2$, $|g_{\varepsilon\mu}^V| \leq 1$ and $|g_{\varepsilon\mu}^S| \leq 1/\sqrt{3}$.

| $ g_{RR}^S < 0.035$ | $ g_{RR}^V < 0.017$ | $ g_{RR}^T \equiv 0$ |

ı

⁴⁴BAYES 11 obtains the limit > 0.99909 (90% CL) with the constraint that $\xi imes (\mu$ LON-GITUDINAL POLARIZATION) $\times \delta/\rho \leq 1.0$.

45 JODIDIO 86 includes data from CARR 83 and STOKER 85. The value here is from the

 $_{
m 46}^{
m effatum.}$ STOKER 85 find $(\xi {
m P}_{\mu} \delta/
ho) >$ 0.9955 and > 0.9966, where the first limit is from new μ spin-rotation data and the second is from combination with CARR 83 data. In $V\!-\!A$ theory, $(\delta/\rho)=1.0$

$\xi' = LONGITUDINAL POLARIZATION OF e^+$

(V-A) theory predicts the longitudinal polarization $=\pm 1$ for e^\pm , respectively. We have flipped the sign for e^- so our programs can average.

 $^{^1\,{\}rm AUBERT}\,$ 09AK and BELOUS 07 fit τ pseudomass spectrum in $\tau\to\,\pi\pi^+\,\pi^-\,\nu_\tau$ decays. Result assumes $m_{\nu_{\tau}}=0$.

 $^{^2}$ ABBIENDI 00A fit au pseudomass spectrum in $au
ightarrow \pi^\pm \leq 2\,\pi^0\,
u_ au$ and $au
ightarrow \pi^{\pm}\pi^{+}\pi^{-} \leq 1\pi^{0}\nu_{\tau}$ decays. Result assumes $m_{\nu_{\tau}}=0$.

 $^{^3}$ BAI 96 fit $\sigma(e^+e^- \to \tau^+\tau^-)$ at different energies near threshold.

 $^{^4}$ ALBRECHT 92M fit τ pseudomass spectrum in $\tau^- \to ~2\pi^-\pi^+\,\nu_\tau$ decays. Result assumes $m_{
u_{ au}} = 0$.

 $^{^5}$ BACINO 78B value comes from $e^\pm X^\mp$ threshold. Published mass 1782 MeV increased by 1 MeV using the high precision $\psi(2S)$ mass measurement of ZHOLENTZ 80 to eliminate the absolute SPEAR energy calibration uncertainty.

⁶ BALEST 93 fit spectra of minimum kinematically allowed τ mass in events of the type $e^+e^- \rightarrow \tau^+\tau^- \rightarrow (\pi^+ n\pi^0 \nu_\tau)(\pi^- m\pi^0 \nu_\tau)$ $n \leq 2, \ m \leq 2, \ 1 \leq n+m \leq 3$. If $m_{\nu_{T}}\neq$ 0, result increases by $(m_{\nu_{T}}^{2}/1100~{\rm MeV}).$

⁷BAI 92 fit $\sigma(e^+e^- \rightarrow \tau^+\tau^-)$ near threshold using $e\mu$ events.

² ACHARD 04G limit is derived from $e^+e^- \rightarrow e^+e^-\tau^+\tau^-$ total cross-section measurements at \sqrt{s} between 189 and 206 GeV, and is on the absolute value of the magnetic moment anomaly.

³ GONZALEZ-SPRINBERG 00 use data on tau lepton production at LEP1, SLC, and

LEP2, and data from colliders and LEP2 to determine limits. Assume imaginary component is zero. 4 ACCIARRI 98E use $Z \rightarrow ~\tau^+\tau^-\gamma$ events. In addition to the limits, the authors also quote a value of $0.004\pm0.027\pm0.023$.

⁵ ACKERSTAFF 98n use $Z \to \tau^+ \tau^- \gamma$ events. The limit applies to an average of the form factor for off-shell τ 's having ρ^2 ranging from m_τ^2 to $(M_Z - m_\tau)^2$.

⁶ ESCRIBANO 97 use preliminary experimental results.

 $^{^7}$ ESCRIBANO 93 limit derived from $\Gamma(Z
ightarrow~ au^+ au^-)$, and is on the absolute value of the magnetic moment anomaly.

SILVERMAN 83 limit is derived from $e^+e^- \to \tau^+\tau^-$ total cross-section measurements for g^2 up to $(37~{\rm GeV})^2$.

| >-3.8 and <3.6 | 95 | ⁶ ACKERSTAFF | 98N | OPAL | 1990-1995 LEP runs |
|------------------|----|--------------------------|-----|------|---------------------------------------------|

| | | | | | $E_{\rm cm}^{ee} = 35 \text{ GeV}$ |

 1 INAMI 03 use $e^+\,e^-\to\,\tau^+\tau^-$ events. 2 GROZIN 09A calculate the contribution to the electron electric dipole moment from the τ electric dipole moment appearing in loops, which is $\Delta d_e=6.9\times 10^{-12}~d_\tau.$ Dividing the REGAN 02 upper limit $\left|d_e\right|\leq 1.6\times 10^{-27}~e$ cm at CL=90% by $6.9\times 10^{-12}~g$ gives the limit

the REGAL 2 appendix |e| = 200000 this limit. 3 ABDALLAH 04K limit is derived from $e^+e^- \rightarrow e^+e^-\tau^+\tau^-$ total cross-section measurements at \sqrt{s} between 183 and 208 GeV and is on the absolute value of d_τ . 4 ACHARD 04G limit is derived from $e^+e^- \rightarrow e^+e^-\tau^+\tau^-$ total cross-section measurements. The section of 200 GeV, and is on the absolute value of d_τ .

surements at \sqrt{s} between 189 and 206 GeV, and is on the absolute value of d_{τ} .

 5 ALBRECHT 00 use $e^+\,e^-\to \tau^+\tau^-$ events. Limit is on the absolute value of Re(d_τ). 6 ACKERSTAFF 98N use $Z\to \tau^+\tau^-\gamma$ events. The limit applies to an average of the form factor for off-shell au's having p^2 ranging from $m_{ au}^2$ to $(M_Z - m_{ au})^2$.

 7 ESCRIBANO 97 derive the relationship $|d_{\tau}|=\cot\theta_W\,|d_{\tau}^W|$ using effective Lagrangian methods, and use a conference result $|d_{\tau}^{W}|<5.8\times10^{-18}$ e cm at 95% CL (L. Silvestris, ICHEP96) to obtain this result.

⁸ ESCRIBANO 97 use preliminary experimental results.

moment. 2 Limit is on the absolute value of the imaginary part of the weak dipole moment, and

applies for $q^2 = m_Z^2$.

τ WEAK ANOMALOUS MAGNETIC DIPOLE MOMENT (α_{τ}^{W})

Electroweak radiative corrections are expected to contribute at the 10^{-6} level. See BERNABEU 95.

The q^2 dependence is expected to be small providing no thresholds are nearby

Lepton Family number (LF), Lepton number (L), or Baryon number (B) violating modes

L means lepton number violation (e.g. $\tau^- \to e^+ \pi^- \pi^-$). Following common usage, LF means lepton family violation and not lepton number violation (e.g. $\tau^- \to e^- \pi^+ \pi^-$). B means baryon number violation.

| | violation (e.g. $	au^- ightarrow e^- \pi^+$ | π^-). | B means baryon numbe | r violation. | |

CONSTRAINED FIT INFORMATION

An overall fit to 66 branching ratios uses 138 measurements and one constraint to determine 31 parameters. The overall fit has a $\chi^2=128.9$ for 108 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\left\langle \delta x_i \delta x_j \right\rangle / (\delta x_i \cdot \delta x_j),$ in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}.$ The fit constrains the x_i whose labels appear in this array to sum to one

 τ

au BRANCHING FRACTIONS

Revised April 2012 by K.G. Hayes (Hillsdale College).

Since the previous edition of this Review, there have been 7 published papers that have contributed to the τ Listings: 4 by the BaBar collaboration and 3 by the Belle collaboration. Four of these papers have provided new upper limits on the branching fractions for neutrinoless τ -decay modes. Of the 59 neutrinoless τ -decay modes in the τ Listings, 17 have had improved limits set. The upper limits have been reduced by factors that range between 1.3 and 43 with the median reduction being a factor of 1.5.

There are now 30 measurements and 13 upper limits from Belle and BaBar on branching fractions of conventional τ -decay modes, up from 1 measurement and 3 upper limits in the 2006 edition of this Review. Sixteen of these measurements are used in the constrained fit to τ branching fractions, and 20 are for τ -decay modes for which older non-B-factory measurements exist. For those 20 measurements, the new B-factory measurements have on average about sixty times the number of events as the most precise earlier measurements, and the statistical uncertainties on the B-factory measurements are on average about eight times smaller. However, the systematic uncertainties now greatly exceed the statistical uncertainties of all B-factory branching fraction measurements of major τ -decay modes. For example, the average ratio of systematic to statistical uncertainty of the B-factory measurements of τ branching fractions larger than 10^{-3} is 17.6, while the average ratio for branching fractions smaller than 10^{-4} is 0.8. Thus, the total uncertainty on the branching fraction measurements from Bfactories is on average only about 3.4 times smaller than the previous most precise non-B-factory measurements.

The constrained fit to τ branching fractions: The Lepton Summary Table and the List of τ -Decay Modes contain branching fractions for 119 conventional τ -decay modes and upper limits on the branching fractions for 31 other conventional τ -decay modes. Of the 119 modes with branching fractions, 82 are derived from a constrained fit to τ branching fraction data. The goal of the constrained fit is to make optimal use of the experimental data to determine τ branching fractions. For example, the branching fractions for the decay mode $\tau^- \to \pi^- \pi^+ \pi^- \pi^0 \nu_{\tau}$ is determined mostly from experimental measurements of the branching fraction for $\tau^- \to h^- h^- h^+ \pi^0 \nu_{\tau}$ and measurements

of exclusive branching fractions for 3-prong modes containing charged kaons and 1 π^0 .

Branching fractions from the constrained fit are derived from a set of basis modes. The basis modes form an exclusive set whose branching fractions are constrained to sum exactly to one. The set of selected basis modes expands as branching fraction measurements for new τ -decay modes are published. The number of basis modes has expanded from 12 in the year 1994 fit to 31 in the 2002 through 2012 fits. The 31 basis modes selected for the 2012 fit are listed in Table 1. See the 1996 edition of this Review [1] for a complete description of our notation for naming τ -decay modes and the selection of the basis modes. For each edition since the 1996 edition, the changes in the selected basis modes from the previous edition are described in the τ Branching Fractions Review. Figure 1 illustrates the basis mode branching fractions from the 2012 fit.

Table 1: Basis modes and fit values (%) for the 2012 fit to τ branching fraction data.

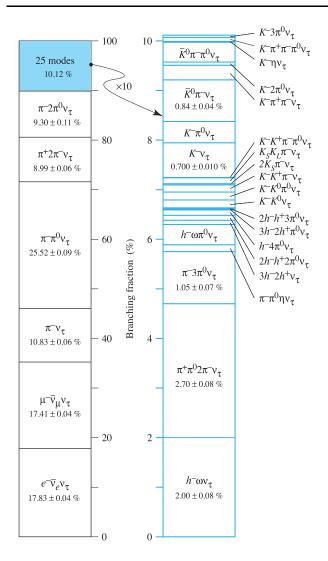

Figure 1: Basis mode branching fractions of the τ . Six modes account for 90% of the decays, 25 modes account for the last 10%. The list of excluded intermediate states for each basis mode has been suppressed.

In selecting the basis modes, assumptions and choices must be made. For example, we assume the decays $\tau^- \to \pi^- K^+ \pi^- >$ $0\pi^0\nu_{\tau}$ and $\tau^-\to\pi^+K^-K^-\geq 0\pi^0\nu\tau$ have negligible branching fractions. This is consistent with standard model predictions for τ decay, although the experimental limits for these branching fractions are not very stringent. The 95% confidence level upper limits for these branching fractions in the current Listings are B($\tau^- \to \pi^- K^+ \pi^- \ge 0 \pi^0 \nu_{\tau}$) < 0.25% and $B(\tau^- \to \pi^+ K^- K^- > 0\pi^0 \nu_{\tau}) < 0.09\%$, values not so different from measured branching fractions for allowed 3-prong modes containing charged kaons. Although our usual goal is to impose as few theoretical constraints as possible so that the world averages and fit results can be used to test the theoretical constraints (i.e., we do not make use of the theoretical constraint from lepton universality on the ratio of the τ -leptonic branching fractions $B(\tau^- \to \mu^- \overline{\nu}_\mu \nu_\tau)/B(\tau^- \to e^- \overline{\nu}_e \nu_\tau) = 0.9726)$, the experimental challenge to identify charged prongs in 3-prong τ decays is sufficiently difficult that experimenters have been forced to make these assumptions when measuring the branching fractions of the allowed decays. We are constrained by the assumptions made by the experimenters.

There are several τ -decay modes with small but well-measured (> 2.5 sigma from zero) branching fractions [2] which cannot be expressed in terms of the selected basis modes and are therefore left out of the fit:

$$\begin{array}{ll} {\rm B}(\tau^-\to\pi^-K_S^0K_L^0\pi^0\nu_\tau) &= (3.1\pm1.2)\times 10^{-4} \\ {\rm B}(\tau^-\to 2K^-K^+\nu_\tau) &= (0.21\pm0.08)\times 10^{-4} \\ {\rm B}(\tau^-\to\eta K^-\pi^0\nu_\tau) &= (0.48\pm0.12)\times 10^{-4} \\ {\rm B}(\tau^-\to\eta \overline{K}^0\pi^-\nu_\tau) &= (0.93\pm0.15)\times 10^{-4}. \end{array}$$

Certain components of other small but well-measured τ -decay modes cannot be expressed in terms of the selected basis modes and therefore are also left out of the fit:

$$\begin{split} & B(\tau^- \to \eta \pi^- \pi^0 \pi^0 \nu_\tau) \times \\ & B(\eta \to \gamma \gamma \text{ or } \eta \to \pi^+ \pi^- \gamma \text{ or } \eta \to 3\pi^0) = (1.1 \pm 0.4) \times 10^{-4}, \\ & B(\tau^- \to \eta \pi^- \pi^+ \pi^- \nu_\tau) \times \\ & B(\eta \to \gamma \gamma \text{ or } \eta \to \pi^+ \pi^- \gamma) \\ & B(\eta \to \gamma \gamma \text{ or } \eta \to \pi^+ \pi^- \gamma) \\ & B(\tau^- \to \phi K^- \nu_\tau) \times \\ & B(\phi \to K_S^0 K_L^0 \text{ or } \phi \to \eta \gamma) \\ & B(\tau^- \to f_1(1285) \pi^- \nu_\tau) B(f_1(1285) \to \rho^0 \gamma) = (0.20 \pm 0.06) \times 10^{-4}, \\ & B(\tau^- \to h^- \omega \pi^0 \pi^0 \nu_\tau) B(\omega \to \pi^0 \gamma) \\ & B(\tau^- \to 2h^- h^+ \omega \nu_\tau) B(\omega \to \pi^0 \gamma) \\ & = (0.12 \pm 0.04) \times 10^{-4}, \\ & B(\tau^- \to 2h^- h^+ \omega \nu_\tau) B(\omega \to \pi^0 \gamma) \\ & = (0.10 \pm 0.02) \times 10^{-4}. \end{split}$$

The sum of these excluded branching fractions is $(0.07 \pm 0.01)\%$. This is near our goal of 0.1% for the internal consistency of the τ Listings for this edition, and thus for simplicity we do not include these small branching fraction decay modes in the basis set.

Beginning with the 2002 edition, the fit algorithm has been improved to allow for correlations between branching fraction measurements used in the fit. If only a few measurements are correlated, the correlation coefficients are listed in the footnote for each measurement. If a large number of measurements are correlated, then the full correlation matrix is listed in the footnote to the measurement that first appears in the τ Listings. Footnotes to the other measurements refer to the first measurement. For example, the large correlation matrices for the branching fraction measurements contained in Refs. [3,4] are listed in Footnotes to the $\Gamma(e^{-}\overline{\nu}_{e}\nu_{\tau})/\Gamma_{\text{total}}$ and $\Gamma(h^-\nu_{\tau})/\Gamma_{\rm total}$ measurements respectively. Sometimes experimental papers contain correlation coefficients between measurements using only statistical errors without including systematic errors. We usually cannot make use of these correlation coefficients.

The 2012 constrained fit has a χ^2 of 128.9 for 108 degrees of freedom, up from 102.9 for 103 degrees of freedom in the 2010 fit. Two basis-mode branching fractions changed by more than 1.0 σ from their 2010 values, $B(\mu^-\overline{\nu}_\mu\nu_\tau)$ and $B(\pi^-\nu_\tau)$, due to new measurements by the BaBar Collaboration [5] of τ -decay

modes containing one charged prong and no neutral particles other than neutrinos.

Inconsistencies in the τ -lepton Branching Fraction Data: Several inconsistencies are known to exist in the branching fraction measurements that are used to determine the τ -lepton branching fractions. The sources of the inconsistencies are unknown. The treatment of discrepant data used for fits and averages is described in the introduction of this Review. Of the 82 branching fractions that are derived from the constrained fit, 12 (15%) have scale factors that are 1.5 or larger, and the largest is 2.7. Of the 37 branching fractions that are not derived from the constrained fit, 20 make use of only one measurement. Of the 17 averages that make use of more than one measurement, 3 (18%) have scale factors that are 1.5 or larger, and the largest is 5.4. Ideograms for 8 branching fractions are currently displayed in the τ Listings.

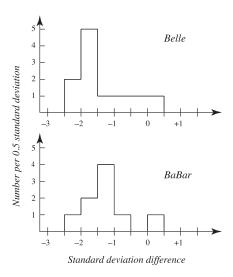

Figure 2: Distribution of the normalized difference between the 20 B-factory measurements of conventional τ -decay branching fractions and non-B-factory measurements. The Belle and BaBar collaborations have published 11 and 9 measurements respectively.

The τ branching fraction measurements by BaBar and Belle tend to be smaller than the non-B-factory measurements. There are 20 B-factory branching fraction measurements of τ -decay modes for which older non-B-factory measurements exist. Comparing the B-factory branching fraction measurements to the earlier non-B-factory measurements reveals a systematic discrepancy between the two sets of measurements. Figure 2 shows a histogram of the normalized difference ((B-factory value minus non-B-factory value)/estimated uncertainty in the difference) for the 20 measurements. The value used for the non-B-factory measurement is the value listed in the latest edition of this Review prior to the first B-factory measurement for that decay mode. Eighteen of the 20 B-factory branching

fraction measurements are smaller than the non-B-factory values. The average normalized difference between the two sets of measurements is -1.30 (-1.41 for the 11 Belle measurements and -1.24 for the 9 BaBar measurements). The Heavy Flavor Averaging Group (HFAG) analysis of τ branching fractions includes a similar comparison of the B-factory and non-B-factory measurements [6].

Belle and BaBar have each published branching fraction measurements for the six τ -decay modes listed in Table 2. The normalized difference between the two measured values is calculated by subtracting the Belle value from the BaBar value and dividing this difference by the quadratic sum of the statistical and systematic errors for each measurement. When a measurement has asymmetric errors, the larger of the two values is used in the quadratic sum. It is apparent from the values in Table 2 that the Belle and BaBar values differ significantly for several of the τ -decay modes.

Table 2: Comparison of the Belle and Babar branching fraction measurements for the six τ -decay modes that both experiments have measured. The normalized difference is the difference between the Belle and BaBar branching fraction values divided by the quadratic sum of the statistical and systematic errors for both measurements.

| Mode | BaBar - Belle |
|------------------------------------------------------|------------------------------------|
| | Normalized Difference $(\#\sigma)$ |
| $\pi^- \pi^+ \pi^- \nu_\tau \text{ (ex. } K^0)$ | +1.4 |
| $K^{-}\pi^{+}\pi^{-}\nu_{\tau} \text{ (ex. } K^{0})$ | -2.9 |
| $K^-K^+\pi^-\nu_	au$ | -2.9 |
| $K^-K^+K^-\nu_{	au}$ | -5.4 |
| $\eta~K^-\nu_{	au}$ | -1.0 |
| $\phi K^- \nu_{\tau}$ | -1.3 |

Overconsistency of Leptonic Branching Fraction Measurements: To minimize the effects of older experiments which often have larger systematic errors and sometimes make assumptions that have later been shown to be invalid, we exclude old measurements in decay modes which contain at least several newer data of much higher precision. As a rule, we exclude those experiments with large errors which together would contribute no more than 5% of the weight in the average. This procedure leaves five measurements for $B_e \equiv B(\tau^- \to e^- \overline{\nu}_e \nu_\tau)$ and five measurements for $B_{\mu} \equiv B(\tau^{-} \to \mu^{-} \overline{\nu}_{\mu} \nu_{\tau})$. For both B_e and B_{μ} , the selected measurements are considerably more consistent with each other than should be expected from the quoted errors on the individual measurements. The χ^2 from the calculation of the average of the selected measurements is 0.34 for B_e and 0.08 for B_{μ} . Assuming normal errors, the probability of a smaller χ^2 is 1.3% for B_e and 0.08% for B_{μ} .

The charged particle here can be $e,\ \mu,$ or hadron. In many analyses, the sum of the topological branching fractions (1, 3, and 5 prongs) is constrained to be unity. Since the 5-prong fraction is very small, the measured 1-prong and 3-prong fractions are highly correlated and cannot be treated as independent quantities in our overall fit. We arbitrarily choose to use the 3-prong fraction in our fit, and leave the 1-prong fraction out. We do, however, use these 1-prong measurements in our average below. The measurements used only for the average are marked "avg," whereas "f&a" marks a result used for the fit and the average

   ^{1} BUSKULIC 96 state their measurement is for B(h^- h^- h^+ \geq 3\pi^0 
u_	au). We assume that
     B(h^-h^-h^+ \geq 4\pi^0\nu_{\tau}) is very small.

τ-DECAY PARAMETERS

au-LEPTON DECAY PARAMETERS

Updated August 2011 by A. Stahl (RWTH Aachen).

The purpose of the measurements of the decay parameters (*i.e.*, Michel parameters) of the τ is to determine the structure (spin and chirality) of the current mediating its decays.

Leptonic Decays: The Michel parameters are extracted from the energy spectrum of the charged daughter lepton $\ell=e,\mu$ in the decays $\tau \to \ell \nu_\ell \nu_\tau$. Ignoring radiative corrections, neglecting terms of order $(m_\ell/m_\tau)^2$ and $(m_\tau/\sqrt{s})^2$, and setting the neutrino masses to zero, the spectrum in the laboratory frame reads

$$\begin{split} \frac{d\Gamma}{dx} &= \frac{G_{\tau\ell}^2 \ m_{\tau}^5}{192 \ \pi^3} \ \times \\ &\left\{ f_0\left(x\right) + \rho f_1\left(x\right) + \eta \frac{m_{\ell}}{m_{\tau}} f_2\left(x\right) - P_{\tau} \left[\xi g_1\left(x\right) + \xi \delta g_2\left(x\right)\right] \right\} \ , \ (1) \end{split}$$

with

$$\begin{split} f_0\left(x\right) &= 2 - 6\,x^2 + 4\,x^3 \\ f_1\left(x\right) &= -\frac{4}{9} + 4\,x^2 - \frac{32}{9}\,x^3 & g_1\left(x\right) &= -\frac{2}{3} + 4\,x - 6\,x^2 + \frac{8}{3}\,x^3 \\ f_2\left(x\right) &= 12\left(1 - x\right)^2 & g_2\left(x\right) &= \frac{4}{9} - \frac{16}{3}\,x + 12\,x^2 - \frac{64}{9}\,x^3 \;. \end{split}$$

The quantity x is the fractional energy of the daughter lepton ℓ , i.e., $x=E_{\ell}/E_{\ell,max}\approx E_{\ell}/(\sqrt{s}/2)$ and P_{τ} is the polarization of the tau leptons. The integrated decay width is given by

$$\Gamma = \frac{G_{\tau\ell}^2 \ m_{\tau}^5}{192 \ \pi^3} \left(1 + 4 \eta \ \frac{m_{\ell}}{m_{\tau}} \right) \ . \tag{2}$$

The situation is similar to muon decays $\mu \to e\nu_e\nu_\mu$. The generalized matrix element with the couplings $g_{\varepsilon\mu}^{\gamma}$ and their relations to the Michel parameters ρ , η , ξ , and δ have been described in the "Note on Muon Decay Parameters." The Standard Model expectations are 3/4, 0, 1, and 3/4, respectively. For more details, see Ref. 1.

Hadronic Decays: In the case of hadronic decays $\tau \to h\nu_{\tau}$, with $h = \pi$, ρ , or a_1 , the ansatz is restricted to purely vectorial currents. The matrix element is

$$\frac{G_{\tau h}}{\sqrt{2}} \sum_{\lambda = R, L} g_{\lambda} \langle \overline{\Psi}_{\omega}(\nu_{\tau}) \mid \gamma^{\mu} \mid \Psi_{\lambda}(\tau) \rangle J_{\mu}^{h}$$
 (3)

with the hadronic current J_{μ}^{h} . The neutrino chirality ω is uniquely determined from λ . The spectrum depends only on a single parameter ξ_{h}

$$\frac{d^{n}\Gamma}{dx_{1}dx_{2}\dots dx_{n}} = f\left(\vec{x}\right) + \xi_{h}P_{\tau}g\left(\vec{x}\right) , \qquad (4)$$

with f and g being channel-dependent functions of the n observables $\vec{x} = (x_1, x_2, \dots, x_n)$ (see Ref. 2). The parameter ξ_h is related to the couplings through

$$\xi_h = |g_L|^2 - |g_R|^2 \ . \tag{5}$$

 ξ_h is the negative of the chirality of the τ neutrino in these decays. In the Standard Model, $\xi_h=1$. Also included in the Data Listings for ξ_h are measurements of the neutrino helicity which coincide with ξ_h , if the neutrino is massless (ASNER 00, ACKERSTAFF 97R, AKERS 95P, ALBRECHT 93C, and ALBRECHT 90I).

Combination of Measurements: The individual measurements are combined, taking into account the correlations between the parameters. In a first fit, universality between the two leptonic decays, and between all hadronic decays, is assumed. A second fit is made without these assumptions. The results of the two fits are provided as OUR FIT in the Data Listings below in the tables whose title includes "(e or mu)" or "(all hadronic modes)," and "(e)," "(mu)" etc., respectively. The measurements show good agreement with the Standard Model. The χ^2 values with respect to the Standard model predictions are 24.1 for 41 degrees of freedom and 26.8 for 56 degrees of freedom, respectively. The correlations are reduced through this combination to less than 20%, with the exception of ρ and η which are correlated by +23%, for the fit with universality and by +70% for $\tau \to \mu \nu_{\mu} \nu_{\tau}$.

Table 1: Coupling constants $g_{\varepsilon\mu}^{\gamma}$. 95% confidence level experimental limits. The limits include the quoted values of A_e , A_{μ} , and A_{π} and assume $A_{\rho}=A_{a_1}=1$.

| $ g_R^V < 0.10$ | $ g_L^V > 0.995$ | |
| $	au 	o a_1 \nu_{	au}$ | | |
| $ g_R^V < 0.16$ | $ g_L^V > 0.987$ | |

Model-independent Analysis: From the Michel parameters, limits can be derived on the couplings $g_{\varepsilon\lambda}^{\kappa}$ without further model assumptions. In the Standard model $g_{LL}^V = 1$ (leptonic decays), and $g_L = 1$ (hadronic decays) and all other couplings vanish. First, the partial decay widths have to be compared to the Standard Model predictions to derive limits on the normalization of the couplings $A_x = G_{\tau x}^2/G_F^2$ with Fermi's constant G_F :

$$A_e = 1.0029 \pm 0.0046$$
 ,
$$A_{\mu} = 0.981 \pm 0.018$$
 ,
$$A_{\pi} = 1.0020 \pm 0.0073$$
 . (6)

Then limits on the couplings (95% CL) can be extracted (see Ref. 3 and Ref. 4). Without the assumption of universality, the limits given in Table 1 are derived.

Model-dependent Interpretation: More stringent limits can be derived assuming specific models. For example, in the framework of a two Higgs doublet model, the measurements correspond to a limit of $m_{H^{\pm}} > 1.9 \text{ GeV} \times \tan \beta$ on the mass of the charged Higgs boson, or a limit of 253 GeV on the mass of the second W boson in left-right symmetric models for arbitrary mixing (both 95% CL). See Ref. 4 and Ref. 5.

 $^{
m 1}$ Combined fit to ARGUS tau decay parameter measurements in ALBRECHT 98, AL-BRECHT 95c, ALBRECHT 93G, and ALBRECHT 94E. ALBRECHT 98 use tau pair events of the type $\tau^-\tau^+ \to (\ell^-\overline{\nu}_\ell\nu_\tau)(\pi^+\pi^0\overline{\nu}_\tau)$, and their charged conjugates.

 2 ABE 970 assume $\eta=$ 0 in their fit. Letting η vary in the fit gives a ρ value of 0.69 \pm

3 Value is from a simultaneous fit for the ρ and η decay parameters to the lepton energy spectrum. Not independent of ALBRECHT 9Bc ρ (e or μ) value which assumes $\eta=0$. Result is strongly correlated with ALBRECHT 95c.

A Combined fit to ARGUS tau decay parameter measurements in ALBRECHT 95c, ALBRECHT 93c, and ALBRECHT 94e.

¹ Combined fit to ARGUS tau decay parameter measurements in ALBRECHT 98, AL-BRECHT 95c, ALBRECHT 93c, and ALBRECHT 94e. ALBRECHT 98 use tau pair events of the type $\tau^-\tau^+ \to (\ell^-\overline{\nu}_\ell\nu_\tau)(\pi^+\pi^0\overline{\nu}_\tau)$, and their charged conjugates. ²ABE 970 assume $\eta=0$ in their fit. Letting η vary in the fit gives a ξ value of 1.02 \pm

3 0.36 \pm 0.05. 3 Combined fit to ARGUS tau decay parameter measurements in ALBRECHT 95c, AL-BRECHT 93G, and ALBRECHT 94E. ALBRECHT 95C uses events of the type $au^- au^+$ $(\ell^- \overline{\nu}_\ell \nu_\tau) (h^+ h^- h^+ \overline{\nu}_\tau)$ and their charged conjugates.

ALBRECHT 93G measurement determines $|\xi|$ for the case $\xi(e)=\xi(\mu)$, but the authors point out that other LEP experiments determine the sign to be positive

These experiments assumed that a fourth generation L^\pm decayed to a fourth generation ν_L (or L^0) where ν_L was stable, or that L^\pm decays to a light ν_ℓ via mixing.

See the "Quark and Lepton Compositeness, Searches for" Listings for limits on radiatively decaying excited leptons, i.e. $\ell^* \to \ell \gamma$. See the "WIMPs and other Particle Searches" section for heavy charged particle search limits in which the charged particle could be a lepton.

 $^{1}\,\text{ACCIARRI}$ 96G assumes LEP result that the associated neutral heavy lepton mass > 40

GeV. ² The AHMED 94 limits are from a search for neutral and charged sequential heavy leptons at HERA via the decay channels $L^- \to e \gamma$, $L^- \to \nu W^-$, $L^- \to e Z$; and $L^{0} \to \nu \gamma$, $L^0 \to e^- W^+$, $L^- \to \nu Z$, where the W decays to $\ell \nu_\ell$, or to jets, and Z decays to $\ell^+\ell^-$ or jets.

³ RILES 90 limits were the result of a special analysis of the data in the case where the mass difference $m_{L^-}-m_{L^0}$ was allowed to be quite small, where L^0 denotes the neutrino into which the sequential charged lepton decays. With a slightly reduced m_{I^\pm} range,

the mass difference extends to about 4 GeV.

4 STOKER 89 (Mark II at PEP) gives bounds on charged heavy lepton (L+) mass for the generalized case in which the corresponding neutral heavy lepton (L^0) in the $\mathrm{SU}(2)$

doublet is not of negligible mass. 5 ABE 88 search for L^+ and $L^- \to \,$ hadrons looking for acoplanar jets. The bound is valid for $m_{\nu} < 10$ GeV.

⁶ ADACHI 88B search for hadronic decays giving acoplanar events with large missing energy. $E_{cm}^{ee} = 52 \text{ GeV}.$

Assumes associated neutrino is approximately massless.

Assumes associated neutrino is approximately massicess. 8 ADEVA 85 analyze one-isolated-muon data and sensitive to τ <10 nanosec. Assume B(lepton) = 0.30. $E_{\rm cm}$ = 40-47 GeV. 9 BARTEL 83 limit is from PETRA \pm^+e^- experiment with average $E_{\rm cm}$ = 34.2 GeV.

 10 BERGER 81B is DESY DORIS and PETRA experiment. Looking for $e^+e^- \rightarrow L^+L^-$. 11 BRANDELIK 81 is DESY-PETRA experiment. Looking for $e^+e^- \rightarrow L^+L^-$. 12 AZIMOV 80 estimated probabilities for M+N type events in $e^+e^- \rightarrow L^+L^-$ deducing semi-hadronic decay multiplicities of L from e^+e^- annihilation data at $E_{\rm cm}=(2/3)m_L$.

Obtained above limit comparing these with $e^+\,e^-$ data (BRANDELIK 80). 13 BARBER 80B looked for $e^+\,e^-
ightarrow \, {\it L}^+\,{\it L}^-$, ${\it L}
ightarrow \, {\it \nu}_{\it L}^+$ X with MARK-J at DESY-PETRA.

 $^{14}\,\mathrm{ROTHE}$ 69 examines previous data on μ pair production and π and K decays.

 $^{16}\mathsf{ANSORGE}$ 73B looks for electron pair production and electron-like Bremsstrahlung. $^{17} \text{BUSHNIN}$ 73 is SERPUKHOV 70 GeV p experiment. Masses assume mean life above 7×10^{-10} and 3×10^{-8} respectively. Calculated from cross section (see "Charged Quasi-Stable Lepton Production Differential Cross Section" below) and 30 GeV muon pair production data.

¹⁸BARNA 68 is SLAC photoproduction experiment.

Neutrino Properties

INTRODUCTION TO THE NEUTRINO PROPERTIES LISTINGS

Revised August 2011 by P. Vogel (Caltech) and A. Piepke (University of Alabama).

The following Listings concern measurements of various properties of neutrinos. Nearly all of the measurements, all of which so far are limits, actually concern superpositions of the mass eigenstates ν_i , which are in turn related to the weak eigenstates ν_{ℓ} , via the neutrino mixing matrix

$$|\nu_{\ell}\rangle = \sum_{i} U_{\ell i} |\nu_{i}\rangle$$
.

In the analogous case of quark mixing via the CKM matrix, the smallness of the off-diagonal terms (small mixing angles) permits a "dominant eigenstate" approximation. However, the present results of neutrino oscillation searches show that the mixing matrix contains two large mixing angles. We cannot, therefore, associate any particular state $|\nu_i\rangle$ with any particular lepton label e, μ or τ . Nevertheless, neutrinos are produced in weak decays with a definite lepton flavor, and are typically detected by the charged current weak interaction again associated with a specific lepton flavor. Hence, the listings for the neutrino mass that follow are separated into the three associated charged-lepton categories. Other properties (mean lifetime, magnetic moment, charge, and charge radius) are no longer separated this way. If needed, the associated lepton flavor is reported in the footnotes.

Measured quantities (mass-squared, magnetic moments, mean lifetimes, etc.) all depend upon the mixing parameters $|U_{\ell i}|^2$, but to some extent also on experimental conditions (e.g., on energy resolution). Most of these observables, in particular mass-squared, cannot distinguish between Dirac and Majorana neutrinos, and are unaffected by CP phases.

Direct neutrino mass measurements are usually based on the analysis of the kinematics of charged particles (leptons, pions) emitted together with neutrinos (flavor states) in various weak decays. The most sensitive neutrino mass measurement to date, involving electron type antineutrinos, is based on fitting the shape of the beta spectrum. The quantity $\langle m_{\beta}^2 \rangle =$ $\sum_{i} |U_{ei}|^2 m_{\nu_i}^2$ is determined or constrained, where the sum is over all mass eigenvalues m_{ν_i} that are too close together to be resolved experimentally. If the energy resolution is better than $\Delta m_{ij}^2 \equiv m_{\nu_i}^2 - m_{\nu_j}^2$, the corresponding heavier m_{ν_i} and mixing parameter could be determined by fitting the resulting spectral anomaly (step or kink).

A limit on $\langle m_{\beta}^2 \rangle$ implies an upper limit on the minimum value m_{min}^2 of $m_{\nu_i}^2$, independent of the mixing parameters U_{ei} : $m_{min}^2 \leq \langle m_{\beta}^2 \rangle$. However, if and when the value of $\langle m_{\beta}^2 \rangle$ is determined and the study of neutrino oscillations provides us with the values of all neutrino mass-squared differences $\Delta m_{ij}^2 \equiv m_i^2 - m_i^2$ and the mixing parameters $|U_{ei}|^2$, then the individual neutrino mass squares $m_{\nu_i}^2 = \langle m_{\beta}^2 \rangle - \sum_i |U_{ei}|^2 \Delta m_{ij}^2$ can be determined.

So far solar, reactor, atmospheric and accelerator neutrino oscillation experiments can be consistently described using three active neutrino flavors, i.e. two mass splittings and three mixing angles. However, several experiments with radioactive sources, reactors, and accelerators imply the possible existence of one or more non-interacting neutrino species.

Lepton Particle Listings Neutrino Properties

Combined three neutrino analyses determine the squared mass differences and two of the mixing angles to within reasonable accuracy. For given $|\Delta m_{ij}^2|$, a limit on $\langle m_{\beta}^2 \rangle$ from beta decay defines an upper limit on the maximum value m_{max} of m_{ν_i} : $m_{max}^2 \leq \langle m_{\beta}^2 \rangle + \sum_{i < j} |\Delta m_{ij}^2|$. The analysis of the low energy beta decay of tritium, combined with the oscillation results, thus limits all active neutrino masses. Traditionally experimental neutrino mass limits obtained from pion decay $\pi^+ \to \mu^+ + \nu_\mu$, or the shape of the spectrum of decay products of the τ lepton, did not distinguish between flavor and mass eigenstates. These results are reported as limits of the μ and τ based neutrino mass. After the determination of the $|\Delta m_{ij}^2|$'s, the corresponding neutrino mass limits are no longer competitive with those derived from low energy beta decays, with the proviso, however, that the oscillation searches, reported below, can be regarded as a reliable source of all $|\Delta m_{ij}^2|$ values.

The spread of arrival times of the neutrinos from SN1987A, coupled with the measured neutrino energies, provided a time-of-flight limit on a quantity similar to $\langle m_{\beta} \rangle \equiv \sqrt{\langle m_{\beta}^2 \rangle}$. This statement, clothed in various degrees of sophistication, has been the basis for a very large number of papers. The resulting limits, however, are no longer comparable with the limits from tritium beta decay.

Constraint on the sum of the neutrino masses can be obtained from the analysis of the cosmic microwave background anisotropy, combined with the galaxy redshift surveys and other data. These limits are reported in a separate table (Sum of Neutrino Masses, m_{tot}). Discussion concerning the model dependence of this limit is continuing.

▽ MASS (electron based)

Those limits given below are for the square root of $m_{\nu_e}^{2({\rm eff})} \equiv \sum_i |{\rm U}_{ei}|^2 m_{\nu_i}^2$. Limits that come from the kinematics of ${}^3{\rm H}\,\beta^-\overline{\nu}$ decay are the square roots of the limits for $m_{\nu_e}^{2({\rm eff})}$. Obtained from the measurements reported in the Listings for " $\overline{\nu}$ Mass Squared," below.

- 1 ASEEV 11 report the analysis of the entire beta endpoint data, taken with the Troitsk integrating electrostatic spectrometer between 1997 and 2002 (some of the earlier runs were rejected), using a windowless gaseous tritium source. The fitted value of m_{ν} , based on the method of Feldman and Cousins, is obtained from the upper limit of the fit for m_{ν}^2 . Previous analysis problems were resolved by careful monitoring of the tritium gas column density. Supersedes LOBASHEV 99 and BELESEV 95.
- ²PAGLIAROLI 10 is critical of the likelihood method used by LOREDO 02.
- ³ KRAUS 05 is a continuation of the work reported in WEINHEIMER 99. This result represents the final analysis of data taken from 1997 to 2001. Various sources of systematic uncertainties have been identified and quantified. The background has been reduced compared to the initial running period. A spectral anomaly at the endpoint, reported in LOBASHEV 99, was not observed.
- 4 ARNABOLDI 03A *et al.* report kinematical neutrino mass limit using β-decay of 187 Re. Bolometric AgReO $_4$ micro-calorimeters are used. Mass bound is substantially weaker than those derived from tritium β-decays but has different systematic uncertainties.
- ⁵ LOREDO 02 updates LOREDO 89.
- 6 LOBASHEV 99 report a new measurement which continues the work reported in BELESEV 95. This limit depends on phenomenological fit parameters used to derive their best fit to m_{ν}^2 , making unambiguous interpretation difficult. See the footnote under " $\overline{\nu}$ Mass Squared."
- 7 WEINHEIMER 99 presents two analyses which exclude the spectral anomaly and result in an acceptable m_{ν}^2 . We report the most conservative limit, but the other is nearly the same. See the footnote under "\$\overline{n}\$ Mass Squared."
- 8 BELESEV 95 (Moscow) use an integral electrostatic spectrometer with adiabatic magnetic collimation and a gaseous tritium sources. A fit to a normal Kurie plot above 18300–18350 eV (to avoid a low-energy anomaly) plus a monochromatic line 7–15 eV below the endpoint yields $m_{\nu}^2=-4.1\pm10.9~{\rm eV}^2,$ leading to this Bayesian limit.
- 9 CHING 95 quotes results previously given by SUN 93; no experimental details are given A possible explanation for consistently negative values of m_H^2 is given.
- 10 HIDDEMANN 95 (Munich) experiment uses atomic tritium embedded in a metal-dioxide lattice. Bayesian limit calculated from the weighted mean $m_{\nu}^2=$ 221 \pm 4244 eV 2 from the two runs listed below.
- 11 STOEFFL 95 (LLNL) result is the Bayesian limit obtained from the m_{ν}^2 errors given below but with m_{ν}^2 set equal to 0. The anomalous endpoint accumulation leads to a value of m_{ν}^2 which is negative by more than 5 standard deviations.
- 12 WEINHEIMER 93 (Mainz) is a measurement of the endpoint of the tritium β spectrum using an electrostatic spectrometer with a magnetic guiding field. The source is molecular tritium frozen onto an aluminum substrate.
- 13 HOLZSCHUH 92B (Zurich) result is obtained from the measurement $m_{\nu}^2=-24\pm48\pm61$ (1σ errors), in eV², using the PDG prescription for conversion to a limit in m_{ν} .
- 14 KAWAKAMI 91 (Tokyo) experiment uses tritium-labeled arachidic acid. This result is the Bayesian limit obtained from the $m^2_{\ \nu}$ limit with the errors combined in quadrature. This was also done in ROBERTSON 91, although the authors report a different procedure.
- 15 ROBERTSON 91 (LANL) experiment uses gaseous molecular tritium. The result is in strong disagreement with the earlier claims by the ITEP group [LUBIMOV 80, BORIS 87 (+ BORIS 88 erratum)] that m_{ν} lies between 17 and 40 eV. However, the probability of a positive m^2 is only 3% if statistical and systematic error are combined in quadrature.
- $^{16}\,\mbox{See}$ also comment in BORIS 87B and erratum in BORIS 88.

- 17 ASEEV 11 report the analysis of the entire beta endpoint data, taken with the Troitsk integrating electrostatic spectrometer between 1997 and 2002, using a windowless gaseous tritium source. The analysis does not use the two additional fit parameters (see LOBASHEV 99) for a step-like structure near the endpoint. Using only the runs where the tritium gas column density was carefully monitored the need for such parameters was eliminated. Supersedes LOBASHEV 99 and BELESEV 95.
- ¹⁸ KRAUS 05 is a continuation of the work reported in WEINHEIMER 99. This result represents the final analysis of data taken from 1997 to 2001. Problems with significantly negative squared neutrino masses, observed in some earlier experiments, have been resolved in this work.

Neutrino Properties

- $^{19}\text{LOBASHEV}$ 99 report a new measurement which continues the work reported in BELE-SEV 95. The data were corrected for electron trapping effects in the source, eliminating the dependence of the fitted neutrino mass on the fit interval. The analysis assuming a pure beta spectrum yields significantly negative fitted $m_\nu^2 \approx -(20\text{-}10) \text{ eV}^2$. This problem is attributed to a discrete spectral anomaly of about 6×10^{-11} intensity with a time-dependent energy of 5–15 eV below the endpoint. The data analysis accounts for this anomaly by introducing two extra phenomenological fit parameters resulting in a best fit of $m_\nu^2 = -1.9 \pm 3.4 \pm 2.2 \text{ eV}^2$ which is used to derive a neutrino mass limit. However, the introduction of phenomenological fit parameters which are correlated with the derived m_ν^2 limit makes unambiguous interpretation of this result difficult.
- 20 WEINHEIMER 99 is a continuation of the work reported in WEINHEIMER 93 . Using a lower temperature of the frozen tritium source eliminated the dewetting of the T_2 film, which introduced a dependence of the fitted neutrino mass on the fit interval in the earlier work. An indication for a spectral anomaly reported in LOBASHEV 99 has been seen, but its time dependence does not agree with LOBASHEV 99. Two analyses, which exclude the spectral anomaly either by choice of the analysis interval or by using a particular data set which does not exhibit the anomaly, result in acceptable m_{ν}^2 fits and are used to derive the neutrino mass limit published by the authors. We list the most conservative of the two.
- 21 BELESEV 95 (Moscow) use an integral electrostatic spectrometer with adiabatic magnetic collimation and a gaseous tritium sources. This value comes from a fit to a normal Kurie plot above 18300–18350 eV (to avoid a low-energy anomaly), including the effects of an apparent peak 7-15 eV below the endpoint.
- $^{22}\,\text{HIDDEMANN}$ 95 (Munich) experiment uses atomic tritium embedded in a metal-dioxide lattice. They quote measurements from two data sets.
- 23 STOEFFL 95 (LLNL) uses a gaseous source of molecular tritium. An anomalous pileup of events at the endpoint leads to the negative value for m_{ν}^2 . The authors acknowledge that "the negative value for the best fit of m_{ν}^2 has no physical meaning" and discuss possible explanations for this effect.
- $^{\rm 24}\,{\rm SUN}$ 93 uses a tritiated hydrocarbon source. See also CHING 95.
- 25 WEINHEIMER 93 (Mainz) is a measurement of the endpoint of the tritium β spectrum using an electrostatic spectrometer with a magnetic guiding field. The source is molecular tritium frozen onto an aluminum substrate.
- $^{26}\,\mathrm{H\,OLZSCHUH}$ 92B (Zurich) source is a monolayer of tritiated hydrocarbon.
- $^{\rm 27}\,{\rm KAWA\,KA\,MI}$ 91 (Tokyo) experiment uses tritium-labeled arachidic acid.
- 28 ROBERTSON 91 (LANL) experiment uses gaseous molecular tritium. The result is in strong disagreement with the earlier claims by the ITEP group [LUBIMOV 80, BORIS 87 (+ BORIS 88 erratum)] that m_{ν} lies between 17 and 40 eV. However, the probability of a positive m_{ν}^2 is only 3% if statistical and systematic error are combined in quadrature.

ν MASS (electron based)

These are measurement of m_{ν} (in contrast to $m_{\overline{\nu}}$, given above). The masses can be different for a Dirac neutrino in the absence of CPT invariance. The possible distinction between ν and $\overline{\nu}$ properties is usually ignored elsewhere in these Listings.

ν MASS (muon based)

Limits given below are for the square root of $\mathit{m}_{\nu_{\mu}}^{2(\mathrm{eff})} \equiv \sum_{i} |\mathsf{U}_{\mu i}|^2 \; \mathit{m}_{\nu_{i}}^2$

In some of the COSM papers listed below, the authors did not distinguish between weak and mass eigenstates.

OUR EVALUATION is based on OUR AVERAGE for the π^\pm mass and the ASSAMAGAN 96 value for the muon momentum for the π^+ decay at rest. The limit is calculated using the unified classical analysis of FELDMAN 98 for a Gaussian distribution near a physical boundary. WARNING: since $m_{\mu}^2(\text{eff})$ is calculated from the differences of large numbers, it and the corresponding limits are extraordinarily sensitive to small changes in the pion mass, the decay muon momentum, and their errors. For example, the limits obtained using JECKELMANN 94, LENZ 98, and the weighted averages are 0.15, 0.29, and 0.19 MeV, respectively.

 29 ASSAMAGAN 96 measurement of p_μ from $\pi^+\to \mu^+\nu$ at rest combined with JECK-ELMANN 94 Solution B pion mass yields $m_\nu^2=-0.016\pm0.023$ with corresponding Bayesian limit listed above. If Solution A is used, $m_\nu^2=-0.143\pm0.024~{\rm MeV}^2.$ Replaces ASSAMAGAN 94.

- 30 DOLGOV 95 removes earlier assumptions (DOLGOV 93) about thermal equilibrium below $T_{\rm QCD}$ for wrong-helicity Dirac neutrinos (ENQVIST 93, FULLER 91) to set more stringent limits.
- 31 ENQVIST 93 bases limit on the fact that thermalized wrong-helicity Dirac neutrinos would speed up expansion of early universe, thus reducing the primordial abundance. FULLER 91 exploits the same mechanism but in the older calculation obtains a larger production rate for these states, and hence a lower limit. Neutrino lifetime assumed to exceed nucleosynthesis time, ~1s.
- 32 Assumes neutrino lifetime >1 s. For Dirac neutrinos only. See also ENQVIST 93.
- $^{
 m 33}\,{\rm A\,NDERHUB}$ 82 kinematics is insensitive to the pion mass.

ν MASS (tau based)

The limits given below are the square roots of limits for $m_{\nu_{\tau}}^{2({\rm eff})} \equiv \sum_i |{\rm U}_{\tau i}|^2 \ m_{\nu_i}^2.$

In some of the ASTR and COSM papers listed below, the authors did not distinguish between weak and mass eigenstates.

- 34 BARATE 98F result based on kinematics of 2939 $\tau^-\to 2\pi^-\pi^+\nu_\tau$ and 52 $\tau^-\to 3\pi^-2\pi^+(\pi^0)\nu_\tau$ decays. If possible 2.5% excited a_1 decay is included in 3-prong sample analysis, limit increases to 19.2 MeV.
- ³⁵ ATHANAS 00 bound comes from analysis of $\tau^- \to \pi^- \pi^+ \pi^- \pi^0 \nu_{\pi}$ decays.
- 36 ACKERSTAFF 98T use $\tau\to 5\pi^\pm\nu_\tau$ decays to obtain a limit of 43.2 MeV (95%CL). They combine this with ALEXANDER 96M value using $\tau\to 3\hbar^\pm\nu_\tau$ decays to obtain quoted limit.
- 37 A MMAR 98 limit comes from analysis of $\tau^-\to 3\pi^-\,2\pi^+\,\nu_\tau$ and $\tau^-\to 2\pi^-\,\pi^+\,2\pi^0\,\nu_\tau$ decay modes.
- 38 ANASTASSOV 97 derive limit by comparing their m_{τ} measurement (which depends on $m_{\nu_{\tau}})$ to BAI 96 m_{τ} threshold measurement.
- 39 FIELDS 97 limit for a Dirac neutrino. For a Majorana neutrino the mass region <0.93 or $>\!31$ MeV is excluded. These bounds assume $N_{\nu}<\!4$ from nucleosynthesis; a wider excluded region occurs with a smaller N_{ν} upper limit.
- 40 SWAIN 97 derive their limit from the Standard Model relationships between the tau mass, lifetime, branching fractions for $\tau^- \to e^- \overline{\nu}_e \nu_\tau, \tau^- \to \mu^- \overline{\nu}_\mu \nu_\tau, \tau^- \to \pi^- \nu_\tau$, and $\tau^- \to K^- \nu_\tau$, and the muon mass and lifetime by assuming lepton universality and using world average values. Limit is reduced to 48 MeV when the CLEO τ mass measurement (BALEST 93) is included; see CLEO's more recent m_{ν_τ} limit (ANASTASSOV 97). Consideration of mixing with a fourth generation heavy neutrino yields $\sin^2\!\theta_L < 0.016$ (95 %CL).
- 41 ALEXANDER 96M bound comes from analyses of $\tau^-\to 3\pi^-2\pi^+\nu_\tau$ and $\tau^-\to h^-h^-h^+\nu_\tau$ decays.
- 42 BOTTINO 96 assumes three generations of neutrinos with mixing, finds consistency with massless neutrinos with no mixing based on 1995 data for masses, lifetimes, and leptonic nartial widths
- $^{43}\,\mathrm{HANNESTAD}$ 96C limit is on the mass of a Majorana neutrino. This bound assumes $N_{\nu}<4$ from nucleosynthesis. A wider excluded region occurs with a smaller N_{ν} upper limit. This paper is the corrected version of HANNESTAD 96; see the erratum: HANNESTAD 96B.
- 44 SOBIE 96 derive their limit from the Standard Model relationship between the tau mass, lifetime, and leptonic branching fraction, and the muon mass and lifetime, by assuming lepton universality and using world average values.

- $^{
 m 45}$ BUSKULIC 95H bound comes from a two-dimensional fit of the visible energy and invariant mass distribution of $au o 5\pi(\pi^0)
 u_{ au}$ decays. Replaced by BARATE 98F
- $^{
 m 46}$ DOLGOV 95 removes earlier assumptions (DOLGOV 93) about thermal equilibrium below $T_{
 m QCD}$ for wrong-helicity Dirac neutrinos (ENQVIST 93, FULLER 91) to set more stringent limits. DOLGOV 96 argues that a possible window near 20 MeV is excluded.
- $^{
 m 47}$ SIGL 95 exclude massive Dirac or Majorana neutrinos with lifetimes between 10^{-3} and 10^8 seconds if the decay products are predominantly γ or $e^+\,e^-$
- $^{48}\, {\tt DODELSON}$ 94 calculate constraints on ν_{τ} mass and lifetime from nucleosynthesis for 4 generic decay modes. Limits depend strongly on decay mode. Quoted limit is valid for all decay modes of Majorana neutrinos with lifetime greater than about 300s. For Dirac neutrinos limits change to < 0.3 or > 33.
- 49 KAWASAKI 94 excluded region is for Majorana neutrino with lifetime >1000 s. Other limits are given as a function of ν_{τ} lifetime for decays of the type $\nu_{\tau} \rightarrow \ \nu_{\mu} \phi$ where ϕ is a Nambu-Goldstone boson.
- ⁵⁰ PERES 94 used PDG 92 values for parameters to obtain a value consistent with mixing. Reexamination by BOTTINO 96 which included radiative corrections and 1995 PDG parameters resulted in two allowed regions, $m_3 < 70\,$ MeV and $140\,$ MeV $m_3 < 149\,$
- 51 CINABRO 93 bound comes from analysis of au^- ightarrow $3\pi^ 2\pi^+$ $u_ au$ and au^- ightarrow $2\pi^-\pi^+2\pi^0\nu_{\tau}$ decay modes.
- 52 DOLGOV 93 assumes neutrino lifetime >100s. For Majorana neutrinos, the low mass limit is 0.5 MeV. KAWANO 92 points out that these bounds can be overcome for a Dirac neutrino if it possesses a magnetic moment. See also DOLGOV 96.
- $^{53}\mathsf{ENQVIST}$ 93 bases limit on the fact that thermalized wrong-helicity Dirac neutrinos would speed up expansion of early universe, thus reducing the primordial abundance. FULLER 91 exploits the same mechanism but in the older calculation obtains a larger production rate for these states, and hence a lower limit. Neutrino lifetime assumed to exceed nucleosynthesis time, ~ 1 s.
- 54 ALBRECHT 92M reports measurement of a slightly lower au mass, which has the effect of reducing the $\nu_{ au}$ mass reported in ALBRECHT 88B. Bound is from analysis of $au^-
 ightarrow$ $3\pi^-\,2\pi^+\,\nu_{\tau}$ mode
- $^{55}\,\mathrm{Assumes}$ neutrino lifetime $>\!1\,\mathrm{s}$. For Dirac neutrinos. See also ENQVIST 93.
- 56 KOLB 91 exclusion region is for Dirac neutrino with lifetime $>\!\!1\,\mathrm{s};$ other limits are given.

Revised August 2009 by K.A. Olive (University of Minnesota).

The limits on low mass $(m_{\nu} \lesssim 1 \text{ MeV})$ neutrinos apply to $m_{\rm tot}$ given by

$$m_{\rm tot} = \sum_{\nu} (g_{\nu}/2) m_{\nu} ,$$

where g_{ν} is the number of spin degrees of freedom for ν plus $\overline{\nu}$: $g_{\nu} = 4$ for neutrinos with Dirac masses; $g_{\nu} = 2$ for Majorana neutrinos. Stable neutrinos in this mass range make a contribution to the total energy density of the Universe which is given by

$$\rho_{\nu} = m_{\text{tot}} n_{\nu} = m_{\text{tot}} (3/11) n_{\gamma}$$
,

where the factor 3/11 is the ratio of (light) neutrinos to photons. Writing $\Omega_{\nu} = \rho_{\nu}/\rho_c$, where ρ_c is the critical energy density of the Universe, and using $n_{\gamma} = 412 \text{ cm}^{-3}$, we have

$$\Omega_{\nu}h^2 = m_{\rm tot}/(94 \text{ eV})$$
.

While an upper limit to the matter density of $\Omega_m h^2 < 0.12$ would constrain $m_{\rm tot} < 11$ eV, much stronger constraints are obtained from a combination of observations of the CMB and the amplitude of density fluctuations on smaller scales from the clustering of galaxies and the Lyman- α forest. These combine to give an upper limit around 0.5 eV.

SUM OF THE NEUTRINO MASSES, mtot

(Defined in the above note), of effectively stable neutrinos (i.e., those with mean lives greater than or equal to the age of the universe). These papers assumed Dirac neutrinos. When necessary, we have generalized the results reported so they apply to $m_{
m tot}$. For other limits, see SZALAY 76, VYSOTSKY 77, BERNSTEIN 81, FREESE 84, SCHRAMM 84, and COWSIK 85

- 57 Constrains the total mass of neutrinos from the Sloan Digital Sky Survey and the five-year
- WMAP data. 58 Constrains the total mass of neutrinos from the 7-year WMAP data including SDSS and HST data. Limit relaxes to 1.19 eV when CMB data is used alone. Supersedes
- ⁵⁹ Constrains the total mass of neutrinos from a combination of CMB data, a recent measurement of H_0 (SHOES), and baryon acoustic oscillation data from SDSS.
- ⁶⁰ Constrains the total mass of neutrinos from SDSS MegaZ LRG DR7 galaxy clustering data combined with CMB, HST, supernovae and baryon acoustic oscillation data. Limit relaxes to 0.47 eV when the equation of state parameter, $w~\neq~1.$
- 61 Constrains the total mass of neutrinos from weak lensing measurements when combined with CMB. Limit improves to 0.54 eV when supernovae and baryon acoustic oscillation observations are included. Assumes ACDM model.
- 62 Constrains the total mass of neutrinos from five-year WMAP data. Limit improves to 0.67eV when supernovae and baryon acoustic oscillation observations are included. Limits quoted assume the Λ CDM model. Supersedes SPERGEL 07.
- 63 Constrains the total mass of neutrinos from weak lensing measurements when combined with CMB. Limit improves to 0.03 $< \Sigma m_{\nu} <$ 0.54 eV when supernovae and baryon acoustic oscillation observations are included. The slight preference for massive neutrinos at the two-sigma level disappears when systematic errors are taken into account. Assumes ACDM model.
- 64 Constrains the total mass of neutrinos from recent Chandra X-ray observations of galaxy clusters when combined with CMB, supernovae, and baryon acoustic oscillation measurements. Assumes flat universe and constant dark-energy equation of state, w.
- 65 Constraints the total mass of neutrinos from recent CMB and SOSS LRG power spectrum data along with bias mass relations from SDSS, DEEP2, and Lyman-Break Galaxies. It assumes ACDM model. Limit degrades to 0.59 eV in a more general wCDM model.
- 66 Constrains the total mass of neutrinos from neutrino oscillation experiments and cosmological data. The most conservative limit uses only WMAP three-year data, while the most stringent limit includes CMB, large-scale structure, supernova, and Lyman-alpha
- 67 Constrains the total mass of neutrinos from recent CMB, large scale structure, SN1a, and baryon acoustic oscillation data. The limit relaxes to 1.75 when WMAP data alone is used with no prior. Paper shows results with several combinations of data sets. Supersedes KRISTIANSEN 06.
- 68 Constrains the total mass of neutrinos from the CMB and the large scale structure data. The most conservative limit is obtained when generic initial conditions are allowed
- 69 Constrains the total mass of neutrinos from recent CMB, large scale structure, Lymanalpha forest, and SN1a data.
- 70 Constrains the total mass of neutrinos from recent CMB and large scale structure data. See also GOOBAR 06. Superseded by HANNESTAD 10.
- 71 Constrains the total mass of neutrinos from the CMB and the final 2dF Galaxy Redshift
- 72 Constrains the total mass of neutrinos from the CMB experiments alone, assuming ΛCDM Universe. FUKUGITA 06 show that this result is unchanged by the 3-year WMAP data.
- 73 Constrains the total mass of neutrinos from the power spectrum of fluctuations derived from the Sloan Digital Sky Survey and the 2dF galaxy redshift survey, WMAP and 27 other CMB experiments and measurements by the HST Key project.
- 74 Constrains the total mass of neutrinos from the power spectrum of fluctuations derived from the Sloan Digital Sky Survey, the 2dF galaxy redshift survey, WMAP and ACBAR. The limit is strengthened to 0.6 eV when measurements by the HST Key project and
- 75 Constrains the fractional contribution of neutrinos to the total matter density in the Universe from WMAP data combined with other CMB measurements, the 2dfGRS data, and Lyman lpha data. The limit does not noticeably change if the Lyman lpha data are not
- derived from the CMB, HST Key project, 2dF galaxy redshift survey, supernovae type Ia, and BBN. ⁷⁶ LEWIS 02 constrains the total mass of neutrinos from the power spectrum of fluctuations

Neutrino Properties

- 77 WA NG 02 constrains the total mass of neutrinos from the power spectrum of fluctuations derived from the CMB and other cosmological data sets such as galaxy clustering and the Lyman α forest.
- 78 FUKUGITA 00 is a limit on neutrino masses from structure formation. The constraint is based on the clustering scale σ_8 and the COBE normalization and leads to a conservative limit of 0.9 eV assuming 3 nearly degenerate neutrinos. The quoted limit is on the sum of the light neutrino masses.
- 79 CROFT 99 result based on the power spectrum of the Ly α forest. If $\Omega_{\rm matter}<$ 0.5, the limit is improved to $m_{\nu}<$ 2.4 ($\Omega_{\rm matter}/0.17\text{--}1)$ eV.

Limits on MASSES of Light Stable Right-Handed ν (with necessarily suppressed interaction strengths)

- 82 GNINENKO 07 use limit on $\overline{\nu}_e$ magnetic moment from LI 03B to derive this result. The limit is considerably weaker than the limits on the charge of ν_e and $\overline{\nu}_e$ from various astrophysics considerations.
- 83 This RAFFELT 99 limit applies to all neutrino flavors which are light enough (<5 keV) to be emitted from globular-cluster red giants.
- 84 This RAFFELT 99 limit is derived from the helioseismological limit on a new energy-loss channel of the Sun, and applies to all neutrino flavors which are light enough (<1 keV) to be emitted from the sun.</p>
- 85 BABU 94 use COOPER-SARKAR 92 limit on ν magnetic moment to derive quoted result. It applies to $\nu_{\mathcal{T}}.$
- 86 DAVIDSON 91 use data from early SLAC electron beam dump experiment to derive charge limit as a function of neutrino mass. It applies to $\nu_{\mathcal{T}}.$
- 87 Exact BARBIELLINI 87 limit depends on assumptions about the intergalactic or galactic magnetic fields and about the direct distance and time through the field. It applies to ν_e .
- ⁸⁸The limit applies to all flavors.

VALUE (units: electron charge) CL%

u (MEAN LIFE) / MASS

Measures $\left[\sum |U_{\ell j}|^2 \; \Gamma_j \; m_j\right]^{-1}$, where the sum is over mass eigenstates which cannot be resolved experimentally. Some of the limits constrain the radiative decay and are based on the limit of the corresponding photon flux. Other apply to the decay of a heavier neutrino into the lighter one and a Majoron or other invisible particle. Many of these limits apply to any ν within the indicated mass range.

Limits on the radiative decay are either directly based on the limits of the corresponding photon flux, or are derived from the limits on the neutrino magnetic moments. In the later case the transition rate for $\nu_i \to \nu_j + \gamma$

is constrained by $\Gamma_{ij}=rac{1}{ au_{ij}}=rac{(m_i^2-m_j^2)^3}{m_j^3}~\mu_{ij}^2$ where μ_{ij} is the neutrino transition moment in the mass eigenstates basis. Typically, the limits on

transition moment in the mass eigenstates basis. Typically, the limits on lifetime based on the magnetic moments are many orders of magnitude more restrictive than limits based on the nonobservation of photons.

- 89 KRAKAUER 91 quotes the limit $\tau/m_{\nu_1}>(0.75\,a^2+21.65\,a+26.3)\,\mathrm{s/eV},$ where a is a parameter describing the asymmetry in the neutrino decay defined as $dN_{\gamma}/d\cos\theta=(1/2)(1+a\cos\theta)$ The parameter a=0 for a Majorana neutrino, but can vary from -1 to 1 for a Dirac neutrino. The bound given by the authors is the most conservative (which applies for a=-1).
- 90 RAFFELT 85 limit on the radiative decay is from solar x- and γ -ray fluxes. Limit depends on ν flux from pp, now established from GALLEX and SAGE to be > 0.5 of expectation.
- 91 REINES 74 looked for ν of nonzero mass decaying radiatively to a neutral of lesser mass + $\gamma.$ Used liquid scintillator detector near fission reactor. Finds lab lifetime 6×10^7 s or more. Above value of (mean life)/mass assumes average effective neutrino energy of 0.2 MeV. To obtain the limit 6×10^7 s REINES 74 assumed that the full $\overline{\nu}_e$ reactor flux could be responsible for yielding decays with photon energies in the interval 0.1 MeV 0.5 MeV. This represents some overestimates of their lower limit is an over-estimate of the lab lifetime (VOGEL 84). If so, OBERAUER 87 may be comparable or better.
- 92 CECCHINI 11 search for radiative decays of solar neutrinos into visible photons during the 2006 total solar eclipse. The range of (mean life)/mass values corresponds to a range of ν_1 masses between 10^{-4} and 0.1 eV.
- 93 MIRIZZI 07 determine a limit on the neutrino radiative decay from analysis of the maximum allowed distortion of the CMB spectrum as measured by the COBE/FIRAS. For the decay $\nu_2 \rightarrow \nu_1$ the lifetime limit is $\lesssim 4 \times 10^{20}$ s for $m_{min} \lesssim 0.14$ eV. For transition with the $|\Delta m_{31}|$ mass difference the lifetime limit is $\sim 2 \times 10^{19}$ s for $m_{min} \lesssim 0.14$ eV and $\sim 5 \times 10^{20}$ s for $m_{min} \gtrsim 0.14$ eV.
- 94 MIRIZZI 07 determine a limit on the neutrino radiative decay from analysis of the cosmic infrared background (CIB) using the Spitzer Observatory data. For transition with the $|\Delta m_{31}|$ mass difference they obtain the lifetime limit $\sim 10^{20}$ s for $m_{min} \lesssim 0.14$ eV.
- 95 WONG 07 use their limit on the neutrino magnetic moment together with the assumed experimental value of $\Delta m_{13}^2 \sim 2 \times 10^{-3} \; \text{eV}^2$ to obtain $\tau_{13}/m_1^3 > 3.2 \times 10^{27} \; \text{s/eV}^3$ for the radiative decay in the case of the inverted mass hierarchy. Similarly to RAFFELT 89 this limit can be violated if electric and magnetic moments are equal to each other. Analogous, but numerically somewhat different limits are obtained for τ_{23} and τ_{21} .
- 96 XIN 05 search for the γ from radiative decay of ν_e produced by the electron capture on 51 Cr. No events were seen and the limit on τ/m_{ν} was derived. This is a weaker limit on the decay of ν_e than KRAKAUER 91.
- 97 XIN 05 use their limit on the neutrino magnetic moment of ν_e together with the assumed experimental value of $\Delta m_{1,3}^2 \sim 2 \times 10^{-3} \, \mathrm{eV}^2$ to obtain $\tau_{13}/m_1^3 > 1 \times 10^{23} \, \mathrm{s/eV}^3$ for the radiative decay in the case of the inverted mass hierarchy. Similarly to RAFFELT 89 this limit can be violated if electric and magnetic moments are equal to each other. Analogous, but numerically somewhat different limits are obtained for τ_{23} and τ_{21} . Again, this limit is specific for ν_e .

Lepton Particle Listings Neutrino Properties

- 98 AHARMIM 04 obtained these results from the solar $\overline{\nu}_e$ flux limit set by the SNO measurement assuming ν_2 decay through nonradiative process $\nu_2 \to \overline{\nu}_1 X$, where X is a Majoron or other invisible particle. Limits are given for the cases of quasidegenerate and hierarchical neutrino masses.
- 99 CECCHINI 04 obtained this bound through the observations performed on the occasion of the 21 June 2001 total solar eclipse, looking for visible photons from radiative decays of solar neutrinos. Limit is a τ/m_{ν_2} in $\nu_2 \rightarrow \nu_1 \gamma$. Limit ranges from ~ 100 to 10^7 s/eV for $0.01 < m_{\nu_1} < 0.1$ eV.
- $100\,\text{EGUCHI}$ 04 obtained these results from the solar \overline{v}_e flux limit set by the KamLAND measurement assuming ν_2 decay through nonradiative process $\nu_2 \to \overline{v}_1 X$, where X is a Majoron or other invisible particle. Limits are given for the cases of quasidegenerate and hierarchical neutrino masses.
- of the right of the lifetime over the mass derived by BANDYOPADHYAY 03 is for ν_2 . They obtained this result using the following solar-neutrino data: total rates measured in CI and Ga experiments, the Super-Kamiokande's zenith-angle spectra, and SNO's day and night spectra. They assumed that ν_1 is the lowest mass, stable or nearly stable neutrino state and ν_2 decays through nonradiative Majoron emission process, $\nu_2 \rightarrow \mathcal{P}_1 + J$, or through nonradiative process with all the final state particles being sterile. The best fit is obtained in the region of the LMA solution.
- 102 DERBIN 02B (also BACK 03B) obtained this bound for the radiative decay from the results of background measurements with Counting Test Facility (the prototype of the Borexino detector). The laboratory gamma spectrum is given as $dN_{\gamma}/d\cos\theta = (1/2)(1+\alpha\cos\theta)$ with α =0 for a Majorana neutrino, and α varying to -1 to 1 for a Dirac neutrino. The listed bound is for the case of α =0. The most conservative bound 1.5×10^3 s eV $^{-1}$ is obtained for the case of α =-1.
- 103 The ratio of the lifetime over the mass derived by JOSHIPURA 02B is for ν_2 . They obtained this result from the total rates measured in all solar neutrino experiments. They assumed that ν_1 is the lowest mass, stable or nearly stable neutrino state and ν_2 decays through nonradiative process like Majoron emission decay, $\nu_2 \rightarrow \nu_1' + J$ where ν_1' state is sterile. The exact limit depends on the specific solution of the solar neutrino problem. The quoted limit is for the LMA solution.
- $104\,{\rm DOLGOV}$ 99 places limits in the (Majorana) τ -associated ν mass-lifetime plane based on nucleosynthesis. Results would be considerably modified if neutrino oscillations exist.
- 105 BILLER 98 use the observed TeV $\gamma\text{-ray}$ spectra to set limits on the mean life of any radiatively decaying neutrino between 0.05 and 1 eV. Curve shows $\tau_{\nu}/\text{B}_{\gamma}>0.15\times10^{21}\,\text{s}$ at 0.05 eV, $>1.2\times10^{21}\,\text{s}$ at 0.17 eV, $>3\times10^{21}\,\text{s}$ at 1 eV, where B $_{\gamma}$ is the branching ratio to photons.
- 106 BLUD MAN 92 sets additional limits by this method for higher mass ranges. Cosmological limits are also obtained.
- 107 Limit on the radiative decay based on nonobservation of γ 's in coincidence with ν 's from SN 1987A
- 108 DODELSON 92 range is for wrong-helicity keV mass Dirac ν 's from the core of neutron star in SN 1987A decaying to ν 's that would have interacted in KAM2 or IMB detectors.
- 109 GRANEK 91 considers heavy neutrino decays to $\gamma\nu_L$ and $3\nu_L$, where m_{ν_L} <100 keV. Lifetime is calculated as a function of heavy neutrino mass, branching ratio into $\gamma\nu_L$, and m_{ee} .
- 110 KRAKAUER 91 quotes the limit for $\nu_e, \tau/m_\nu > (0.3a^2 + 9.8a + 15.9)\,\text{s/eV},$ where a is a parameter describing the asymmetry in the radiative neutrino decay defined as $dN_\gamma/d\cos\theta = (1/2)(1+a\cos\theta)~a=0$ for a Majorana neutrino, but can vary from -1 to 1 for a Dirac neutrino. The bound given by the authors is the most conservative (which applies for a=-1).
- $^{111}\,\mathrm{WALKER}$ 90 uses SN 1987A γ flux limits after 289 days.
- $112\,\text{CHUPP}$ 89 should be multiplied by a branching ratio (about 1) and a detection efficiency (about 1/4), and pertains to radiative decay of any neutrino to a lighter or sterile neutrino.
- 113 RAFFELT 89 uses KYULDJIEV 84 to obtain $\tau m^3>3\times 10^{18}\,\mathrm{s}$ eV 3 (based on $\overline{\nu}_e\,e^-$ cross sections). The bound for the radiative decay is not valid if electric and magnetic transition moments are equal for Dirac neutrinos.
- $^{114}\, \rm RAFFELT$ 89B analyze stellar evolution and exclude the region 3 \times 10 $^{12}~<~\tau m^3$ $<~3\times 10^{21}\, \rm s\, eV^3.$
- 115 Model-dependent theoretical analysis of SN 1987A neutrinos. Quoted limit is for $\left[\sum_j |U_{\ell j}|^2 \; \Gamma_j \; m_j\right]^{-1}$, where $\ell = \mu, \; \tau$. Limit is 3.3 \times 10¹⁴ s/eV for $\ell = e$.
- 116 OBERAUER 87 looks for photons and $e^+\,e^-$ pairs from radiative decays of reactor neutrinos.
- 117 BINETRUY 84 finds $au < 10^8$ s for neutrinos in a radiation-dominated universe.
- $^{118}\, {\rm These}$ experiments look for $\nu_{\pmb k} \ \to \ \nu_{\pmb j} \, \gamma$ or $\overline{\nu}_{\pmb k} \ \to \ \overline{\nu}_{\pmb j} \, \gamma.$
- 119 STECKER 80 limit based on UV background; result given is $\tau > 4 \times 10^{22}$ s at $m_{\nu} = 20$ eV.
- $^{120}\,\mathrm{FALK}$ 78 finds lifetime constraints based on supernova energetics.
- 121 COWSIK 77 considers variety of scenarios. For neutrinos produced in the big bang, present limits on optical photon flux require $\tau>10^{23}\,\mathrm{s}$ for $m_{\nu}\sim 1$ eV. See also COWSIK 79 and GOLDMAN 79.

ν MAGNETIC MOMENT

The coupling of neutrinos to an electromagnetic field is a characterized by a 3×3 matrix λ of the magnetic (μ) and electric (d) dipole moments $(\lambda=\mu$ - id). For Majorana neutrinos the matrix λ is antisymmetric and only transition moments are allowed, while for Dirac neutrinos λ is a general 3×3 matrix. In the standard electroweak theory extended to include neutrino masses (see FUJIKAWA 80) $\mu_{\nu}=3eG_{F}m_{\nu}/(8\pi^{2}\sqrt{2})=3.2\times10^{-19}(m_{\nu}/\mathrm{eV})\mu_{B}$, i.e. it is unobservably small given the known small neutrino masses. In more general models there is no longer a proportionality between neutrino mass and its magnetic moment, even though

only massive neutrinos have nonvanishing magnetic moments without fine tuning.

Laboratory bounds on λ are obtained via elastic $\nu\text{-}e$ scattering, where the scattered neutrino is not observed. The combinations of matrix elements of λ that are constrained by various experiments depend on the initial neutrino flavor and on its propagation between source and detector (e.g., solar ν_e and reactor $\overline{\nu}_e$ do not constrain the same combinations). The listings below therefore identify the initial neutrino flavor.

Other limits, e.g. from various stellar cooling processes, apply to all neutrino flavors. Analogous flavor independent, but weaker, limits are obtained from the analysis of $e^+e^-\to \nu\overline{\nu}\gamma$ collider experiments.

- $122\,\mathrm{BEDA}$ 10 report $\overline{\nu}_e\,\mathrm{e}^-$ scattering results, using the Kalinin Nuclear Power Plant and a shielded Ge detector. The recoil electron spectrum is analyzed between 2.9 and 45 keV. Supersedes BEDA 07. This is the most stringent limit on the magnetic moment of reactor $\overline{\nu}_e$.
- 123 AUERBACH 01 limit is based on the LSND ν_e and ν_μ electron scattering measurements. The limit is slightly more stringent than KRAKAUER 90.
- $^{124}\,\text{SCHWIENHORST}$ 01 quote an experimental sensitivity of 4.9×10^{-7}
- 125 DENIZ 10 observe reactor $\overline{v}_e e$ scattering with recoil kinetic energies 3–8 MeV using Csl(Tl) detectors. The observed rate and spectral shape are consistent with the Standard Model prediction, leading to the reported constraint on \overline{v}_e magnetic moment.
- 126 KUZNETSOV 09 obtain a limit on the flavor averaged magnetic moment of Dirac neutrinos from the time averaged neutrino signal of SN1987A. Improves and supersedes the analysis of BARBIERI 88 and AYALA 99.
- 127 ARPESELLA 08A obtained this limit using the shape of the recoil electron energy spectrum from the Borexino 192 live days of solar neutrino data.

Neutrino Properties

- $^{128}\, \text{BEDA}$ 07 performed search for electromagnetic $\overline{\nu}_{e}\text{-}e$ scattering at Kalininskaya nuclear reactor. A Ge detector with active and passive shield was used and the electron recoil spectrum between 3.0 and 61.3 keV analyzed. Superseded by BEDA 10.
- 129 WONG 07 performed search for non-standard $\overline{\nu}_{e^-}$ e scattering at the Kuo-Sheng nuclear reactor. Ge detector equipped with active anti-Compton shield is used. Most stringent laboratory limit on magnetic moment of reactor $\overline{
 u}_e$. Supersedes LI 03B.
- 130 DARAKTCHIEVA 05 present the final analysis of the search for non-standard $\overline{\nu}_e$ -e scattering component at Bugey nuclear reactor. Full kinematical event reconstruction of both the kinetic energy above 700 keV and scattering angle of the recoil electron, by use of TPC. Most stringent laboratory limit on magnetic moment. Supersedes DARAKTERING 020 TCHIEVA 03.
- 131 XIN 05 evaluated the $u_{
 m p}$ flux at the Kuo-Sheng nuclear reactor and searched for nonstandard ν_e -e scattering. Ge detector equipped with active anti-Compton shield was used. This laboratory limit on magnetic moment is considerably less stringent than the limits for reactor $\overline{
 u}_e$, but is specific to u_e .
- $^{132}\,\mathrm{GRIFOLS}$ 04 obtained this bound using the SNO data of the solar $^{8}\mathrm{B}$ neutrino flux measured with deuteron breakup. This bound applies to $\mu_{
 m eff}=(\mu_{21}^2+\mu_{22}^2+\mu_{23}^2)^{1/2}.$
- 133 LIU 04 obtained this limit using the shape of the recoil electron energy spectrum from the Super-Kamiokande-I 1496 days of solar neutrino data. Neutrinos are assumed to have only diagonal magnetic moments, $\mu_{\nu 1}=\mu_{\nu 2}$. This limit corresponds to the oscillation parameters in the vacuum oscillation region.
- 134 LIU 04 obtained this limit using the shape of the recoil electron energy spectrum from the Super-Kamiokande-1 1496 live-day solar neutrino data, by limiting the oscillation parameter region in the L MA region allowed by solar neutrino experiments plus KamLAND. $\mu_{\nu 1}=\mu_{\nu 2}$ is assumed. In the LMA region, the same limit would be obtained even if neutrinos have off-diagonal magnetic moments.
- $^{135}\,\mathrm{BACK}$ 03B obtained this bound from the results of background measurements with Counting Test Facility (the prototype of the Borexino detector). Standard Solar Model flux was assumed. This μ_{ν} can be different from the reactor μ_{ν} in certain oscillation scenarios (see BEACOM 99).
- $136\,\mathrm{DARAKTCHIEVA}$ 03 searched for non-standard $\overline{\nu}_e\text{-e}$ scattering component at Bugey nuclear reactor. Full kinematical event reconstruction by use of TPC. Superseded by DARAKTCHIEVA 05.
- 137 LI 03B used Ge detector in active shield near nuclear reactor to test for nonstandard $\overline{\nu}_{e}$ -e
- 138 GRIMUS 02 obtain stringent bounds on all Majorana neutrino transition moments from a simultaneous fit of LMA-MSW oscillation parameters and transition moments to global solar neutrino data , reactor data. Using only solar neutrino data, a 90% CL bound of $6.3 \times 10^{-10} \mu_B$ is obtained.
- 139 TANIMOTO 00 combined $e^+\,e^ightarrow\,
 u\,\overline{
 u}\gamma$ data from VENUS, TOPAZ, and AMY.
- $^{140}\,\mathrm{AYALA}$ 99 improves the limit of BARBIERI 88.
- 141 BEACOM 99 obtain the limit using the shape, but not the absolute magnitude which is affected by oscillations, of the solar neutrino spectrum obtained by Superkamiokande (825 days). This $\mu_{
 u}$ can be different from the reactor $\mu_{
 u}$ in certain oscillation scenarios.
- 142 RAFFELT 99 is an update of RAFFELT 90. This limit applies to all neutrino flavors which are light enough (< 5 keV) to be emitted from globular-cluster red giants. This limit pertains equally to electric dipole moments and magnetic transition moments, and it applies to both Dirac and Majorana neutrinos.
- 143 RAFFELT 99 is essentially an update of BERNSTEIN 63, but is derived from the helioseismological limit on a new energy-loss channel of the Sun. This limit applies to all neutrino flavors which are light enough $(<1~{\rm keV})$ to be emitted from the Sun. This limit pertains equally to electric dipole and magnetic transition moments, and it applies to both Dirac and Majorana neutrinos.
- $^{144}\,\mathrm{ACCIARRI}$ 97Q result applies to both direct and transition magnetic moments and for $a^2 = 0$
- $^{145}\, {\sf ELMFORS}$ 97 calculate the rate of depolarization in a plasma for neutrinos with a magnetic moment and use the constraints from a big-bang nucleosynthesis on additional degrees of freedom.
- $^{\rm 146}\,{\rm Applies}$ to absolute value of magnetic moment.
- $147\,\text{DERBIN}$ 93 determine the cross section for 0.6–2.0 MeV electron energy as $(1.28\pm0.63)\times\sigma_{\text{Weak}}.$ However, the (reactor on reactor off)/(reactor off) is only $\sim1/100.$
- 148 COOPER-SARKAR 92 assume $f_{\overline{D}_S}/f_{\pi}$ = 2 and D_S , \overline{D}_S production cross section = 2.6 μb to calculate ν flux.
- $^{149}\,\text{ViDYAKIN}$ 92 limit is from a $e\overline{\nu}_e$ elastic scattering experiment. No experimental details are given except for the cross section from which this limit is derived. Signal/noise was 1/10. The limit uses $\sin^2 heta_W = 0.23$ as input.
- 150 DORENBOSCH 91 corrects an incorrect statement in DORENBOSCH 89 that the ν magnetic moment is < 1 \times 10 $^{-9}$ at the 95%CL. DORENBOSCH 89 measures both $u_{\mu}\overset{ extbf{G}}{e}$ and $\overline{
 u}e$ elastic scattering and assume $\mu(
 u)=\mu(\overline{
 u})$.
- $^{151}\,\mathrm{KRAKAUER}$ 90 experiment fully reported in ALLEN 93.
- $^{152}\,\mathrm{RAFFELT}$ 90 limit applies for a diagonal magnetic moment of a Dirac neutrino, or for a transition magnetic moment of a Majorana neutrino. In the latter case, the same analysis gives $<1.4\times10^{-12}$. Limit at 95%CL obtained from δM_C .
- $153\,\mathrm{Significant}$ dependence on details of stellar models.
- 154 FUKUGITA 88 find magnetic dipole moments of any two neutrino species are bounded by $_{\mu}~<~10^{-16}~[10^{-9}~G/B_{0}]$ where B_{0} is the present-day intergalactic field strength.
- 155 GROTCH 88 combined data from MAC, ASP, CELLO, and Mark J.
- $^{156}\,\mathrm{For}~m_{\nu}=$ 8–200 eV. NUSSINOV 87 examines transition magnetic moments for $\nu_{\mu}\to$ ν_e and obtain $< 3 \times 10^{-15}$ for $m_{\nu} > 16$ eV and $< 6 \times 10^{-14}$ for $m_{\nu} > 4$ eV.
- $^{157}\mathrm{We}$ obtain above limit from SUTHERLAND 76 using their limit f < 1/3.
- $^{158}\, ext{KIM}$ 74 is a theoretical analysis of $\overline{
 u}_{\mu}$ reaction data.

NEUTRINO CHARGE RADIUS SQUARED

We report limits on the so-called neutrino charge radius squared. While the straight-forward definition of a neutrino charge radius has been proven to be gauge-dependent and, hence, unphysical (LEE 77C), there have been attempts to define a physically observable neutrino charge radius (BERNABEU 00, BERNABEU 02). The issue is still controversial (FU-JIKAWA 03, BERNABEU 03). A more general interpretation of the experimental results is that they are limits on certain nonstandard contributions to neutrino scattering

- 159 DENIZ 10 observe reactor $\overline{\nu}_e\,e$ scattering with recoil kinetic energies 3–8 MeV using CsI((TI)) detectors. The observed rate and spectral shape are consistent with the Standard Model prediction, leading to the reported constraint on $\overline{
 u}_e$ charge radius.
- 160 Based on analysis of CCFR 98 results. Limit is on $\langle r_V^2 \rangle + \langle r_A^2 \rangle$. The CHARM II and E734 at BNL results are reanalyzed, and weaker bounds on the charge radius squared than previously published are obtained. The NuTeV result is discussed; when tentatively interpreted as ν_μ charge radius it implies $\langle r_V^2 \rangle + \langle r_A^2 \rangle = (4.20 \pm 1.64) \times 10^{-33}$ cm².
- 161 Results of LEP-2 are interpreted as limits on the axial-vector charge radius squared of a Majorana $\nu_{ au}$. Slightly weaker limits for both vector and axial-vector charge radius squared are obtained for the Dirac case, and somewhat weaker limits are obtained from the analysis of lower energy data (LEP-1.5 and TRISTAN)
- 162 AUERBACH 01 measure $\nu_e \, e$ elastic scattering with LSND detector. The cross section agrees with the Standard Model expectation, including the charge and neutral current interference. The 90% CL applies to the range shown.
- $^{163}\,\mathrm{VIDYA\,KIN}$ 92 limit is from a $ear{
 u}$ elastic scattering experiment. No experimental details are given except for the cross section from which this limit is derived. Signal/noise was 1/10. The limit uses $\sin^2\!\theta_{\,W}=$ 0.23 as input.
- 164 Result is obtained from reanalysis given in ALLEN 91, followed by our reduction to obtain
- ¹⁶⁵ GRIFOLS 89B sets a limit of $\langle r^2 \rangle < 0.2 \times 10^{-32} \, \mathrm{cm}^2$ for right-handed neutrinos.

Number of Neutrino Types

The neutrinos referred to in this section are those of the Standard SU(2)×U(1) Electroweak Model possibly extended to allow nonzero neutrino masses. Light neutrinos are those with $m < m_Z/2$. The limits are on the number of neutrino mass eigenstates, including ν_1 , ν_2 , and ν_3 .

THE NUMBER OF LIGHT NEUTRINO TYPES FROM COLLIDER EXPERIMENTS

Revised March 2008 by D. Karlen (University of Victoria and TRIUMF).

The most precise measurements of the number of light neutrino types, N_{ν} , come from studies of Z production in e^+e^- collisions. The invisible partial width, $\Gamma_{\rm inv}$, is determined by subtracting the measured visible partial widths, corresponding to Z decays into quarks and charged leptons, from the total Z width. The invisible width is assumed to be due to N_{ν} light neutrino species each contributing the neutrino partial width Γ_{ν} as given by the Standard Model. In order to reduce the model dependence, the Standard Model value for the ratio of the neutrino to charged leptonic partial widths, $(\Gamma_{\nu}/\Gamma_{\ell})_{\rm SM}=1.991\pm0.001$, is used instead of $(\Gamma_{\nu})_{\rm SM}$ to determine the number of light neutrino types:

$$N_{\nu} = \frac{\Gamma_{\rm inv}}{\Gamma_{\ell}} \left(\frac{\Gamma_{\ell}}{\Gamma_{\nu}} \right)_{\rm SM} . \tag{1}$$

The combined result from the four LEP experiments is $N_{\nu} = 2.984 \pm 0.008$ [1].

In the past, when only small samples of Z decays had been recorded by the LEP experiments and by the Mark II at SLC, the uncertainty in N_{ν} was reduced by using Standard Model fits to the measured hadronic cross sections at several center-of-mass energies near the Z resonance. Since this method is

Number of Neutrino Types

much more dependent on the Standard Model, the approach described above is favored.

Before the advent of the SLC and LEP, limits on the number of neutrino generations were placed by experiments at lower-energy e^+e^- colliders by measuring the cross section of the process $e^+e^- \to \nu \overline{\nu} \gamma$. The ASP, CELLO, MAC, MARK J, and VENUS experiments observed a total of 3.9 events above background [2], leading to a 95% CL limit of $N_{\nu} < 4.8$. This process has a much larger cross section at center-of-mass energies near the Z mass and has been measured at LEP by the ALEPH, DELPHI, L3, and OPAL experiments [3]. These experiments have observed several thousand such events, and the combined result is $N_{\nu} = 3.00 \pm 0.08$. The same process has also been measured by the LEP experiments at much higher center-of-mass energies, between 130 and 208 GeV, in searches for new physics [4]. Combined with the lower energy data, the result is $N_{\nu} = 2.92 \pm 0.05$.

Experiments at $p\overline{p}$ colliders also placed limits on N_{ν} by determining the total Z width from the observed ratio of $W^{\pm} \to \ell^{\pm} \nu$ to $Z \to \ell^{+} \ell^{-}$ events [5]. This involved a calculation that assumed Standard Model values for the total W width and the ratio of W and Z leptonic partial widths, and used an estimate of the ratio of Z to W production cross sections. Now that the Z width is very precisely known from the LEP experiments, the approach is now one of those used to determine the W width.

Double- β Decay

OMITTED FROM SUMMARY TABLE

NEUTRINOLESS DOUBLE- β DECAY

Revised August 2011 by P. Vogel (Caltech) and A. Piepke (University of Alabama).

Neutrinoless double-beta $(0\nu\beta\beta)$ decay would signal violation of total lepton number conservation. The process can be mediated by an exchange of a light Majorana neutrino, or by an exchange of other particles. However, the existence of $0\nu\beta\beta$ -decay requires Majorana neutrino mass, no matter what the actual mechanism is. As long as only a limit on the lifetime is available, limits on the effective Majorana neutrino mass, on the lepton-number violating right-handed current or other possible mechanisms mediating $0\nu\beta\beta$ -decay can be obtained, independently of the actual mechanism. These limits are listed in the next three tables, together with a claimed $0\nu\beta\beta$ -decay signal reported by part of the Heidelberg-Moscow collaboration. A 6σ excess of counts at the decay energy is used for a determination of the Majorana neutrino mass. This signal has not yet been independently confirmed. In the following we assume that the exchange of light Majorana neutrinos $(m_{\nu_i} \leq 10 \text{ MeV})$ contributes dominantly to the decay rate.

Besides a dependence on the phase space $(G^{0\nu})$ and the nuclear matrix element $(M^{0\nu})$, the observable $0\nu\beta\beta$ -decay rate is proportional to the square of the effective Majorana mass $\langle m_{\beta\beta} \rangle$, $(T_{1/2}^{0\nu})^{-1} = G^{0\nu} \cdot |M^{0\nu}|^2 \cdot \langle m_{\beta\beta} \rangle^2$, with $\langle m_{\beta\beta} \rangle^2 = |\sum_i U_{ei}^2 m_{\nu_i}|^2$. The sum contains, in general, complex *CP*-phases in U_{ei}^2 , *i.e.*, cancellations may occur. For three neutrino flavors, there are

three physical phases for Majorana neutrinos and one for Dirac neutrinos. The two additional Majorana phase differences affect only processes to which lepton-number-changing amplitudes contribute. Given the general 3×3 mixing matrix for Majorana neutrinos, one can construct other analogous lepton number violating quantities, $\langle m_{\ell\ell'} \rangle = \sum_i U_{\ell i} U_{\ell' i} m_{\nu_i}$. However, these are currently much less constrained than $\langle m_{\beta\beta} \rangle$.

Nuclear structure calculations are needed to deduce $\langle m_{\beta\beta} \rangle$ from the decay rate. While $G^{0\nu}$ can be calculated reliably, the computation of $M^{0\nu}$ is subject to uncertainty. Comparing different nuclear model evaluations indicates a factor ~ 2 spread in the calculated nuclear matrix elements. The particle physics quantities to be determined are thus nuclear model-dependent, so the half-life measurements are listed first. Where possible, we reference the nuclear matrix elements used in the subsequent analysis. Since rates for the more conventional $2\nu\beta\beta$ decay serve to calibrate the nuclear theory, results for this process are also given.

Oscillation experiments utilizing atmospheric-, accelerator-, solar-, and reactor-produced neutrinos and anti-neutrinos yield strong evidence that at least some neutrinos are massive. However, these findings shed no light on the mass hierarchy (i.e., on the sign of Δm^2_{atm}), the absolute neutrino mass values or the properties of neutrinos under CPT-conjugation (Dirac or Majorana).

All confirmed oscillation experiments can be consistently described using three interacting neutrino species with two mass splittings and three mixing angles. Full three flavor analyses such as e.g. [2] yield: $|\Delta m_{atm}^2| \equiv |m_3^2 - (m_2^2 + m_1^2)/2| = (2.39_{-0.20}^{+0.27}) \times 10^{-3} \text{ eV}^2$ and $\sin^2\theta_{atm} \equiv \sin^2\theta_{23} = 0.466_{-0.100}^{+0.136}$ for the parameters observed in atmospheric and accelerator experiments. Oscillations of solar ν_e and reactor $\bar{\nu}_e$ lead to $\Delta m_\odot^2 \equiv m_2^2 - m_1^2 = (7.67_{-0.36}^{+0.34}) \times 10^{-5} \text{ eV}^2$ and $\sin^2\theta_\odot \equiv \sin^2\theta_{12} = 0.312_{-0.034}^{+0.040}$. (All errors correspond to 95% CL) The investigation of reactor $\bar{\nu}_e$ at \sim 1 km baseline, combined with solar neutrino and long baseline reactor experiments, indicates that electron type neutrinos couple only weakly to the third mass eigenstate with $\sin^2\theta_{13} < 0.036$.

Based on the 3-neutrino analysis: $\langle m_{\beta\beta} \rangle^2 \approx |\cos^2\theta_{\odot}m_1 + e^{i\Delta\alpha_{21}}\sin^2\theta_{\odot}m_2 + e^{i\Delta\alpha_{31}}\sin^2\theta_{13}m_3|^2$, with $\Delta\alpha_{21}$, $\Delta\alpha_{31}$ denoting the physically relevant Majorana CP-phase differences (possible Dirac phase δ is absorbed in these $\Delta\alpha$). Given the present knowledge of the neutrino oscillation parameters one can derive the relation between the effective Majorana mass and the mass of the lightest neutrino, as illustrated in the left panel of Fig. 1. The three mass hierarchies allowed by the oscillation data: normal $(m_1 < m_2 < m_3)$, inverted $(m_3 < m_1 < m_2)$, and degenerate $(m_1 \approx m_2 \approx m_3)$, result in different projections. The width of the innermost hatched bands reflects the uncertainty introduced by the oscillation parameters are taken into account, then the allowed areas are widened as shown by the outer bands of Fig. 1. Because of the overlap of the

Double- β Decay

different mass scenarios a measurement of $\langle m_{\beta\beta} \rangle$ in the degenerate or inversely hierarchical ranges would not determine the hierarchy. The middle panel of Fig. 1 depicts the relation of $\langle m_{\beta\beta} \rangle$ with the summed neutrino mass $M=m_1+m_2+m_3$, constrained by observational cosmology. The oscillation data thus allow to test whether observed values of $\langle m_{\beta\beta} \rangle$ and M are consistent within the 3 neutrino framework. The right hand panel of Fig. 1, finally, shows $\langle m_{\beta\beta} \rangle$ as a function of the average mass $\langle m_{\beta} \rangle = [\Sigma |U_{ei}|^2 m_{\nu_i}^2]^{1/2}$ determined through the analysis of low energy beta decays. The rather large intrinsic width of the $\beta\beta$ -decay constraint essentially does not allow to positively identify the inverted hierarchy, and thus the sign of Δm_{atm}^2 , even in combination with these other observables. Naturally, if the value of $\langle m_{\beta\beta} \rangle \leq 0.01$ eV is ever established then normal hierarchy becomes the only possible scenario.

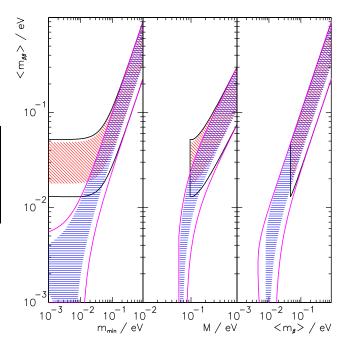

Figure 1: The left panel shows the dependence of $\langle m_{\beta\beta} \rangle$ on the absolute mass of the lightest neutrino m_{min} . The middle panel shows $\langle m_{\beta\beta} \rangle$ as a function of the summed neutrino mass M, while the right panel depicts $\langle m_{\beta\beta} \rangle$ as a function of the mass $\langle m_{\beta} \rangle$. In all panels, the width of the hatched areas is due to the unknown Majorana phases and thus irreducible. The allowed areas given by the solid lines are obtained by taking into account the errors of the oscillation parameters. The two sets of solid lines correspond to the normal and inverted hierarchies. These sets merge into each other for $\langle m_{\beta\beta} \rangle \geq 0.1 \text{ eV}$, which corresponds to the degenerate mass pattern.

It should be noted that systematic uncertainties of the nuclear matrix elements are not folded into the mass limits reported by $\beta\beta$ -decay experiments. Taking this additional uncertainty into account would further widen the projections. The uncertainties in oscillation parameterers affect the width of the allowed bands in an asymmetric manner, as shown in Fig. 1. For example, for the degenerate mass pattern $(\langle m_{\beta\beta} \rangle \geq 0.1 \text{ eV})$ the upper edge is simply $\langle m_{\beta\beta} \rangle \sim m$, where m is the common mass of the degenerate multiplet, independent of the oscillation parameters, while the lower edge is $m \cos(2\theta_{\odot})$. Similar arguments explain the other features of Fig. 1.

If the neutrinoless double-beta decay is observed, it will be possible to fix a range of absolute values of the masses m_{ν_i} . Unlike the direct neutrino mass measurements, however, a limit on $\langle m_{\beta\beta} \rangle$ does not allow one to constrain the individual mass values m_{ν_i} even when the mass differences Δm^2 are known.

Neutrino oscillation data imply, for the first time, the existence of a lower limit ~ 0.013 eV for the Majorana neutrino mass for the inverted hierarchy mass pattern while $\langle m_{\beta\beta} \rangle$ could, by fine tuning, vanish in the case of the normal mass hierarchy. Several new double-beta searches have been proposed to probe the interesting $\langle m_{\beta\beta} \rangle$ mass range.

If lepton-number-violating right-handed current weak interactions exist, their strength can be characterized by the phenomenological coupling constants η and λ (η describes the coupling between the right-handed lepton current and lefthanded quark current while λ describes the coupling when both currents are right-handed). The $0\nu\beta\beta$ decay rate then depends on $\langle \eta \rangle = \eta \sum_{i} U_{ei} V_{ei}$ and $\langle \lambda \rangle = \lambda \sum_{i} U_{ei} V_{ei}$ that vanish for massless or unmixed neutrinos ($V_{\ell j}$ is a matrix analogous to $U_{\ell j}$ but describing the mixing with the hypothetical right-handed neutrinos). This mechanism of the $0\nu\beta\beta$ decay could be, in principle, distinguished from the light Majorana neutrino exchange by the observation of the single electron spectra. The limits on $\langle \eta \rangle$ and $\langle \lambda \rangle$ are listed in a separate table. The reader is cautioned that a number of earlier experiments did not distinguish between η and λ . In addition, see the section on Majoron searches for additional limits set by these experiments.

Half-life Measurements and Limits for Double- β Decay

In most cases the transitions (Z,A) \rightarrow (Z+2,A) +2e^- + (0 or 2) $\overline{\nu}_e$ to the 0+ ground state of the final nucleus are listed. However, we also list transitions that increase the nuclear charge (2e+, e+/EC and ECEC) and transitions to excited states of the final nuclei (0 $_i^+$, 2+, and 2 $_i^+$). In the following Listings, only best or comparable limits or lifetimes for each isotope are reported and only those with $T_{1/2} > 10^{20}$ years that are relevant for particle physics. For 2ν decay, which is well established, only measured half-lives are reported.

- 1 ACKERMAN 11 use the EXO-200 liquid Xe TPC filled with \sim 175 kg of enriched 136 Xe to determine the 2ν halflife of 136 Xe. 2 ARNOLD 11 use enriched 130 Te in the NEMO-3 detector to measure the 2ν $\beta\beta$ decay rate. This result is in agreement with, but more accurate than ARNABOLDI 03.
- 3 ARNOLD 11 use the NEMO-3 detector to obtain a limit for the 0 ν $\beta\beta$ decay.This result is less significant than ARNABOLDI 05.
- 4 BARABASH 11 use 100 g of enriched 112 Sn to determine a limit for the ECEC 0
 u decay to the 0 $^+_2$ state of $^{112}{
 m Cd}$ by searching for the de-excitation γ with a Ge detector. This decay mode is a candidate for resonant rate enhancement.
- 5 BARABASH 11 use 100 g of enriched 112 Sn to determine a limit for the ECEC 0
 u decay to the 0 $_2^+$ state of $^{112}{\rm Cd}$ by searching for the de-excitation γ with a Ge detector.
- 6 BARABASH 11 use 100 g of enriched 112 Sn to determine a limit for the ECEC 0ν decay to the 0 $^+_{\rm 1}$ state of $^{112}{\rm Cd}$ by searching for the de-excitation γ with a Ge detector.
- 7 BARABASH 11 use 100 g of enriched $^{112}{\rm Sn}$ to determine a limit for the ECEC 0 ν decay to the ground state of $^{112}{\rm Cd}$ by searching for the de-excitation γ with a Ge detector. § Supersedes DANEVICH 03 and ARNOLD 96.
- ⁹ Supersedes BRUDANIN 00 and BALYSH 96.
- 10 BARABASH 11A use the NEMO-3 detector to measure etaeta 2u rates and place limits on etaeta 0
 u half lives for various nuclides.
- 11 Supersedes ARNABOLDI 03.
- 12 Supersedes ARNOLD 05A, ARNOLD 04, ASHITKOV 01, EJIRI 01, and DASSIE 95.
- 13 Supersedes ARNOLD 05A, ARNOLD 04, ARNOLD 98, and ELLIOTT 92.
- 14 Less restrictive than ARNABOLDI 08. 15 Less restrictive than DANEVICH 03.
- 16 Less restrictive than UMEHARA 08 and OGAWA 04. 17 BELLI 11D use ZnWO $_4$ scintillator calorimeters to search for various $\beta\beta$ decay modes of 64 Zn, 70 Zn, 180 W, and 186 W.
- 18 RUKHADZE 11 uses 13.6 g of enriched ¹⁰⁶Cd to search for the neutrinoless ECEC decay into an excited state of ^{106}Pd and its characteristic $\gamma\text{-radiation}$ using the TGV2 detector. This decay mode is a candidate for resonant rate enhancement, however, hindered by the large spin difference.
- the large spin ourseence. 19 ARGYRIADES 10 use 9.4 \pm 0.2 g of 96 Zr in NEMO-3 detector and identify its $2\nu\beta\beta$ decay. The result is in agreement and supersedes ARNOLD 99. 20 ARGYRIADES 10 use 9.4 \pm 0.2 g of 96 Zr in NEMO-3 detector and obtain a limit of the $0\nu\beta\beta$ decay. The result is in agreement and supersedes ARNOLD 99.
- $^{21}\text{ARGYRIADES}\,10$ use 9.4 $\pm\,0.2$ g of ^{96}Zr in NEMO-3 detector and obtain a limit of the 0
 uetaeta decay into the first excited 0^+_1 state in $^{96}\,\mathrm{Mo}.$
- 22 BELLI 10 use enriched 100 Mo with 4 HP Ge detectors to record the 590.8 and 539.5 keV γ rays from the decay of the 0_1^+ state in 100 Ru both in singles and coincidences. This result confirms the measurement of KIDD 09 and ARNOLD 07 and supersedes them.
- 23 ARGYRIADES 09 use the NEMO-3 tracking calorimeter containing 36.5 g of 150 Nd, a total exposure of 924.7 days, to derive a limit for the $0\nu\beta\beta$ half-life. Supersedes DESILVA 97.
- 24 ARGYRIADES 09 use the NEMO-3 tracking calorimeter containing 36.5 g of 150 Nd, a total exposure of 924.7 days, to determine the value of the $2\nu\beta\beta$ half-life. This result is in marginal agreement, but has somewhat smaller error bars, than DESILVA 97.
- 25 BELLI 09A use ZnWO₄ scintillating crystals to search for various modes of $\beta\beta$ decay. This work improves the limits for different modes of 64 Zn decay into the ground state of 64 Ni, in this case for the 0ν β^+ EC mode. Supersedes BELLI 08.
- 26 BELLI 09A use ZnWO $_4$ scintillating crystals to search for various modes of etaeta decay. This work improves the limits for different modes of ⁶⁴ Zn decay into the ground state of 64 Ni, in this case for the 0ν ECEC mode. Supersedes BELLI 08.
- $^{27}\,\mathrm{KIDD}$ 09 combine past and new data with an improved coincidence detection efficiency determination. The result agrees with ARNOLD 95. Supersedes DEBRAECKELEER 01 and BARABASH 95.
- $^{28} \mathrm{ARNABOLDI}$ 08 use high resolution TeO_2 bolometer calorimeter to search for double beta decay of ¹³⁰Te. Supersedes ARNABOLDI 05.
- 29 BELLI 08 use ZnWO $_4$ scintillation calorimeter to search for neutrinoless eta^+ plus electron capture decay of 64 Zn. The halflife limit for the 2ν mode is 2.1×10^{20} years.
- 30 BELLI 08B use CdWO $_4$ scintillation calorimeter to search for 0u etaeta decay of 114 Cd.
- $^{31}\,\mathrm{UMEHARA}$ 08 use CaF_2 scintillation calorimeter to search for double beta decay of 48 Ca. Limit is significantly more stringent than quoted sensitivity: 18×10^{21} years.
- 32 First exclusive measurement of 2ν -decay to the first excited 0^+_1 -state of daughter nucleus. ARNOLD 07 use the NEMO-3 tracking calorimeter to detect all particles emitted in decay. Result agrees with the inclusive $(0\nu+2\nu)$ measurement of DEBRAECKELEER 01.
- 33 Limit on 0ν -decay to the first excited 0_1^+ -state of daughter nucleus using NEMO-3 tracking calorimeter. Supersedes DASSIE 95.

Double- β Decay

- 34 Limit on 0
 u-decay to the first excited 2^+ -state of daughter nucleus using NEMO-3 tracking calorimeter.
- 35 BARABASH 07 use Ge calorimeter to search for γ -radiation following double electron capture or β^+ plus electron capture decays of 74 Se to the ground state of 74 Ge. This limit is based on the search for the 511 keV annihilation radiation. Various other limits, for the capture from different atomic shells and also to the excited states, are reported
- 36 BARABASH 07 use Ge calorimeter to search for $\gamma-$ radiation following double electron capture decay of 74 Se into the second excited 2+-state of 74 Ge. That transition has been considered due to a possible resonance enhancement. The 2ν mode would be suppressed for this decay by its extremely small phase space factor.
- 37 KLAPDOR-KLEINGROTHAUS 06A present re-analysis of data originally published in KLAPDOR-KLEINGROTHAUS 04A. Modified pulse shape analysis leads the authors to claim improved 6σ statistical evidence for observation of 0ν -decay, compared to 4.2 σ in KLAPDOR-KLEINGROTHAUS 04A. Analysis of the systematic uncertainty is not presented. Supersedes KLAPDOR-KLEINGROTHAUS 04A.
- 38 Supersedes ARNABOLDI 04. Bolometric TeO $_2$ detector array CUORICINO is used for high resolution search for $0\nu\beta\beta$ decay. The half-life limit is derived from 3.09 kg yr ¹³⁰Te exposure.
- 39 NEMO-3 tracking calorimeter containing 6.9 kg of enriched 100 Mo is used in ARNOLD 05A. A limit for $0\nu\beta\beta$ half-life of 100 Mo is reported. Supersedes ARNOLD 04.
- 40 NEMO-3 tracking calorimeter is used in ARNOLD 05A to place limit on 0
 uetaeta half-life of 82 Se. Detector contains 0.93 kg of enriched 82 Se. Supersedes ARNOLD 04.
- 41 ARNOLD 05A use the NEMO-3 tracking calorimeter to determine the 2
 uetaeta half-life of $100\,\mathrm{Mo}$ with high statistics and low background (389 days of data taking). Supersedes
- $^{42} \, \mathrm{AR} \, \mathrm{NOLD}$ 05A use the NEMO-3 tracking detector to determine the $2 \nu \, \beta \, \beta$ half-life of ⁸²Se with high statistics and low background (389 days of data taking). Supersedes ARNOLD 04
- 43 ARNOLD 04 use the NEMO-3 tracking detector to determine the limit for 0
 uetaeta halflife of 82 Se. This represents an improvement, by a factor of \sim 10, when compared with ELLIOTT 92. It supersedes the limit of ARNOLD 98 for this decay using NEMO-2.
- 44 ARNOLD 04 use the NEMO-3 tracking detector to determine the $2\nu\beta\beta$ halfilfe of 100 Mo with high statistics and low background. The halfilfe is determined assuming the Single State Dominance. It is in agreement with, and more accurate than, previous determinations. Supersedes DASSIE 95 determination of this quantity with NEMO-2.
- 45 BARABASH 04 perform an inclusive measurement of the etaeta decay of 150 Nd into the first excited (0^+_1) state of 150 Sm. Gamma radiation emitted in decay of the excited state is detected.
- $^{
 m 46}\,{\rm Decay}$ into first excited state of daughter nucleus.
- $^{
 m 47}$ Two neutrino decay into ground state. Relatively large error mainly due to uncertainties in background determination. Reported value is shorter than the geochemical measurements of KIRSTEN 83 and BERNATOWICZ 92 but in agreement with LIN 88 and
- 48 Supersedes ALESSANDRELLO 00. Array of TeO $_2$ crystals in high resolution cryogenic calorimeter. Some enriched in 128 Te. Ground state to ground state decay.
- 49 Calorimetric measurement of 2ν ground state decay of 116 Cd using enriched CdWO $_4$ scintillators. Agrees with EJIRI 95 and ARNOLD 96. Supersedes DA NEVICH 00.
- 50 Limit on 0
 u decay of 116 Cd using enriched CdWO $_{A}$ scintillators. DANEVICH 00.
- 51 Limit on 0x decay of 116 Cd into first excited 2^+ state of daughter nucleus using enriched CdWO $_4$ scintillators. Supersedes DANEVICH 00.
- 52 Limit on 0 ν decay of 116 Cd into first excited 0 $^+$ state of daughter nucleus using enriched CdWO $_4$ scintillators. Supersedes DANEVICH 00.
- 53 Limit on 0
 u decay of 116 Cd into second excited 0^+ state of daughter nucleus using enriched CdWO₄ scintillators. Supersedes DANEVICH 00. 54 Limit on the 0ν ground state decay of 186 W using enriched CdWO₄ scintillators.
- 55 Limit on the 0ν decay of 186 W to the first excited 2^+ state of the daughter nucleus using enriched CdWO4 scintillators.
- $^{56}\,\text{Results}$ of the Heidelberg-Moscow experiment (KLAPDOR-KLEINGROTHAUS 01 and GUENTHER 97) are reanalyzed using a new simulation of the complete background spectrum. The $\beta\beta 2\nu$ -decay rate is deduced from a 41.57 kg-y exposure. The result is in agreement and supersedes the above referenced halflives with similar statistical and
- 57 AALSETH 02B limit is based on 117 mol-yr of data using enriched Ge detectors. Background reduction by means of pulse shape analysis is applied to part of the data set. Reported limit is slightly less restrictive than that in KLAPDOR-KLEINGROTHAUS 01 However, it excludes part of the allowed half-life range reported in KLAPDOR-KLEINGROTHAUS 01B for the same nuclide. The analysis has been criticized in KLAPDOR-KLEINGROTHAUS 04B. The criticism was addressed and disputed in ΔAI SETH 04. in AALSETH 04
- 58 BERNABEI 02D report a limit for the 0 ν , 0 $^+$ $\;\to$ 0 $^+$ decay of 134 Xe, present in the source at 17%, by considering the maximum number of events for this mode compatible with the fitted smooth background.
- 59 BERNABEI 02D report a limit for the 0 ν , 0+ \rightarrow 0+ decay of 136 Xe, by considering the maximum number of events for this mode compatible with the fitted smooth background. The quoted sensitivity is 450 \times 10 21 yr. The Feldman and Cousins method is used to obtain the quoted limit.
- 60 ASHITKOV 01 result for 0
 u of 100 Mo is less stringent than EJIRI 01.
- $^{61}\,\mathrm{DA\,NEVICH}$ 01 place limit on 0ν decay of $^{160}\,\mathrm{Gd}$ using $\mathrm{Gd}_2\mathrm{SiO}_5$:Ce crystal scintillators. The limit is more stringent than KOBAYASHI 95
- 62 DANEVICH 01 place limits on 0u decay of 160 Gd into excited 2^+ state of daughter nucleus using $\operatorname{Gd}_2\operatorname{SiO}_5$: Ce crystal scintillators.

- 63 DEBRAECKELEER 01 performed an inclusive measurement of the etaeta decay into the second excited state of the daughter nucleus. A novel coincidence technique counting the de-excitation photons is employed. The result agrees with BARABASH 95.
- 64 KLAPDOR-KLEINGROTHAUS 01 is a continuation of the work published in BAUDIS 99. Isotopically enriched Ge detectors are used in calorimetric measurement. The most stringent bound is derived from the data set in which pulse-shape analysis has been used to reduce background. Exposure time is 35.5 kg y. Supersedes BAUDIS 99 as most stringent
- 65 WIESER 01 reports an inclusive geochemical measurement of 96 Zr $\beta\beta$ half life. Their result agrees within 2σ with ARNOLD 99 but only marginally, within 3σ , with KAWASHIMA 93.
- 66 BRUDANIN 00 determine the 2
 u halflife of 48 Ca. Their value is less accurate than
- 67 ARNOLD 99 measure directly the 2ν decay of Zr for the first time, using the NEMO-2 tracking detector and an isotopically enriched source. The lifetime is more accurate than the geochemical result of KAWASHIMA 93.
- 68 ARNOLD 98 measure the 2ν decay of 82 Se by comparing the spectra in an enriched and natural selenium source using the NEMO-2 tracking detector. The measured half-life is in agreement, perhaps slightly shorter, than ELLIOTT 92.
- 69 ARNOLD 98 determine the limit for 0
 u decay to the excited 2^+ state of 82 Se using the NEMO-2 tracking detector.
- 70 ALSTON-GARNJOST 97 report evidence for 2
 u decay of 100 Mo. This decay has been also observed by EJIRI 91, DASSIE 95, and DESILVA 97.
- 71 DESILVA 97 result for 2ν decay of 100 Mo is in agreement with ALSTON-GARNJOST 97 and DASSIE 95. This measurement has the smallest errors.
- 72 DESILVA 97 result for 2ν decay of 150 Nd is in marginal agreement with ARTEMEV 93. It has smaller errors.
- 73 ARNOLD 96 measure the 2ν decay of 116 Cd. This result is in agreement with EJIRI 95, but has smaller errors. Supersedes ARNOLD 95.
- 74 BALYSH 96 measure the 2ν decay of 48 Ca, using a passive source of enriched 48 Ca in
- 75 TAKAOKA 96 measure the geochemical half-life of 130 Te. Their value is in disagreement with the quoted values of BERNATOWICZ 92 and KIRSTEN 83; but agrees with several other unquoted determinations, e.g., MANUEL 91.
- 76 BARABASH 95 cannot distinguish 0ν and 2ν , but it is inferred indirectly that the 0ν mode accounts for less than 0.026% of their event sample. They also note that their result disagrees with the previous experiment by the NEMO group (BLUM 92).
- $^{77}\,\mathrm{BERNATOWICZ}$ 92 finds $^{128}\mathrm{Te}/^{130}\mathrm{Te}$ activity ratio from slope of $^{128}\mathrm{Xe}/^{132}\mathrm{Xe}$ vs $130\, {\rm Xe}/132\, {\rm Xe}$ ratios during extraction, and normalizes to lead-dated ages for the $130\, {\rm Te}$ lifetime. The authors state that their results imply that "(a) the double beta decay of $^{128}\mathrm{Te}$ has been firmly established and its half-life has been determined ... without any ambiguity due to trapped Xe interferences... (b) Theoretical calculations ... underany ambiguity use to trapped xe interleades... (i) Theoretical calculations... undersection to the property of the property o reevaluated cosmic-ray ¹²⁸Xe production corrections.
- 78 TURKEVICH 91 observes activity in old U sample. The authors compare their results with theoretical calculations. They state "Using the phase-space factors of Boehm and Vogel (BOEHM 87) leads to matrix element values for the 238 U transition in the same range as deduced for 130 Te and 76 Ge. On the other hand, the latest theoretical estimates (STAUDT 90) give an upper limit that is 10 times lower. This large discrepancy implies either a defect in the calculations or the presence of a faster path than the standard two-neutrino mode in this case." See BOEHM 87 and STAUDT 90.
- 79 Result agrees with direct determination of ELLIOTT 92.
- 80 Inclusive half life inferred from mass spectroscopic determination of abundance of etaeta-Inclusive half life inferred from mass spectroscopic determination of abundance of $\beta\beta$ -decay product 130 Te in mineral kitkaite (NiTeSe). Systematic uncertainty reflects variations in U-Xe gas-retention-age derived from different uranite samples. Agrees with geochemical determination of TAKAOKA 96 and direct measurement of ARNABOLDI 03. Inconsistent with results of KIRSTEN 83 and BERNATOWICZ 92.
- Inconsistent with results of KIRSTEN 83 and BERNATOWICZ 92. 81 Ratio of inclusive double beta half lives of 128 Te and 130 Te determined from minerals melonite (NiTe₂) and altaite (PbTe) by means of mass spectroscopic measurement of abundance of $\beta\beta$ -decay products. As gas-retention-age could not be determined the authors use half life of 130 Te (LIN 88) to infer the half life of 128 Te. No estimate of the systematic uncertainty of this method is given. The directly determined half life ratio agrees with BERNATOWICZ 92. However, the inferred 128 Te half life disagrees with RISTEN 83 and REPNATOWICZ 92. KIRSTEN 83 and BERNATOWICZ 92.
- 82 KIRSTEN 83 reports " 2σ " error. References are given to earlier determinations of the 130 Te lifetime

$\langle m_{ u} angle$, The Effective Weighted Sum of Majorana Neutrino Masses Contributing to Neutrinoless Double- $oldsymbol{eta}$ Decay

 $\langle m_{
u}
angle = |\Sigma| U_{1\, i}^2 m_{
u_i}^{}|$, where the sum goes from 1 to n and where n= number of neutrino generations, and u_j is a Majorana neutrino. Note that $U_{e\,j}^2$, not $|U_{e\,j}|^2$, occurs in the sum. The possibility of cancellations has been stressed. In the following Listings, only best or comparable limits or lifetimes for each isotope are reported.

- 83 BARABASH 11A limit is based on NEMO-3 data for 100 Mo. The reported range reflects different nuclear matrix elements. Supersedes ARNOLD 05A and ARNOLD 04
- ⁸⁴BARABASH 11A limit is based on NEMO-3 data for ⁸²Se. The reported range reflects
- different nuclear matrix elements. Supersedes ARNOLD 05A and ARNOLD 04. 85 ARGYRIADES 10 use 96 Zr and the NEMO-3 tracking detector to obtain the reported mass limit. The range reflects the fluctuation of the nuclear matrix elements considered.
- 86 ARGYRIADES 09 limit is based on data taken with the NEMO-3 detector and $^{15\,0}$ Nd. A range of nuclear matrix elements that include the effect of nuclear deformation have
- 87 Limit was obtained using high resolution ${
 m TeO_2}$ bolometer calorimeter to search for double beta decay of ¹³⁰Te. Reported range of limits reflects spread of matrix element calculations used. Supersedes ARNABOLDI 05.
- 88 Limit was obtained using CaF $_2$ scintillation calorimeter to search for double beta decay of ⁴⁸Ca. Reported range of limits reflects spread of QRPA and SM matrix element calculations used. Supersedes OGAWA 04.
- 89 ARNOLD 07 use NEMO-3 half life limit for 0ν -decay of 100 Mo to the first excited 0^+_1 state of daughter nucleus to obtain neutrino mass limit. The spread reflects the choice of two different nuclear matrix elements. This limit is not competitive when compared to the decay to the ground state.
- 90 ARNOLD 07 use NEMO-3 half life limit for 0 ν -decay of 100 Mo to the first excited 2 $^+$ -state of daughter nucleus to obtain neutrino mass limit. This limit is not competitive when compared to the decay to the ground state.
- 91 Re-analysis of data originally published in KLAPDOR-KLEINGROTHAUS 04A. Modified pulse shape analysis leads the authors to claim 6σ statistical evidence for observation of 0
 u-decay. Authors use matrix element of STAUDT 90. Uncertainty of nuclear matrix element is not reflected in stated error. Supersedes KLAPDOR-KLEINGROTHAUS 04A.
- 92 Supersedes ARNABOLDI 04. Reported range of limits due to use of different nuclear matrix element calculations
- 93 Mass limits reported in ARNOLD 05A are derived from 100 Mo data, obtained by the NEMO-3 collaboration. The range reflects the spread of matrix element calculations considered in this work. Supersedes ARNOLD 04.
- 94 Neutrino mass limits based on 82 Se data utilizing the NEMO-3 detector. The range reported in ARNOLD 05A reflects the spread of matrix element calculations considered in this work. Supersedes ARNOLD 04.
- 95 Supersedes ARNABOLDI 03. Reported range of limits due to use of different nuclear matrix element calculations.
- 96 ARNOLD 04 limit is based on the nuclear matrix elements of SIMKOVIC 99, STOICA 01 and CIVITARESE 03.
- 97 Supersedes KLAPDOR-KLEINGROTHAUS 02D. Event excess at ββ-decay energy is used to derive Majorana neutrino mass using the nuclear matrix elements of STAUDT 90. The mass range shown is based on the authors evaluation of the uncertainties of the decay of the state of the st STAUDT 90 matrix element calculation. If this uncertainty is neglected, and only statistical errors are considered, the range in $\langle m \rangle$ becomes (0.2–0.6) eV at the 3 σ level.
- 98 Calorimetric CaF $_2$ scintillator. Range of limits reflects authors' estimate of the uncertainty of the nuclear matrix elements. Replaces YOU 91 as the most stringest limit based
- 99 Supersedes ALESSANDRELLO 00. Cryogenic calorimeter search. Reported a range reflecting uncertainty in nuclear matrix element calculations.
- 100 Limit for $\langle m_p \rangle$ is based on the nuclear matrix elements of STAUDT 90 and ARNOLD 96. Supersedes DANEVICH 00.
- 101 AALSETH 02B reported range of limits on $\langle m_{\nu} \rangle$ reflects the spread of theoretical nuclear matrix elements. Excludes part of allowed mass range reported in KLAPDOR-KLEINGROTHAUS 01B.
- $102\, {\rm BERNABEI}$ 020 limit is based on the matrix elements of SIMKOVIC 02. The range of neutrino masses based on a variety of matrix elements is 1.1–2.9 eV.

- $^{103}\,\text{KLAPDOR-KLEINGROTHAUS}$ 02D is a detailed description of the analysis of the data collected by the Heidelberg-Moscow experiment, previously presented in KLAPDOR-KLEINGROTHAUS 01B. Matrix elements in STAUDT 90 have been used. See the footnote in the preceding table for further details. See also KLAPDOR-KLEINGROTHAUS 02B.
- 104 The range of the reported $\langle m_{
 u} \rangle$ values reflects the spread of the nuclear matrix elements. On axis value assuming $\langle \lambda \rangle = \langle \eta \rangle = 0$.
- $105~{\rm KLAPDOR\text{-}KLEINGROTHAUS}$ 01 uses the calculation by STAUDT 90. Using several other models in the literature could worsen the limit up to 1.2eV. This is the most stringent experimental bound on m_{ν^+} It supersedes BAUDIS 99B.
- $^{106} \, \mathrm{AR} \, \mathrm{NOLD}$ 99 limit based on the nuclear matrix elements of STAUDT 90.
- $^{107} \mbox{BERNATOWICZ}$ 92 finds these majorana neutrino mass limits assuming that the measured geochemical decay width is a limit on the 0ν decay width. The range is the range found using matrix elements from HAXTON 84, TOMODA 87, and SUHONEN 91. Further details of the experiment are given in BERNATOWICZ 93.
- $^{108}\, extsf{ELLIOTT}$ 92 uses the matrix elements of HAXTON 84.

Limits on Lepton-Number Violating (V+A) Current Admixture

For reasons given in the discussion at the beginning of this section, we list only results from 1989 and later. $\langle \lambda \rangle = \lambda \sum U_{ej} V_{ej}$ and $\langle \eta \rangle = \eta \sum U_{ej} V_{ej}$, where the sum is over the number of neutrino generations. This sum vanishes for massless or unmixed neutrinos. In the following Listings, only best or comparable limits or lifetimes for each isotope are reported.

| $\langle \lambda \rangle (10^{-6})$ | CL% | $\langle \eta \rangle (10^{-8})$ | CL% | <i>ISOTOPE</i> | METHOD | DOCUMENT ID |

- 109 ARNOLD 07 use NEMO-3 half life limit for 0
 u-decay of 100 Mo to the first excited $^{2+}$ state of daughter nucleus to limit the right-right handed admixture of weak currents $\langle \lambda \rangle$. This limit is not competitive when compared to the decay to the ground state
- 110 Re-analysis of data originally published in KLAPDOR-KLEINGROTHAUS 04A. Modified pulse shape analysis leads the authors to claim 6σ statistical evidence for observation of 0ν -decay. Authors use matrix element of MUTO 89 to determine $\langle\lambda\rangle$ and $\langle\eta\rangle$. Uncertainty of nuclear matrix element is not reflected in stated errors.
- 111 AR NOLD 05A derive limit for $\langle\lambda
 angle$ based on 100 Mo data collected with NEMO-3 detector. No limit for $\langle \eta \rangle$ is given. Supersedes ARNOLD 04.
- 112 ARNOLD 05A derive limit for $\langle\lambda
 angle$ based on 82 Se data collected with NEMO-3 detector. No limit for $\langle \eta \rangle$ is given. Supersedes ARNOLD 04.
- 113 ARNOLD 04 use the matrix elements of SUHONEN 94 to obtain a limit for $\langle \lambda
 angle$, no limit for $\langle \eta \rangle$ is given. This limit is more stringent than the limit in EJIRI 01 for the same nucleus.
- 114 ARNOLD 04 use the matrix elements of TOMODA 91 and SUHONEN 91 to obtain a limit for $\langle\lambda\rangle$, no limit for $\langle\eta\rangle$ is given.
- $^{115}\,\mathrm{Supersedes}$ ALESSANDRELLO 00. Cryogenic calorimeter search. Reported a range reflecting uncertainty in nuclear matrix element calculations
- 116 Limits for $\langle\lambda\rangle$ and $\langle\eta\rangle$ are based on nuclear matrix elements of STAUDT 90. Supersedes DANEVICH 00.
- 117 The range of the reported $\langle\lambda\rangle$ and $\langle\eta\rangle$ values reflects the spread of the nuclear matrix elements. On axis value assuming $\langle m_{
 u} \rangle = 0$ and $\langle \lambda \rangle = \langle \eta \rangle = 0$, respectively.
- $^{118}\,\mathrm{GUENTHER}$ 97 limits use the matrix elements of STAUDT 90. Supersedes BALYSH 95 and BALYSH 92.
- 119 VUILLEUMIER 93 uses the matrix elements of MUTO 89. Based on a half-life limit 2.6×10^{23} y at 90%CL.
- 120 BERNATOWICZ 92 takes the measured geochemical decay width as a limit on the 0
 uwidth, and uses the SUHONEN 91 coefficients to obtain the least restrictive limit on η . Further details of the experiment are given in BERNATOWICZ 93.

Neutrino Mixing

With the exception of a few possible anomalies such as LSND, current neutrino data can be described within the framework of a 3×3 mixing matrix between the flavor eigenstates ν_e , ν_μ , and ν_τ and the mass eigenstates ν_1 , ν_2 , and ν_3 . (See Eq. (13.79) of the review "Neutrino Mass, Mixing, and Oscillations" by K. Nakamura and S.T. Petcov.) The Listings are divided into the following sections:

- (A) Neutrino fluxes and event ratios: shows measurements which correspond to various oscillation tests for Accelerator, Reactor, Atmospheric, and Solar neutrino experiments. Typically ratios involve a measurement in a realm sensitive to oscillations compared to one for which no oscillation effect is expected.
- (B) Three neutrino mixing parameters: shows measurements of $\sin^2(2\theta_{12})$, $\sin^2(2\theta_{23})$, Δm_{21}^2 , Δm_{32}^2 , and $\sin^2(2\theta_{13})$

which are all interpretations of data based on the three neutrino mixing scheme described in the review "Neutrino Mass, Mixing, and Oscillations." by K. Nakamura and S.T. Petcov. Many parameters have been calculated in the two-neutrino approximation.

(C) Other neutrino mixing results: shows measurements and limits for the probability of oscillation for experiments which might be relevant to the LSND oscillation claim. Included are experiments which are sensitive to $\nu_{\mu} \rightarrow \nu_{e}$, $\bar{\nu}_{\mu} \rightarrow \bar{\nu}_{e}$, sterile neutrinos, and CPT tests.

(A) Neutrino fluxes and event ratios

Events (observed/expected) from accelerator u_{μ} experiments.

Some neutrino oscillation experiments compare the flux in two or more detectors. This is usually quoted as the ratio of the event rate in the far detector to the expected rate based on an extrapolation from the near detector in the absence of oscillations.

- 1 Based on the observation of 112 events when $158.1^{+}_{-8.6}^{9.2}$ were expected without oscillations. Including not only the number of events but also the shape of the energy distribution, the evidence for oscillation is at the level of about 4.3 σ . Supersedes ALIU 05.
- $^2\,\text{This}$ ratio is based on the observation of 215 events compared to an expectation of 336 \pm 14 without oscillations. See also ADAMSON 08.
- $^3{\rm This}$ ratio is based on the observation of 107 events at the far detector 250 km away from KEK, and an expectation of 151 $^{+12}_{-10}$

Events (observed/expected) from reactor $\overline{\nu}_e$ experiments.

The quoted values are the ratios of the measured reactor $\overline{\nu}_e$ event rate at the quoted distances, and the rate expected without oscillations. The expected rate is based on the experimental data for the most significant reactor fuels (235 U, 239 Pu, 241 Pu) and on calculations for 238 U.

A recent re-evaluation of the spectral conversion of electron to $\overline{\nu}_e$ in MUELLER 11 results in an upward shift of the reactor $\overline{\nu}_e$ spectrum by 3% and, thus, might require revisions to the ratios listed in this table.

- 1 ABE 12 determine the $\overline{\nu}_e$ interaction rate in a single detector, located 1050 m from the cores of two reactors. The rate normalization is fixed by the results of the Bugey4 reactor experiment, thus avoiding any dependence on possible very short baseline oscillations.
- ² AHN 12 use two identical detectors, placed at flux weighted distances of 408.56 m and 1433.99m from six reactor cores, to determine the $\overline{\nu}_e$ interaction rate ratio.
- 3 AN 12 use six identical detectors with three placed near the reactor cores (flux-weighted baselines of 470 m and 576 m) and the remaining three at the far hall (at the flux averaged distance of 1648 m from all six reactor cores) to determine the $\overline{\nu}_e$ interaction rate ratios.

⁴ This ratio is based on the observation of 56 events with an expectation of $80.1^{+6.2}_{-5.4}$

Lepton Particle Listings Neutrino Mixing

- 4 DENIZ 10 observe reactor $\overline{\nu}_e\,e$ scattering with recoil kinetic energies 3–8 MeV using CsI(TI) detectors. The observed rate is consistent with the Standard Model prediction, leading to a constraint on $\sin^2\!\theta_{W}=0.251\pm0.031 ({\rm stat})\pm0.024 ({\rm sys})$.
- ⁵ Updated result of KamLAND, including the data used in EGUCHI 03. Note that the survival probabilities for different periods are not directly comparable because the effective baseline varies with power output of the reactor sources involved, and there were large variations in the reactor power production in Japan in 2003.
- $^6\,{\sf EGUCHI}$ 03 observe reactor neutrino disappearance at \sim 180 km baseline to various Japanese nuclear power reactors.
- $^{7}\,\mathrm{BOEHM}$ 01 search for neutrino oscillations at 0.75 and 0.89 km distance from the Palo Verde reactors.
- 8 APOLLONIO 99, APOLLONIO 98 search for neutrino oscillations at 1.1 km fixed dis-APOLLONIO 99, APOLLONIO 98 search for heatring oscillations at 1.1 km liked ulstrance from Chooz reactors. They use $\overline{\sigma}_e p - e^+ n$ in Gd-loaded scintillator taget APOLLONIO 99 supersedes APOLLONIO 98. See also APOLLONIO 03 for detailed description.
- $^{9}\, {\sf GREENWOOD}$ 96 search for neutrino oscillations at 18 m and 24 m from the reactor at Savannah River.
- 10 DECLAIS 94 result based on integral measurement of neutrons only. Result is ratio of measured cross section to that expected in standard $\it V\!-\!A$ theory. Replaced by ACHKAR 95.
- $^{
 m 11}\,{
 m KWON}$ 81 represents an analysis of a larger set of data from the same experiment as BOEHM 80.

– Atmospheric neutrinos –

Neutrinos and antineutrinos produced in the atmosphere induce μ -like and e-like events in underground detectors. The ratio of the numbers of the two kinds of events is defined as μ/e . It has the advantage that systematic effects, such as flux uncertainty, tend to cancel, for both experimental and theoretical values of the ratio. The "ratio of the ratios" of experimental to theoretical μ/e , $R(\mu/e)$, or that of experimental to theoretical μ/total , $R(\mu/{
m total})$ with ${
m total}=\mu+e$, is reported below. If the actual value is not unity, the value obtained in a given experiment may depend on the experimental conditions. In addition, the measured "up-down asymmetry" for μ $(N_{up}(\mu)/N_{down}(\mu))$ or e $(N_{up}(e)/N_{down}(e))$ is reported. The expected "up-down asymmetry" is nearly unity if there is no neutrino

$R(\mu/e) = (Measured Ratio <math>\mu/e) / (Expected Ratio <math>\mu/e)$

- $^{
 m 1}$ ASHIE 05 results are based on an exposure of 92 kton yr during the complete Super-Kamiokande I running period. The analyzed data sample consists of fully-contained single-ring e-like events with 0.1 GeV/c < p_e and μ -like events 0.2 GeV/c < p_{μ} . both having a visible energy < 1.33 GeV. These criteria match the definition used by FUKUDA 94.
- 2 ASHIE 05 results are based on an exposure of 92 kton yr during the complete Super-Kamiokande I running period. The analyzed data sample consists of fully-contained single-ring events with visible energy >1.33 GeV and partially-contained events. All partially-contained events are classified as $\mu\text{-like}.$
- $^3\, {\sf SANCHEZ}$ 03 result is based on an exposure of 5.9 kton yr, and updates ALLISON 99 result. The analyzed data sample consists of fully-contained e-flavor and μ -flavor events having lepton momentum > 0.3 GeV/c.
- $^4\,{\sf FUKUDA}$ 96B studied neutron background in the atmospheric neutrino sample observed in the Kamiokande detector. No evidence for the background contamination was found.
- 5 DAUM 95 results are based on an exposure of 2.0 kton yr which includes the data used by BERGER 90B. This ratio is for the contained and semicontained events. DAUM 95 also report $R(\mu/e)=0.99\pm0.13\pm0.08$ for the total neutrino induced data sample which includes upward going stopping muons and horizontal muons in addition to the contained and semicontained events.
- $^6\,\text{FUKUDA}$ 94 result is based on an exposure of 7.7 kton yr and updates the HIRATA 92 result. The analyzed data sample consists of fully-contained e-like events with 0.1 < $ho_e <$ 1.33 GeV/c and fully-contained μ -like events with 0.2 < $ho_{\mu} <$ 1.5 GeV/c.
- 7 FUKUDA 94 analyzed the data sample consisting of fully contained events with visible energy > 1.33 GeV and partially contained μ -like events.
- 8 BECKER-SZENDY 92B reports the fraction of nonshowering events (mostly muons from atmospheric neutrinos) as $0.36\pm0.02\pm0.02$, as compared with expected fraction $0.51\pm0.01\pm0.05$. After cutting the energy range to the Kamiokande limits, BEIER 92 finds $R(\mu/e)$ very close to the Kamiokande value.

$R(\nu_{\mu}) = (Measured Flux of \nu_{\mu}) / (Expected Flux of \nu_{\mu})$

- $^1\,\text{ADAMSON}$ 06 uses a measurement of 107 total neutrinos compared to an expected rate of 127 \pm 13 without oscillations.
- 2 AMBROSIO 01 result is based on the upward through-going muon tracks with $E_{\mu}>1$ GeV. The data came from three different detector configurations, but the statistics is largely dominated by the full detector run, from May 1994 to December 2000. The total live time, normalized to the full detector configuration, is 6.17 years. The first error is the statistical error, the second is the systematic error, dominated by the theoretical error in the predicted flux.
- ³ AMBROSIO 00 result is based on the upgoing partially contained event sample. It came from 4.1 live years of data taking with the full detector, from April 1994 to February 1999. The average energy of atmospheric muon neutrinos corresponding to this sample is 4 GeV. The first error is statistical, the second is the systematic error, dominated by the 25% theoretical error in the rate (20% in the flux and 15% in the cross section, added in the control of the control in quadrature). Within statistics, the observed deficit is uniform over the zenith angle.
- A MBROSIO 00 result is based on the combined samples of downgoing partially contained events and upgoing stopping events. These two subsamples could not be distinguished due to the lack of timing information. The result came from 4.1 live years of data taking with the full detector, from April 1994 to February 1999. The average energy of atmospheric muon neutrinos corresponding to this sample is 4 GeV. The first error is statistical, the second is the systematic error, dominated by the 25% theoretical error in the rate (20% in the flux and 15% in the cross section, added in quadrature). Within statistics, the observed deficit is uniform over the zenith angle.
- $^{5}\,\mathrm{AMBROSIO}$ 98 result is for all nadir angles and updates AHLEN 95 result. The lower AMBROSIO 98 result is for all hadir angles and updates AHLEN 95 result. The lower cutoff on the muon energy is 1 GeV. In addition to the statistical and systematic errors, there is a Monte Carlo flux error (theoretical error) of ± 0.13 . With a neutrino oscillation hypothesis, the fit either to the flux or zenith distribution independently yields $\sin^2 2\theta = 1.0$ and $\Delta(m^2) \sim a$ few times 10^{-3} eV². However, the fit to the observed zenith distribution gives a maximum probability for χ^2 of only 5% for the best oscillation
- 6 CASPER 91 correlates showering/nonshowering signature of single-ring events with parent atmospheric-neutrino flavor. They find nonshowering ($\approx \nu_\mu$ induced) fraction is $0.41\pm0.03\pm0.02$, as compared with expected 0.51 ± 0.05 (syst).
- 7 AGLIETTA 89 finds no evidence for any anomaly in the neutrino flux. They define $\rho=(\text{measured number of }\nu_{\mu}\text{'s}).$ They report $\rho(\text{measured}) = \rho(\text{expected}) = 0.96 + 0.32$
- 8 From this data BOLIEV 81 obtain the limit $\Delta(m^2)~\leq~6 imes 10^{-3}~{\rm eV}^2$ for maximal mixing, $u_{\mu}
 eq
 u_{\mu}$ type oscillation.

- ²ADAMSON 06 result is obtained with the MINOS far detector with an exposure of 4.54 kton yr, based on contained events. The expected ratio is calculated by assuming the same oscillation parameters for neutrinos and antineutrinos.

Solar neutrinos

Solar neutrinos are produced by thermonuclear fusion reactions in the Sun. Radiochemical experiments measure particular combinations of fluxes from various neutrino-producing reactions, whereas water-Cherenkov experiments mainly measure a flux of neutrinos from decay of ⁸B. Solar neutrino fluxes are composed of all active neutrino species, u_e , u_μ , and $u_{ au}$. In addition, some other mechanisms may cause antineutrino components in solar neutrino fluxes. Each measurement method is sensitive to a particular component or a combination of components of solar neutrino fluxes. For details, see Section 13.4 of Reviews, Tables, and Plots

u_e Capture Rates from Radiochemical Experiments

- $^{
 m 1}$ ABE 11 reports the Super-Kamiokande-III results for 548 live days from August 4, 2006 to August 18, 2008. The analysis threshold is 5.0 MeV, but the event sample in the 5.0-6.5 MeV total electron range has a total live time of 298 days.
- 2 ABE 11 recalculated the Super-Kamiokande-II results using 8 B spectrum of WIN-
- TER 06A.

 3 ABE 11 recalculated the Super-Kamiokande-I results using 8B spectrum of WINTER 06A. 4 ABE 11B use a 123 kton-day exposure of the KamLAND liquid scintillation detector to measure the 8 B solar neutrino flux. They utilize $\nu-e$ elastic scattering above a reconstructed-energy threshold of 5.5 MeV, corresponding to 5 MeV electron recoil energy. 299 electron recoil candidate events are reported, of which 157 \pm 23.6 are assigned
- to background. 5 BELLINI 10A reports the Borexino result with 3 MeV energy threshold for scattered electrons. The data correspond to 345.3 live days with a target mass of 100 t, between July 15, 2007 and August 23, 2009.
- $^6\mathrm{AHARMIM}$ 08 reports the results from SNO Phase III measurement using an array of ³He proportional counters to measure the rate of NC interactions in heavy water, over the period between November 27, 2004 and November 28, 2006, corresponding to 385.17 live days. A simultaneous fit was made for the number of NC events detected by the proportional counters and the numbers of NC, CC, and ES events detected by the PMTs, where the spectral distributions of the ES and CC events were not constrained to the ⁸B
- $^7\,\mathrm{CRAVENS}$ 08 reports the Super-Kamiokande-II results for 791 live days from December 2002 to October 2005. The photocathode coverage of the detector is 19% (reduced from 40% of that of Super-Kamiokande-I due to an accident in 2001). The analysis threshold for the average flux is 7 MeV.
- $^8\, {\rm HOSAKA}$ 06 reports the final results for 1496 live days with Super-Kamiokande-I between May 31, 1996 and July 15, 2001, and replace FUKUDA 02 results. The analysis threshold is 5 MeV except for the first 280 live days (6.5 MeV).
- ⁹ AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, corresponding to 391.4 live days, and update AHMED 04A. The CC, ES, and NC events were statistically separated. In one method, the ⁸B energy spectrum was not constrained. In the other method, the constraint of an undistorted ⁸B energy spectrum was added for comparison with AHMAD 02 results.
- 10 AHMAD 02 reports the 8 B solar-neutrino flux measured via u e elastic scattering above the kinetic energy threshold of 5 MeV. The data correspond to 306.4 live days with SNO between November 2, 1999 and May 28, 2001, and updates AHMAD 01 results.
- 11 AH MAD 01 reports the 8 B solar-neutrino flux measured via νe elastic scattering above the kinetic energy threshold of 6.75 MeV. The data correspond to 241 live days with SNO between November 2, 1999 and January 15, 2001.
- 12 FUKUDA 96 results are for a total of 2079 live days with Kamiokande II and III from January 1987 through February 1995, covering the entire solar cycle 22, with threshold $\mathrm{E}_e >$ 9.3 MeV (first 449 days), > 7.5 MeV (middle 794 days), and > 7.0 MeV (last 836 days). These results update the HIRATA 90 result for the average ⁸B solar-neutrino flux and HIRATA 91 result for the day-night variation in the $^8\mathrm{B}$ solar-neutrino flux. The total data sample was also analyzed for short-term variations: within experimental errors, no strong correlation of the solar-neutrino flux with the sunspot numbers was found.

 $^{^{}m 1}$ ADAMSON 06 result is obtained with the MINOS far detector with an exposure of 4.54 kton yr. The expected ratio is calculated with no neutrino oscillation

- 1 AHARMIM 10 reports this result from a joint analysis of SNO Phase I+II data with the "effective electron kinetic energy" threshold of 3.5 MeV. This result is obtained with the assumption of unitarity, which relates the NC, CC, and ES rates. The data were fit with the free parameters directly describing the total 8 B neutrino flux and the energy-dependent ν_e survival probability.
- 2 AHARMIM 08 reports the results from SNO Phase III measurement using an array of 3 He proportional counters to measure the rate of NC interactions in heavy water, over the period between November 27, 2004 and November 28, 2006, corresponding to 385.17 live days. A simultaneous fit was made for the number of NC events detected by the proportional counters and the numbers of NC, CC, and ES events detected by the PMTs, where the spectral distributions of the ES and CC events were not constrained to the $^8\mathrm{B}$ shape.
- 3 AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, corresponding to 391.4 live days, and update AHMED 04A. The CC, ES, and NC events were statistically separted. In one method, the $^8\mathrm{B}$ energy spectrum was not constrained. In the other method, the constraint of an undistorted $^8\mathrm{B}$ energy spectrum was added for comparison with AHMAD 02 results.
- 4 AHMAD 02 determined the total flux of active 8 B solar neutrinos by directly measuring the neutral-current reaction, $\nu_\ell \, d \to n \rho \nu_\ell$, which is equally sensitive to ν_e, ν_μ , and ν_τ . The complete description of the SNO Phase I data set is given in AHARMIM 07.
- ⁵ AHMAD 01 deduced the total flux of active ⁸B solar neutrinos by combining the SNO charged-current result (AHMAD 01) and the Super-Kamiokande νe elastic-scattering result (FUKUDA 01).

¹ CRAVENS 08 reports the Super-Kamiokande-II results for 791 live days from December 2002 to October 2005. The photocathode coverage of the detector is 19% (reduced from 40% of that of Super-Kamiokande-I due to an accident in 2001). The analysis threshold for the day and night fluxes is 7.5 MeV.

Neutrino Mixing

- ² HOSAKA 06 reports the final results for 1496 live days with Super-Kamiokande-I between May 31, 1996 and July 15, 2001, and replace FUKUDA 02 results. The analysis threshold is 5 MeV except for the first 280 live days (6.5 MeV).
- 3 This result with reduced statistical uncertainty is obtained by assuming two-neutrino oscillations within the LMA (large mixing angle) region and by fitting the time variation of the solar neutrino flux measured via ν_e elastic scattering to the variations expected from neutrino oscillations. For details, see SMY 04. There is an additional small systematic error of ± 0.0004 coming from uncertainty of oscillation parameters.
- 4 AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, with 176.5 days of the live time recorded during the day and 214.9 days during the night. This result is obtained with the spectral distribution of the CC events not constrained to the $^8\mathrm{B}$ shape.
- 5 AH MAD 02B results are based on the charged-current interactions recorded between November 2, 1999 and May 28, 2001, with the day and night live times of 128.5 and 177.9 days, respectively. The complete description of the SNO Phase I data set is given in AHARMIM 07.
- 6 AHMAD 02B results are derived from the charged-current interactions, neutral-current interactions, and νe elastic scattering, with the total flux of active neutrinos constrained to have no asymmetry. The data were recorded between November 2, 1999 and May 28, 2001, with the day and night live times of 128.5 and 177.9 days, respectively. The complete description of the SNO Phase I data set is given in AHARMIM 07.

ϕ_{ES} (⁷Be)

 ^7Be solar-neutrino flux measured via ν_e elastic scattering. This process is sensitive to all active neutrino flavors, but with reduced sensitivity to ν_μ, ν_τ due to the cross-section difference, $\sigma(\nu_{\mu,\tau} e) \sim 0.2~\sigma(\nu_e \, e).$ If the ^7Be solar-neutrino flux involves nonelectron flavor active neutrinos, their contribution to the flux is ~ 0.2 times that of ν_μ .

(B) Three-neutrino mixing parameters

INTRODUCTION TO THREE-NEUTRINO MIXING PARAMETERS LISTINGS

Updated April 2012 by M. Goodman (ANL).

Introduction and Notation: With the exception of the LSND anomaly, current accelerator, reactor, solar and atmospheric neutrino data can be described within the framework of a 3×3 mixing matrix between the flavor eigenstates ν_e , ν_μ and ν_τ and mass eigenstates ν_1 , ν_2 and ν_3 . (See equation 13.79 of the review "Neutrino Mass, Mixing and Oscillations" by K. Nakamura and S.T. Petcov.) Whether or not this is the ultimately correct framework, it is currently widely used to parametrize neutrino mixing data and to plan new experiments.

The mass differences are called $\Delta m^2_{21} \equiv m^2_2 - m^2_1$ and $\Delta m^2_{32} \equiv m^2_3 - m^2_2$. In these listings, we assume

$$\Delta m_{32}^2 \sim \Delta m_{31}^2 \tag{1}$$

although in the future, experiments may be precise enough to measure these separately. The angle are labeled θ_{12} , θ_{23} and θ_{13} . The CP violating phase is called δ , but that does not yet appear in the listings. The familiar two neutrino form for oscillations is

$$P(\nu_a \to \nu_b) = \sin^2(2\theta) \sin^2(\Delta m^2 L/4E). \tag{2}$$

Despite the fact that the mixing angles have been measured to be much larger than in the quark sector, the two neutrino form is often a very good approximation and is used in many situations.

The angles appear in the equations below in many forms. They most often appear as $\sin^2(2\theta)$. The listings currently use this convention.

Accelerator neutrino experiments: Ignoring the small Δm_{21}^2 scale, CP violation, and matter effects, the equations for the probability of appearance in an accelerator oscillation experiment are:

$$P(\nu_{\mu} \to \nu_{\tau}) = \sin^2(2\theta_{23})\cos^4(\theta_{13})\sin^2(\Delta m_{32}^2 L/4E)$$
 (3)

$$P(\nu_{\mu} \to \nu_{e}) = \sin^{2}(2\theta_{13})\sin^{2}(\theta_{23})\sin^{2}(\Delta m_{32}^{2}L/4E)$$
 (4)

$$P(\nu_e \to \nu_\mu) = \sin^2(2\theta_{13}) \sin^2(\theta_{23}) \sin^2(\Delta m_{32}^2 L/4E)$$
 (5)

$$P(\nu_e \to \nu_\tau) = \sin^2(2\theta_{13})\cos^2(\theta_{23})\sin^2(\Delta m_{32}^2 L/4E)$$
. (6)

For the case of negligible θ_{13} , these probabilities vanish except for $P(\nu_{\mu} \rightarrow \nu_{\tau})$, which then takes the familiar two-neutrino form.

Current and future long-baseline accelerator experiments are studying non-zero θ_{13} through $P(\nu_{\mu} \rightarrow \nu_{e})$. Including the CP terms and low mass scale, the equation for neutrino oscillation in vacuum is:

$$P(\nu_{\mu} \to \nu_{e}) = P1 + P2 + P3 + P4$$

$$P1 = \sin^{2}(\theta_{23}) \sin^{2}(2\theta_{13}) \sin^{2}(\Delta m_{32}^{2} L/4E)$$

$$P2 = \cos^{2}(\theta_{23}) \sin^{2}(2\theta_{13}) \sin^{2}(\Delta m_{21}^{2} L/4E)$$

$$P3 = -/+ J \sin(\delta) \sin(\Delta m_{32}^{2} L/4E)$$

$$P4 = J \cos(\delta) \cos(\Delta m_{32}^{2} L/4E)$$
(7)

 $^{^1}$ BALATA 06 obtained this result from the search for $\overline{\nu}_e$ interactions with Counting Test Facility (the prototype of the Borexino detector).

where

$$J = \cos(\theta_{13})\sin(2\theta_{12})\sin(2\theta_{13})\sin(2\theta_{23}) \times \sin(\Delta m_{32}^2 L/4E)\sin(\Delta m_{21}^2 L/4E)$$
(8)

and the sign in P3 is negative for neutrinos and positive for antineutrinos respectively. For most new long-baseline accelerator experiments, P2 can safely be neglected but the other three terms could be comparable. Also, depending on the distance and the mass hierarchy, matter effects will need to be included.

Reactor neutrino experiments: Nuclear reactors are prolific sources of $\bar{\nu}_e$ with an energy near 4 MeV. The oscillation probability can be expressed

$$P(\bar{\nu}_e \to \bar{\nu}_e) = 1 - \cos^4(\theta_{13}) \sin^2(2\theta_{12}) \sin^2(\Delta m_{21}^2 L/4E) - \cos^2(\theta_{12}) \sin^2(2\theta_{13}) \sin^2(\Delta m_{31}^2 L/4E) - \sin^2(\theta_{12}) \sin^2(2\theta_{13}) \sin^2(\Delta m_{32}^2 L/4E)$$
 (9)

not using the approximation in Eq. (1). For short distances (L<5 km) we can ignore the second term on the right and can reimpose approximation Eq. (1). This takes the familiar two neutrino form with θ_{13} and Δm_{32}^2 :

$$P(\bar{\nu}_e \to \bar{\nu}_e) = 1 - \sin^2(2\theta_{13})\sin^2(\Delta m_{32}^2 L/4E).$$
 (10)

For long distances and small θ_{13} , the last two terms in Eq. (9) oscillate rapidly and average to zero for an experiment with finite energy resolution, leading to the familiar two neutrino form but with θ_{12} and Δm_{21}^2 .

Solar and Atmospheric neutrino experiments: Solar neutrino experiments are sensitive to ν_e disappearance and have allowed the measurement of θ_{12} and Δm_{21}^2 . They are also sensitive to θ_{13} . We identify $\Delta m_{\odot}^2 = \Delta m_{21}^2$ and $\theta_{\odot} = \theta_{12}$.

Atmospheric neutrino experiments are primarily sensitive to ν_{μ} disappearance through $\nu_{\mu} \to \nu_{\tau}$ oscillations, and have allowed the measurement of θ_{23} and Δm_{32}^2 . We identify $\Delta m_A^2 = \Delta m_{32}^2$ and $\theta_A = \theta_{23}$. Despite the large ν_e component of the atmospheric neutrino flux, it is difficult to measure Δm_{21}^2 effects. This is because of a cancellation between $\nu_{\mu} \to \nu_e$ and $\nu_e \to \nu_{\mu}$ together with the fact that the ratio of ν_{μ} and ν_e atmospheric fluxes, which arise from sequential π and μ decay, is near 2.

Oscillation Parameter Listings: In Section (B) we encode the three mixing angles θ_{12} , θ_{23} , θ_{13} and two mass squared differences Δm_{21}^2 and Δm_{32}^2 . Our knowledge of θ_{12} and Δm_{21}^2 comes from the KamLAND reactor neutrino experiment together with solar neutrino experiments. Our knowledge of θ_{23} and Δm_{32}^2 comes from atmospheric neutrino experiments and long-baseline accelerator experiments. Results on θ_{13} come from reactor antineutrino disappearance experiments. There are also results from long-baseline accelerator experiments looking for ν_e appearance. The interpretation of both kinds of results depends on Δm_{32}^2 , and the accelerator results also depend on the mass hierarchy, θ_{23} and the CP violating phase δ .

 $^{1}\,\mbox{GANDO}\,11$ obtain this result with three-neutrino fit using the KamLAND + solar data. Supersedes ABE 08A.

² ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. CPT invariance is assumed.

³ ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, and SAGE data.

 4 ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{32}^2 fixed to $2.4\times 10^{-3}~\rm eV^2$, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. The normal neutrino mass hierarchy and CPT invariance are assumed.

 5 ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{32}^2 fixed to $2.4\times 10^{-3}~\rm eV^2$, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, and GALLEX/GNO data. The normal neutrino mass hierarchy is assumed.

6 BELLINI 11A obtained this result by a two-neutrino oscillation analysis using KamLAND, Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal 743 24 (2011)) with the exception that the ⁸B flux was left free. CPT invariance is assumed.

⁷BELLINI 11A obtained this result by a two-neutrino oscillation analysis using Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENBELLI 11 (Astrophysical Journal **743** 24 (2011)) with the exception that the ⁸B flux was left free.

8 GANDO 11 obtain this result with three-neutrino fit using the KamLAND data only.
Supersedes ABE 08A.

⁹ AHARMIM 10 global solar neutrino data include SNO's low-energy-threshold analysis survival probability day/night curves, SNO Phase III integral rates (AHARMIM 08), CI (CLEVELAND 98), SAGE (ABDURASHITOV 09), Gallex/GNO (HAMPEL 99, ALT-MANN 05), Borexino (ARPESELLA 08A), SK-I zenith (HOSAKA 06), and SK-II day/night spectra (CRAVENS 08).

10 AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data and KamLAND data (ABE 08A). CPT invariance is assumed.

11 AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data.
12 AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value

 $^{12} \rm AHARMIM\,10$ obtained this result by a three-neutrino oscillation analysis with the value of Δm_{31}^2 fixed to $2.3\times 10^{-3}~\rm eV^2$, using global solar neutrino data and KamLAND data (ABE 08A). CPT invariance is assumed.

 13 AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{31}^2 fixed to $^{2.3}\times 10^{-3}$ eV², using global solar neutrino data.

Neutrino Mixing

- 14 ABE 08A obtained this result by a rate + shape + time combined geoneutrino and reactor two-neutrino fit for Δm_{21}^2 and $\tan^2\theta_{12}$, using KamLAND data only.
- 15 ABE 08A obtained this result by means of a two-neutrino fit using KamLAND, Homestake, SAGE, GALLEX, GNO, SK (zenith angle and E-spectrum), the SNO χ^2 -map, and solar flux data. CPT invariance is assumed.
- 16 The result given by AHARMIM 08 is $\theta=(34.4^{+1.3}_{-1.2})^{\circ}$. This result is obtained by a two-neutrino oscillation analysis using solar neutrino data including those of Borexino (ARPESELLA 08A) and Super-Kamiokande-I (HOSAKA 06), and KamLAND data (ABE 08A). CPT invariance is assumed.
- $^{17}\,\text{HOSAKA}$ 06 obtained this result by a two-neutrino oscillation analysis using SK ν_e data, CC data from other solar neutrino experiments, and KamLAND data (ARAKI 05). CPT invariance is assumed.
- ¹⁸ HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the data from Super-Kamiokande, SNO (AHMAD 02 and AHMAD 02B), and KamLAND (ARAKI 05) experiments. CPT invariance is assumed.
- $^{19}\mathrm{HOSAKA}$ 06 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02B) solar neutrino data.
- 20 The result given by AHARMIM 05A is $\theta=(33.9\pm1.6)^\circ$. This result is obtained by a two-neutrino oscillation analysis using SNO pure deuteron and salt phase data, SK ν_e data, Cl and Ga CC data, and KamLAND data (ARAKI 05). CPT invariance is assumed. AHARMIM 05A also quotes $\theta=(33.9^{+2.4}_{-2.2})^\circ$ as the error enveloping the 68% CL two-dimensional region. This translates into $\sin^2 2 \;\theta=0.86^{+0.05}_{-0.06}$.
- 21 AHARMIM 05A obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in figure 35a of AHARMIM 05A. AHARMIM 05A also quotes $\tan^2\theta=0.45 {+0.09 \atop 0.08}$ as the error enveloping the 68% CL two-dimensional region. This translates into $\sin^2\theta=0.86 {+0.05 \atop 0.07}$.
- 22 ARAKI 05 obtained this result by a two-neutrino oscillation analysis using KamLAND and solar neutrino data. CPT invariance is assumed. The 1σ error shown here is translated from the number provided by the KamLAND collaboration, $\tan^2\theta=0.40^{+0.07}_{-0.05}$. The corresponding number quoted in ARAKI 05 is $\tan^2\theta=0.40^{+0.10}_{-0.07}$ ($\sin^2\theta=0.82\pm0.07$), which envelops the 68% CL two-dimensional region.
- 23 The result given by AHMED 04A is $\theta=(32.5^{+1.7}_{-1.6})^{\circ}$. This result is obtained by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (EGUCHI 03). CPT invariance is assumed. AHMED 04A also quotes $\theta=(32.5^{+2.4}_{-2.3})^{\circ}$ as the error enveloping the 68% CL two-dimensional region. This translates into $\sin^2 2~\theta=0.82\pm0.06$.
- 24 AHMED 04A obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 5(a) of AHMED 04A. The best-fit point is $\Delta(m^2)=6.5\times 10^{-5}~{\rm eV}^2, \tan^2\theta=0.40~(\sin^22~\theta=0.82).$
- 25 The result given by SMY 04 is $\tan^2\theta=0.44\pm0.08$. This result is obtained by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (IANNI 03). *CPT* invariance is assumed.
- 26 SMY 04 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The 1σ errors are read from Fig. 6(a) of SMY 04.
- 27 SMY 04 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02B) solar neutrino data. The 1σ errors are read from Fig. 6(a) of SMY 04.
- 28 AHMAD 02B obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4(b) of AHMAD 02B. The best fit point is $\Delta(m^2)=5.0\times 10^{-5}~{\rm eV}^2$ and $\tan\theta=0.34~(\sin^2\!2~\theta=0.76).$
- 29 FUKUDA 02 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4 of FUKUDA 02. The best fit point is $\Delta(m^2) = 6.9 \times 10^{-5} \ \text{eV}^2$ and $\tan^2\theta = 0.38 \ (\sin^22 \ \theta = 0.80)$.

- $^1\,\mbox{GANDO}\,11$ obtain this result with three-neutrino fit using the KamLAND + solar data. Supersedes ABE 08A.
- ²ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. CPT invariance is assumed.
- ³ ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, and SAGE data.
- 4 ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{32}^2 fixed to $2.4\times 10^{-3}~\rm eV^2$, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. The normal neutrino mass hierarchy and CPT invariance are assumed.
- 5 ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{32}^2 fixed to $2.4\times 10^{-3}~\rm eV^2$, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, and GALLEX/GNO data. The normal neutrino mass hierarchy is assumed.
- ⁶ BELLINI 11A obtained this result by a two-neutrino oscillation analysis using KamLAND, Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal 743 24 (2011)) with the exception that the ⁸B flux was left free. CPT invariance is assumed.
- 7 assumed.
 7 BELLINI 11A obtained this result by a two-neutrino oscillation analysis using Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal **743** 24 (2011)) with the exception that the ⁸B flux was left free.
- 8 GANDO 11 obtain this result with three-neutrino fit using the KamLAND data only. Supersedes ABE 08A.
- Supersedes ABE USA.

 9 AHARMIM 10 global solar neutrino data include SNO's low-energy-threshold analysis survival probability day/night curves, SNO Phase III integral rates (AHARMIM 08), CI (CLEVELAND 98), SAGE (ABDURASHITOV 09), Gallex/GNO (HAMPEL 99, ALT-MANN 05), Borexino (ARPESELLA 08A), SK-I zenith (HOSAKA 06), and SK-II day/night spectra (CRAVENS 08).
- 10 AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data and KamLAND data (ABE 08A). CPT invariance is assumed.
- $^{11} \rm AHARMIM~10$ obtained this result by a two-neutrino oscillation analysis using global solar neutrino data. $^{12} \rm AHARMIM~10$ obtained this result by a three-neutrino oscillation analysis with the value
- 12 AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{31}^2 fixed to 2.3×10^{-3} eV², using global solar neutrino data and KamLAND data (ABE 08A). *CPT* invariance is assumed.
- 13 AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{31}^2 fixed to $^{2.3} \times 10^{-3}$ eV², using global solar neutrino data.
- 14 ABE 08A obtained this result by a rate + shape + time combined geoneutrino and reactor two-neutrino fit for Δm_{21}^2 and $\tan^2\theta_{12}$, using KamLAND data only.
- 15 ABE 08A obtained this result by means of a two-neutrino fit using KamLAND, Homestake, SAGE, GALLEX, GNO, SK (zenith angle and E-spectrum), the SNO χ^2 -map, and solar flux data. $\it CPT$ invariance is assumed.
- 16 AHARMIM 08 obtained this result by a two-neutrino oscillation analysis using all solar neutrino data including those of Borexino (ARPESELLA 08A) and Super-Kamiokande-I (HOSAKA 06), and KamLAND data (ABE 08A). CPT invariance is assumed.
- $^{17}\,\mathrm{HOSAKA}$ 06 obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLA ND data (ARAKI 05). CPT invariance is assumed.
- ¹⁸ HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the data from Super-Kamiokande, SNO (AHMAD 02 and AHMAD 02B), and KamLAND (ARAKI 05) experiments. CPT invariance is assumed.
- $^{19}\,\mathrm{HOSAKA}$ 06 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02B) solar neutrino data.
- 20 HOSAKA 06 obtained this result from the consistency between the observed and expected day-night flux asymmetry amplitude. The listed 68% CL range is derived from the 1σ boundary of the amplitude fit to the data. Oscillation parameters are constrained to be in the LMA region. The mixing angle is fixed at $\tan^2\theta=0.44$ because the fit depends only very weekly on it.

Lepton Particle Listings Neutrino Mixing

- 21 AHARMIM 05a obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (ARAKI 05). $\it CPT$ invariance is assumed. AHARMIM 05a also quotes $\Delta(m^2)=(8.0^{+0.6}_{-0.4})\times 10^{-5}~eV^2$ as the error enveloping the 68% CL two-
- 22 AHARMIM 05A obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in figure 35a of AHARMIM 05A. AHARMIM 05A also quotes $\Delta(m^2)=(6.5 \stackrel{+}{-} \frac{4.4}{2.3}) \times 10^{-5} \text{ eV}^2$ as the error enveloping the 68% CL two-...
- 23 ARAKI 05 obtained this result by a two-neutrino oscillation analysis using KamLAND and solar neutrino data. CPT invariance is assumed. The 1σ error shown here is provided by the KamLAND collaboration. The error quoted in ARAKI 05, $\Delta(m^2)=(7.9^+0.6)$ × 10^{-5} , envelops the 68% CL two-dimensional region.
- ²⁴ AHMED 04A obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (EGUCHI 03). CPT invariance is assumed. AHMED 04A also quotes $\Delta(\mathit{m}^2) = (7.1 ^{+}_{-0.6}^{+1.2}) \times 10^{-5} \ \text{eV}^2$ as the error enveloping the 68% CL twodimensional region.
- 25 AHMED 04A obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 5(a) of AHMED 04A. The best-fit point is $\Delta(m^2)=6.5\times 10^{-5}~{\rm eV}^2, \tan^2\theta=0.40~(\sin^22~\theta=0.82).$
- 26 SMY 04 obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (IANNI 03). CPT invariance is assumed.
- $27\,\text{SMY}$ 04 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The 1σ errors are read from Fig. 6(a) of SMY 04.
- 28 SMY 04 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02B) solar neutrino data. The 1σ errors are read from Fig. 6(a) of SMY 04.
- ²⁹AHMAD 02B obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4(b) of AHMAD 02B. The best fit point is $\Delta(m^2) = 5.0 \times 10^{-5} \ \text{eV}^2 \ \text{and} \ \tan \theta = 0.34 \ (\sin^2 \! 2 \ \theta = 0.76).$
- 30 FUKUDA 02 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4 of FUKUDA 02. The best fit point is $\Delta(m^2)$ $= 6.9 \times 10^{-5} \text{ eV}^2 \text{ and } \tan^2 \theta = 0.38 \text{ (sin}^2 2 \theta = 0.80).$

$\sin^{2}(2\theta_{23})$

The ranges below correspond to the projection onto the $\sin^2(2\theta_{23})$ axis of the 90% CL contours in the $\sin^2(2\theta_{23}) - \Delta m_{32}^2$ plane presented by the authors. The values are reported with one standard deviation uncertainty.

- $^1\,\text{ABE}$ 11c obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande-I+II+III atmospheric neutrino data. ABE 11c also reported results under
- Kamiokande-|+||+||| atmospheric neutrino data. ABE 11c also reported results under a two-neutrino disappearance model with separate mixing parameters between ν and $\overline{\nu}$, and obtained $\sin^2 2\theta > 0.93$ for ν and $\sin^2 2\theta > 0.83$ for $\overline{\nu}$ at 90% C.L. ² ADAMSON 118 obtained this result by a two-neutrino oscillation analysis of antineutrinos in an antineutrino enhanced beam with 1.71×10^{20} protons on target. This results is consistent with the neutrino measurements of ADAMSON 11 at 2% C.L. ³ WENDELL 10 obtained this result ($\sin^2 \theta_{23} = 0.407-0.583$) by a three-neutrino oscillation analysis using the Super-Kamiokande-|+||+||| atmospheric neutrino data, assuming
- $heta_{13}=0$ but including the solar oscillation parameters Δm_{21}^2 and $\sin^2 heta_{12}$ in the fit.

- 4 WENDELL 10 obtained this result ($\sin^2 \theta_{23} = 0.43$ –0.61) by a three-neutrino oscillation analysis with one mass scale dominance ($\Delta m_{21}^2=0$) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06A result.
- 5 WENDELL 10 obtained this result (sin $^2\theta_{23} =$ 0.44–0.63) by a three-neutrino oscillation analysis with one mass scale dominance ($\Delta m_{21}^2=0$) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06A result.
- 6 ADAMSON 06 obtained this result by a two-neutrino oscillation analysis of the L/E distribution using 4.54 kton yr atmospheric neutrino data with the MINOS far detector.
- ⁷ Supercedes ALIU 05.
- 8 MICHAEL 06 best fit is for maximal mixing. See also ADAMSON 08.
- ⁹The best fit is for maximal mixing.
- $^{
 m 10}$ ALLISON 05 result is based upon atmospheric neutrino interactions including upwardstopping muons, with an exposure of 5.9 kton yr. From a two-flavor oscillation analysis the best-fit point is $\Delta m^2=0.0017~{\rm eV}^2$ and $\sin^2(2\theta)=0.97$.
- $^{11}{\rm ASHIE}$ 05 obtained this result by a two-neutrino oscillation analysis using 92 kton yr atmospheric neutrino data from the complete Super-Kamiokande I running period.
- 12 AMBROSIO 04 obtained this result, without using the absolute normalization of the neutrino flux, by combining the angular distribution of upward through-going muon tracks with ${\it E}_{\mu} > 1$ GeV, ${\rm N}_{low}$ and ${\rm N}_{high}$, and the numbers of inDown + UpStop and inUp events. Here, N_{low} and N_{high} are the number of events with reconstructed neutrino energies < 30 GeV and > 130 GeV, respectively. InDown and InUp represent events with downward and upward-going tracks starting inside the detector due to neutrino interactions, while Up stop represents entering upward-going tracks which stop in the detector. The best fit is for maximal mixing.
- 13 ASHIE 04 obtained this result from the L(flight length)/E(estimated neutrino energy) distribution of ν_{μ} disappearance probability, using the Super-Kamiokande-I 1489 live-day atmospheric neutrino data.
- $^{14}\,\mathrm{There}$ are several islands of allowed region from this K2K analysis, extending to high values of Δm^2 . We only include the one that overlaps atmospheric neutrino analyses. The best fit is for maximal mixing.
- $^{15}\,\mathrm{A\,MB\,ROSIO}$ 03 obtained this result on the basis of the ratio R $=\,\mathrm{N}_{low}/\mathrm{N}_{high}$, where N_{low} and N_{high} are the number of upward through-going muon event reconstructed neutrino energy < 30 GeV and > 130 GeV, respectively. The data came from the full detector run started in 1994. The method of FELDMAN 98 is used to obtain
- 16 AMBROSIO 03 obtained this result by using the ratio R and the angular distribution of the upward through-going muons. R is given in the previous note and the angular distribution is reported in AMBROSIO 01. The method of FELDMAN 98 is used to obtain the limits. The best fit is to maximal mixing.
- 17 SANCHEZ 03 is based on an exposure of 5.9 kton yr. The result is obtained using a likelihood analysis of the neutrino L/E distribution for a selection μ flavor sample while the e-flavor sample provides flux normalization. The method of FELDMAN 98 is used to obtain the allowed region. The best fit is $\sin^2(2\theta)=0.97$.
- 18 A MB ROSIO 01 result is based on the angular distribution of upward through-going muon tracks with $E_{\mu} > 1$ GeV. The data came from three different detector configurations, but the statistics is largely dominated by the full detector run, from May 1994 to December 2000. The total live time, normalized to the full detector configuration is 6.17 years. The best fit is obtained outside the physical region. The method of FELDMAN 98 is used to obtain the limits. The best fit is for maximal mixing.
- $^{
 m 19}$ AMBROSIO 01 result is based on the angular distribution and normalization of upward through-going muon tracks with $E_{\mu}~>1$ GeV. See the previous footnote
- ²⁰ FU KUDA 99c obtained this result from a total of 537 live days of upward through-going muon data in Super-Kamiokande between April 1996 to January 1998. With a threshold of E $_{\mu}$ > 1.6 GeV, the observed flux is $(1.74\pm0.07\pm0.02)\times10^{-13}$ cm $^{-2}$ s $^{-1}$ sr $^{-1}$ The best fit is $\sin^2(2\theta) = 0.95$.
- 21 FU KUDA 990 obtained this result from a simultaneous fitting to zenith angle distributions of upward-stopping and through-going muons. The flux of upward-stopping muons of minimum energy of 1.6 GeV measured between April 1996 and January 1998 is (0.39 \pm $0.04\pm0.02)\times10^{-13}$ cm $^{-2}$ s $^{-1}$ sr $^{-1}$. This is compared to the expected flux of (0.73 \pm 0.16 (theoretical error)) $\times 10^{-13}$ cm $^{-2}$ s $^{-1}$ sr $^{-1}$. The best fit is to maximal mixing.
- $^{22}{\rm FU\,KUDA}$ 990 obtained this result from the zenith dependence of the upward-stopping/through-going flux ratio. The best fit is to maximal mixing.
- $^{23}\,\mathrm{FU\,KUDA}$ 98c obtained this result by an analysis of 33.0 kton yr atmospheric neutrino data. The best fit is for maximal mixing.
- 24 HATAKEYAMA 98 obtained this result from a total of 2456 live days of upward-going muon data in Kamiokande between December 1985 and May 1995. With a threshold of $E_{\mu} > 1.6$ GeV, the observed flux of upward through-going muons is $(1.94 \pm 0.10 + 0.07) \times (1.94 \pm 0.07) \times (1.$ 10^{-13} cm $^{-2}$ s $^{-1}$ sr $^{-1}$. This is compared to the expected flux of (2.46 \pm 0.54 (theoretical error)) $\times 10^{-13}~\text{cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$. The best fit is for maximal mixing.
- $^{25}\,\mathrm{HATAKEYAMA}$ 98 obtained this result from a combined analysis of Kamiokande contained events (FUKUDA 94) and upward going muon events. The best fit is $\sin^2(2\theta) =$
- 26 FU KUDA 94 obtained the result by a combined analysis of sub- and multi-GeV atmospheric neutrino events in Kamiokande. The best fit is for maximal mixing.

Δm_{32}^2

The sign of Δm_{32}^2 is not known at this time. Only the absolute value is quoted below. Unless otherwise specified, the ranges below correspond to the projection onto the Δm_{32}^2 axis of the 90% CL contours in the $\sin^2(2\theta_{23}) - \Delta m_{32}^2$ plane presented by the authors. The values are reported with one standard deviation uncertainty.

- 1 ABE 11c obtained this result by a two-neutrino oscillation analysis with separate mixing parameters between neutrinos and antineutrinos, using the Super-Kamiokande-I+II+III atmospheric neutrino data. The corresponding 90% CL neutrino oscillation parameter range obtained from this analysis is $\Delta m^2=1.7-3.0\times 10^{-3}~{\rm eV}^2$.
- 2 ADAMSON 118 obtained this result by a two-neutrino oscillation analysis of antineutrinos in an antineutrino enhanced beam with 1.71×10^{20} protons on target. This results is consistent with the neutrino measurements of ADAMSON 11 at 2% C.L.
- 3 ADAMSON 11c obtains this result based on a study of antineutrinos in a neutrino beam and assumes maximal mixing in the two-flavor approximation.
- 4 WENDELL 10 obtained this result by a three-neutrino oscillation analysis with one mass scale dominance ($\Delta m_{21}^2=0$) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06A result.
- 5 ADAMSON 06 obtained this result by a two-neutrino oscillation analysis of the L/E distribution using 4.54 kton yr atmospheric neutrino data with the MINOS far detector.
- ⁶ The best fit in the physical region is for $\Delta m^2 = 2.8 \times 10^{-3} \text{ eV}^2$.
- Supercedes ALIU 05
- 8 MICHAEL 06 best fit is $2.74\times 10^{-3}~\text{eV}^2.$ See also ADAMSON 08.
- ⁹ALLISON 05 result is based on an atmospheric neutrino observation with an exposure of 5.9 kton yr. From a two-flavor oscillation analysis the best-fit point is $\Delta m^2 = 0.0017$ eV² and $\sin^2 2 \theta = 0.97$.
- 10 ASHIE 05 obtained this result by a two-neutrino oscillation analysis using 92 kton yr atmospheric neutrino data from the complete Super-Kamiokande I running period. The best fit is for $\Delta m^2 = 2.1 \times 10^{-3} \ eV^2$.
- 11 AMBROSIO 04 obtained this result, without using the absolute normalization of the neutrino flux, by combining the angular distribution of upward through-going muon tracks with $E_{\mu} > 1$ GeV, N_{low} and N_{high} , and the numbers of InDown + UpStop and InUp events. Here, N_{low} and N_{high} are the number of events with reconstructed neutrino energies < 30 GeV and > 130 GeV, respectively. InDown and InUp represent events with downward and upward-going tracks starting inside the detector due to neutrino interactions, while UpStop represents entering upward-going tracks which stop in the detector. The best fit is for $\Delta m^2 = 2.3 \times 10^{-3} \ {\rm eV}^2$.
- $^{12}\text{ASHIE}$ 04 obtained this result from the L(flight length)/E(estimated neutrino energy) distribution of ν_{μ} disappearance probability, using the Super-Kamiokande-I 1489 live-day atmospheric neutrino data. The best fit is for $\Delta m^2=2.4\times 10^{-3}~\text{eV}^2.$
- 13 There are several islands of allowed region from this K2K analysis, extending to high values of Δm^2 . We only include the one that overlaps atmospheric neutrino analyses. The best fit is for $\Delta m^2=2.8\times 10^{-3}~\text{eV}^2.$
- 14 AMBROSIO 03 obtained this result on the basis of the ratio R = N_{low}/N_{high}, where N_{low} and N_{high} are the number of upward through-going muon events with reconstructed neutrino energy < 30 GeV and > 130 GeV, respectively. The data came from the full detector run started in 1994. The method of FELDMAN 98 is used to obtain the limits. The best fit is for $\Delta m^2 = 2.5 \times 10^{-3} \ \mbox{eV}^2$.
- 15 AMBROSIO 03 obtained this result by using the ratio R and the angular distribution of the upward through-going muons. R is given in the previous note and the angular distribution is reported in AMBROSIO 01. The method of FELDMAN 98 is used to obtain the limits. The best fit is for $\Delta m^2=2.5\times 10^{-3}~\text{eV}^2.$
- 16 SANCHEZ 03 is based on an exposure of 5.9 kton yr. The result is obtained using a likelihood analysis of the neutrino L/E distribution for a selection μ flavor sample while the e-flavor sample provides flux normalization. The method of FELDMAN 98 is used to obtain the allowed region. The best fit is for $\Delta m^2 = 5.2 \times 10^{-3} \ eV^2$.
- 17 AMBROSIO 01 result is based on the angular distribution of upward through-going muon tracks with $E_{\mu}>1$ GeV. The data came from three different detector configurations, but the statistics is largely dominated by the full detector run, from May 1994 to December 2000. The total live time, normalized to the full detector configuration is 6.17 years. The best fit is obtained outside the physical region. The method of FELDMAN 98 is used to obtain the limits.

- 18 AMBROSIO 01 result is based on the angular distribution and normalization of upward through-going muon tracks with $E_{\mu}~>1$ GeV. See the previous footnote.
- 19 FUKUDA 99c obtained this result from a total of 537 live days of upward through-going muon data in Super-Kamiokande between April 1996 to January 1998. With a threshold of $E_{\mu} > 1.6$ GeV, the observed flux is $(1.74 \pm 0.07 \pm 0.02) \times 10^{-13}$ cm $^{-2}$ s $^{-1}$ sr $^{-1}$. The best fit is for $\Delta m^2 = 5.9 \times 10^{-3}$ eV 2 .
- 20 FUKUDA 990 obtained this result from a simultaneous fitting to zenith angle distributions of upward-stopping and through-going muons. The flux of upward-stopping muons of minimum energy of 1.6 GeV measured between April 1996 and January 1998 is $(0.39\pm0.04\pm0.02)\times10^{-13}$ cm $^{-2}s^{-1}sr^{-1}$. This is compared to the expected flux of (0.73 ± 0.16) (theoretical error)) $\times10^{-13}$ cm $^{-2}s^{-1}sr^{-1}$. The best fit is for $\Delta m^2=3.9\times10^{-3}$ eV².
- $^{21}\text{FUKUDA}$ 99D obtained this result from the zenith dependence of the upward-stopping/through-going flux ratio. The best fit is for $\Delta m^2=3.1\times 10^{-3}~\text{eV}^2$.
- 22 FUKUDA 98c obtained this result by an analysis of 33.0 kton yr atmospheric neutrino data. The best fit is for $\Delta m^2=2.2\times 10^{-3}$ eV 2 .
- ²³ HATAKEYAMA 98 obtained this result from a total of 2456 live days of upward-going muon data in Kamiokande between December 1985 and May 1995. With a threshold of $E_{\mu}>1.6$ GeV, the observed flux of upward through-going muons is $(1.94\pm0.10^{+0.07}_{-0.06})\times10^{-13}$ cm $^{-2}{\rm s}^{-1}{\rm s}^{-1}$. This is compared to the expected flux of $(2.46\pm0.54$ (theoretical error)) $\times10^{-13}$ cm $^{-2}{\rm s}^{-1}{\rm s}^{-1}$. The best fit is for $\Delta m^2=2.2\times10^{-3}$ eV².
- 24 HATAKEYAMA 98 obtained this result from a combined analysis of Kamiokande contained events (FUKUDA 94) and upward going muon events. The best fit is for $\Delta m^2=13\times 10^{-3}~\text{eV}^2.$
- 25 FUKUDA 94 obtained the result by a combined analysis of sub- and multi-GeV atmospheric neutrino events in Kamiokande. The best fit is for $\Delta m^2=16\times 10^{-3}~{\rm eV}^2$.

$\sin^2(2\theta_{13})$

At present time direct measurements of $\sin^2(2\,\theta_{13})$ are derived from the reactor $\overline{\nu}_e$ disappearance at distances corresponding to the Δm_{32}^2 value, i.e. L $\sim \,$ 1km. Alternatively, limits can also be obtained from the analysis of the solar neutrino data and accelerator-based $\nu_\mu \to \, \nu_e$ experiments.

- 1 ABE 12 determine the $\overline{\nu}_e$ interaction rate in a single detector, located 1050 m from the cores of two reactors. The rate normalization is fixed by the results of the Bugey4 reactor experiment, thus avoiding any dependence on possible very short baseline oscillations. The value of $\Delta m_{31}^2=2.4\times 10^{-3}~\text{eV}^2$ is used in the analysis.
- 2 AHN 12 use two identical detectors, placed at flux weighted distances of 408.56 m and 1433.99 m from six reactor cores, to determine the mixing angle θ_{13} . This rate-only analysis excludes the no-oscillation hypothesis at 4.9 standard deviations. The value of $\Delta m_{31}^2 = (2.32 \pm 0.12^{+0.12}_{-0.08}) \times 10^{-3} \ \text{eV}^2$ was assumed in the analysis.

- $^3\,\mathrm{A\,N}$ 12 use six identical detectors with three placed near the reactor cores (flux-weighted baselines of 470 m and 576 m) and the remaining three at the far hall (at the flux averaged distance of 1648 m from all six reactor cores) to determine the mixing angle θ_{13} using the \overline{v}_e observed interaction rate ratios. This rate-only analysis excludes the no-oscillation hypothesis at 5.2 standard deviations. The value of $\Delta m^2_{31}=(2.32^{+0.12}_{-0.08})\times 10^{-3}~{\rm eV}^2$ was assumed in the analysis.
- ⁴ ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{32}^2 fixed to 2.4×10^{-3} eV², using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. This result implies an upper bound of $\sin^2\!\theta_{13} < 0.059$ (95% CL) or $\sin^2\!2\theta_{13} < 0.22$ (95% CL). The normal neutrino mass hierarchy and CPT invariance are assumed.
- 5 ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of Δm^2_{32} fixed to $2.4\times 10^{-3}~{\rm eV}^2$, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, and GALLEX/GNO data. The normal neutrino mass hierarchy is assumed.
- 6 The quoted limit is for $\Delta m^2_{32}=2.4\times 10^{-3}$ eV 2 , $\theta_{23}=\pi/2$, $\delta=$ 0, and the normal mass hierarchy. For other values of δ , the 68% region spans from 0.03 to 0.25, and the 90% region from 0.02 to 0.32.
- 7 The quoted limit is for $\Delta m_{32}^2=2.4\times 10^{-3}$ eV², $\theta_{23}=\pi/2$, $\delta=$ 0, and the inverted mass hierarchy. For other values of δ , the 68% region spans from 0.04 to 0.30, and the 90% region from 0.02 to 0.39.
- 8 The quoted limit is for $\Delta m_{32}^{2}=2.32\times10^{-3}~\rm{eV^{2}},~\theta_{23}=\pi/2,~\delta=0,$ and the normal mass hierarchy. For other values of δ , the 68% region spans from 0.02 to 0.12, and the 90% region from 0 to 0.16.
- 9 The quoted limit is for $\Delta m_{32}^2=2.32\times 10^{-3}~{\rm eV^2},\, \theta_{23}=\pi/2,\, \delta=0,$ and the inverted mass hierarchy. For other values of δ , the 68% region spans from 0.02 to 0.16, and the 90% region from 0 to 0.21.
- $^{
 m 10}$ FOGLI 11 obtained this result from an analysis using the atmospheric, accelerator long baseline, CHOOZ, solar, and KamLAND data. Recently, MUELLER 11 suggested an average increase of about 3.5% in normalization of the reactor v_e fluxess, and using these fluxes, the fitted result becomes 0.10 ± 0.03 . 11 GANDO 11 report $\sin^2\theta_{13}=0.020\pm0.016$. This result was obtained with three-neutrino fit using the KamLAND + solar data.
- 12 GANDO 11 report $\sin^2\theta_{13}=0.032\pm0.037$. This result was obtained with three-neutrino fit using the KamLAND data only.
- 13 This result corresponds to the limit of <0.12 at 90% CL for $\Delta m_{32}^2=2.43\times 10^{-3}~{\rm eV}^2,$ $\theta_{23}=\pi/2,$ and $\delta=0.$ For other values of δ , the 90% CL region spans from 0.16.
- ¹⁴This result corresponds to the limit of <0.20 at 90% CL for $\Delta m_{32}^2=2.43\times 10^{-3}$ eV², $heta_{23}=\pi/2$, and $\delta=0$. For other values of δ , the 90% CL region spans from 0 to 0.21.
- 32 A M/2, and 6 B of North Mark and 6 B, and
- ¹⁶ AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{31}^2 fixed to 2.3×10^{-3} eV², using global solar neutrino data and KamLAND data (ABE 08A). CPT invariance is assumed. This result implies an upper bound of $\sin^2 \theta_{13} < \cos^2 \theta_{13}$ 0.057 (95% CL) or $\sin^2 2\theta_{13} <$ 0.22 (95% CL).
- 17 AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of Δm_{31}^2 fixed to $2.3\times 10^{-3}~\text{eV}^2$, using global solar neutrino data.
- 18 WENDELL 10 obtained this result by a three-neutrino oscillation analysis with one mass scale dominance $(\Delta m_{21}^2=0)$ using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06A result.
- 19 The quoted limit is for $\Delta m^2_{32}=2.43\times 10^{-3}~\rm eV^2,~\theta_{23}=\pi/2,$ and $\delta=0.$ For other values of $\delta,$ the 68% CL region spans from 0.02 to 0.26.
- 20 The quoted limit is for $\Delta m_{32}^2=2.43\times 10^{-3}~\rm eV^2,~\theta_{23}=\pi/2$, and $\delta=0.$ For other values of δ , the 68% CL region spans from 0.04 to 0.34.
- $^{21}\,\text{FOGLI}$ 08 obtained this result from a global analysis of all neutrino oscillation data, that is, solar + KamLAND + atmospheric + accelerator long baseline + CHOOZ.
- $^{22}\mathsf{FOGLI}$ 08 obtained this result from an analysis using the solar and KamLAND neutrino
- ²³FOGLI 08 obtained this result from an analysis using the atmospheric, accelerator long baseline, and CHOOZ neutrino oscillation data.
- 24 YAMAMOTO 06 searched for $u_{\mu}
 ightarrow
 u_{e}$ appearance. Assumes $2 \sin^{2}(2 heta_{\mu\,e}) =$ $\sin^2(2\theta_{13})$. The quoted limit is for $\Delta m_{32}^2 = 1.9 \times 10^{-3} \text{ eV}^2$. That value of Δm_{32}^2 is the one- σ low value for AHN 06A. For the AHN 06A best fit value of $2.8\times10^{-3}~{\rm eV}^2$, the $\sin^2(2\theta_{13})$ limit is < 0.26. Supersedes AHN 04.
- 25 AHN 04 searched for $u_{\mu}
 ightarrow \;
 u_e$ appearance. Assuming 2 $\sin^2(2\; heta_{\mu_e}) = \sin^2(2\; heta_{13})$, a limit on sin² $(2 \ \theta_{\mu_2})$ is converted to a limit on sin² $(2 \ \theta_{13})$. The quoted limit is for $\Delta m_{32}^2 = 1.9 \times 10^{-3} \ \text{eV}^2$. That value of Δm_{32}^2 is the one- σ low value for ALIU 05. For the ALIU 05 best fit value of $2.8 \times 10^{-3} \ \text{eV}^2$, the $\sin^2(2 \ \theta_{13})$ limit is < 0.30.
- ²⁶The quoted limit is for $\Delta m_{32}^2=1.9\times 10^{-3}~{\rm eV}^2$. That value of Δm_{32}^2 is the 1- σ low value for ALIU 05. For the ALIU 05 best fit value of 2.8 \times 10 $^{-3}$ eV 2 , the $\sin^2 2 \, \theta_{13}$ limit is < 0.19. In this range, the θ_{13} limit is larger for lower values of Δm_{32}^2 , and smaller for higher values of Δm_{32}^2 .
- 27 The quoted limit is for $\Delta m^2_{32}=1.9\times 10^{-3}~\text{eV}^2.$ That value of Δm^2_{32} is the 1- σ low value for ALIU 05. For the ALIU 05 best fit value of $2.8 \times 10^{-3} \text{ eV}^{2}$, the $\sin^2 2 \theta_{13}$
- 28 The quoted limit is for $\Delta m^2_{32}=$ 2.43 $\times\,10^{-3}$ eV 2 . That value of Δm^2_{32} is the central the $\sin^2 2\,\theta_{13}$ limit is < 0.16. See also APOLLONIO 03 for a detailed description of the experiment.

(C) Other neutrino mixing results

The LSND collaboration reported in AGUILAR 01 a signal which is consistent with $\overline{
u}_{\mu}
ightarrow \overline{
u}_e$ oscillations. In a three neutrino framework, this would be a measurement of θ_{12} and Δm_{21}^2 . This does not appear to be consistent with the interpretation of other neutrino data. The MiniBooNE expersions iment, reported in AGUILAR-AREVALO 07, does a two-neutrino analysis which, assuming $\it CPT$ conservation, rules out AGUILAR 01. The following listings include results which might be relevant towards understanding these observations. They include searches for $\nu_{\mu} o \; \nu_e, \overline{\nu}_{\mu} o \; \overline{\nu}_e$, sterile neutrino oscillations, and $\ensuremath{\mathit{CPT}}$ violation.

$\Delta(m^2)$ for $\sin^2(2\theta)=1~(u_{\mu} ightarrow~ u_e)$

- $^{
 m 1}$ AGUILAR 01 is the final analysis of the LSND full data set. Search is made for the $u_{\mu}
 ightarrow \
 u_{e}$ oscillations using u_{μ} from π^{+} decay in flight by observing beam-on electron events from $\nu_{\rm e}{\rm C} \to e^- X$. Present analysis results in 8.1 \pm 12.2 \pm 1.7 excess events in the $60{<}E_{\rm e}^{}<200$ MeV energy range, corresponding to oscillation probability of 0.10 \pm 0.16 \pm 0.04%. This is consistent, though less significant, with the previous result of ATHANASSOPOULOS 98, which it supersedes. The present analysis uses selection criteria developed for the decay at rest region, and is less effective in removing the background above 60 MeV than ATHANASSOPOULOS 98.
- 2 ATHANASSOPOULOS 98 is a search for the $\nu_{\mu} \rightarrow \ \nu_{e}$ oscillations using ν_{μ} from π^+ decay in flight. The 40 observed beam-on electron events are consistent with ν_{e} C \rightarrow e^- X; the expected background is 21.9 ± 2.1 . Authors interpret this excess as evidence for an oscillation signal corresponding to oscillations with probability (0.26 \pm 0.10 \pm 0.05)%. Although the significance is only 2.3 σ , this measurement is an important and consistent cross check of ATHANASSOPOULOS 96 who reported evidence for $\overline{
 u}_{\mu}
 ightarrow \overline{
 u}_e$ oscillations from μ^+ decay at rest. See also ATHANASSOPOULOS 98B.
- ³LOVERRE 96 uses the charged-current to neutral-current ratio from the combined CHARM (ALLABY 86) and CDHS (ABRAMOWICZ 86) data from 1986.

$\sin^2(2\theta)$ for "Large" $\Delta(m^2)$ $(\nu_{\mu} \rightarrow \nu_{e})$

- 1 The limit is $\sin^22\theta < 0.9 \times 10^{-3}$ at $\Delta m^2 = 2~\text{eV}^2.$ That value of Δm^2 corresponds to the smallest mixing angle consistent with the reported signal from LSND in AGUILAR 01.
- 2 The limit becomes $\sin^2 2 heta < 0.15$ at $\Delta m^2 = 2.8 imes 10^{-3}$ eV 2 , the bets-fit value of the u_{μ} disappearance analysis in K2K.
- 3 AGUILAR 01 is the final analysis of the LSND full data set of the search for the u_{μ} ightarrow $\nu_{\rm P}$ oscillations. See footnote in preceding table for further details.
- $^4\,\text{ATHANASSOPOULOS}$ 98 report (0.26 \pm 0.10 \pm 0.05)% for the oscillation probability; the value of $\sin^2 2\theta$ for large Δm^2 is deduced from this probability. See footnote in preceding table for further details, and see the paper for a plot showing allowed regions. If effect is due to oscillation, it is most likely to be intermediate $\sin^2 2\theta$ and Δm^2 . See also ATHANASSOPOULOS 98B.
- ⁵ LOVERRE 96 uses the charged-current to neutral-current ratio from the combined CHARM (ALLABY 86) and CDHS (ABRAMOWICZ 86) data from 1986.
- 6 VILAIN 94c limit derived by combining the u_μ and $\overline{
 u}_\mu$ data assuming *CP* conservation.

$\Delta(m^2)$ for $\sin^2(2\theta) = 1$ $(\overline{\nu}_{\mu} \rightarrow \overline{\nu}_{e})$

| < 0.14 | 90 | ⁸ FREEDMAN | 93 | CNTR | LAMPF |

- 1 This value is for a two neutrino oscillation analysis for excess antineutrino events with E $_{\nu}>$ 475 MeV. The best fit is at 0.07. The allowed region is consistent with LSND reported by AGUILAR 01. Supercedes AGUILAR-AREVALO 09B.
- $^2\,\mathrm{This}$ value is for a two neutrino oscillation analysis for excess antineutrino events with ${\sf E}_{
 u} >$ 200 MeV with subtraction of the expected 12 events low energy excess seen in the neutrino component of the beam. The best fit value is 0.007 for $\Delta(m^2)=4.4~{\rm eV}^2.$
- 3 ARMBRUSTER 02 is the final analysis of the KARMEN 2 data for 17.7 m distance from the ISIS stopped pion and muon neutrino source. It is a search for $\overline{
 u}_e$, detected by the inverse β -decay reaction on protons and ^{12}C . 15 candidate events are observed, and 15.8 ± 0.5 background events are expected, hence no oscillation signal is detected. The results exclude large regions of the parameter area favored by the LSND experiment.
- 4 AGUILAR 01 is the final analysis of the LSND full data set. It is a search for $\overline{
 u}_e$ 30 m from LAMPF beam stop. Neutrinos originate mainly for π^+ decay at rest. $\overline{\nu}_e$ are detected through $\overline{v}_e p \to e^+ n$ ($20 < E_{e^+} < 60$ MeV) in delayed coincidence with $np \to d\gamma$. Authors observe $87.9 \pm 22.4 \pm 6.0$ total excess events. The observation is attributed to $\overline{v}_\mu \to \overline{v}_e$ oscillations with the oscillation probability of $0.264 \pm 0.067 \pm 0.045\%$, consistent with the previously published result. Taking into account all constraints, the most favored allowed region of oscillation parameters is a band of $\Delta(m^2)$ from C.2–2.0 eV². Supersedes ATHANASSOPOULOS 95, ATHANASSOPOULOS 96, and ATHANASSOPOULOS 98.
- 5 ATHANASSOPOULOS 96 is a search for $\overline{
 u}_{e}$ 30 m from LAMPF beam stop. Neutrinos originate mainly from π^+ decay at rest. $\overline{
 u}_e$ could come from either $\overline{
 u}_\mu \to \overline{
 u}_e$ or $u_e
 ightarrow \overline{
 u}_e$; our entry assumes the first interpretation. They are detected through $\overline{
 u}_e p
 ightarrow$ e⁺ n (20 MeV < E_{e^+} < 60 MeV) in delayed coincidence with $np \rightarrow d\gamma$. Authors observe 51 \pm 20 \pm 8 total excess events over an estimated background 12.5 \pm 2.9. ATHANASSOPOULOS 96B is a shorter version of this paper.
- 6 ATHANASSOPOULOS 95 error corresponds to the 1.6σ band in the plot. The expected background is 2.7 ± 0.4 events. Corresponds to an oscillation probability of $(0.34^{+0.20}_{-0.18}\pm0.07)\%$. For a different interpretation, see HILL 95. Replaced by ATHANASSOPOULOS 96.
- ⁷ HILL 95 is a report by one member of the LSND Collaboration, reporting a different conclusion from the analysis of the data of this experiment (see ATHANASSOPOULOS 95). Contrary to the rest of the LSND Collaboration, Hill finds no evidence for the neutrino oscillation $\overline{
 u}_{\mu}
 ightarrow \ \overline{
 u}_{e}$ and obtains only upper limits.
- 8 FREEDMAN 93 is a search at LAMPF for $\overline{\nu}_e$ generated from any of the three neutrino types $\nu_{\mu},\,\overline{\nu}_{\mu},\,$ and ν_e which come from the beam stop. The $\overline{\nu}_e$'s would be detected by the reaction $\overline{
 u}_e \, p \,
 ightarrow \, e^+ \, n$. FREEDMAN 93 replaces DURKIN 88.

- $^{
 m 1}$ This value is for a two neutrino oscillation analysis for excess antineutrino events with $\rm E_{\nu}>475$ MeV. At 90% CL there is no solution at high $\Delta(m^2).$ The best fit is at maximal mixing. The allowed region is consistent with LSND reported by AGUILAR 01. Supercedes AGUILAR-AREVALO 09B.
- ²This value is for a two neutrino oscillation analysis for excess antineutrino events with ${\rm E}_{
 u} >$ 200 MeV with subtraction of the expected 12 events low energy excess seen in the neutrino component of the beam. At 90% CL there is no solution at high $\Delta(m^2)$. The best fit value is 0.007 for $\Delta(m^2) = 4.4 \text{ eV}^2$.
- $^3\,\text{This}$ result is inconclusive with respect to small amplitude mixing suggested by LSND.
- ⁴ ARMBRUSTER 02 is the final analysis of the KARMEN2 data. See footnote in the preceding table for further details, and the paper for the exclusion plot.
- 5 AGUILAR 01 is the final analysis of the LSND full data set. The deduced oscillation probability is 0.264 \pm 0.067 \pm 0.045%; the value of $\sin^2 2\theta$ for large $\Delta(m^2)$ is twice this probability (although these values are excluded by other constraints). See footnote in preceding table for further details, and the paper for a plot showing allowed regions. Supersedes ATHANASSOPOULOS 95, ATHANASSOPOULOS 96, and ATHANASSOPOULOS 98.
- 6 ATHANASSOPOULOS 96 reports $(0.31\pm0.12\pm0.05)\%$ for the oscillation probability; the value of $\sin^2 2\theta$ for large $\Delta(m^2)$ should be twice this probability. See footnote in preceding table for further details, and see the paper for a plot showing allowed regions.
- 7 ATHANASSOPOULOS 95 error corresponds to the 1.6σ band in the plot. The expected background is 2.7 \pm 0.4 events. Corresponds to an oscillation probability of $(0.34 \stackrel{+}{-} 0.18 \pm 0.07)\%$. For a different interpretation, see HILL 95. Replaced by ATHANASSOPOULOS 96.
- 8 HILL 95 is a report by one member of the LSND Collaboration, reporting a different conclusion from the analysis of the data of this experiment (see ATHANASSOPOULOS 95). Contrary to the rest of the LSND Collaboration, Hill finds no evidence for the neutrino oscillation $\overline{
 u}_{\mu}
 ightarrow \overline{
 u}_{e}$ and obtains only upper limits.

AMBROSIO 01 MCRO matter effects ² FUKUDA 0.0 SKAM neutral currents + matter effects

- 1 AMBROSIO 01 tested the pure 2-flavor $\nu_{\mu} \to \nu_{\rm S}$ hypothesis using matter effects which change the shape of the zenith-angle distribution of upward through-going muons. With maximum mixing and $\Delta(m^2)$ around 0.0024 eV 2 , the $\nu_{\mu} \to \nu_{\rm S}$ oscillation is disfavored with 99% confidence level with respect to the $\nu_{\mu} \to \nu_{\tau}$ hypothesis.
- 2 FUKUDA 00 tested the pure 2-flavor $\nu_{\mu} \rightarrow \nu_{s}$ hypothesis using three complementary atmospheric-neutrino data samples. With this hypothesis, zenith-angle distributions are expected to show characteristic behavior due to neutral currents and matter effects. In the $\Delta(m^2)$ and $\sin^2 2 heta$ region preferred by the Super-Kamiokande data, the u_{μ} - $\nu_{\rm S}$ hypothesis is rejected at the 99% confidence level, while the $\nu_{\mu}
 ightarrow \nu_{ au}$ hypothesis consistently fits all of the data sample.

- CPT tests -

Heavy Neutral Leptons, Searches for

(A) Heavy Neutral Leptons

- Stable Neutral Heavy Lepton MASS LIMITS ----

Note that LEP results in combination with REUSSER 91 exclude a fourth stable neutrino with $\it m < 2400$ GeV.

| VALUE (GeV) | CL% | DO CUMENT ID | | TECN | COMMENT |

| >42.7 | 95 | DECAMP | 90F | ALEP | Dirac |

 $^{^1}$ ADEVA 90s limits for the heavy neutrino apply if the mixing with the charged leptons satisfies $|u_{1\,j}|^2+|u_{2\,j}|^2+|u_{3\,j}|^2>6.2\times 10^{-8}$ at $m_{L^0}=$ 20 GeV and $>5.1\times 10^{-10}$ for $m_{L^0}=$ 40 GeV.

— Heavy Neutral Lepton MASS LIMITS —

Limits apply only to heavy lepton type given in comment at right of data Listings.

See the "Quark and Lepton Compositeness, Searches for" Listings for limits on radiatively decaying excited neutral leptons, i.e. $\nu^* \to \nu \gamma$.

Kink search in nuclear β decay

 $< \! 3 \times 10^{-6}$

High-sensitivity follow-up experiments show that indications for a neutrino with mass $17\ keV$ (Simpson, Hime, and others) were not valid. Accordingly, we no longer list the experiments by these authors and some others which made positive claims of 17 keV neutrino emission. Complete listings are given in the 1994 edition (Physical Review D50 1173 (1994)) and in the 1998 edition (The European Physical Journal C3 1 (1998)). We list below only the best limits on $|U_{ex}|^2$ for each $m_{\nu_{\nu}}$. See WIETFELDT 96 for a comprehensive review.

⁶ These results assume that neutrinos make up dark matter in the galactic halo.

⁷Limits based on annihilations in the sun and are due to an absence of high energy neutrinos detected in underground experiments.

 $^{^{8}\,\}mathrm{MORI}$ 92B results assume that neutrinos make up dark matter in the galactic halo. Limits based on annihilations in earth are also given.

 $^{^9\,\}mathrm{REUSSER}$ 91 uses existing $\beta\beta$ detector (see FISHER 89) to search for CDM Dirac

 $^{^{\}rm 10}\,{\rm ENQVIST}$ 89 argue that there is no cosmological upper bound on heavy neutrinos.

 $^{^{12}}$ BRYMAN 83B obtain upper limits from both direct peak search and analysis of B($\pi
ightarrow$ $e\nu)/B(\pi \to \mu \nu)$. Latter limits are not listed, except for this entry (i.e. — we list the most stringent limits for given mass).

 $^{^{13}}$ Analysis of $(\pi^+ \to~e^+\,\nu_e)/(\pi^+ \to~\mu^+\,\nu_\mu)$ and $(K^+ \to~e^+\,\nu_e)/(K^+ \to~\mu^+\,\nu_\mu)$ decay ratios.

 $^{^{14}}$ Analysis of $(K^+ \rightarrow e^+ \nu_e)$ spectrum.

 $^{^{16}\,\}mathrm{GALEAZZI}$ 01 use an cryogenic microcalorimeter to search for mass 50–1000 eV neutrino admixtures using the 187 Re beta spectrum with 2.4 keV endpoint. They derive limits for the admixture of heavy neutrinos, ranging from 9×10^{-3} for mass 1 keV to 0.116 for mass 100 eV. This is a significant improvement with respect to HIDDEMANN 95, especially for masses below \sim 500 MeV, where the limit is about a factor of \sim 2 higher.

 $^{^{17}}$ HOLZSCHUH 00 use an iron-free eta spectrometer to measure the 35 S eta decay spectrum. An analysis of the spectrum in the energy range 56–173 keV is used to derive limits for the admixture of heavy neutrinos. This extends the range of neutrino masses explored in HOLZSCHUH 99.

 $^{^{18}}$ DRAGOUN 99 analyze the eta decay spectrum of 241 Pu in the energy range 0.2–9.2 keV to derive limits for the admixture of heavy neutrinos. It is not competitive with

 $^{^{19}}$ HOLZSCHUH 99 use an iron-free eta spectrometer to measure the 63 Nieta decay spectrum. An analysis of the spectrum in the energy rage 33–67.8 keV is used to derive limits for the admixture of heavy neutrinos.

 $^{^{20}}$ HINDI 98 obtain a limit on heavy neutrino admixture from EC decay of 37 Ar by measuring the time-of-flight distribution of the recoiling ions in coincidence with x-rays or Auger electrons. The authors report upper limit for $|U_{\rm ex}|^2$ of $\approx 3\%$ for $m_{\nu_{\chi}} = 500$ keV, 1% for $m_{\nu_{
m v}}$ =550 keV, 2% for $m_{\nu_{
m v}}$ =600 keV, and 4% for m_{χ} =650 keV. Their reported limits for $m_{\nu_{\nu}} \leq 450$ keV are inferior to the limits of SCHRECKENBACH 83.

 $^{^{21}}$ In the beta spectrum from tritium eta decay nonvanishing or mixed $m_{\overline{
u}_1}$ state in the mass region 0.01-4 keV. For $m_{\nu_{\nu}}$ <1 keV, their upper limit on $|U_{\rm ex}|^2$ becomes less

²² KALBFLEISCH 93 extends the 17 keV neutrino search of BAHRAN 92, using an improved proportional chamber to which a small amount of $^3{\rm H}$ is added. Systematics are significantly reduced, allowing for an improved upper limit. The authors give a 99% confidence limit on $|U_{e\, X}|^2$ as a function of m_{ν_X} in the range from 13.5 keV to 17.5 keV. See also the related papers BAHRAN 93, BAHRAN 93B, and BAHRAN 95 on theoretical aspects of beta spectra and fitting methods for heavy neutrinos.

²³ MORTARA 93 limit is from study using a high-resolution solid-state detector with a superconducting solenoid. The authors note that "The sensitivity to neutrino mass is verified by measurement with a mixed source of 35 S and 14 C, which artificially produces a distortion in the beta spectrum similar to that expected from the massive neutrino."

 $^{^{24}\,\}mathrm{DEUTSCH}$ 90 search for emission of heavy $\overline{\nu}_e$ in super-allowed beta decay of $^{20}\mathrm{F}$ by spectral analysis of the electrons.

 $^{^{25}}$ This limit was taken from the figure 3 of APALIKOV 85; the text gives a more restrictive limit of 1.7 $\times 10^{-3}$ at CL $\,=\,90\%$

 $^{^{26}}$ SCHRECKENBACH 83 is a combined measurement of the β^+ and β^- spectrum.

 $^{^{27}}$ SHROCK 80 was a retroactive analysis of data on several superallowed eta decays to search for kinks in the Kurie plot.

 $^{^{28}\,\}mathrm{Application}$ of test to search for kinks in β decay Kurie plots.

- 29 BACK 03A searched for heavy neutrinos emitted from 8 B decay in the Sun using the decay $\nu_{h} o \nu_{e} \, e^{+} \, e^{-}$ in the Counting Test Facility (the prototype of the Borexino detector) and obtained limits on heavy neutrino admixture for the ν_{h} mass range 1.1–12
- 30 ABREU 97I long-lived $\nu_{\rm X}$ analysis. Short-lived analysis extends limit to lower masses with decreasing sensitivity except at 3.5 GeV, where the limit is the same as at 6 GeV.
- 31 HAGNER 95 obtain limits on heavy neutrino admixture from the decay $u_h
 ightarrow \,
 u_e \, e^+ \, e^$ at a nuclear reactor for the ν_h mass range 2–9 MeV.
- 32 BARANOV 93 is a search for neutrino decays into $e^+e^-\nu_e$ using a beam dump experiment at the 70 GeV Serpukhov proton synchrotron. The limits are not as good as those achieved earlier by BERGSMA 83 and BERNARDI 86, BERNARDI 88.
- $^{
 m 33}\,{
 m BURCHAT}$ 90 includes the analyses reported in JUNG 90, ABRAMS 89c, and WENDT 87.
- 34 OBERAUER 87 bounds from search for u
 ightarrow
 u'ee decay mode using reactor (anti)neutrinos.
- 35 COOPER-SARKAR 85 also give limits based on model-dependent assumptions for ν_{τ} flux. We do not list these. Note that for this bound to be nontrivial, x is not equal to 3, i.e. ν_{χ} cannot be the dominant mass eigenstate in ν_{τ} since $m_{\nu_{3}}$ <70 MeV (ALBRECHT 85). Also, of course, x is not equal to 1 or 2, so a fourth generation would be required for this bound to be nontrivial.
- 36 BERGSMA 83B also quote limits on $\lfloor U_{e3} \rfloor^2$ where the index 3 refers to the mass eigenstate dominantly coupled to the τ . Those limits were based on assumptions about the D_S mass and $D_S \rightarrow ~\tau \nu_{\tau}$ branching ratio which are no longer valid. See COOPER-SARKAR 85.

- $37\,\mathrm{ASTIER}$ 02 search for anomalous pion decay into a 33.9 MeV neutral particle. No evidence was found and the sensitivity to the branching ratio $\mathrm{B}(\pi\to\mu X)\cdot\mathrm{B}(X\to\nu e^+e^-)$ is as low as 3.7×10^{-15} , depending on the X lifetime.
- 38 DAUM 00 search for anomalous pion decay into a 33.9 MeV neutral particle that might be responsible for the time-distribution anomaly observed by the KARMEN Collaboration.
- 39 FORMAGGIO 00 search for anomalous pion decay into a 33.9 MeV neutral particle $\it Q^{0}$ That might be responsible for the time-distribution anomaly observed by the KARMEN Collaboration. In the E815 (NuTeV) experiment at Fermilab no evidence was found, with sensitivity for the pion branching ratio B($\pi \to \mu Q^0$)·B($Q^0 \to \text{visible}$) as low as
- 40 ASSAMAGAN 98 obtain a limit on heavy neutrino admixture from π^+ decay essentially at rest, by measuring with good resolution the momentum distribution of the muons. However, the search uses an ad hoc shape correction. The authors report upper limit for $|U_{\mu\chi}|^2$ of 0.22 for $m_{\nu}=0.53\,$ MeV, 0.029 for $m_{\nu}=0.75\,$ MeV, and 0.016 for $m_{\nu}=0.05\,$ MeV, and 0.018 for $m_{\nu}=0.05\,$ MeV, 0.018 for $m_{\nu}=0.05\,$ 1.0 MeV at 90%CL.
- $^{41}\,\mathrm{BRYMAN}$ 96 search for massive unconventional neutrinos of mass $m_{
 u_\chi}$ in π^+ decay.
- $^{42}\rm{ARMBRUSTER}$ 95 study the reactions $^{12}\rm{C}(\nu_e,e^-)$ $^{12}\rm{N}$ and $^{12}\rm{C}(\nu,\nu')$ $^{12}\rm{C}^*$ induced by neutrinos from π^+ and μ^+ decay at the ISIS neutron spallation source at the Rutherford-Appleton laboratory. An anomaly in the time distribution can be interpreted as the decay $\pi^+\to~\mu^+\nu_X$, where ν_X is a neutral weakly interacting particle with mass ≈ 33.9 MeV and spin 1/2. The lower limit to the branching ratio is a function of the lifetime of the new massive neutral particle, and reaches a minimum of a few $\times\,10^{-16}$ for $\tau_X\sim 5\,\mathrm{s}$.
- 43 From experiments of π^+ and π^- decay in flight at PSI, to check the claim of the KARMEN Collaboration quoted above (ARMBRUSTER 95).
- ⁴⁴ $\pi^+ \rightarrow \ \mu^+ \, \nu_{\mu}$ peak search experiment.
- 45 K $^+$ ightarrow $\mu^+\,
 u_\mu$ peak search experiment.

 $^{^{53} \}text{ABREU 97} \text{l long-lived } \nu_{\text{X}}$ analysis. Short-lived analysis extends limit to lower masses with decreasing sensitivity except at 3.5 GeV, where the limit is the same as at 6 GeV.

⁵⁴ VILAIN 95c is a search for the decays of heavy isosinglet neutrinos produced by neutral current neutrino interactions. Limits were quoted for masses in the range from 0.3 to 24 GeV. The best limit is listed above.

⁵⁵ BURCHAT 90 includes the analyses reported in JUNG 90, ABRAMS 89c, and WENDT 87.

 $^{^{56}\,\}mathrm{See}$ also limits on $|\mathit{U}_{3x}|$ from WENDT 87.

 $^{^{57}}$ COOPER-SARKAR 85 also give limits based on model-dependent assumptions for ν_{τ} flux. We do not list these. Note that for this bound to be nontrivial, x is not equal to 3, i.e. ν_{X} cannot be the dominant mass eigenstate in ν_{τ} since $m_{\nu_{3}}~<$ 70 MeV (ALBRECHT 851). Also, of course, x is not equal to 1 or 2, so a fourth generation would be required for this bound to be nontrivial.

 $^{^{59}}$ ABREU 971 long-lived $\nu_{\rm X}$ analysis. Short-lived analysis extends limit to lower masses with decreasing sensitivity.

⁶⁰BURCHAT 90 includes the analyses reported in JUNG 90, ABRAMS 89c, and WENDT 87.

QUARK MASSES

Updated Jan 2012 by A.V. Manohar (University of California, San Diego) and C.T. Sachrajda (University of Southampton).

A. Introduction

This note discusses some of the theoretical issues relevant for the determination of quark masses, which are fundamental parameters of the Standard Model of particle physics. Unlike the leptons, quarks are confined inside hadrons and are not observed as physical particles. Quark masses therefore cannot be measured directly, but must be determined indirectly through their influence on hadronic properties. Although one often speaks loosely of quark masses as one would of the mass of the electron or muon, any quantitative statement about the value of a quark mass must make careful reference to the particular theoretical framework that is used to define it. It is important to keep this scheme dependence in mind when using the quark mass values tabulated in the data listings.

Historically, the first determinations of quark masses were performed using quark models. The resulting masses only make sense in the limited context of a particular quark model, and cannot be related to the quark mass parameters of the Standard Model. In order to discuss quark masses at a fundamental level, definitions based on quantum field theory be used, and the purpose of this note is to discuss these definitions and the corresponding determinations of the values of the masses.

B. Mass parameters and the QCD Lagrangian

The QCD [1] Lagrangian for N_F quark flavors is

$$\mathcal{L} = \sum_{k=1}^{N_F} \overline{q}_k (i \not\!\!D - m_k) q_k - \frac{1}{4} G_{\mu\nu} G^{\mu\nu} , \qquad (1)$$

where $\not{\!\! D} = (\partial_{\mu} - igA_{\mu}) \gamma^{\mu}$ is the gauge covariant derivative, A_{μ} is the gluon field, $G_{\mu\nu}$ is the gluon field strength, m_k is the mass parameter of the $k^{\rm th}$ quark, and q_k is the quark Dirac field. After renormalization, the QCD Lagrangian Eq. (1) gives finite values for physical quantities, such as scattering amplitudes. Renormalization is a procedure that invokes a subtraction scheme to render the amplitudes finite, and requires the introduction of a dimensionful scale parameter μ . The mass parameters in the QCD Lagrangian Eq. (1) depend on the renormalization scheme used to define the theory, and also on the scale parameter μ . The most commonly used renormalization scheme for QCD perturbation theory is the $\overline{\rm MS}$ scheme.

The QCD Lagrangian has a chiral symmetry in the limit that the quark masses vanish. This symmetry is spontaneously broken by dynamical chiral symmetry breaking, and explicitly broken by the quark masses. The nonperturbative scale of dynamical chiral symmetry breaking, Λ_{χ} , is around 1 GeV [2]. It is conventional to call quarks heavy if $m > \Lambda_{\chi}$, so that explicit

chiral symmetry breaking dominates (c, b, and t quarks are heavy), and light if $m < \Lambda_{\chi}$, so that spontaneous chiral symmetry breaking dominates (u, d and s quarks are light). The determination of light- and heavy-quark masses is considered separately in sections D and E below.

At high energies or short distances, nonperturbative effects, such as chiral symmetry breaking, become small and one can, in principle, determine quark masses by analyzing mass-dependent effects using QCD perturbation theory. Such computations are conventionally performed using the $\overline{\rm MS}$ scheme at a scale $\mu\gg\Lambda_\chi$, and give the $\overline{\rm MS}$ "running" mass $\overline{m}(\mu)$. We use the $\overline{\rm MS}$ scheme when reporting quark masses; one can readily convert these values into other schemes using perturbation theory.

The μ dependence of $\overline{m}(\mu)$ at short distances can be calculated using the renormalization group equation,

$$\mu^{2} \frac{\mathrm{d}\overline{m}(\mu)}{\mathrm{d}\mu^{2}} = -\gamma(\overline{\alpha}_{s}(\mu)) \,\overline{m}(\mu), \qquad (2)$$

where γ is the anomalous dimension which is now known to four-loop order in perturbation theory [3,4]. $\overline{\alpha}_s$ is the coupling constant in the $\overline{\rm MS}$ scheme. Defining the expansion coefficients γ_r by

$$\gamma\left(\overline{\alpha}_{s}\right) \equiv \sum_{r=1}^{\infty} \gamma_{r} \left(\frac{\overline{\alpha}_{s}}{4\pi}\right)^{r},$$

the first four coefficients are given by

$$\begin{split} \gamma_1 &= 4, \\ \gamma_2 &= \frac{202}{3} - \frac{20N_L}{9}, \\ \gamma_3 &= 1249 + \left(-\frac{2216}{27} - \frac{160}{3}\zeta\left(3\right)\right)N_L - \frac{140}{81}N_L^2, \\ \gamma_4 &= \frac{4603055}{162} + \frac{135680}{27}\zeta\left(3\right) - 8800\zeta\left(5\right) \\ &+ \left(-\frac{91723}{27} - \frac{34192}{9}\zeta\left(3\right) + 880\zeta\left(4\right) + \frac{18400}{9}\zeta\left(5\right)\right)N_L \\ &+ \left(\frac{5242}{243} + \frac{800}{9}\zeta\left(3\right) - \frac{160}{3}\zeta\left(4\right)\right)N_L^2 \\ &+ \left(-\frac{332}{243} + \frac{64}{27}\zeta\left(3\right)\right)N_L^3, \end{split}$$

where N_L is the number of active light quark flavors at the scale μ , i.e. flavors with masses $< \mu$, and ζ is the Riemann zeta function ($\zeta(3) \simeq 1.2020569$, $\zeta(4) \simeq 1.0823232$, and $\zeta(5) \simeq 1.0369278$). In addition, as the renormalization scale crosses quark mass thresholds one needs to match the scale dependence of m below and above the threshold. There are finite threshold corrections; the necessary formulae can be found in Ref. [5].

The quark masses for light quarks discussed so far are often referred to as current quark masses. Nonrelativistic quark models use constituent quark masses, which are of order $350\,\mathrm{MeV}$ for the u and d quarks. Constituent quark masses

Quarks

model the effects of dynamical chiral symmetry breaking, and are not related to the quark mass parameters m_k of the QCD Lagrangian Eq. (1). Constituent masses are only defined in the context of a particular hadronic model.

C. Lattice Gauge Theory

The use of the lattice simulations for ab initio determinations of the fundamental parameters of QCD, including the coupling constant and quark masses (except for the top-quark mass) is a very active area of research (see the review on Lattice Quantum Chromodynamics in this Review). Here we only briefly recall those features which are required for the determination of quark masses. In order to determine the lattice spacing (a, i.e. the distance between neighboring points of the lattice) and quark masses, one computes a convenient and appropriate set of physical quantities (frequently chosen to be a set of hadronic masses) for a variety of input values of the quark masses. The true (physical) values of the quark masses are those which correctly reproduce the set of physical quantities being used for the calibration.

The values of the quark masses obtained directly in lattice simulations are bare quark masses, corresponding to a particular discretization of QCD and with the lattice spacing as the ultraviolet cut-off. In order for these results to be useful in phenomenological applications, it is necessary to relate them to renormalized masses defined in some standard renormalization scheme such as \overline{MS} . Provided that both the ultraviolet cut-off a^{-1} and the renormalization scale are much greater than $\Lambda_{\rm OCD}$, the bare and renormalized masses can be related in perturbation theory. However, in order to avoid uncertainties due to the unknown higher-order coefficients in lattice perturbation theory, most results obtained recently use non-perturbative renormalization to relate the bare masses to those defined in renormalization schemes which can be simulated directly in lattice QCD (e.g. those obtained from quark and gluon Green functions at specified momenta in the Landau gauge [50] or those defined using finite-volume techniques and the Schrödinger functional [51]). The conversation to the $\overline{\rm MS}$ scheme (which cannot be simulated) is then performed using continuum perturbation theory.

The determination of quark masses using lattice simulations is well established and the current emphasis is on the reduction and control of the systematic uncertainties. With improved algorithms and access to more powerful computing resources, the precision of the results has improved immensely in recent years. Particularly pleasing is the observation that results obtained using different formulations of lattice QCD, with different systematic uncertainties, give results which are largely consistent with each other. This gives us broad confidence in the estimates of the systematic errors. As the precision of the results approaches the percent level, more attention will now have to be given to sources of systematic uncertainty which have only been studied in a limited way up to now. In particular most current simulations are performed with degenerate u

and d quarks and without including electromagnetic effects. Vacuum polarisation effects are included with $N_f=2+1$ or $N_f=2$ flavors of sea quarks, although simulations with charm sea quarks are now beginning. In earlier reviews, results were presented from simulations in which vacuum polarization effects were completely neglected (this is the so-called quenched approximation), leading to systematic uncertainties which could not be estimated reliably. It is no longer necessary to include quenched results in compilations of quark masses.

D. Light quarks

In this section we review the determination of the masses of the light quarks u, d and s from lattice simulations and then discuss the consequences of the approximate chiral symmetry.

Lattice Gauge Theory: The most reliable determinations of the strange quark mass m_s and of the average of the up and down quark masses $m_{ud} = (m_u + m_d)/2$ are obtained from lattice simulations. As explained in section C above, the simulations are performed with degenerate up and down quarks $(m_u = m_d)$ and so it is the average which is obtained directly from the computations. Below we discuss attempts to derive m_u and m_d separately using lattice results in combination with other techniques, but here we briefly present our estimate of the current status of the latest lattice results. Based largely on references [19–26], which have among the most reliable estimates of the systematic errors, our summary is

$$\overline{m}_s = (93.5 \pm 2.5) \,\text{MeV}, \quad \overline{m}_{ud} = (3.40 \pm 0.25) \,\text{MeV}$$
 (3)

and

$$\frac{\overline{m}_s}{\overline{m}_{ud}} = 27.5 \pm 0.3. \tag{4}$$

The masses are given in the $\overline{\rm MS}$ scheme at a renormalization scale of 2 GeV. Because the errors are dominated by systematics, these results are not simply the combinations of all the results in quadrature, but include a judgement of the remaining uncertainties. Since the different collaborations use different formulations of lattice QCD, the (relatively small) variations of the results between the groups provides important information about the reliability of the estimates.

Current lattice simulations are performed in the isospin symmetry limit, i.e. with the masses of the up and down quarks equal, $m_u = m_d \equiv m_{ud}$ and, apart from Refs. [31,32], electromagnetic effects are not included in the simulation. It is the average of the physical up and down quark masses which is determined directly. In order to estimate m_u and m_d separately, further experimental and theoretical inputs have to be included. Recent studies which combine lattice data with studies of isospin breaking effects using chiral perturbation theory and phenomenology include those by the MILC [20,27] and BMW [22,23] collaborations and by the Flavianet Lattice Averaging Group [32]. Based on these results we summarise the current status as

$$\frac{\overline{m}_u}{\overline{m}_d} = 0.46(5)$$
, $\overline{m}_u = 2.15(15) \,\text{MeV}$, $\overline{m}_d = 4.70(20) \,\text{MeV}$. (5)

Again the masses are given in the $\overline{\rm MS}$ scheme at a renormalization scale of 2 GeV. Of particular importance is the fact that $m_u \neq 0$ since there would have been no strong CP problem had m_u been equal to zero.

The quark mass ranges for the light quarks given in the listings combine the lattice and continuum values and use the PDG method for determining errors given in the introductory notes.

Chiral Perturbation Theory: For light quarks, one can use the techniques of chiral perturbation theory [6–8] to extract quark mass ratios. The mass term for light quarks in the QCD Lagrangian is

$$\overline{\Psi}M\Psi = \overline{\Psi}_L M\Psi_R + \overline{\Psi}_R M^{\dagger} \Psi_L, \tag{6}$$

where M is the light quark mass matrix,

$$M = \begin{pmatrix} m_u & 0 & 0\\ 0 & m_d & 0\\ 0 & 0 & m_s \end{pmatrix}, \tag{7}$$

 $\Psi=(u,d,s)$, and L and R are the left- and right-chiral components of Ψ given by $\Psi_{L,R}=P_{L,R}\Psi,\ P_L=(1-\gamma_5)/2,$ $P_R=(1+\gamma_5)/2$. The mass term is the only term in the QCD Lagrangian that mixes left- and right-handed quarks. In the limit $M\to 0$, there is an independent $SU(3)\times U(1)$ flavor symmetry for the left- and right-handed quarks. The vector U(1) symmetry is baryon number; the axial U(1) symmetry of the classical theory is broken in the quantum theory due to the anomaly. The remaining $G_\chi=\mathrm{SU}(3)_L\times\mathrm{SU}(3)_R$ chiral symmetry of the QCD Lagrangian is spontaneously broken to $SU(3)_V$, which, in the limit $M\to 0$, leads to eight massless Goldstone bosons, the π 's, K's, and η .

The symmetry G_χ is only an approximate symmetry, since it is explicitly broken by the quark mass matrix M. The Goldstone bosons acquire masses which can be computed in a systematic expansion in M, in terms of low-energy constants, which are unknown nonperturbative parameters of the effective theory, and are not fixed by the symmetries. One treats the quark mass matrix M as an external field that transforms under G_χ as $M \to LMR^\dagger$, where $\Psi_L \to L\Psi_L$ and $\Psi_R \to R\Psi_R$ are the $SU(3)_L$ and $SU(3)_R$ transformations, and writes down the most general Lagrangian invariant under G_χ . Then one sets M to its given constant value Eq. (7), which implements the symmetry breaking. To first order in M one finds that [9]

$$m_{\pi^0}^2 = B (m_u + m_d) ,$$

$$m_{\pi^{\pm}}^2 = B (m_u + m_d) + \Delta_{em} ,$$

$$m_{K^0}^2 = m_{\overline{K}^0}^2 = B (m_d + m_s) ,$$

$$m_{K^{\pm}}^2 = B (m_u + m_s) + \Delta_{em} ,$$

$$m_{\eta}^2 = \frac{1}{3} B (m_u + m_d + 4m_s) ,$$
(8)

with two unknown constants B and $\Delta_{\rm em}$, the electromagnetic mass difference. From Eq. (8), one can determine the quark mass ratios [9]

$$\begin{split} \frac{m_u}{m_d} &= \frac{2m_{\pi^0}^2 - m_{\pi^+}^2 + m_{K^+}^2 - m_{K^0}^2}{m_{K^0}^2 - m_{K^+}^2 + m_{\pi^+}^2} = 0.56 , \\ \frac{m_s}{m_d} &= \frac{m_{K^0}^2 + m_{K^+}^2 - m_{\pi^+}^2}{m_{K^0}^2 + m_{\pi^+}^2 - m_{K^+}^2} = 20.2 , \end{split} \tag{9}$$

to lowest order in chiral perturbation theory, with an error which will be estimated below. Since the mass ratios extracted using chiral perturbation theory use the symmetry transformation property of M under the chiral symmetry G_{χ} , it is important to use a renormalization scheme for QCD that does not change this transformation law. Any mass independent subtraction scheme such as $\overline{\rm MS}$ is suitable. The ratios of quark masses are scale independent in such a scheme, and Eq. (9) can be taken to be the ratio of $\overline{\rm MS}$ masses. Chiral perturbation theory cannot determine the overall scale of the quark masses, since it uses only the symmetry properties of M, and any multiple of M has the same G_{χ} transformation law as M.

Chiral perturbation theory is a systematic expansion in powers of the light quark masses. The typical expansion parameter is $m_K^2/\Lambda_\chi^2 \sim 0.25$ if one uses SU(3) chiral symmetry, and $m_\pi^2/\Lambda_\chi^2 \sim 0.02$ if instead one uses SU(2) chiral symmetry. Electromagnetic effects at the few percent level also break SU(2) and SU(3) symmetry. The mass formulæ Eq. (8) were derived using SU(3) chiral symmetry, and are expected to have approximately a 25% uncertainty due to second order corrections. This estimate of the uncertainty is consistent with the lattice results found in Eq. (3) and Eq. (4).

There is a subtlety which arises when one tries to determine quark mass ratios at second order in chiral perturbation theory. The second order quark mass term [10]

$$\left(M^{\dagger}\right)^{-1} \det M^{\dagger} \tag{10}$$

(which can be generated by instantons) transforms in the same way under G_{χ} as M. Chiral perturbation theory cannot distinguish between M and $\left(M^{\dagger}\right)^{-1} \det M^{\dagger}$; one can make the replacement $M \to M(\lambda) = M + \lambda M \left(M^{\dagger}M\right)^{-1} \det M^{\dagger}$ in the chiral Lagrangian,

$$M(\lambda) = \operatorname{diag}(m_u(\lambda), m_d(\lambda), m_s(\lambda))$$

$$= \operatorname{diag} (m_u + \lambda m_d m_s, \ m_d + \lambda m_u m_s, \ m_s + \lambda m_u m_d), (11)$$

and leave all observables unchanged.

The combination

$$\left(\frac{m_u}{m_d}\right)^2 + \frac{1}{Q^2} \left(\frac{m_s}{m_d}\right)^2 = 1 \tag{12}$$

where

$$Q^2 = \frac{m_s^2 - \hat{m}^2}{m_d^2 - m_u^2}, \qquad \hat{m} = \frac{1}{2} (m_u + m_d),$$

Quarks

is insensitive to the transformation in Eq. (11). Eq. (12) gives an ellipse in the $m_u/m_d-m_s/m_d$ plane. The ellipse is well-determined by chiral perturbation theory, but the exact location on the ellipse, and the absolute normalization of the quark masses, has larger uncertainties. Q is determined to be in the range 21–25 from $\eta \to 3\pi$ decay and the electromagnetic contribution to the K^+-K^0 and $\pi^+-\pi^0$ mass differences [11].

The absolute normalization of the quark masses cannot be determined using chiral perturbation theory. Other methods, such as lattice simulations discussed above or spectral function sum rules [12,13] for hadronic correlation functions, which we review next are necessary.

Sum Rules: Sum rule methods have been used extensively to determine quark masses and for illustration we briefly discuss here their application to hadronic τ decays [14]. Other applications involve very similar techniques.

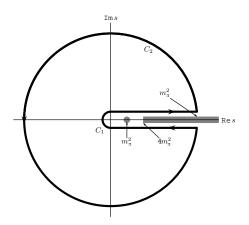

Figure 1: The analytic structure of $\Pi(s)$ in the complex s-plane. The contours C_1 and C_2 are the integration contours discussed in the text.

The experimentally measured quantity is R_{τ} ,

$$\frac{\mathrm{d}R_{\tau}}{\mathrm{d}s} = \frac{\mathrm{d}\Gamma/\mathrm{d}s \left(\tau^{-} \to \text{hadrons} + \nu_{\tau}(\gamma)\right)}{\Gamma\left(\tau^{-} \to e^{-}\overline{\nu}_{e}\nu_{\tau}(\gamma)\right)}$$
(13)

the hadronic invariant mass spectrum in semihadronic τ decay, normalized to the leptonic τ decay rate. It is useful to define q as the total momentum of the hadronic final state, so $s=q^2$ is the hadronic invariant mass. The total hadronic τ decay rate R_{τ} is then given by integrating $\mathrm{d}R_{\tau}/\mathrm{d}s$ over the kinematically allowed range $0 \le s \le M_{\tau}^2$.

 R_{τ} can be written as

$$R_{\tau} = 12\pi \int_{0}^{M_{\tau}^{2}} \frac{\mathrm{d}s}{M_{\tau}^{2}} \left(1 - \frac{s}{M_{\tau}^{2}}\right)^{2} \times \left[\left(1 + 2\frac{s}{M_{\tau}^{2}}\right) \operatorname{Im}\Pi^{T}(s) + \operatorname{Im}\Pi^{L}(s)\right]$$
(14)

where $s=q^2$, and the hadronic spectral functions $\Pi^{L,T}$ are defined from the time-ordered correlation function of two weak

currents is the time-ordered correlator of the weak interaction current $(j^{\mu}(x))$ and $j^{\nu}(0)$ by

$$\Pi^{\mu\nu}(q) = i \int \mathrm{d}^4 x \; e^{iq \cdot x} \left\langle 0 \right| T \left(j^{\mu}(x) j^{\nu}(0)^{\dagger} \right) \left| 0 \right\rangle, \tag{15}$$

$$\Pi^{\mu\nu}(q) = (-g^{\mu\nu} + q^{\mu}q^{\nu})\Pi^{T}(s) + q^{\mu}q^{\nu}\Pi^{L}(s), \tag{16}$$

and the decomposition Eq. (16) is the most general possible structure consistent with Lorentz invariance.

By the optical theorem, the imaginary part of $\Pi^{\mu\nu}$ is proportional to the total cross-section for the current to produce all possible states. A detailed analysis including the phase space factors leads to Eq. (14). The spectral functions $\Pi^{L,T}(s)$ are analytic in the complex s plane, with singularities along the real axis. There is an isolated pole at $s=m_{\pi}^2$, and single- and multi-particle singularities for $s \geq 4m_{\pi}^2$, the twoparticle threshold. The discontinuity along the real axis is $\Pi^{L,T}(s+i0^+) - \Pi^{L,T}(s-i0^+) = 2i \text{Im } \Pi^{L,T}(s)$. As a result, Eq. (14) can be rewritten with the replacement Im $\Pi^{L,T}(s) \rightarrow$ $-i\Pi^{L,T}(s)/2$, and the integration being over the contour C_1 . Finally, the contour C_1 can be deformed to C_2 without crossing any singularities, and so leaving the integral unchanged. One can derive a series of sum rules analogous to Eq. (14) by weighting the differential τ hadronic decay rate by different powers of the hadronic invariant mass,

$$R_{\tau}^{kl} = \int_0^{M_{\tau}^2} \mathrm{d}s \, \left(1 - \frac{s}{M_{\tau}^2}\right)^k \left(\frac{s}{M_{\tau}^2}\right)^l \frac{\mathrm{d}R_{\tau}}{\mathrm{d}s} \tag{17}$$

where dR_{τ}/ds is the hadronic invariant mass distribution in τ decay normalized to the leptonic decay rate. This leads to the final form of the sum rule(s),

$$R_{\tau}^{kl} = -6\pi i \int_{C_2} \frac{\mathrm{d}s}{M_{\tau}^2} \left(1 - \frac{s}{M_{\tau}^2} \right)^{2+k} \left(\frac{s}{M_{\tau}^2} \right)^l \times \left[\left(1 + 2 \frac{s}{M_{\tau}^2} \right) \Pi^T(s) + \Pi^L(s) \right]. \tag{18}$$

The manipulations so far are completely rigorous and exact, relying only on the general analytic structure of quantum field theory. The left-hand side of the sum rule Eq. (18) is obtained from experiment. The right hand-side can be computed for s far away from any physical cuts using the operator product expansion (OPE) for the time-ordered product of currents in Eq. (15), and QCD perturbation theory. The OPE is an expansion for the time-ordered product Eq. (15) in a series of local operators, and is an expansion about the $q \to \infty$ limit. It gives $\Pi(s)$ as an expansion in powers of $\alpha_s(s)$ and $\Lambda_{\rm QCD}^2/s$, and is valid when s is far (in units of $\Lambda_{\rm QCD}^2$) from any singularities in the complex s-plane.

The OPE gives $\Pi(s)$ as a series in α_s , quark masses, and various non-perturbative vacuum matrix element. By computing $\Pi(s)$ theoretically, and comparing with the experimental values of R_{τ}^{kl} , one determines various parameters such as α_s and the quark masses. The theoretical uncertainties in using Eq. (18) arise from neglected higher order corrections (both

Quark Particle Listings Quarks

perturbative and non-perturbative), and because the OPE is no longer valid near the real axis, where Π has singularities. The contribution of neglected higher order corrections can be estimated as for any other perturbative computation. The error due to the failure of the OPE is more difficult to estimate. In Eq. (18), the OPE fails on the endpoints of C_2 that touch the real axis at $s=M_\tau^2$. The weight factor $(1-s/M_\tau^2)$ in Eq. (18) vanishes at this point, so the importance of the endpoint can be reduced by choosing larger values of k.

E. Heavy quarks

For heavy-quark physics one can exploit the fact that $m_Q \gg \Lambda_{\rm QCD}$ to construct effective theories (m_Q) is the mass of the heavy quark Q). The masses and decay rates of hadrons containing a single heavy quark, such as the B and D mesons can be determined using the heavy quark effective theory (HQET) [33]. The theoretical calculations involve radiative corrections computed in perturbation theory with an expansion in $\alpha_s(m_Q)$ and non-perturbative corrections with an expansion in powers of $\Lambda_{\rm QCD}/m_Q$. Due to the asymptotic nature of the QCD perturbation series, the two kinds of corrections are intimately related; an example of this are renormalon effects in the perturbative expansion which are associated with non-perturbative corrections.

Systems containing two heavy quarks such as the Υ or J/Ψ are treated using non-relativistic QCD (NRQCD) [34]. The typical momentum and energy transfers in these systems are $\alpha_s m_Q$, and $\alpha_s^2 m_Q$, respectively, so these bound states are sensitive to scales much smaller than m_Q . However, smeared observables, such as the cross-section for $e^+e^- \to \bar{b}b$ averaged over some range of s that includes several bound state energy levels, are better behaved and only sensitive to scales near m_Q . For this reason, most determinations of the c,b quark masses using perturbative calculations compare smeared observables with experiment [35–37].

There are many continuum extractions of the c and b quark masses, some with quoted errors of 10 MeV or smaller. There are systematic effects of comparable size, which are typically not included in these error estimates. Reference [30], for example, shows that even though the error estimate of m_c using the rapid convergence of the α_s perturbation series is only a few MeV, the central value of m_c can differ by a much larger amount depending on which algorithm (all of which are formally equally good) is used to determine m_c from the data. This leads to a systematic error from perturbation theory of around 20 MeV for the c quark and 25 MeV for the b quark. Electromagnetic effects, which also are important at this precision, are often not included. For this reason, we inflate the errors on the continuum extractions of m_c and m_b . The average values of m_c and m_b from continuum determinations are (see Sec. G for the 1S scheme)

$$\overline{m}_c(\overline{m}_c) = (1.275 \pm 0.025) \,\mathrm{GeV}$$

$$\overline{m}_b(\overline{m}_b) = (4.18 \pm 0.03) \,\mathrm{GeV} \,, \quad m_b^{1\mathrm{S}} = (4.65 \pm 0.03) \,\mathrm{GeV} \,.$$

Lattice simulations of QCD lead to discretization errors which are powers of $m_Q a$ (modulated by logarithms); the power depends on the formulation of lattice QCD being used and in most cases is quadratic. Clearly these errors can be reduced by performing simulations at smaller lattice spacings, but also by using *improved* discretizations of the theory. Recently, with more powerful computing resources, better algorithms and techniques, it has become possible to perform simulations in the charm quark region and beyond, also decreasing the extrapolation which has to be performed to reach the b-quark. A novel approach proposed in [52] has been to compare the lattice results for moments of correlation functions of $c\overline{c}$ quark-bilinear operators to perturbative calculations of the same quantities at 4-loop order. In this way both the strong coupling constant and the charm quark mass can be determined with remarkably small errors; in particular $\overline{m}_c(\overline{m}_c) = 1.273(6) \,\text{GeV}$ [26]. This lattice determination also uses the perturbative expression for the current-current correlator, and so has the perturbation theory systematic error discussed above.

Traditionally, the main approach to controlling the discretization errors in lattice studies of heavy quark physics is to perform simulations of the effective theories such as HQET and NRQCD. This remains an important technique, both in its own right and in providing additional information for extrapolations from lower masses to the bottom region. Using effective theories, m_b is obtained from what is essentially a computation of the difference of $M_{H_b}-m_b$, where M_{H_b} is the mass of a hadron H_b containing a b-quark. The relative error on m_b is therefore much smaller than that for $M_{H_b} - m_b$, and this is the reason for the small errors quoted in section G. The principal systematic errors are the matching of the effective theories to QCD and the presence of power divergences in a^{-1} in the $1/m_b$ corrections which have to be subtracted numerically. The use of HQET or NRQCD is less precise for the charm quark, but in this case, as mentioned above, direct QCD simulations have recently become possible.

F. Pole Mass

For an observable particle such as the electron, the position of the pole in the propagator is the definition of its mass. In QCD this definition of the quark mass is known as the pole mass. It is known that the on-shell quark propagator has no infrared divergences in perturbation theory [40,41], so this provides a perturbative definition of the quark mass. The pole mass cannot be used to arbitrarily high accuracy because of nonperturbative infrared effects in QCD. The full quark propagator has no pole because the quarks are confined, so that the pole mass cannot be defined outside of perturbation theory. The relation between the pole mass m_Q and the $\overline{\rm MS}$ mass \overline{m}_Q is known to three loops [42,43,44,45]

$$\begin{split} m_Q &= \overline{m}_Q(\overline{m}_Q) \bigg\{ 1 + \frac{4\overline{\alpha}_s(\overline{m}_Q)}{3\pi} \\ &+ \left[-1.0414 \sum_k \left(1 - \frac{4}{3} \frac{\overline{m}_{Q_k}}{\overline{m}_Q} \right) + 13.4434 \right] \left[\frac{\overline{\alpha}_s(\overline{m}_Q)}{\pi} \right]^2 \end{split}$$

Quark Particle Listings Quarks

+
$$\left[0.6527N_L^2 - 26.655N_L + 190.595\right] \left[\frac{\overline{\alpha}_s(\overline{m}_Q)}{\pi}\right]^3$$
, (19)

where $\overline{\alpha}_s(\mu)$ is the strong interaction coupling constants in the $\overline{\text{MS}}$ scheme, and the sum over k extends over the N_L flavors Q_k lighter than Q. The complete mass dependence of the α_s^2 term can be found in [42]; the mass dependence of the α_s^3 term is not known. For the b-quark, Eq. (19) reads

$$m_b = \overline{m}_b (\overline{m}_b) [1 + 0.09 + 0.05 + 0.03],$$
 (20)

where the contributions from the different orders in α_s are shown explicitly. The two and three loop corrections are comparable in size and have the same sign as the one loop term. This is a signal of the asymptotic nature of the perturbation series [there is a renormalon in the pole mass]. Such a badly behaved perturbation expansion can be avoided by directly extracting the $\overline{\rm MS}$ mass from data without extracting the pole mass as an intermediate step.

G. Numerical values and caveats

The quark masses in the particle data listings have been obtained by using a wide variety of methods. Each method involves its own set of approximations and uncertainties. In most cases, the errors are an estimate of the size of neglected higher-order corrections or other uncertainties. The expansion parameters for some of the approximations are not very small (for example, they are $m_K^2/\Lambda_\chi^2 \sim 0.25$ for the chiral expansion and $\Lambda_{\rm QCD}/m_b \sim 0.1$ for the heavy-quark expansion), so an unexpectedly large coefficient in a neglected higher-order term could significantly alter the results. It is also important to note that the quark mass values can be significantly different in the different schemes.

The heavy quark masses obtained using HQET, QCD sum rules, or lattice gauge theory are consistent with each other if they are all converted into the same scheme and scale. We have specified all masses in the $\overline{\rm MS}$ scheme. For light quarks, the renormalization scale has been chosen to be $\mu = 2 \,\text{GeV}$. The light quark masses at 1 GeV are significantly different from those at $2 \, \text{GeV}$, $\overline{m}(1 \, \text{GeV})/\overline{m}(2 \, \text{GeV}) \sim 1.35$. It is conventional to choose the renormalization scale equal to the quark mass for a heavy quark, so we have quoted $\overline{m}_Q(\mu)$ at $\mu = \overline{m}_Q$ for the c and b quarks. Recent analyses of inclusive B meson decays have shown that recently proposed mass definitions lead to a better behaved perturbation series than for the $\overline{\rm MS}$ mass, and hence to more accurate mass values. We have chosen to also give values for one of these, the b quark mass in the 1S-scheme [46,47]. Other schemes that have been proposed are the PS-scheme [48] and the kinetic scheme [49].

If necessary, we have converted values in the original papers to our chosen scheme using two-loop formulæ. It is important to realized that our conversions introduce significant additional errors. In converting to the $\overline{\rm MS}$ b-quark mass, for example, the three-loop conversions from the 1S and pole masses give values about 40 MeV and 135 MeV lower than the two-loop

conversions. The uncertainty in $\alpha_s(M_Z)=0.1187(20)$ gives an uncertainty of ± 20 MeV and ± 35 MeV respectively in the same conversions. We have not added these additional errors when we do our conversions. The α_s value in the conversion is correlated with the α_s value used in determining the quark mass, so the conversion error is not a simple additional error on the quark mass.

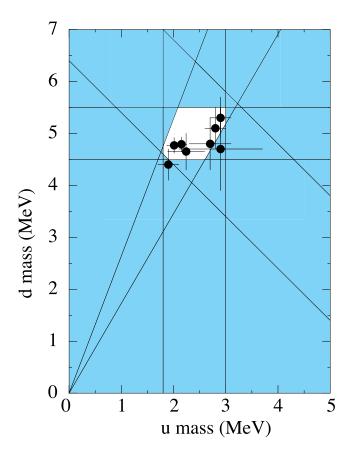

Figure 2: The allowed region (shown in white) for up quark and down quark masses. This region was determined in part from papers reporting values for m_u and m_d (data points shown) and in part from analysis of the allowed ranges of other mass parameters (see Fig. 3). The parameter $(m_u + m_d)/2$ yields the two downward-sloping lines, while m_u/m_d yields the two rising lines originating at (0,0).

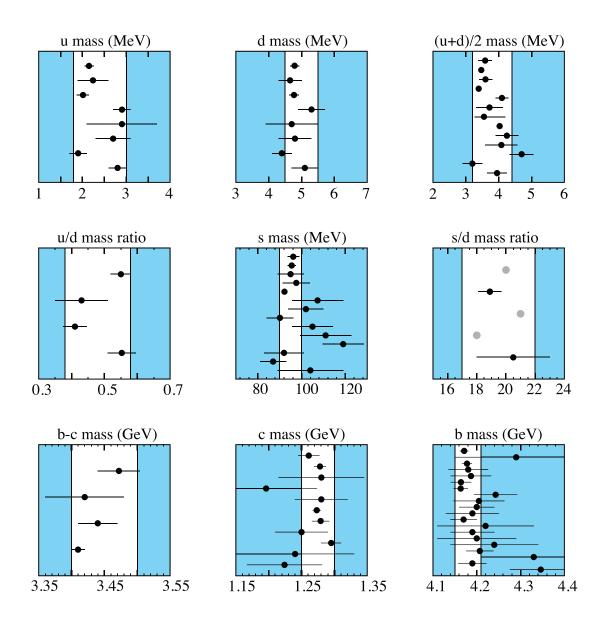

Figure 3. The values of each quark mass parameter taken from the Data Listings. The points are in chronological order with the more recent measurements at the top. Points from papers reporting no error bars are colored grey. The shaded regions indicate values excluded by our evaluations; some regions were determined in part through examination of Fig. 2.

LIGHT QUARKS (u, d, s)

OMITTED FROM SUMMARY TABLE

u-QUARK MASS

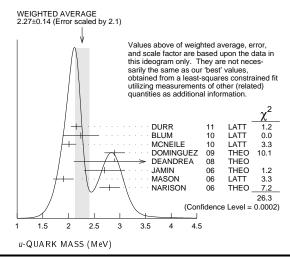

The u-, d-, and s-quark masses are estimates of so-called "current-quark masses," in a mass- independent subtraction scheme such as $\overline{\rm MS}$. The ratios m_u/m_d and m_s/m_d are extracted from pion and kaon masses using chiral symmetry. The estimates of d and u masses are not without controversy and remain under active investigation. Within the literature there are even suggestions that the u-quark could be essentially massless. The s-quark mass is estimated from ${\rm SU}(3)$ splittings in hadron masses.

We have normalized the $\overline{\text{MS}}$ masses at a renormalization scale of $\mu=2$ GeV. Results quoted in the literature at $\mu=1$ GeV have been rescaled by dividing by 1.35. The values of "Our Evaluation" were determined in part via Figures 1 and 2.

Light Quarks (u, d, s)

- $^{21}\mathrm{AOKI}$ 11A determine quark masses from a lattice computation of the hadron spectrum using $N_f=2+1$ dynamical flavors of domain wall fermions
- 22 DURR $^{'}$ 11 determine quark mass from a lattice computation of the meson spectrum using $N_f = 2 + 1$ dynamical flavors. The lattice simulations were done at the physical quark mass, so that extrapolation in the quark mass was not needed.

 23 BLOSSIER 10 determines quark masses from a computation of the hadron spectrum
- using N_f =2 dynamical twisted-mass Wilson fermions.
- 24 DAVIES 10 and MCNEILE 10 determine $\overline{m}_C(\mu)/\overline{m}_S(\mu)=11.85\pm0.16$ using a lattice computation with $N_f=2+1$ dynamical fermions of the pseudoscalar meson masses. Mass \overline{m} is obtained from this using the value of m_C from ALLISON 08 or MCNEILE 10 and the BAZAVOV 10 values for the light quark mass ratio, m_S/\overline{m} .
- $^{25}\, \mathsf{DOMINGUEZ}$ 09 use QCD finite energy sum rules for the two-point function of the divergence of the axial vector current computed to order α_c^4 .
- 26 ALLTON 08 use a lattice computation of the π , K, and Ω masses with $2{+}1$ dynamical flavors of domain wall quarks, and non-perturbative renormalization.
- Have 50 domain wan quants, and non-personal recommendation of the light meson spectrum with 2+1 dynamical flavors of $\mathcal{O}(a)$ improved Wilson quarks, and one-loop perturbative renormalization.
- 28 BLUM 07 determine quark masses from the pseudoscalar meson masses using a QED plus QCD lattice computation with two dynamical quark flavors.
- plus QCD lattice computation with two dynamical quark navors. 29 GOCKELER 06 use an unquenched lattice computation of the axial Ward Identity with $N_f=2$ dynamical light quark flavors, and non-perturbative renormalization, to obtain $\overline{m}(2\,\text{GeV})=4.08\pm0.25\pm0.19\pm0.23\,\text{MeV}$, where the first error is statistical, the second and third are systematic due to the fit range and force scale uncertainties, respectively. We have combined the systematic errors linearly.
- 30 GOCKELER 06A use an unquenched lattice computation of the pseudoscalar meson masses with $N_f=2$ dynamical light quark flavors, and non-perturbative renormalization.
- 31 MASON 06 extract light quark masses from a lattice simulation using staggered fermions with an improved action, and three dynamical light quark flavors with degenerate u and d quarks. Perturbative corrections were included at NNLO order.
- ³² NARISON 06 uses sum rules for $e^+e^- \rightarrow \text{hadrons}$ to order α_s^3 to determine m_s combined with other determinations of the quark mass ratios.
- 33 BLOSSIER 08 use a lattice computation of pseudoscalar meson masses and decay constants with 2 dynamical flavors and non-perturbative renormalization
- ³⁴DOMINGUEZ-CLARIMON 08B obtain an inequality from sum rules for the scalar two-
- 35 NAKAMURA 08 do a lattice computation using quenched domain wall fermions and
- non-perturbative renormalization. 36 AUBIN 04 perform three flavor dynamical lattice calculation of pseudoscalar meson
- masses, with one-loop perturbative renormalization constant. 37 AOKI 03 uses quenched lattice simulation of the meson and baryon masses with degenerate light quarks. The extrapolations are done using quenched chiral perturbation
- The errors given in AOKI 03B were $^{+0.046}_{-0.069}$. We changed them to ± 0.3 for calculating the overall best values. AOKI 03B uses lattice simulation of the meson and baryon masses with two dynamical light quarks. Simulations are performed using the $\mathcal{O}(a)$ improved
- Wilson action. 39 BECIREVIC 03 perform quenched lattice computation using the vector and axial Ward identities. Uses $\mathcal{O}(a)$ improved Wilson action and nonperturbative renormalization.
- 40 CHIU 03 determines quark masses from the pion and kaon masses using a lattice simulation with a chiral fermion action in quenched approximation.

- $^{
 m 41}\,{
 m BLUM}$ 07 determine quark masses from the pseudoscalar meson masses using a QED
- PELOWI Of determine quark masses from the pseudoscalar meson masses using a QED plus QCD lattice computation with two dynamical quark flavors.
 42 AUBIN 04A perform three flavor dynamical lattice calculation of pseudoscalar meson masses, with continuum estimate of electromagnetic effects in the kaon masses.
 43 NELSON 03 computes coefficients in the order ρ⁴ chiral Lagrangian using a lattice
- calculation with three dynamical flavors. The ratio $m_{\it u}/m_{\it d}$ is obtained by combining this with the chiral perturbation theory computation of the meson masses to order p^4 .
- 44 LEUTWYLER 96 uses a combined fit to $\eta \to 3\pi$ and $\psi' \to J/\psi \ (\pi,\eta)$ decay rates, and the electromagnetic mass differences of the π and K.

s-QUARK MASS

See the comment for the u quark above

VALUE (MeV.)

We have normalized the $\overline{\sf MS}$ masses at a renormalization scale of $\mu=2$ GeV. Results quoted in the literature at $\mu=1$ GeV have been rescaled by dividing by 1.35.

- using $N_f = 2 + 1$ dynamical flavors of domain wall fermions.
- 46 DURR 11 determine quark mass from a lattice computation of the meson spectrum using $N_f=2+1$ dynamical flavors. The lattice simulations were done at the physical quark mass, so that extrapolation in the quark mass was not needed.
- $^{
 m 47}$ BLOSSIER 10 determines quark masses from a computation of the hadron spectrum using $N_f = 2$ dynamical twisted-mass Wilson fermions
- 48 BLUM 10 determines light quark masses using a QCD plus QED lattice computation of the electromagnetic mass splittings of the low-lying hadrons. The lattice simulations use 2+1 dynamical quark flavors.

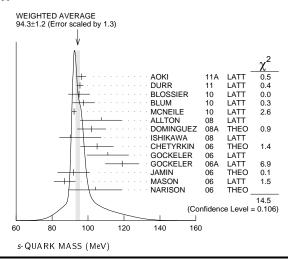

- 49 DAVIES 10 and MCNEILE 10 determine $\overline{m}_{\mathcal{C}}(\mu)/\overline{m}_{\mathcal{S}}(\mu)=11.85\pm0.16$ using a lattice computation with $N_f=2+1$ dynamical fermions of the pseudoscalar meson masses. Mass $m_{\mathcal{S}}$ is obtained from this using the value of $m_{\mathcal{C}}$ from ALLISON 08 or MCNEILE 10.
- 50 ALLTON 08 use a lattice computation of the $\pi,\,K,$ and Ω masses with 2+1 dynamical flavors of domain wall quarks, and non-perturbative renormalization.
- $^{51}\, {\sf DOMINGUEZ}$ 08A make determination from QCD finite energy sum rules for the pseudoscalar two-point function computed to order α_s^4 .
- 52 ISHIKAWA 08 use a lattice computation of the light meson spectrum with 2+1 dynamical flavors of $\mathcal{O}(a)$ improved Wilson quarks, and one-loop perturbative renormalization.
- 53 CHETYRKIN 06 use QCD sum rules in the pseudoscalar channel to order $lpha_c^4$
- 54 GOCKELER 06 use an unquenched lattice computation of the axial Ward Identity with $N_f=2$ dynamical light quark flavors, and non-perturbative renormalization, to obtain $\overline{m}_S(2~{\rm GeV})=111\pm6\pm4\pm6~{\rm MeV},$ where the first error is statistical, the second and third are systematic due to the fit range and force scale uncertainties, respectively. We have combined the systematic errors linearly.
- 55 GOCKELER 06A use an unquenched lattice computation of the pseudoscalar meson masses with $N_f=2$ dynamical light quark flavors, and non-perturbative renormalization.
- 56 JAMIN 06 determine $\overline{m}_{\rm S}({
 m 2~GeV})$ from the spectral function for the scalar $K\pi$ form
- factor.

 57 MASON 06 extract light quark masses from a lattice simulation using staggered fermions with an improved action, and three dynamical light quark flavors with degenerate u and d quarks. Perturbative corrections were included at NNLO order.
- ⁵⁸ NARISON 06 uses sum rules for $e^+e^- \rightarrow$ hadrons to order α_s^3
- $^{59}\,\mathrm{BLOSSIER}$ 08 use a lattice computation of pseudoscalar meson masses and decay constants with 2 dynamical flavors and non-perturbative renormalization
- 60 NAKAMURA 08 do a lattice computation using quenched domain wall fermions and
- non-perturbative renormalization.
- non-perturbative renormalization.

 61 BLUM 07 determine quark masses from the pseudoscalar meson masses using a QED plus QCD lattice computation with two dynamical quark flavors.

 62 NARISON 06 obtains the quoted range from positivity of the spectral functions.

 63 BAIKOV 05 determines $\overline{m}_S(M_T) = 100 \frac{5}{3} + \frac{11}{17}$ from sum rules using the strange spectral function in τ decay. The computations were done to order α_c^3 , with an estimate of the $lpha_{s}^{4}$ terms. We have converted the result to $\mu=2$ GeV.
- 64 GAMIZ 05 determines $\overline{m}_{_{\rm S}}({\rm 2~GeV})$ from sum rules using the strange spectral function in au decay. The computations were done to order $lpha_s^2$, with an estimate of the $lpha_s^3$ terms.
- 65 GORBUNOV 05 use hadronic tau decays to N³LO, including power corrections.
- 66 NARISON 05 determines $\overline{m}_{\rm S}({\rm 2~GeV})$ from sum rules using the strange spectral function in au decay. The computations were done to order $lpha_s^3$.
- $^{67}\mathrm{AUBIN}$ 04 perform three flavor dynamical lattice calculation of pseudoscalar meson masses, with one-loop perturbative renormalization constant.
- 68 AOKI 03 uses quenched lattice simulation of the meson and baryon masses with degenerate light quarks. The extrapolations are done using quenched chiral perturbation theory. Determines $m_s=113.8\pm2.3^{+5.8}_{-2.9}$ using K mass as input and $m_s=142.3\pm5.8^{+22}_{-2.9}$ using K ϕ mass as input. We have performed a weighted average of these values.
- 69 Midss as liptur. We have performed a meganic and baryon masses with two dynamical light quarks. Simulations are performed using the $\mathcal{O}(a)$ improved Wilson action.
- $^{70}\,\mathrm{BECIREVIC}$ 03 perform quenched lattice computation using the vector and axial Ward dientities. Uses $\mathcal{O}(a)$ improved Wilson action and nonperturbative renormalization. They also quote \overline{m}/m_s =24.3 \pm 0.2 \pm 0.6.
- $^{71}\,\text{CHIU}$ 03 determines quark masses from the pion and kaon masses using a lattice simulation with a chiral fermion action in quenched approximation.
- 72 GAMIZ 03 determines m_s from SU(3) breaking in the τ hadronic width. The value of $V_{u\,s}$ is chosen to satisfy CKM unitarity.
- 73 GAMIZ 03 determines m_S from SU(3) breaking in the τ hadronic width. The value of V_{US} is taken from the PDG.

 $^{74}\,\mathrm{GAO}$ 97 uses electromagnetic mass splittings of light mesons.

 75 LEUTWYLER 96 uses a combined fit to $\eta\to 3\pi$ and $\psi'\to J/\psi~(\pi,\eta)$ decay rates, and the electromagnetic mass differences of the π and K.

 76 DONOGHUE 92 result is from a combined analysis of meson masses, $\eta
ightarrow 3\pi$ using second-order chiral perturbation theory including nonanalytic terms, and $(\psi(2S) \to J/\psi(1S) \pi)/(\psi(2S) \to J/\psi(1S) \eta)$.

 77 GERARD 90 uses large N and η - η' mixing.

78 LEUTWYLER 908 determines quark mass ratios using second-order chiral perturbation theory for the meson and baryon masses, including nonanalytic corrections. Also uses Weinberg sum rules to determine L_7 .

c-QUARK MASS

The c-quark mass corresponds to the "running" mass $m_{\, C} \, \left(\mu \, = \, m_{\, C} \right)$ in the $\overline{\text{MS}}$ scheme. We have converted masses in other schemes to the $\overline{\text{MS}}$ scheme using two-loop QCD perturbation theory with $\alpha_s(\mu=m_c)=$ 0.38 \pm 0.03. The value 1.275 \pm 0.025 GeV for the $\overline{\text{MS}}$ mass corresponds to 1.67 ± 0.07 GeV for the pole mass (see the "Note on Quark Masses").

- $^{\rm 1}$ NARISON 12A determines m_{C} using sum rules for the vector current correlator to order α_s^3 , including the effect of gluon condensates up to dimension eight.
- 2 BODENSTEIN 11 determine $\overline{m}_{\rm C}(3~{\rm GeV})=0.987\pm0.009$ GeV and $\overline{m}_{\rm C}(\overline{m}_{\rm C})=1.278\pm0.009$ GeV using QCD sum rules for the charm quark vector current correlator.
- 3 LASCHKA 11 determine the c mass from the charmonium spectrum. The theoretical computation uses the heavy $Q\overline{Q}$ potential to order $1/m_Q$ obtained by matching the short-distance perturbative result onto lattice QCD result at larger scales.
- ⁴ AUBERT 10A determine the b- and c-quark masses from a fit to the inclusive decay spectra in semileptonic B decays in the kinetic scheme (and convert it to the $\overline{\text{MS}}$ scheme)
- BLOSSIER 10 determines quark masses from a computation of the hadron spectrum using $N_f{=}2$ dynamical twisted-mass Wilson fermions.
- 6 MCNEILE 10 determines $m_{\cal C}$ by comparing four-loop perturbative results for the pseudoscalar current to lattice simulations with $N_f=2+1$ sea-quarks by the HPQCD collaboscalar current $^{\circ}$

- 7 CHETYRKIN 09 determine m_C and m_D from the $e^+\,e^-\to Q\,\overline{Q}$ cross-section and sum rules, using a four-loop computation of the heavy quark vacuum polarization. They also determine $m_{C}(3~{\rm GeV}) = 0.986 \pm 0.013 {\rm GeV}$
- $^{8}\,\mathrm{SIGNER}$ 09 determines the c-quark mass using non-relativistic sum rules to analyze the ightarrow $c\,\overline{c}$ cross-section near threshold. Also determine the PS mass $m_{PS}(\mu_F = 0.7)$ $GeV) = 1.50 \pm 0.04 \text{ GeV}.$
- $^9\,\text{BOUGHEZAL}$ 06 result comes from the first moment of the hadronic production crosssection to order α_s^3
- $^{10}\,\mathrm{BUCH\,MULLER}$ 06 determine m_b and m_c by a global fit to inclusive B decay spectra.
- 11 HOANG 06 determines $\overline{m}_{\mathcal{C}}(\overline{m}_{\mathcal{C}})$ from a global fit to inclusive B decay data. The Bdecay distributions were computed to order $\alpha_s^2 \beta_0$, and the conversion between different m_C mass schemes to order α_s^3
- S 2B BODENSTEIN 10 determines $\overline{m}_{C}(3~{\rm GeV})=1.008\pm0.026~{\rm GeV}$ using finite energy sum rules for the vector current correlator. The authors have converted this to $\overline{m}_{C}(\overline{m}_{C})$ using $\alpha_{S}(M_{Z})=0.1189\pm0.0020.$
- 13 NARISON 10 determines m_c from ratios of moments of vector current correlators computed to order α_s^3 and including the dimension-six gluon condensate.
- 14 ALLISON 08 determine $m_{\it C}$ by comparing four-loop perturbative results for the pseudoscalar current correlator to lattice simulations by the HPQCD collaboration. The result has been updated in MCNEILE 10.
- 15 KUHN 07 determine $\overline{m}_{\mathcal{C}}(\mu=$ 3 GeV $)=0.986\pm0.013$ GeV and $\overline{m}_{\mathcal{C}}(\overline{m}_{\mathcal{C}})$ from a four-loop sum-rule computation of the cross-section for $e^+e^ightarrow$ hadrons in the charm threshold
- 16 AUBERT 04x obtain m_c from a fit to the hadron mass and lepton energy distributions in semileptonic B decay. The paper quotes values in the kinetic scheme. The $\overline{\text{MS}}$ value has been provided by the BABAR collaboration.
- $^{17}\,\mathrm{HOANG}$ 04 determines $\overline{m}_{\mathcal{C}}(\overline{m}_{\mathcal{C}})$ from moments at order $\alpha_{\mathcal{S}}^2$ of the charm production cross-section in e^+e^- annihilation.
- 18 DEDIVITIIS 03 use a quenched lattice computation of heavy-heavy and heavy-light me-
- son masses. $^{19}\,\mathrm{EIDEMULLER}$ 03 determines m_b and m_c using QCD sum rules. $^{20}\,\mathrm{ERLER}$ 03 determines m_b and m_c using QCD sum rules. Includes recent BES data.
- $^{21}\,{\rm ZYABLYUK}$ 0.3 determines m $_c$ by using QCD sum rules in the pseudoscalar channel and comparing with the η_c mass.

b-QUARK MASS

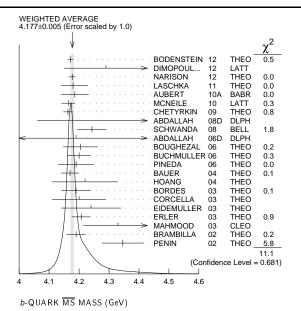

The first value is the "running mass" $\overline{m}_b(\mu=\overline{m}_b)$ in the $\overline{\text{MS}}$ scheme, and the second value is the 1S mass, which is half the mass of the $\varUpsilon(1S)$ in perturbation theory. For a review of different quark mass definitions and their properties, see EL-KHADRA 02. The $15\,\mathrm{mass}$ is better suited for use in analyzing B decays than the $\overline{\mathrm{MS}}$ mass because it gives a stable perturbative expansion. We have converted masses in other schemes to the $\overline{\rm MS}$ mass and 15 mass using two-loop QCD perturbation theory with $\alpha_S(\mu=\overline{m}_b)=0.223\pm0.008.$ The values 4.18 \pm 0.03 GeV for the $\overline{\rm MS}$ mass and 4.65 \pm 0.03 GeV for the 15 mass correspond to 4.78 \pm 0.06 GeV for the pole mass, using the two-loop conversion formula. A discussion of masses in different schemes can be found in the "Note on Quark Masses."

- $^{
 m 1}$ BODENSTEIN 12 determine m_b using sum rules for the vector current correlator and the $e^+e^- o Q\,\overline{Q}$ total cross-section. We have converted $\overline{m}_b(\overline{m}_b)$ to the 1S scheme.
- 2 DIMOPOULOS 12 determine quark masses from a lattice computation using N_f = dynamical flavors of twisted mass fermions. We have converted $\overline{m}_b(\overline{m}_b)$ to the 1S
- 3 Determines m_b to order α_5^3 , including the effect of gluon condensates up to dimension eight combining the methods of NARISON 12 and NARISON 12A. We have converted $\overline{m}_b(\overline{m}_b)$ to the 1S scheme.
- ^4 LASCHKA 11 determine the b mass from the charmonium spectrum. The theoretical computation uses the heavy $Q\overline{Q}$ potential to order $1/m_Q$ obtained by matching the short-distance perturbative result onto lattice QCD result at larger scales. We have converted $\overline{m}_b(\overline{m}_b)$ to the 1S scheme.
- ⁵ AUBERT 10A determine the *b* and *c*-quark masses from a fit to the inclusive decay spectra in semileptonic B decays in the kinetic scheme (and convert it to the $\overline{\text{MS}}$ scheme). We have converted this to the 1S scheme.
- 6 MCNEILE 10 determines m_b by comparing four-loop perturbative results for the pseudoscalar current to lattice simulations with $N_f=2+1$ sea-quarks by the HPQCD collaboration. We have converted \overline{m}_b (\overline{m}_b) to the 1S scheme.
- 7 CHETYRKIN 09 determine m_{C} and m_{D} from the $e^+\,e^-\to Q\,\overline{Q}$ cross-section and sum rules, using a four-loop computation of the heavy quark vacuum polarization. We have converted their m_{D} to the 1S scheme.

- 8 ABDALLAH 08D determine $\overline{m}_b(M_Z)=3.76\pm1.0$ GeV from a leading order study of four-jet rates at LEP. We have converted this to $\overline{m}_b(\overline{m}_b)$ and m_b^{1S}
- 9 SCHWANDA 08 measure moments of the inclusive photon spectrum in $B
 ightarrow X_S \, \gamma$ decay to determine m_h^{1S} . We have converted this to $\overline{\rm MS}$ scheme.
- 10 ABDALLAH 06D determine $m_b(M_Z)=2.85\pm0.32$ GeV from Z-decay three-jet events containing a b-quark. We have converted this to $\overline{m}_b(\overline{m}_b)$ and $m_b^{1S}.$
- $^{11} \mbox{BOUGHEZAL 06 $\overline{\mbox{MS}}$}$ scheme result comes from the first moment of the hadronic production cross-section to order α_s^3 . We have converted it to the 1S scheme.
- 12 BUCH MULLER 06 determine m_b and m_c by a global fit to inclusive $\it B$ decay spectra. We have converted this to the 1S scheme.
- NNLO) of sum rules of the bottom production cross-section in $e^+\,e^-$ annihilation. We
- have converted it to the 1S scheme. 14 BAUER 04 determine $m_b,\,m_c$ and m_b-m_c by a global fit to inclusive B decay spectra.
- $^{15}\,\mathrm{We}$ have converted $\,m_b^{}$ to the 1S scheme
- 16 HOANG 04 determines $\overline{m}_b(\overline{m}_b)$ from moments at order $lpha_S^2$ of the bottom production cross-section in e^+e^- annihilation.
- 17 BORDES 03 determines m_b using QCD finite energy sum rules to order α_s^2
- 18 CORCELLA 03 determines \overline{m}_b using sum rules computed to order α_s^2 . Includes charm quark mass effects.
- 19 EIDEMULLER 03 determines \overline{m}_b and \overline{m}_c using QCD sum rules.
- 20 ERLER 03 determines \overline{m}_b and \overline{m}_c using QCD sum rules. Includes recent BES data. 21 MAHMOOD 03 determines m_b^{LS} by a fit to the lepton energy moments in $B\to X_c\ell\nu_\ell$ decay. The theoretical expressions used are of order $1/m^3$ and $\alpha_s^2\beta_0$. We have converted
- their result to the $\overline{\rm MS}$ scheme. 22 BRAMBILLA 02 determine $\overline{m}_b(\overline{m}_b)$ from a computation of the $\Upsilon(1S)$ mass to order α_s^4 , including finite m_c corrections. We have converted this to the 1S scheme.
- ²³ PENIN 02 determines \overline{m}_b from the spectrum of the \varUpsilon system.
- $^{24}\,\mathrm{NARISO\,N}\,12$ determines $m_{\,b}$ using exponential sum rules for the vector current correlator to order α_c^3 , including the effect of gluon condensates up to dimension eight. We have converted $\frac{s}{m}_{b}(\overline{m}_{b})$ to the 1S scheme.
- 25 NARISON $^{-1}$ determines m_b using sum rules for the vector current correlator to order $lpha_c^3$, including the effect of gluon condensates up to dimension eight. We have converted $\overline{m}_b(\overline{m}_b)$ to the 1S scheme.
- 26 NARISON 10 determines m_b from ratios of moments of vector current correlators computed to order α_c^3 and including the dimension-six gluon condensate. These values are
- taken from the erratum to that reference. 27 GUAZZINI 08 determine $m_b(\overline{m}_b)$ from a quenched lattice simulation of heavy meson masses. The ± 0.08 is an estimate of the quenching error. We have converted these values to the 15 scheme.
- 28 DELLA-MORTE O7 determine $\overline{m}_b(\overline{m}_b)$ from a computation of the spin-averaged B meson mass using quenched lattice HQET at order 1/m. The ± 0.08 is an estimate of the quenching error
- ²⁹ KUHN 07 determine $\overline{m}_b(\mu=$ 10 GeV) $=3.609\pm0.025$ GeV and $\overline{m}_b(\overline{m}_b)$ from a fourloop sum-rule computation of the cross-section for $e^+e^ightarrow$ hadrons in the bottom
- threshold region. We have converted this to the 1S scheme. 30 GRAY 05 determines $\overline{m}_b(\overline{m}_b)$ from a lattice computation of the \varUpsilon spectrum. The simulations have 2+1 dynamical light flavors. The b quark is implemented using NRQCD.
- 31 AUBERT 04x obtain m_b from a fit to the hadron mass and lepton energy distributions in semileptonic B decay. The paper quotes values in the kinetic scheme. The $\overline{\text{MS}}$ value has been provided by the BABAR collaboration, and we have converted this to the 1S
- 32 MCNEILE 04 use lattice QCD with dynamical light quarks and a static heavy quark to compute the masses of heavy-light mesons.
- 33 BAUER 03 determine the b quark mass by a global fit to B decay observables. The experimental data includes lepton energy and hadron invariant mass moments in semileptonic $B \to X_c \ell \nu_\ell$ decay, and the inclusive photon spectrum in $B \to X_s \gamma$ decay. The theoretical expressions used are of order $1/m^3$, and $\alpha_s^2\beta_0$.
- $^{34}\,\mathrm{DEDIVITIIS}$ 03 use a quenched lattice computation of heavy-heavy and heavy-light me-

THE TOP QUARK

Updated December 2011 by T.M. Liss (Univ. Illinois) and A. Quadt (Univ. Göttingen).

A. Introduction: The top quark is the Q = 2/3, $T_3 = +1/2$ member of the weak-isospin doublet containing the bottom quark (see the review on the "Electroweak Model and Constraints on New Physics" for more information). This note summarizes the properties of the top quark (mass, production cross section, decay branching ratios, etc.), and provides a discussion of the experimental and theoretical issues involved in their determination

B. Top quark production at the Tevatron and LHC: In hadron collisions, top quarks are produced dominantly in pairs through the QCD processes $q\overline{q} \to t\overline{t}$ and $gg \to t\overline{t}$. In $p\overline{p}$ collisions at the Tevatron with $\sqrt{s} = 1.96$ TeV the most recent calculations are at NLO with next-to-leading-log soft gluon resummation [1], and at approximate next-to-next-to-leading order (NNLO) [2]. Cacciari et al. give a production cross section of 7.93 pb for $m_t = 172.5 \text{ GeV/c}^2$ with MRST2006nnlo PDFs. Over the range 150 GeV/ $c^2 \le m_t \le 190 \text{ GeV}/c^2$ the calculated cross section changes by approximately $0.24 \text{ pb/(GeV/c}^2)$ for m_t greater or less than 172.5 GeV/c². An approximate NNLO calculation by Kidonakis and Vogt yields a production cross section of 7.68 pb for $m_t = 172.5 \text{ GeV/c}^2 \text{ using MRST2006nnlo}$, with nearly the same mass-dependence. The difference in the central value obtained using different PDFs is typically a few tenths of a pb or less. Langenfeld et al. [3], in an approximate NNLO calculation find 7.04 pb for $m_t = 173 \text{ GeV/c}^2 \text{ using}$ MSTW2008nnlo. The uncertainties on these calculations, due to the choice of scale, which is set at $\mu = m_t$, are typically 0.5 pb or less. In pp collisions at the LHC with $\sqrt{s} = 7$ TeV, Langenfeld et al. calculate an approximate NNLO production cross section of 161 pb for $m_t = 172.5 \text{ GeV/c}^2$ using CTEQ6.6 with an uncertainty of less than 10%. Approximately 85% of the production cross section at the Tevatron is from $q\bar{q}$ annihilation, with the remainder from gluon-gluon fusion [4], while at LHC energies about 90% of the production is from the latter process at $\sqrt{s} = 14 \text{ TeV} \ (\approx 80\% \text{ at } \sqrt{s} = 7 \text{ TeV})$. The resulting theoretical prediction of the top quark cross-section at the LHC is $\sigma_{t\bar{t}} = 165^{+11}_{-16}$ pb, assuming a top quark mass of 172.5 GeV/c^2 [5].

Somewhat smaller cross sections are expected from electroweak single top production mechanisms, namely from $q\overline{q}' \to t\overline{b}$ [6] and $qb \to q't$ [7], mediated by virtual s-channel and t-channel W bosons, respectively. At the Tevatron, the production cross sections of top and antitop are identical, while at the LHC they are not. Approximate NNLO cross sections for t-channel single top quark production are calculated for $m_t = 173 \text{ GeV/c}^2$ to be 1.04 pb in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV and 41.7 pb in pp collisions at $\sqrt{s} = 7$ TeV [8]. For the s-channel, these calculations yield 0.52 pb for the Tevatron, and 3.2 pb for $\sqrt{s} = 7$ TeV LHC [9]. The corresponding single anti-top-quark cross sections at the LHC are 22.5 pb and 1.4 pb for t- and s-channel, respectively, at $\sqrt{s} = 7$ TeV. At LHC energies, the production of a single top quark in association with a W⁻ boson, through $bg \to W^- t$, becomes relevant. At $\sqrt{s} = 7$ TeV, an approximate NNLO calculation using the MSTW2008 PDF gives 8.1 pb [10]. The production cross section for single anti-top quarks in this channel $(W^{+}\bar{t})$ is the same as for single top quarks.

The cross sections for single top production are proportional to $|V_{tb}|^2$, and no assumption is needed on the number of quark families or on the unitarity of the CKM matrix in extracting $|V_{tb}|$. Separate measurements of the s- and t-channel processes provide sensitivity to physics beyond the Standard Model (SM) [11].

The identification of top quarks in the electroweak singletop channel is much more difficult than in the QCD $t\bar{t}$ channel, due to a less distinctive signature and significantly larger backgrounds.

In top decay, the Ws and Wd final states are expected to be suppressed relative to Wb by the square of the CKM matrix elements V_{ts} and V_{td} . Assuming unitarity of the three-generation CKM matrix, these matrix element values are estimated to be less than 0.043 and 0.014, respectively, implying a value of $V_{tb} > 0.999$ (see the review "The CKM Quark-Mixing Matrix" for more information). With a mass above the Wb threshold, and V_{tb} close to unity, the decay width of the top quark is expected to be dominated by the two-body channel $t \to Wb$. Neglecting terms of order m_b^2/m_t^2 , α_s^2 , and $(\alpha_s/\pi)M_W^2/m_t^2$, the width predicted in the Standard Model (SM) at NLO is [12]:

$$\Gamma_{t} = \frac{G_{F} m_{t}^{3}}{8\pi\sqrt{2}} \left(1 - \frac{M_{W}^{2}}{m_{t}^{2}}\right)^{2} \left(1 + 2\frac{M_{W}^{2}}{m_{t}^{2}}\right) \left[1 - \frac{2\alpha_{s}}{3\pi} \left(\frac{2\pi^{2}}{3} - \frac{5}{2}\right)\right],\tag{1}$$

where m_t refers to the top quark pole mass. The width for a value of $m_t = 171 \text{ GeV/c}^2$, close to the world average, is 1.29 GeV/c^2 (we use $\alpha_s(M_Z) = 0.118$) and increases with mass. With its correspondingly short lifetime of $\approx 0.5 \times 10^{-24}$ s, the top quark is expected to decay before top-flavored hadrons or $t\bar{t}$ -quarkonium-bound states can form [13]. The order α_s^2 QCD corrections to Γ_t are also available [14], thereby improving the overall theoretical accuracy to better than 1%.

The final states for the leading pair-production process can be divided into three classes:

A.
$$t\overline{t} \to W^+ b W^- \overline{b} \to q \overline{q}' b q'' \overline{q}''' \overline{b},$$
 (45.7%)
B. $t\overline{t} \to W^+ b W^- \overline{b} \to q \overline{q}' b \ell^- \overline{\nu}_\ell \overline{b} + \ell^+ \nu_\ell b q'' \overline{q}''' \overline{b},$ (43.8%)

C.
$$t\overline{t} \to W^+ b W^- \overline{b} \to \hat{\overline{\ell}} \nu_{\ell} b \ell' \overline{\nu}_{\ell'} \overline{b}$$
. (10.5%)

The quarks in the final state evolve into jets of hadrons. A, B, and C are referred to as the all-jets, lepton+jets (ℓ +jets), and dilepton ($\ell\ell$) channels, respectively. Their relative contribu-

and dilepton ($\ell\ell$) channels, respectively. Their relative contributions, including hadronic corrections, are given in parentheses assuming lepton universality. While ℓ in the above processes refers to e, μ , or τ , most of the results to date rely on the e and μ channels. Therefore, in what follows, we will use ℓ to refer to e or μ , unless otherwise noted.

The initial and final-state quarks can radiate gluons that can be detected as additional jets. The number of jets reconstructed in the detectors depends on the decay kinematics, as well as on the algorithm for reconstructing jets used by the analysis. The transverse momenta of neutrinos are reconstructed from the imbalance in transverse momentum measured in each event (missing p_T , which is here also missing E_T).

NLO Monte Carlo programs are available for the $t\bar{t}$ production processes [15]. Theoretical estimates of the background processes (W or Z bosons+jets and dibosons+jets) using leading order (LO) calculations have large uncertainties. While this limitation affects estimates of the overall production rates, it is believed that the LO determination of event kinematics, and of the fraction of W+multi-jet events that contain b- or c-quarks, are relatively accurate [16]. Comparison to CDF and DØ data,

however, indicates the *b*- and *c*-quark fractions to be underestimated by the LO generators and hence does not seem to support the theoretical expectations.

C. Top quark measurements: Since the discovery of the top quark, direct measurements of $t\bar{t}$ production have been made at three center-of-mass energies, providing stringent tests of QCD. The first measurements were made in Run I at the Tevatron at $\sqrt{s}=1.8$ TeV. In Run II at the Tevatron relatively precise measurements were made at $\sqrt{s}=1.96$ TeV. Finally, beginning in 2010 measurements have been made at the LHC at $\sqrt{s}=7$ TeV.

Production of single top quarks through electroweak production mechanisms has now been measured with good precision at the Tevatron at $\sqrt{s} = 1.96$ TeV, and at the LHC at $\sqrt{s} = 7$ TeV. Recent measurements are beginning to separate the s- and t-channel production cross sections, and at the LHC, the Wt mechanism as well, though only t-channel is well measured to date. The measurements allow an extraction of the CKM matrix element V_{tb} .

The top quark mass is now measured at the 0.6% level, by far the most precisely measured quark mass. Together with the W boson mass measurement, this places strong constraints on the mass of the Standard Model Higgs boson.

With more than 5 fb⁻¹ of Tevatron data analyzed as of this writing, and 1-2 fb⁻¹ of LHC data, many properties of the top quark are now being measured with precision. These include properties related to the production mechanism, such as $t\bar{t}$ spin correlations, forward-backward or charge asymmetries, and differential production cross sections, as well as properties related to the t-W-b decay vertex, such as the helicity of the W bosons from the top decay. In addition, many searches for physics beyond the Standard Model are being performed with increasing reach in both production and decay channels.

In the following sections we review the current status of measurements of the characteristics of the top quark.

C.1 Top quark production

 $C.1.1 \ t\overline{t}$ production Fig. 1 summarizes the $t\overline{t}$ production cross-section measurements from both the Tevatron and LHC. The most recent measurement from D0 [17], combining the measurements from the dilepton and lepton plus jets final states in $5.4~{\rm fb^{-1}}$, is $7.56^{+0.63}_{-0.56}~{\rm pb}$. From CDF the most precise measurement made recently [18] is in 4.6 fb^{-1} and is a combination of dilepton, lepton plus jets, and all-hadronic final-state measurements, yielding 7.50 ± 0.48 pb. Both of these measurements assume a top mass of 172.5 GeV/c². The dependence of the cross section measurements on the value chosen for the mass is less than that of the theory calculations because it only affects the determination of the acceptance. In some analyses also the shape of topological variables might be modified. At LHC energies, ATLAS [19] combines measurements in the lepton plus jets and dilepton final states with $0.7 \, \mathrm{fb^{-1}}$ to find $176 \pm 14 \, \mathrm{pb}$, whereas a more recent analysis of that dataset in the lepton plus jets channel without b-tagging yields the most precise result of 179 ± 12 pb [20] and a measurement in the all-jets channels using 1.02 fb⁻¹ yields 167 ± 80 pb [21]. CMS [22] uses 0.8 - 1.1 fb⁻¹ in the lepton plus jets channel and measures 164 ± 14 pb. In the all-hadronic channel they use 1.1 fb⁻¹ for a cut-based event selection combined with a kinematic fit and obtain 136 ± 45 pb [23]. These should be compared to the theoretical calculations that yield 7.9 - 6.7 pb for top masses from 170 to 175 GeV/c² respectively [1] at $\sqrt{s} = 1.96$ TeV and $\sigma_{t\bar{t}} = 165^{+11}_{-16}$ pb, assuming $m_t = 172.5$ GeV/c² at $\sqrt{s} = 7$ TeV at the LHC [5](see Listings).

Most of these measurements assume a $t \to Wb$ branching ratio of 100%. CDF and DØ have made direct measurements of the $t \to Wb$ branching ratio [24]. Comparing the number of events with 0, 1 and 2 tagged b jets in the lepton+jets channel, and also in the dilepton channel, using the known b-tagging efficiency, the ratio $R = B(t \to Wb)/\sum_{q=d,s,b} B(t \to Wq)$ can be extracted. In 5.4 fb⁻¹ of data, DØ measures $R = 0.90 \pm 0.04$, 2.5 σ from unity. A significant deviation of R from unity would imply either non-SM top decay (for example a flavor-changing neutral-current decay), or a fourth generation of quarks.

CDF also performs measurements of the $t\bar{t}$ production cross section normalized to the Z production cross section in order to reduce the impact of the luminosity uncertainty.

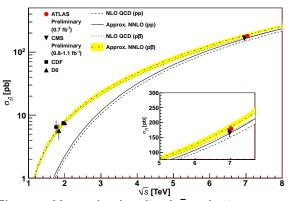

Figure 1: Measured and predicted $t\bar{t}$ production cross sections from Tevatron energies in $p\bar{p}$ collisions to LHC energies in pp collisions. Tevatron data points at $\sqrt{s}=1.8$ TeV are from Refs. [25] and [26]. Those at $\sqrt{s}=1.96$ TeV are from Refs. [17] and [18]. The ATLAS and CMS data points are from Refs. [20] and [22], respectively. Theory curves are generated using HATHOR [5] with input from Ref. [27] for the NLO curves and Ref. [2] for the approximate NNLO curves. Figure adapted from Ref. [19].

In Fig. 1, one sees the importance of $p\overline{p}$ at Tevatron energies where the valence antiquarks in the antiprotons contribute to the dominant $q\overline{q}$ production mechanism. At LHC energies the dominant production mode is gluon-gluon fusion and the $pp-p\overline{p}$ difference nearly disappears. The excellent agreement of these measurements with the theory calculations is a strong validation of QCD and the soft-gluon resummation techniques employed in

the calculations. The measurements are not yet precise enough to distinguish between the NLO and approximate NNLO calculations including their respective PDF uncertainties.

C.1.2 Single-top production Single-top quark production was first observed in 2009 by $D\emptyset$ [28] and CDF [29,30] at the Tevatron. The production cross section at the Tevatron is roughly half that of the $t\bar{t}$ cross section, but the final state with a single W-boson and typically two jets is less distinct than that for $t\bar{t}$ and much more difficult to distinguish from the background of W+jets and other sources. A recent review of the first observation and the techniques used to extract the signal from the backgrounds can be found in [31].

The dominant production at the Tevatron is through schannel and t-channel W-boson exchange. Associated production with a W-boson (Wt production) has a cross section that is too small to observe at the Tevatron. The t-channel process includes $qb \rightarrow q't$ and $qg \rightarrow q't\overline{b}$, while the s-channel process is $q\overline{q'} \to t\overline{b}$. The s- and t-channel productions can be separated kinematically. This is of particular interest because potential physics beyond the Standard Model, such as fourth-generation quarks, heavy W and Z bosons, or flavor-changing-neutralcurrents [11], would affect the s- and t-channels differently. However, the separation is difficult and initial observations and measurements at the Tevatron by both experiments were of combined s + t-channel production. The two experiments combined their measurements for maximum precision with a resulting s+t channel production cross section of $2.76^{+0.58}_{-0.47}$ pb [32]. The measured value assumes a top quark mass of 170 GeV/c^2 . The mass dependence of the result comes both from the acceptance dependence and from the $t\bar{t}$ background evaluation. Also the shape of discriminating topological variables is sensitive to m_t . It is therefore not necessarily a simple linear dependence but amounts to only a few tenths of picobarns over the range $170 - 175 \text{ GeV/c}^2$. The measured value agrees well with the theoretical calculation at $m_t = 173 \text{ GeV/c}^2 \text{ of } \sigma_{s+t} = 3.12 \text{ pb}$ (including both top and anti-top production) [8,9].

Both experiments have done separate measurements of the s- and t-channel cross sections by reoptimizing the analysis for one or both of the channels separately. In a simultaneous measurement of s- and t-channel cross sections, CDF measures $\sigma_s=1.8^{+0.7}_{-0.5}$ pb and $\sigma_t=0.8^{+0.4}_{-0.4}$ pb, respectively, in 3.2 fb⁻¹ of data [30], while DØ measures $2.7^{+0.7}_{-0.6}$ pb and $0.7^{+0.4}_{-0.4}$ pb, respectively in 5.4 fb⁻¹ of integrated luminosity [33]. In a separate analysis, optimized for the s-channel alone, CDF measures $1.49^{+0.92}_{-0.75}$ pb in 3.2 fb⁻¹ of data [34].

Recently, DØ has measured the t-channel production cross section separately in 5.4 fb⁻¹ of data [35] using a variety of advanced analysis techniques similar to those described in [31]. These take advantage of kinematic differences in such things as the leading b-tagged jet p_T , centrality of jets, lepton charge times η of the jets, and the scalar sum of the energy of the final state objects. The s-channel production is considered a background and integrated over the full measured s-channel

plane. The $p\overline{p}\to tqb+X$ cross section is measured to be 2.90±0.59 pb, assuming a top quark mass of 172.5 GeV/c². This is in good agreement with the theoretical value at this mass of 2.08±0.13 pb [8]. It should be noted that the theory citations here list cross sections for t or \overline{t} alone, whereas the experiments measure the sum. At the Tevatron these cross sections are equal. The theory values quoted here already include this factor of two.

At the LHC the t-channel cross section is expected to be more than three times as large as s-channel and Wt production, combined. Both ATLAS and CMS have measured single top production cross sections at $\sqrt{s} = 7$ TeV in pp collisions. In the measurement of the t-channel cross section, both experiments treat s-channel and Wt production as backgrounds. ATLAS uses a counting experiment in 0.7 fb^{-1} and combines W+2 and 3 jet data to measure $\sigma_t = 90^{+32}_{-22}$ pb [36]. In 36 pb⁻¹ of data, CMS uses a boosted decision tree and kinematic observables to separate signal from background, and combines the two measurements to find $\sigma_t = 83.6 \pm 30.0$ pb [37]. The experimental uncertainties are still too large for a precision test, but the measurements are consistent with the theoretical expectation of 64.2 $^{+1.8}_{-1.1}$ pb at $m_t = 173 \text{ GeV/c}^2$ [8]. This theoretical value is the sum of the t and \overline{t} production cross sections, which individually are 41.7 pb and 22.5 pb, respectively, at $\sqrt{s} = 7 \text{ TeV}.$

The s-channel production cross section is expected to be only 4.6 ± 0.3 pb for $m_t = 173 \text{ GeV/c}^2$ at $\sqrt{s} = 7 \text{ TeV } [9]$, and has not yet been observed at LHC. The Wt process has also not yet been observed, but appears a bit closer and has a theoretical cross section of 15.6 ± 1.2 pb [10]. This is of interest because it probes the W-t-b vertex in a different kinematic region than s- and t-channel production, and because of its similarity to the associated production of a charged-Higgs boson and a top quark. The signal is difficult to extract because of its similarity to the $t\bar{t}$ signature. Similarly, it is difficult to uniquely define because at NLO a subset of diagrams have the same final state as $t\bar{t}$ and the two interfere [38]. The cross section is calculated using the diagram removal technique [39] to define the signal process. In the diagram removal technique the interfering diagrams are removed, at the amplitude level, from the signal definition (an alternate technique, diagram subtraction removes these diagrams at the cross-section level and yields similar results). These techniques work provided the selection cuts are defined such that the interference effects are small, which is usually the case.

At ATLAS, a search is performed in 0.7 fb^{-1} using dilepton decays of the two putative W bosons in the final state and selecting events with exactly one high- p_T jet and large missing E_T [40]. No significant signal is observed yet, and the background-only hypothesis is rejected at only the 1.2σ level. Interpreted as a signal, the measured cross section is 14 ± 11 pb. At CMS a recent result has been released using 2.7 fb^{-1} of data. CMS also uses the dilepton channel and selects events with at least one high- p_T jet and large missing E_T [41]. The

CMS analysis requires exactly one b-tagged jet, which helps to distinguish the signal from non-top backgrounds and from $t\bar{t}$ production. The observed data are inconsistent with the background-only hypothesis at the 2.7σ level. If interpreted as a signal, the measured cross section is 22^{+9}_{-7} pb, consistent with the theoretical expectation.

The CKM matrix element V_{tb} is extracted from the measured cross sections using the ratio to the theoretical values, which assume $V_{tb} = 1.0$. The extracted value therefore depends on the theoretical cross section. The results, including limits at the 95% C.L., are summarized in Table 1.

Table 1: Measurements and 95% C.L. limits of $|V_{tb}|$ from single-top results.

| $ V_{tb} $ | Source | $\int \mathcal{L} dt \ (fb^{-1})$ | Ref. |
|-----------------------------------|---------------|-----------------------------------|------|
| $ V_{tb} = 0.88 \pm 0.07$ | DØ+CDF Run II | 2.3-3.2 | [32] |
| $ V_{tb} > 0.77$ | DØ+CDF Run II | 2.3-3.2 | [32] |
| $ V_{tb} = 1.02^{+0.10}_{-0.11}$ | DØ | 5.4 | [33] |
| $ V_{tb} = 1.14 \pm 0.22$ | CMS | 0.036 | [37] |
| $ V_{tb} > 0.62$ | CMS | 0.036 | [37] |

C.1.3 Top Quark Forward-Backward & Charge Asymmetry:

NLO calculations predict a small forward-backward asymmetry in $t\bar{t}$ production at the Tevatron of ($\approx 5.0 \pm 1.5$)% [42]. The asymmetry arises from an interference between the Born and box diagrams for $t\bar{t}$ production and between diagrams with initial- and final-state gluon radiation. Both CDF and DØ have measured asymmetry values in excess of the SM prediction, fueling speculation about exotic production mechanisms (see, for example, [43] and references therein). The first measurement of this asymmetry by DØ in 0.9 fb⁻¹ [44] found an asymmetry at the detector level of $(12 \pm 8)\%$. The first CDF measurement in 1.9 fb⁻¹ [45] yielded $(24 \pm 14)\%$ at parton level. Both values were higher, though statistically consistent with the small SM expectation. With the addition of more data, the uncertainties have been reduced, but the measured asymmetries remain in excess of the SM expectation. The most recent measurement from DØ in 5.4 fb⁻¹ finds an asymmetry, corrected for detector acceptance and resolution, of $(19.6 \pm 6.5)\%$ [46]. From CDF, the most recent measurement combines results in the lepton+jets and dilepton channels, using up to 5.3 fb^{-1} , and finds $(20.1 \pm 6.7)\%$ [47]. CDF has recently reported a massdependent asymmetry [48], with a larger asymmetry at large $t\bar{t}$ invariant mass. DØ does not see any significant increase at large mass [46].

At LHC, where the dominant $t\bar{t}$ production mechanism is the charge-symmetric gluon-gluon fusion, the measurement is more difficult. For the sub-dominant $q\bar{q}$ production mechanism, the symmetric pp collision does not define a forward and backward direction. Instead, the charge asymmetry is defined

t

in terms of a positive versus a negative $t - \overline{t}$ rapidity difference. Both CMS [49] and ATLAS [50] have made preliminary measurements of the charge asymmetry in almost 1 fb⁻¹. The uncertainties are still too large for a precision test, but both measurements are consistent with the very small asymmetry expected at the LHC while also not being inconsistent with the larger asymmetry observed at the Tevatron.

C.2 Top Quark Properties

C.2.1 Top Quark Mass Measurements: The most precisely studied property of the top quark is its mass. The top mass has been measured in the lepton+jets, the dilepton, and the all-jets channel by both CDF and DØ. At the LHC, both CMS and ATLAS have made measurements in the lepton+jets channel, CMS also in the dilepton channel. The latest results are summarized in Table 2. The lepton+jets channel yields the most precise single measurements because of good signal to background (in particular after b-tagging) and the presence of only a single neutrino in the final state. The momentum of a single neutrino can be reconstructed (up to a quadratic ambiguity) via the missing E_T measurement and the constraint that the lepton and neutrino momenta reconstruct to the known W boson mass.

A large number of techniques have now been applied to measuring the top mass. The original 'template method' [51], in which Monte Carlo templates of reconstructed mass distributions are fit to data, has evolved into a precision tool in the lepton+jets channel, where the systematic uncertainty due to the jet energy scale uncertainty is controlled by a simultaneous, in situ, fit to the $W \to jj$ hypothesis [52]. The latest measurements with this technique, which is now also used in the all-jets channel, are from ATLAS and CDF. In 0.7 fb⁻¹ of data in the lepton+jets channel, ATLAS already achieves a total uncertainty of better than 2%, with a statistical component of close to 0.5% [53]. The measurement from CDF with 5.6 fb⁻¹ [54] achieves a precision of better than 1% in the lepton+jets channel and is combined with a measurement in the dilepton channel yielding a precision of about 0.8%.

The template method is complemented by the 'matrix element' method. This method was first applied by the DØ Collaboration [55], and is similar to a technique originally suggested by Kondo et al. [56] and Dalitz and Goldstein [57]. In the matrix element method a probability for each event is calculated as a function of the top mass, using a LO matrix element for the production and decay of $t\bar{t}$ pairs. The in situ calibration of dijet pairs to the $W \to jj$ hypothesis is now also used with the matrix element technique to constrain the jet energy scale uncertainty. The latest measurement with this technique is from DØ in the lepton+jets channel with 3.6 fb⁻¹ yielding an uncertainty of about 0.9% [58].

CMS has measured the top mass at LHC using an 'ideogram' method, first used by DØ [59], in which a constrained fit is performed and an event-by-event likelihood for signal or background is calculated taking into account all jet-parton assignments. In the lepton+jets channel at CMS, the measurement has a precision of 2% in just $0.036~{\rm fb^{-1}}$. The precision is slightly improved by a combination with a measurement in the dilepton channel.

In the dilepton channel, the signal to background is typically very good, but reconstruction of the mass is non-trivial because there are two neutrinos in the final state, yielding a kinematically unconstrained system. A variety of techniques have been developed to handle this. Recently, an analytic solution to the problem has been proposed [60], but this has not yet been used in the mass measurement. The most precise measurements in the dilepton channel come from the application of the matrix element technique, in which an integration is performed over the unmeasured neutrino energies. A detailed description of the use of the matrix element technique in the dilepton channel is given in [61]. The most recent measurement in the dilepton channel by DØ uses 5.4 fb⁻¹ of data and has a precision of better than 2% [62].

Several other techniques also yield precise measurements in the dilepton channel. In the neutrino weighting technique a weight is assigned by assuming a top mass value and applying energy-momentum conservation to the top decay, resulting in up to four possible pairs of solutions for the neutrino and anti-neutrino momenta. The missing E_T calculated in this way is then compared to the observed missing E_T to assign a weight [63]. Another recent measurement in the dilepton channel uses the Dalitz and Goldstein technique [64]. The precision of these techniques approaches that of the matrix element technique, but the measurements to date have used only 2 fb^{-1} of data.

In the all-jets channel there is no ambiguity due to neutrino momenta, but the signal to background is significantly poorer due to the severe QCD multijets background. The emphasis therefore has been on background modeling, and reduction through event selection. The most recent measurement in the all-jets channel, by CDF in 5.8 fb⁻¹ [65], uses a template method for reconstruction and achieves a precision of almost 1%

A recent measurement from CDF in 5.7 fb⁻¹ uses a neural net to select events with a missing E_T plus jets signature [66]. A modified template method is used to extract the top mass, and a precision of about 1.5% is achieved.

The dominant systematic uncertainty in these methods is the understanding of the jet energy scale, and so several techniques have been developed that have little sensitivity to the jet energy scale uncertainty. These include the measurement of the top mass using the following techniques: Fitting of the lepton p_T spectrum of candidate events [67]; Fitting of the transverse decay length of the b-jet (L_{xy}) [68]; Fitting the invariant mass of a lepton from the W-decay and a muon from the semileptonic b decay [69].

Several measurements have now been made in which the top mass is extracted from the measured cross section using the theoretical relationship between the mass and the production cross section. This allows an extraction of both the pole and $\overline{\rm MS}$ mass [70]. The direct measurements of the top mass, such as those shown in Table 2, are generally assumed to be measurements of the pole mass. Strictly speaking, the mass measured in these direct measurements is the mass used in the Monte Carlo generators, but the relation between the Monte Carlo generator mass and the pole mass is uncertain at the level of 1 GeV [71], which is now comparable to the measurement uncertainty.

Table 2: Measurements of top quark mass from Tevatron and LHC. $\int \mathcal{L} dt$ is given in fb⁻¹. The results shown are mostly preliminary (not yet submitted for publication as of December 2011); for a complete set of published results see the Listings. Statistical uncertainties are listed first, followed by systematic uncertainties.

| $m_t \; (\mathrm{GeV}/c^2)$ | Source | $\int \mathcal{L} dt$ | Ref. Channel |

^{*} PDG uses this result as its best value. It is a combination of published measurements. See Listings for more details.

Current global fits performed within the SM or its minimal supersymmetric extension, in which the top-mass measurements play a crucial role, provide indications for a relatively light Higgs (see " H^0 Indirect Mass Limits" in the Particle Listings of this Review for more information). Such fits, including Z-pole data [77] and direct measurements of the mass and width of the W-boson, yield a pole top mass $m_t = 179^{+12}_{-9} \text{ GeV/c}^2$ [78]. A fit including additional electroweak precision data (see the review "Electroweak Model and Constraints on New Physics" in this Review) yields $m_t = 177.5^{+9.4}_{-7.8} \text{ GeV/c}^2$. Both indirect evaluations are in good agreement with the direct top quark mass measurements. A review of top quark mass measurements can be found in reference [79].

C.2.2 Top Quark Spin Correlations and Width: One of the unique features of the top quark is that it typically decays before its spin can be depolarized by the strong interaction. Thus the top quark polarisation is directly observable via the angular distribution of its decay products. Hence, it is possible to define and measure observables sensitive to the top quark spin and its production mechanism. Although the top and antitop quarks are produced in strong interactions essentially unpolarized in hadron collisions, the spins of t and \bar{t} are correlated. For QCD processes, the $t\bar{t}$ system is dominantly produced in a 3S_1 state with parallel spins for $q\bar{q}$ annihilation or in a 1S_0 state with antiparallel spins for gluon-gluon fusion. Hence, the situation at the Tevatron and at the LHC are complementary. The sensitivity to top spin is greatest when the top quark daughters are down-type fermions (charged leptons or d-type quarks), in which case the joint angular distribution is [80–82]

$$\frac{1}{\sigma} \frac{d^2 \sigma}{d(\cos \theta_+) d(\cos \theta_-)} = \frac{1 + \kappa \cdot \cos \theta_+ \cdot \cos \theta_-}{4}, \tag{2}$$

where θ_+ and θ_- are the angles of the daughters in the top rest frames with respect to a particular spin quantization axis. The maximum value for κ , 0.782 at NLO at the Tevatron [83], is found in the off-diagonal basis [80] while at the LHC the value at NLO is 0.326 in the helicity basis [83]. The spin correlation could be modified by a new production mechanism such as Z' bosons, Kaluza-Klein gluons or the Higgs boson.

CDF uses 5.1 fb⁻¹ in the dilepton channel to measure the correlation coefficient in the beam axis [84]. They use the expected distributions of $(\cos\theta_+,\cos\theta_-)$ and $(\cos\theta_b,\cos\theta_{\bar{b}})$ of the charged leptons or the *b*-quarks in the $t\bar{t}$ signal and background templates to calculate a likelihood of observed reconstructed distributions as a function of assumed κ . They determine the 68% confidence interval for the correlation coefficient κ as $-0.52 < \kappa < 0.61$ or $\kappa = 0.04 \pm 0.56$ assuming $m_t = 172.5 \ {\rm GeV/c^2}$.

CDF also analyzes lepton+jets events in 5.3 fb⁻¹ [85] assuming $m_t = 172.5 \text{ GeV/c}^2$. They form three separate templates - the same-spin template, the opposite-spin template, and the background template for the 2-dimensional distributions in $\cos(\theta_l)\cos(\theta_d)$ vs. $\cos(\theta_l)\cos(\theta_b)$. The fit to the data in the helicity basis returns an opposite helicity fraction of $F_{OH} = 0.74 \pm 0.24(stat) \pm 0.11(syst)$. Converting this to the spin correlation coefficient yields $\kappa_{helicity} = 0.48 \pm 0.48(stat) \pm 0.22(syst)$. In the beamline basis, they find an opposite spin fraction of $F_{OS} = 0.86 \pm 0.32(stat) \pm 0.13(syst)$ which can be converted into a correlation coefficient of $\kappa_{beam} = 0.72 \pm 0.64(stat) \pm 0.26(syst)$.

DØ performs a measurement of the ratio f of events with correlated t and \bar{t} spins to the total number of $t\bar{t}$ events in 5.3 fb⁻¹ in the l+jets channel using a matrix element technique [86]. From 729 events they obtain $f_{meas}=1.15^{+0.42}_{-0.43}$ (stat + syst) and can exclude values of f<0.420 at the 95% C.L. In the dilepton channel [87], they also use a matrix element method and can exclude the hypothesis that the spins of the $t\bar{t}$ are uncorrelated at the 97.7% C.L.. The combination [86] yields $f_{meas}=0.85\pm0.29$ (stat + syst) and a $t\bar{t}$ production cross section which is in good agreement with the SM prediction

^{**}The TEVEWWG world average is a combination of published Run 1 and preliminary or pub. Run-II meas., yielding a χ^2 of 8.3 for 11 deg. of freedom.

t

and previous measurements. For an expected fraction of f=1, they can exclude f<0.481 at the 95% C.L. For the observed value of $f_{meas}=0.85$, they can exclude f<0.344(0.052) at the 95(99.7)% C.L. The observed fraction f_{meas} translates to a measured asymmetry value of $A_{meas}=0.66\pm0.23$ (stat + syst). They therefore obtain first evidence of SM spin correlation at 3.1 standard deviations.

Using 5.4 fb⁻¹ of data, DØ measures the correlation in the dilepton channel also from the angles of the two leptons in the t and \bar{t} rest frames, yielding a correlation strength $C=0.10\pm0.45$ [88], in agreement with the NLO QCD prediction, but also in agreement with the no correlation hypothesis.

The ATLAS collaboration has performed a study of spin correlation in $t\bar{t}$ production at $\sqrt{s}=7$ TeV using 0.70 fb⁻¹ of data. Candidate events are selected in the dilepton topology with large missing transverse energy and at least two jets. The difference in azimuthal angle between the two charged leptons is compared to the expected distributions in the Standard Model, and to the case where the top quarks are produced with uncorrelated spin. Using the helicity basis as the quantisation axis, the strength of the spin correlation between the top and antitop quark is measured to be $A_{helicity} = 0.34^{+0.15}_{-0.11}$ [89], which is in agreement with the NLO Standard Model prediction.

Related to the measurement of top-spin correlations, which requires a top lifetime less than the hadronization timescale, is the measurement of the top width. The top width is expected to be of order 1 $\rm GeV/c^2$ (Eq. 1). The sensitivity of current experiments does not approach this level in direct measurements.

CDF presents a measurement of the top quark width in the lepton+jets decay channel of $t\bar{t}$ events from a data sample corresponding to 4.3 fb⁻¹ of integrated luminosity, yielding 756 events. The top quark mass and the mass of the hadronically decaying W boson that comes from the top quark decay are reconstructed for each event and compared with templates of different top quark widths (Γ_t) and deviations from nominal jet energy scale (ΔJES) to perform a simultaneous fit for both parameters, where ΔJES is used for the in situ calibration of the jet energy scale. By applying a Feldman-Cousins approach, they establish an upper limit at 95% C.L. of $\Gamma_t < 7.6$ GeV and a two-sided 68% C.L. interval of 0.3 GeV $< \Gamma_t < 4.4$ GeV [90], consistent with the Standard Model prediction.

DØ extracts the total width of the top quark from the partial decay width $\Gamma(t \to Wb)$ and the branching fraction $B(t \to Wb)$. $\Gamma(t \to Wb)$ is obtained from the measured t-channel cross section for single top quark production in 2.3 fb⁻¹, and $B(t \to Wb)$ is extracted from a measurement of the ratio $R = B(t \to Wb)/B(t \to Wq)$ in $\bar{t}t$ events in lepton+jets channels with 0, 1 and 2 b-tags in 1 fb⁻¹ of integrated luminosity. Assuming $B(t \to Wq) = 1$, where q includes any kinematically accessible quark, the result is: $\Gamma_t = 1.99^{+0.69}_{-0.55}$ GeV which translates to a top quark lifetime of $\tau_t = (3.3^{+1.3}_{-0.9}) \times 10^{-25}$ s. Assuming a high mass fourth generation b' quark and unitarity of the fourgeneration quark-mixing matrix, they set the first upper limit on $|V_{tb'}| < 0.63$ at 95% C.L. [91].

C.2.3 W Boson Helicity in Top Quark Decay: The Standard Model dictates that the top quark has the same vector-minus-axial-vector (V-A) charged-current weak interactions $\left(-i\frac{g}{\sqrt{2}}V_{tb}\gamma^{\mu}\frac{1}{2}(1-\gamma_{5})\right)$ as all the other fermions. In the SM, the fraction of top quark decays to longitudinally polarized W bosons is similar to its Yukawa coupling and hence enhanced with respect to the weak coupling. It is expected to be [92] $\mathcal{F}_{0}^{\text{SM}} \approx x/(1+x)$, $x=m_{t}^{2}/2M_{W}^{2}$ ($\mathcal{F}_{0}^{\text{SM}} \sim 70\%$ for $m_{t}=175~\text{GeV}/c^{2}$). Fractions of left-handed, right-handed, or longitudinal W bosons are denoted as \mathcal{F}_{-} , \mathcal{F}_{+} , and \mathcal{F}_{0} respectively. In the SM, \mathcal{F}_{-} is expected to be $\approx 30\%$ and $\mathcal{F}_{+} \approx 0\%$.

The Tevatron and the LHC experiments use various techniques to measure the helicity of the W boson in top quark decays, in both the lepton+jets events and dilepton channels.

The first method uses a kinematic fit, similar to that used in the lepton+jets mass analyses, but with the top quark mass constrained to a fixed value, to improve the reconstruction of final-state observables, and render the under-constrained dilepton channel solvable. The distribution of the helicity angle $(\cos \theta^*)$ between the lepton and the b quark in the W rest frame provides the most direct measure of the W helicity. In a simplified version of this approach, the $\cos \theta^*$ distribution is reduced to a forward-backward asymmetry.

The second method (p_T^{ℓ}) uses the different lepton p_T spectra from longitudinally or transversely polarized W-decays to determine the relative contributions.

A third method uses the invariant mass of the lepton and the *b*-quark in top decays $(M_{\ell b}^2)$ as an observable, which is directly related to $\cos \theta^*$.

At the LHC, top quark pairs in the dilepton channels are reconstructed by solving a set of six independent kinematic equations on the missing transverse energy in x- and in y-direction, two W-masses, and the two top/antitop quark masses. In addition, the two jets with the largest p_T in the event are interpreted as b-jets. The pairing of the jets to the charged leptons is based on the minimisation of the sum of invariant masses m_{min} . Simulations show that this criterion gives the correct pairing in 68% of the events.

Finally, the Matrix Element method (ME) has also been used, in which a likelihood is formed from a product of event probabilities calculated from the ME for a given set of measured kinematic variables and assumed W-helicity fractions. The results of recent CDF, DØ and ATLAS analyses are summarized in Table 3.

The datasets are now large enough to allow for a simultaneous fit of \mathcal{F}_0 and \mathcal{F}_+ , which we denote by '2-param' in the table. Results with either \mathcal{F}_0 or \mathcal{F}_+ fixed at its SM value are denoted '1-param'. For the simultaneous fits the correlation coefficient between the two values is about -0.8 for both experiments. A complete set of published results can be found in the Listings. All results are in agreement with the SM expectation.

Table 3: Measurement and 95% C.L. upper limits of the W helicity in top quark decays. Most results listed are preliminary and not yet submitted for publication, as of December 2011. A full set of published results is given in the Listings.

C.2.4 Top Quark Electric Charge: The top quark is the only quark whose electric charge has not been measured through production at threshold in e^+e^- collisions. Furthermore, it is the only quark whose electromagnetic coupling has not been observed and studied until recently. Since the CDF and DØ analyses on top quark production did not associate the b, \bar{b} , and W^\pm uniquely to the top or antitop, decays such as $t \to W^+ \bar{b}, \bar{t} \to W^- b$ were not excluded. A charge 4/3 quark of this kind is consistent with current electroweak precision data. The $Z \to \ell^+ \ell^-$ and $Z \to b\bar{b}$ data, in particular the discrepancy between A_{LR} from SLC at SLAC and $A_{FB}^{0,b}$ of b-quarks and $A_{FB}^{0,\ell}$ of leptons from LEP at CERN, can be fitted with a top quark of mass $m_t = 270 \text{ GeV/c}^2$, provided that the right-handed b quark mixes with the isospin +1/2 component of an exotic doublet of charge -1/3 and -4/3 quarks, $(Q_1, Q_4)_R$ [98,99].

DØ studies the top quark charge in double-tagged lepton+jets events, CDF does it in single-tagged lepton+jets and dilepton events. Assuming the top and antitop quarks have equal but opposite electric charge, then reconstructing the charge of the b-quark through jet charge discrimination techniques, the $|Q_{top}| = 4/3$ and $|Q_{top}| = 2/3$ scenarios can be differentiated. For the exotic model of Chang et al. [99] with a top quark charge $|Q_{top}| = 4/3$, DØ excludes the exotic model at 91.2% C.L.% [100] using 370 pb⁻¹, while CDF excludes the model at 99% C.L. [101] in 5.6 fb⁻¹. Both results indicate that the observed particle is indeed consistent with being a SM $|Q_{top}| = 2/3$ quark. In 0.70 fb⁻¹, ATLAS performed a similar

analysis, reconstructing the *b*-quark charge either via a jetcharge technique or via the lepton charge in soft muon decays in combination with a kinematic likelihood fit. They exclude the exotic scenario at more than 5 σ [102].

The electromagnetic or the weak coupling of the top quark can be probed directly by investigating $t\bar{t}$ events with an additional gauge boson, like $t\bar{t}\gamma$ and $t\bar{t}Z$ events. Top quark pair events with additional photons in the final state are directly sensitive to the $t\bar{t}\gamma$ vertex.

CDF performs a search for events containing a lepton, a photon, significant missing transverse momentum, and a jet identified as containing a b-quark and at least three jets and large total transverse energy in 1.9 fb⁻¹. They find 16 $t\bar{t}\gamma$ events with an expectation from SM sources of $11.2^{+2.3}_{-2.1}$ events which they translate into a measurement of the $t\bar{t}\gamma$ cross section measurement of 0.15 ± 0.08 pb [103]. Recently, CDF repeated this measurement with 6.0 fb⁻¹ and reported evidence for the observation of $t\bar{t}\gamma$ production with a cross section $\sigma_{t\bar{t}\gamma}=0.18\pm0.08$ pb and a ratio of $\sigma_{t\bar{t}\gamma}/\sigma_{t\bar{t}}=0.024\pm0.009$ [104].

ATLAS performed a first measurement of the $t\bar{t}\gamma$ cross section in pp collisions at $\sqrt{s}=7$ TeV using 1.04 fb⁻¹ of data. Events are selected that contain a large transverse momentum electron or muon and a large transverse momentum photon, yielding 52 and 70 events in the electron and muon samples, respectively. The resulting cross section times branching ratio into the single lepton and dilepton channels for $t\bar{t}\gamma$ production with a photon with transverse momentum above 8 GeV is $\sigma(t\bar{t}\gamma)=2.0\pm0.5(stat.)\pm0.7(syst.)\pm0.1(lumi.)$ pb [105], which is consistent with theoretical calculations. A real test, however, of the vector and axial vector couplings in $t\bar{t}\gamma$ events or searches for possible tensor couplings of top quarks to photons will only be feasible with an integrated luminosity of several fb⁻¹ in the future.

C.3 Searches for Non-Standard Model Top Quark Production & Decay:

Motivated by the large mass of the top quark, several models suggest that the top quark plays a role in the dynamics of electroweak symmetry breaking. One example is topcolor [106], where a large top quark mass can be generated through the formation of a dynamic $t\bar{t}$ condensate, X, which is formed by a new strong gauge force coupling preferentially to the third generation. Another example is topcolor-assisted technicolor [107], predicting a heavy Z' boson that couples preferentially to the third generation of quarks with cross sections expected to be visible at the Tevatron and the LHC. CDF, DØ ATLAS, and CMS have searched for $t\bar{t}$ production via intermediate, narrowwidth, heavy-vector bosons X in the lepton+jets, the dilepton or the all-jets channels.

CDF has searched for resonant production of $t\bar{t}$ pairs in 4.8 fb⁻¹ of data in the lepton+jets channel. A matrix element reconstruction technique is used; for each event a probability density function (pdf) of the $t\bar{t}$ candidate invariant mass is sampled. These pdfs are used to construct a likelihood function, whereby the cross section for resonant $t\bar{t}$ production is

t

estimated, given a hypothetical resonance mass and width. The data indicate no evidence of resonant production of $t\bar{t}$ pairs. A benchmark model of leptophobic $Z\to t\bar{t}$ is excluded with $m_{Z'}<900$ GeV at 95% C.L. [108]. A similar analysis has been performed in the all-jets channel using 2.8 fb⁻¹ of data [109]. In the absence of any evidence for top-antitop quark resonant production upper limits on the production cross section times branching ratio for a specific topcolor assisted technicolor model with width of $\Gamma_{Z'}=0.012M_{Z'}$ are set. Within this model, they exclude Z' bosons with masses below 805 GeV at the 95% C.L.

DØ has searched for narrow $t\bar{t}$ resonances that decay into a lepton+jets final state based on 5.3 fb⁻¹. They place upper limits on the production cross section times branching fraction to $t\bar{t}$ in comparison to the prediction for a leptophobic topcolor Z' boson. They exclude such a resonance at the 95% C.L. for masses below 835 GeV at width $\Gamma_{Z'}=0.012M_{Z'}$ [110]. This limit turns out to be independent of couplings of the $t\bar{t}$ resonance (pure vector, pure axial-vector, or Standard Model Z-like) and is valid for any narrow resonance decaying 100% to a $t\bar{t}$ final state.

ATLAS has performed a search for $t\bar{t}$ resonances in the lepton+jets final states using 0.2 fb⁻¹ of data at $\sqrt{s} = 7$ TeV. No evidence for a resonance is found. Using the reconstructed $t\bar{t}$ mass spectrum, limits are set on the production crosssection times branching ratio to $t\bar{t}$ for narrow and wide resonances. For narrow Z' models, the observed 95% C.L. limits range from approximately 38 pb to 3.2 pb for masses going from $m_{Z'} = 500 \text{ GeV}$ to $m_{Z'} = 1300 \text{ GeV}$ [111]. In Randall-Sundrum models, Kaluza-Klein gluons with masses below 650 GeV are excluded at 95% C.L. Using 1.04 fb⁻¹ of data in the dilepton channel, they have not observed any significant excess and place upper limits at the 95% C.L. on the cross section times branching ratio of the resonance decaying to $t\bar{t}$ pairs as a function of the resonance pole mass. A lower mass limit of 0.84 TeV is set for the case of a Kaluza Klein gluon resonance in the Randall-Sundrum Model [112].

CMS performs a search for massive neutral bosons decaying via a top-antitop quark pair. The analysis is based on 36 pb⁻¹ of data. From a combined analysis of the muon plus jets and electron plus jets decay modes no significant signal is observed, and upper limits on the production cross section as a function of the boson mass are reported [113]. They also perform a search for narrow heavy resonances decaying to top quark pairs in the μ +jets channel using 1.1 fb⁻¹ and set sub-picobarn limits at 95% C.L. on $\sigma(pp \to Z' \to t\bar{t})$ for invariant Z' masses above 1.35 TeV/c² [114]. Using 0.9 fb⁻¹, they search in the all-hadronic channel for sufficiently heavy resonances with decay products partially or fully merged into one jet. They set sub-picobarn limits on $\sigma_{Z'} \times B(Z' \to t\bar{t})$ at 95% C.L. for Z' heavier than 1.1 TeV/c² [115]

Both CDF and DØ have searched for non-SM top decays [116–121], particularly those expected in supersymmetric models, such as $t \to H^+b$, followed by $H^+ \to \tau^+\bar{\nu}$ or $c\bar{s}$. The $t \to H^+b$ branching ratio has a minimum at

 $\tan \beta = \sqrt{m_t/m_b} \simeq 6$, and is large in the region of either $\tan \beta \ll 6$ or $\tan \beta \gg 6$. In the former range, $H^+ \to c\overline{s}$ is dominant, while $H^+ \to \tau^+ \bar{\nu}$ dominates in the latter range. These studies are based either on direct searches for these final states, or on top "disappearance." In the standard lepton+jets or dilepton cross-section analyses, any charged-Higgs decays are not detected as efficiently as $t \to W^\pm b$, primarily because the selection criteria are optimized for the standard decays, and because of the absence of energetic isolated leptons in Higgs decays. A significant $t \to H^+ b$ contribution would give rise to measured $t\overline{t}$ cross sections that would be lower than the prediction from the SM (assuming that non-SM contributions to $t\overline{t}$ production are negligible), and the measured cross-section ratio $\sigma_{t\overline{t}}^{\ell+jets}/\sigma_{t\overline{t}}^{\ell\ell}$ would differ from unity.

In Run II, CDF has searched for charged-Higgs production in dilepton, lepton+jets, and lepton+hadronic tau final states, considering possible H^+ decays to $c\bar{s}$, $\tau\bar{\nu}$, t^*b , or W^+h^0 , in addition to the SM decay $t \to W^+ b$ [118,119]. Depending on the top and Higgs-decay branching ratios, which are scanned in a particular 2-Higgs doublet benchmark model, the number of expected events in these decay channels can show an excess or deficit when compared to SM expectations. A modelindependent interpretation yields a limit of $B(t \to H^{\pm}b) < 0.91$ at 95% C.L. for $m_{H^{\pm}} \approx 100$ GeV, and $B(t \to H^{\pm}b) < 0.4$ in the tauonic model with $B(H^{\pm} \to \tau \nu) = 100\%$. In a more recent search, the dijet invariant mass in lepton+jets events has been used in 2.2 fb⁻¹ to search for a charged Higgs decaying to $c\bar{s}$ with mass above the W boson mass. The absence of a signal leads to a 95% C.L. limit of $B(t \to H^{\pm}b) \times B(H^{\pm} \to c\bar{s}) < 0.1$ to 0.3 for masses between 90 and 150 GeV/c^2 [119].

In 1 fb⁻¹ of integrated luminosity, the DØ collaboration has used the $t\bar{t}$ dilepton and lepton+jets events, including τ lepton channels, to search for evidence of charged-Higgs decays into τ leptons via the ratio of events with τ leptons to those with e and μ [120], global fits [121] and topological searches [122]. They exclude regions of $B(t \to H^{\pm}b)$ as a function of Higgs mass, ranging from $B(t \to H^{\pm}b) > 0.12$ at low mass to $B(t \to H^{\pm}b) > 0.2$ at high mass. In a companion analysis they look for evidence of leptophobic charged Higgs production in top decays in which the Higgs decays purely hadronically, leading to a suppression of the measured $t\bar{t}$ rate in all leptonic channels. They exclude $B(t \to H^{\pm}b) > 0.2$ for charged-Higgs masses between 80 and 155 GeV/c².

DØ combines measurements of the top quark pair production cross section in the ℓ +jets, $\ell\ell$, and $\tau\ell$ final states (where ℓ is an electron or muon) in 1 fb⁻¹ of data, yielding $\sigma_{t\bar{t}}=8.18^{+0.98}_{-0.87}$ pb for $m_t=170$ GeV, or based on QCD predictions extract a top quark mass consistent with the world average. In addition, they measure the cross section ratios to be $\sigma_{ll}/\sigma_{lj}=0.86^{+0.19}_{-0.17}(stat+syst)$ and $\sigma_{\tau l}/\sigma_{ll+lj}=0.97^{+0.32}_{-0.29}(stat+syst)$. Based on this, they set upper limits on the branching fractions $B(t\to H^+b\to \tau^+\nu b)$ and $B(t\to H^+b\to c\bar{s}b)$ as a function of the charged Higgs boson mass [123].

In 35 pb⁻¹, ATLAS searches for the decay $H^+ \to c\bar{s}$ in the lepton+jets channel by investigation of the invariant jj-mass spectrum. The observed limits are within one standard deviation of the expected limits and range from B=0.25 to 0.14 for $m_{H^\pm}=90$ to 130 GeV/c² [124]. In 1.03 fb⁻¹ ATLAS searches for $t\bar{t}\to\tau(\to hadrons)+jets$. They set a 95% C.L. limit on the production of branching ratios $B(t\to bH^\pm)\times B(H^\pm\to\tau\nu)$ of 0.03 to 0.10 for H^\pm masses in the range 90 GeV/c² < $m_{H^\pm}<160$ GeV/c² [125]. A similar analysis with τ decaying to leptons in 1.03 fb⁻¹, assuming $B(H^\pm\to\tau\nu)=1$, this leads to 95% C.L. upper limits on the branching fraction $B(t\to bH^\pm)$ between 5.2% and 14.1% for H^\pm masses in the range 90 GeV/c² < $m_H^\pm<160$ GeV/c² [126].

The ATLAS collaboration has also searched for FCNC processes in $0.7~{\rm fb}^{-1}$ of $t\bar{t}$ events with one top quark decaying through FCNC $(t \to qZ)$ and the other through the Standard Model dominant mode $(t \to bW)$. Only the decays of the Z boson to charged leptons and leptonic W boson decays were considered as signal, leading to a final state topology characterised by the presence of three isolated leptons, at least two jets and missing transverse energy from the undetected neutrino. No evidence for an FCNC signal was found. An upper limit on the $t \to qZ$ branching ratio of $B(t \to qZ) < 1.1\%$ is set at the 95% confidence level, compatible with the expected limit, assuming no FCNC decay, of $B(t \to qZ) < 1.3\%$ [127].

More details, and the results of these studies for the exclusion in the m_{H^\pm} , $\tan\beta$ plane, can be found in the review "Higgs Bosons: Theory and Searches" and in the " H^+ Mass Limits" section of the Higgs Particle Listings of the current edition.

Using up to 2.7 fb⁻¹ of data, DØ has measured the Wtb coupling form factors by combining information from the W boson helicity in top quark decays in $t\bar{t}$ events and single-top quark production, allowing to place limits on the left-handed and right-handed vector and tensor couplings [128–130].

In 2.3 fb⁻¹, DØ excludes the production of W' bosons with masses below 863 GeV/c² for a W' boson with Standard Model-like couplings, below 885 GeV/c² for a W' boson with right-handed couplings that is allowed to decay to both leptons and quarks, and below 890 GeV/c² for a W' boson with right-handed couplings that is only allowed to decay to quarks [131]. CDF has recently released W' limits also using the single-top analysis [132]. In 1.9 fb⁻¹ of Run-II data, a W' with Standard Model couplings is searched for in the $t\bar{b}$ decay mode. Masses below 800 GeV/c² are excluded, assuming that any right-handed neutrino is lighter than the W', and below 825 GeV/c² if the right-handed neutrino is heavier than the W'.

CDF reported a search for flavor-changing neutral-current (FCNC) decays of the top quark $t \to q\gamma$ and $t \to qZ$ in the Run-I data [133], and recently with enhanced sensitivity in Run II [134]. The SM predicts such small rates that any observation would be a sign of new physics. CDF assumes that one top decays via FCNC, while the other decays via Wb. The Run-I analysis included a $t \to q\gamma$ search in which two signatures are examined, depending on whether the W decays leptonically

or hadronically. For leptonic W decay, the signature is $\gamma\ell$ and missing E_T and two or more jets, while for hadronic W decay, it is $\gamma+\geq 4$ jets. In either case, one of the jets must have a secondary vertex b tag. One event is observed $(\mu\gamma)$ with an expected background of less than half an event, giving an upper limit on the top branching ratio of $B(t\to q\gamma)<3.2\%$ at 95% C.L. In the search for $t\to qZ$, CDF considers $Z\to \mu\mu$ or ee and $W\to qq'$, giving a Z+ four jets signature. A Run-II dataset of 1.9 fb⁻¹ is found consistent with background expectations and a 95% C.L. on the $t\to qZ$ branching fraction of <3.7% (for $m_t=175~{\rm GeV/c^2}$) is set [134]. By comparison to the number expected from the theoretical production cross section, CDF has used the observed number of double b-tagged lepton+jets candidate events to place limits on a variety of decay modes, ranging from $B(t\to Zc)<13\%$ to $B(t\to invisible)<9\%$ [135].

In 4.1 fb⁻¹, DØ performs a search for events with $t\bar{t} \to \ell' \nu \ell \bar{\ell} + {\rm jets}$ $(\ell,\ell'=e,\mu)$ and extracts limits on the branching ratio $B(t\to Zq)(q=u,c$ quarks) < 3.2%) at 95% C.L. [136]. DØ performs also in single-top event candidates with an additional jet searches for flavor changing neutral currents via quark-gluon couplings, using 2.3 fb⁻¹. They find consistency between background expectation and observed data and set cross section limits at the 95% C.L. of $\sigma_{tgu} < 0.20$ pb and $\sigma_{tgc} < 0.27$ pb which corresponds to limits on the top quark decay branching fractions of $B(t\to gu) < 2.0 \cdot 10^{-4}$ and $B(t\to gc) < 3.9 \cdot 10^{-3}$ [137].

Constraints on FCNC couplings of the top quark can also be obtained from searches for anomalous single-top production in e^+e^- collisions, via the process $e^+e^- \to \gamma, Z^* \to t\overline{q}$ and its charge-conjugate (q = u, c), or in $e^{\pm}p$ collisions, via the process $e^{\pm}u \rightarrow e^{\pm}t$. For a leptonic W decay, the topology is at least a high- p_T lepton, a high- p_T jet and missing E_T , while for a hadronic W-decay, the topology is three high- p_T jets. Limits on the cross section for this reaction have been obtained by the LEP collaborations [138] in e^+e^- collisions, and by H1 [139] and ZEUS [140] in $e^{\pm}p$ collisions. When interpreted in terms of branching ratios in top decay [141,142], the LEP limits lead to typical 95% C.L. upper bounds of $B(t \to qZ) < 0.137$. Assuming no coupling to the Z boson, the 95% C.L. limits on the anomalous FCNC coupling $\kappa_{\gamma} < 0.13$ and < 0.27 by ZEUS and H1, respectively, are stronger than the CDF limit of $\kappa_{\gamma} < 0.42$, and improve over LEP sensitivity in that domain. The H1 limit is slightly weaker than the ZEUS limit due to an observed excess of five-candidate events over an expected background of 3.2 ± 0.4 . If this excess is attributed to FCNC top quark production, this leads to a total cross section of $\sigma(ep \to e + t + X, \sqrt{s} = 319 \text{ GeV}) < 0.25 \text{ pb } [139,143].$

t-QUARK MASS

We first list the direct measurements of the top quark mass which employ the event kinematics and then list the measurements which extract a top quark mass from the measured $t\overline{t}$ cross-section using theory calculations. A discussion of the definition of the top quark mass in these measurements can be found in the review "The Top Quark."

OUR EVALUATION of 173.5 \pm 0.6 \pm 0.8 GeV is an average of published top mass measurements from Tevatron Run-I (1992–1996) and Run-II (2001–present) and of the LHC. The Tevatron average (173.4 \pm 0.6 \pm 0.8 GeV) was provided by the Tevatron Electroweak Working Group (TEVEWWG). It takes correlated uncertainties into account and has a χ^2 of 8.5 for 11 degrees of freedom. We include in OUR EVALUATION the measurement from CHATRCHYAN 11F assuming uncorrelated systematic uncertainties. The average would be 173.4 \pm 0.6 \pm 0.8 GeV if we assumed fully correlated systematics between the Tevatron average and CHATRCHYAN 11F.

For earlier search limits see PDG 96, Physical Review **D54** 1 (1996). We no longer include a compilation of indirect top mass determinations from Standard Model Electroweak fits in the Listings (our last compilation can be found in the Listings of the 2007 partial update). For a discussion of current results see the reviews "The Top Quark" and "Electroweak Model and Constraints on New Physics."

t-Quark Mass (Direct Measurements)

The following measurements extract a t-quark mass from the kinematics of $t\overline{t}$ events. They are sensitive to the top quark mass used in the MC generator that is usually interpreted as the pole mass, but the theoretical uncertainty in this interpretation is hard to quantify. See the review "The Top Quark" and references therein for more information

t-Quark MS Mass from Cross-Section Measurements

The top quark $\overline{\rm MS}$ or pole mass can be extracted from a measurement of $\sigma(t\bar{t})$ by using theory calculations. We quote below the $\overline{\rm MS}$ mass. See the review "The Top Quark" and references therein for more information.

- 1 Based on 5.7 fb $^{-1}$ in $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV. Events with an identified charged lepton or small E_T are rejected from the event sample, so that the measurement is statistically independent from those in the $\ell+$ jets and all hadronic channels while being sensitive to those events with a τ lepton in the final state. Supersedes AALTONEN 07B.
- 2 Based on 5.6 fb $^{-1}$ in $p\bar{p}$ collisions at $\sqrt{s}=1.96$ TeV. Employs a multi-dimensional template likelihood technique where the lepton plus jets (one or two b-tags) channel gives $172.2\pm1.2\pm0.9$ GeV while the dilepton channel yields $170.3\pm2.0\pm3.1$ GeV. The results are combined. OUR EVALUATION includes the measurement in the dilepton
- 3 Based on 3.6 fb $^{-1}$ in $p\overline{p}$ collisions at $\sqrt{s}=$ 1.96 TeV. ABAZOV 11P reports 174.94 $0.83\pm0.78\pm0.96$ GeV, where the first uncertainty is from statistics, the second from JES, and the last from other systematic uncertainties. We combine the JES and systematic uncertainties. A matrix-element method is used where the JES uncertainty is constrained by the W mass. ABAZOV 11P describes a measurement based on 2.6 fb $^{-1}$ that is combined with ABAZOV 08AH, which employs an independent $1~{
 m fb}^{-1}$ of data.
- 4 Based on a matrix-element method which employs 5.4 fb $^{-1}$ in $p\overline{p}$ collisions at $\sqrt{s}=$

- 1.96 TeV. 5 Based on 36 pb $^{-1}$ of pp collisions at $\sqrt{s}=7$ TeV. A Kinematic Method using b-tagging and an analytical Matrix Weighting Technique give consistent results and are combined. 6 Based on 5.6 fb $^{-1}$ in $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV. The likelihood calculated using a matrix element method gives $m_t=173.0\pm0.7(\mathrm{stat})\pm0.6(\mathrm{JES})\pm0.9(\mathrm{syst})$ GeV, for a total uncertainty of 1.2 GeV. 7 Based on 1.9 fb $^{-1}$ in $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV. The result is from the measurement using the transverse decay length of b-hadrons and that using the transverse momentum of the W decay muons, which are both insensitive to the JES (jet energy scale) uncertainty. OUR EVALUATION uses only the measurement exploiting the decay length significance which yields $166.9^{+9.5}_{-8.5}(\mathrm{stat})\pm2.9$ (syst) GeV. The measurement that uses the lepton transverse momentum is excluded from the average because of a statistical correlation with other samples. 8 Based on 2.9 fb $^{-1}$ in $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV. The first error is from statistics
- 8 Based on 2.9 fb $^{-1}$ in $p\overline{p}$ collisions at $\sqrt{s}=$ 1.96 TeV. The first error is from statistics and JES uncertainty, and the latter is from the other systematics. Neural-network-based kinematical selection of 6 highest ${\it E_T}$ jets with a vtx $\it b$ -tag is used to distinguish signal from background.
- $\begin{array}{l} \text{Obtain detaglorism.} \\ \text{Obtain detaglorism.} \\ \text{It is based upon the maximum likelihood method which makes use of the leading order} \end{array}$ matrix elements.
- 10 Based on 125 ± 7 pb $^{-1}$ of data at $\sqrt{s}=1.8$ TeV. 11 Based on ~ 106 pb $^{-1}$ of data at $\sqrt{s}=1.8$ TeV. 12 Based on 109 ± 7 pb $^{-1}$ of data at $\sqrt{s}=1.8$ TeV.
- 13 See AFFOLDER 01 for details of systematic error re-evaluation.
- The Based on the first observation of all hadronic decays of $t\bar{t}$ pairs. Single b-quark tagging with jet-shape variable constraints was used to select signal enriched multi-jet events. The updated systematic error is listed. See AFFOLDER 01, appendix C.

 15 Based on 3.2 fb⁻¹ in $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV. The first error is from statistics and JES combined, and the latter is from the other systematic uncertainties. The result is obtained using a published may be updated where the top quark mass.
- is obtained using an unbinned maximum likelihood method where the top quark mass and the JES are measured simultaneously, with $\Delta_{JES}=0.3\pm0.3 ({\rm stat}).$
- 16 Uses a likelihood fit of the lepton p_T distribution based on 2.7 fb $^{-1}$ in $p\overline{p}$ collisions at $\sqrt{s} = 1.96 \text{ TeV}.$
- $\sqrt{s}=1.96$ TeV. 17 Based on 3.4 fb $^{-1}$ in $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV. The result is obtained by combining the MT2 variable method and the NWA (Neutrino Weighting Algorithm). The MT2 method alone gives $m_t=168.0^{+4.8}_{-4.0}({\rm stat})\pm 2.9({\rm syst})$ GeV with smaller systematic error due to small JES uncertainty.
- 18 Based on 2 fb^{-1} of data at $\sqrt{s} = 1.96$ TeV. The top mass is obtained from the measurement of the invariant mass of the lepton (e or μ) from W decays and the soft μ in b-jet. The result is insensitive to jet energy scaling.

 19 Based on 1.9 fb^{-1} of data at $\sqrt{s} = 1.96 \text{ TeV}$. The first error is from statistics and jet
- ^-Based on 1.7 b ^- of data at $\sqrt{s}=1.96$ TeV. The first error is from statistics and jet energy scale uncertainty, and the latter is from the other systematics. Matrix element method with effective propagators. 20 Based on 943 pb $^{-1}$ of data at $\sqrt{s}=1.96$ TeV. The first error is from statistical and jet-energy-scale uncertainties, and the latter is from other systematics. AALTONEN 09k selected 6 jet events with one or more vertex b-tags and used the tree-level matrix element to construct tompolate for fixed and between
- selected of the ventes with older models of signal and background. $^{21} \text{Based on } 1.9 \text{ fb}^{-1} \text{ of data at } \sqrt{s} = 1.96 \text{ TeV}. \text{ The first error is from statistical and jet-energy-scale (JES) uncertainties, and the second is from other systematics. Events with lepton + jets and those with dilepton + jets were simultaneously fit to constrain <math>m_t$ and JES. Lepton + jets data only give $m_t = 171.8 \pm 2.2 \text{ GeV}$, and dilepton data $m_t = 171.8 \pm 1.2 \text{ GeV}$. only give $m_t = 171.2^{+5.3}_{-5.1} \text{ GeV}$.
- 22 Based on 2 fb $^{-1}$ of data at $\sqrt{s}=$ 1.96 TeV. Matrix Element method. Optimal selection criteria for candidate events with two high p_T leptons, high E_T , and two or more jets with and without b-tag are obtained by neural network with neuroevolution technique to
- minimize the statistical error of m_t . 23 Based on 2.9 fb $^{-1}$ of data at $\sqrt{s}=1.96$ TeV. Mass m_t is estimated from the likelihood for the eight-fold kinematical solutions in the plane of the azimuthal angles of the two
- neutrino momenta. 2^4 Based on 1 fb⁻¹ of data at $\sqrt{s}=1.96$ TeV. Events with two identified leptons, and those with one lepton plus one isolated track and a b-tag were used to constrain m_t . The result is a combination of the ν WT (ν Weighting Technique) result of 176.2 \pm 4.8 \pm 2.1 GeV and the MWT (Matrix-element Weighting Technique) result of 173.2 \pm 4.9 \pm 2.0 GeV
- 25 Reports measurement of $170.7 + \frac{4.2}{3.9} \pm 2.6 \pm 2.4$ GeV based on $1.2 \, \mathrm{fb^{-1}}$ of data at $\sqrt{s} = 1.96$ TeV. The last error is due to the theoretical uncertainty on $\sigma_{t\overline{t}}$. Without the cross-section constraint a top mass of $169.7^{+5.2}_{-4.9} \pm 3.1$ GeV is obtained.
- ²⁶ Template method.
- 27 Result is based on 1 fb $^{-1}$ of data at $\sqrt{s}=1.96$ TeV. The first error is from statistics and jet energy scale uncertainty, and the latter is from the other systematics.
 28 Based on 310 pb $^{-1}$ of data at $\sqrt{s}=1.96$ TeV.
- ²⁹ Ideogram method.
- To determine the signal acceptance is from $\tau \nu + 4$ jets. Events with 4 or more jets with $E_T > 15$ GeV, significant missing E_T , and secondary vertex b-tag are used in the fit. About 44% of the signal acceptance is from $\tau \nu + 4$ jets. Events with identified e or μ are vetoed to provide a statistically independent measurement.
- 31 Based on $1.02~{
 m fb}^{-1}$ of data at $\sqrt{s}=1.96~{
 m TeV}.$

- 32 Based on 955 pb $^{-1}$ of data $\sqrt{s}=$ 1.96 TeV. m_t and JES (Jet Energy Scale) are fitted simultaneously, and the first error contains the JES contribution of 1.5 GeV.
- 33 Matrix element method. 34 Based on 425 pb $^{-1}$ of data at $\sqrt{s}=1.96$ TeV. The first error is a combination of statistics gives $\frac{1}{2} = \frac{1}{2} = \frac$ and JES (Jet Energy Scale) uncertainty, which has been measured simultaneously to give JES $=0.989\pm0.029(\text{stat})$.
- 35 Based on 370 pb $^{-1}$ of data at $\sqrt{s}=1.96$ TeV. Combined result of MWT (Matrix-element Weighting Technique) and ν WT (ν Weighting Technique) analyses is 178.1 \pm 6.7 ± 4.8 GeV
- $6.7\pm4.8\,\mathrm{GeV}$. $36\,\mathrm{Based}$ on $1.0\,\mathrm{fb}^{-1}$ of data at $\sqrt{s}=1.96\,\mathrm{TeV}$. ABULENCIA 07D improves the matrix element description by including the effects of initial-state radiation. $37\,\mathrm{Based}$ on $695\,\mathrm{pb}^{-1}$ of data at $\sqrt{s}=1.96\,\mathrm{TeV}$. The transverse decay length of the b hadron is used to determine m_t , and the result is free from the JES (jet energy scale) in the second of the se uncertainty.
- 38 Based on \sim 400 pb $^{-1}$ of data at $\sqrt{s}=1.96$ TeV. The first error includes statistical and systematic jet energy scale uncertainties, the second error is from the other systematics. The result is obtained with the b-tagging information. The result without b-tagging is $169.2 \substack{+5.0 + 1.5 \\ -7.4 - 1.4}$ GeV. Superseded by ABAZOV 08AH.
- 39 Based on 318 pb $^{-1}$ of data at $\sqrt{s}=$ 1.96 TeV
- ⁴⁰ Dynamical likelihood method.
- 41 Based on 340 pb $^{-1}$ of data at $\sqrt{s}=$ 1.96 TeV.
- 42 Based on 360 pb $^{-1}$ of data at $\sqrt{s}=$ 1.96 TeV.
- 43 Based on $110.2 \pm 5.8~{
 m pb}^{-1}$ at $\sqrt{s} = 1.8~{
 m TeV}$.
- ⁴⁴ Based on the all hadronic decays of $t\bar{t}$ pairs. Single b-quark tagging via the decay chain $b\to c\to \mu$ was used to select signal enriched multijet events. The result was obtained by the maximum likelihood method after bias correction.
- $^{
 m 45}$ Obtained by combining the measurements in the lepton + jets [AFFOLDER 01], all-jets [ABE 97R, ABE 99B], and dilepton [ABE 99B] decay topologies.
- 46 Obtained by combining the D0 result m_t (GeV) = $168.4\pm12.3\pm3.6$ from 6 di-lepton events (see also ABBOTT 98D) and m_t (GeV) = $173.3\pm5.6\pm5.5$ from lepton+jet events (ABBOTT 98F).
- events (ABBUT For). 47 Obtained by combining the CDF results of m_t (GeV)=167.4 \pm 10.3 \pm 4.8 from 8 dilepton events, m_t (GeV)=175.9 \pm 4.8 \pm 5.3 from lepton+jet events (ABE 98E), and m_t (GeV)=186.0 \pm 10.0 \pm 5.7 from all-jet events (ABE 97R). The systematic errors in the latter two measurements are changed in this paper.
- 48 See ABAZOV 04 G.
- ⁴⁹ The updated systematic error is listed. See AFFOLDER 01, appendix C.
- 50 Obtained by combining the DØ results of $m_t ({\rm GeV}) = \!\! 168.4 \pm 12.3 \pm 3.6$ from 6 dilepton events and $m_t ({\rm GeV}) = \!\! 173.3 \pm 5.6 \pm 5.5$ from 77 lepton+jet events.
- 51 Obtained by combining the DØ results from dilepton and lepton+jet events, and the CDF results (ABE 99B) from dilepton, lepton+jet events, and all-jet events.
- ⁵² Based on 5.3 fb⁻¹ in $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV. ABAZOV 11s uses the measured $t\overline{t}$ production cross section of $8.13^{+1.02}_{-0.90}$ pb [ABAZOV 11E] in the lepton plus jets channel to obtain the top quark $\overline{\text{MS}}$ mass by using an approximate NNLO computation (MOCH 08, LANGENFELD 09). The corresponding top quark pole mass is $167.5^{+5.4}_{-4.9}$ GeV. A different theory calculation (AHRENS 10, AHRENS 10A) is also used and yields
- m $_{\ell}^{\overline{\rm MS}}$ = 154.5 $_{-4.3}^{+5.0}$ GeV. Sasked on 1 fb¹ of data at \sqrt{s} = 1.96 TeV. Uses the ℓ + jets, $\ell\ell$, and $\ell\tau$ + jets channels. ABAZOV 09AG extract the pole mass of the top quark using two different calculations that yield 169.1 $_{-5.2}^{+5.9}$ GeV (MOCH 08, LANGENFELD 09) and 168.2 $_{-5.4}^{+5.9}$
- 54 Based on 1 fb¹ of data at $\sqrt{s}=1.96$ TeV. Uses the $\ell\ell$ and $\ell\tau$ + jets channels. ABAZOV 09R extract the pole mass of the top quark using two different calculations that yield $173.3^{+9.8}_{-8.6}$ GeV (MOCH 08, LANGENFELD 09) and $171.5^{+9.9}_{-8.8}$ GeV (CAC-CIARI 08).

†

- 1 Based on 2.3 fb $^{-1}$ in $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV. ABAZOV 118 extracted \varGamma_t from the partial width $\varGamma(t\to Wb)=1.92^{+0.58}_{-0.51}$ GeV measured using the t-channel single top production cross section, and the branching fraction br $t\to Wb=0.962^{+0.066}_{-0.065}(\text{stat})^{+0.064}_{-0.052}(\text{syst}).$ The $\varGamma(t\to Wb)$ measurement gives the 95% CL lowerbound of $\varGamma(t\to Wb)$ and hence that of \varGamma_t .
- Results are based on 4.3 fb⁻¹ of data in $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV. The top quark mass and the hadronically decaying W boson mass are reconstructed for each candidate events and compared with templates of different top quark width. The two sided 68% CL interval is 0.3 GeV< $\Gamma_t <$ 4.4 GeV for $m_t = 172.5$ GeV.

 3 Based on 955 pb⁻¹ of $p\overline{p}$ collision data at $\sqrt{s}=1.96$ TeV. AALTONEN 09M selected
- 3 Based on 955 pb $^{-1}$ of $p\overline{p}$ collision data at $\sqrt{s}=1.96$ TeV. AALTONEN 09M selected $t\overline{t}$ candidate events for the $\ell+\cancel{E}_T+$ jets channel with one or two b-tags, and examine the decay width dependence of the reconstructed m_t distribution. The result is for $m_t=175$ GeV, whereas the upper limit is lower for smaller m_t .

t DECAY MODES

| | Mode | Fraction (Γ _i /Γ) | Confidence level |
|----------------------------------|--------------------------|-----------------------------------|------------------|

- 1 Based on 5.4 fb $^{-1}$ of data. The error is statistical and systematic combined. The result is a combination of 0.95 \pm 0.07 from ℓ + jets channel and 0.86 \pm 0.05 from $\ell\ell$ channel. $|\mathsf{V}^{tb}|=0.95\pm0.02$ follows from the result by assuming unitarity of the 3x3 CKM matrix.
- 2 ACOSTA 05A result is from the analysis of lepton + jets and di-lepton + jets final states of $t\bar{t}$ candidate events with $\sim 162~{\rm pb}^{-1}$ of data at $\sqrt{s}=1.96~{\rm TeV}$. The first error is statistical and the second systematic. It gives R > 0.61, or $|V_{th}| > 0.78$ at 95% CL.
- 3 Result is based on 0.9 fb $^{-1}$ of data. The 95% CL lower bound R > 0.79 gives $|V_{tb}|>$ 0.89 (95% CL).
- 4 ABAZOV 06K result is from the analysis of $t\,\overline{t}\to\ell\nu+\geq3$ jets with 230 pb $^{-1}$ of data at $\sqrt{s}=1.96$ TeV. It gives R > 0.61 and $\left|V_{tb}\right|>0.78$ at 95% CL. Superseded by ABAZOV 08M. 5 AFFOLDER 01C measures the top-quark decay width ratio $R=\Gamma(Wb)/\Gamma(Wq)$, where
- ⁵ AFFOLDER 01c measures the top-quark decay width ratio $R = \Gamma(Wb)/\Gamma(Wq)$, where q is a d, s, or b quark, by using the number of events with multiple b tags. The first error is statistical and the second systematic. A numerical integration of the likelihood function gives R > 0.61 (0.56) at 90% (95%) CL. By assuming three generation unitarity, $|V_{t\,b}| = 0.97^{+0.16}_{-0.12}$ or $|V_{t\,b}| > 0.78$ (0.75) at 90% (95%) CL is obtained. The result is based on 109 pb $^{-1}$ of data at $\sqrt{s} = 1.8$ TeV.

$\Gamma(\ell\nu_{\ell}$ anything)/ Γ_{total} ν_{ALUE} 0.094±0.024 ν_{L} $\nu_$

- 1 AARON 09A looked for single top production via FCNC in $e^\pm p$ collisions at HERA with 474 pb $^{-1}$. The upper bound of the cross section gives the bound on the FCNC coupling $\kappa_{t\,u\,\gamma}/\Lambda < 1.03~{\rm TeV}^{-1}$, which corresponds to the result for $m_t=175~{\rm GeV}.$
- 2 CHEKANOV 03 looked for single top production via FCNC in the reaction $e^\pm p \to e^\pm$ (t or \overline{t}) X in 130.1 pb $^{-1}$ of data at \sqrt{s} =300–318 GeV. No evidence for top production and its decay into b W was found. The result is obtained for m_t =175 GeV when B(γc)=B(Z q)=0, where q is a u or c quark. Bounds on the effective t-u- γ and t-u-Z couplings are found in their Fig. 4. The conversion to the constraint listed is from private communication, E. Gallo, January 2004.
- 3 ABDALLAH 04c looked for single top production via FCNC in the reaction $e^+e^-\to \overline{t}c$ or $\overline{t}u$ in S41 pb $^{-1}$ of data at $\sqrt{s}{=}189{+}208$ GeV. No deviation from the SM is found, which leads to the bound on B($t\to\gamma q$), where q is a u or a c quark, for $m_t=175$ GeV when B($t\to Zq){=}0$ is assumed. The conversion to the listed bound is from private communication, O. Yushchenko, April 2005. The bounds on the effective $t{-}q{-}\gamma$ and $t{-}q{-}Z$ couplings are given in their Fig. 7 and Table 4, for $m_t=170{-}180$ GeV, where most conservative bounds are found by choosing the chiral couplings to maximize the negative interference between the virtual γ and Z exchange amplitudes.
- AKTAS 04 looked for single top production via FCNC in e^\pm collisions at HERA with 118.3 pb⁻¹, and found 5 events in the e or μ channels. By assuming that they are due to statistical fluctuation, the upper bound on the $tu\gamma$ coupling $\kappa_t u\gamma < 0.27$ (95% CL) is obtained. The conversion to the partial width limit, when $B(\gamma c) = B(Zu) = B(Zc) = 0$, is from private communication, E. Perez, May 2005.
- 5 ACHARD 021 looked for single top production via FCNC in the reaction $e^+\,e^-\to \overline{t}\,c$ or $\overline{t}\,u$ in 634 pb $^-1$ of data at $\sqrt{s}=189$ –209 GeV. No deviation from the SM is found, which leads to a bound on the top-quark decay branching fraction $B(\gamma\,q)$, where q is a u or c quark. The bound assumes $B(Z\,q)=0$ and is for $m_{\,t}=175$ GeV; bounds for $m_{\,t}=170$ GeV and 180 GeV and $B(Z\,q)\neq 0$ are given in Fig. 5 and Table 7.
- 6 ABE 98G looked for $t\bar{t}$ events where one t decays into $q\gamma$ while the other decays into b W. The quoted bound is for $\Gamma(\gamma\,q)/\Gamma(W\,b).$

- 1 Based on 4.1 fb $^{-1}$ of data. ABAZOV 11M searched for FCNC decays of the top quark in $t\overline{t}\to\ell^+\ell^-\ell'^\pm\nu$ + jets $(\ell,\ell'=e,\mu)$ final states, and absence of the signal gives the head
- The bound. 2 Result is based on 1.9 fb $^{-1}$ of data at $\sqrt{s}=1.96$ TeV. $t\overline{t}\to WbZq$ or ZqZq processes have been looked for in $Z+\geq 4$ jet events with and without b-tag. No signal leads to the bound B($t\to Zq$) <0.037 (0.041) for $m_{t}=175$ (170) GeV.
- ³ ABDALLAH 04c looked for single top production via FCNC in the reaction $e^+e^- \to \overline{\iota} c$ or $\overline{\iota} u$ in 541 pb⁻¹ of data at $\sqrt{s}{=}$ 189-208 GeV. No deviation from the SM is found, which leads to the bound on $B(t \to Zq)$, where q is a u or a c quark, for $m_t = 175$ GeV when $B(t \to \gamma q) = 0$ is assumed. The conversion to the listed bound is from private communication, O. Yushchenko, April 2005. The bounds on the effective t-q- γ and t-q-Z-couplings are given in their Fig. 7 and Table 4, for $m_t = 170$ -180 GeV, where most conservative bounds are found by choosing the chiral couplings to maximize the negative interference between the virtual γ and Z exchange amplitudes.
- 4 ACHARD 02J looked for single top production via FCNC in the reaction $e^+e^-\to \overline{t}\,c$ or $\overline{t}\,u$ in 634 pb $^{-1}$ of data at \sqrt{s} = 189–209 GeV. No deviation from the SM is found, which leads to a bound on the top-quark decay branching fraction B(Zq), where q is a u or c quark. The bound assumes B(γq)=0 and is for m_t = 175 GeV; bounds for m_t =170 GeV and 180 GeV and B(γq) $\neq 0$ are given in Fig. 5 and Table 7. Table 6 gives constraints on t-c-e-e four-fermi contact interactions.
- constraints on t-c-e-e four-termi contact interactions. HEISTER 02Q looked for single top production via FCNC in the reaction $e^+e^- \to \overline{t}c$ or $\overline{t}u$ in 214 pb $^{-1}$ of data at \sqrt{s} = 204-209 GeV. No deviation from the SM is found, which leads to a bound on the branching fraction B(Zq), where q is a u or c quark. The bound assumes B(γq)=0 and is for m_t = 174 GeV. Bounds on the effective t- (c or u)- γ and t- (c or u)-Z couplings are given in their Fig. 2.
- γ and t- (c of u) Z couplings are given in their Fig. 2. 6 ABBIENDI 01T looked for single top production via FCNC in the reaction $e^+e^- \to \overline{t}c$ or $\overline{t}u$ in 600 pb⁻¹ of data at \sqrt{s} = 189-209 GeV. No deviation from the SM is found, which leads to bounds on the branching fractions B(Zq) and $B(\gamma q)$, where q is a u or c quark. The result is obtained for m_t = 174 GeV. The upper bound becomes 9.7% (20.6%) for m_t = 169 (179) GeV. Bounds on the effective t- (c or u)- γ and t- (c or u)-Z couplings are given in their Fig. 4.
- 7 Based on $p\overline{p}$ data of $1.52\,{\rm fb}^{-1}$. AALTONEN 09AL compared $t\overline{t}\to WbWb\to\ell\nu bjjb$ and $t\overline{t}\to Zc\,Wb\to\ell\nu\ell jjb$ decay chains, and absence of the latter signal gives the bound. The result is for 100% longitudinally polarized Z boson and the theoretical $t\overline{t}$ production cross section The results for different Z polarizations and those without the cross section assumption are given in their Table XII.
- 8 BARATE 00s looked for single top production via FCNC in the reaction $e^+\,e^-\to \overline{t}\,c$ or $\overline{t}u$ in 411 pb $^{-1}$ of data at c.m. energies between 189 and 202 GeV. No deviation from

the SM is found, which leads to a bound on the branching fraction. The bound assumes B(γq)=0. Bounds on the effective t- (c or u)- γ and t- (c or u)-Z couplings are given in their Fig. 4.

ABE 986 looked for $t\overline{t}$ events where one t decays into three jets and the other decays into qZ with $Z\to\ell\ell$. The quoted bound is for $\Gamma(Zq)/\Gamma(Wb)$.

t-quark EW Couplings

W helicity fractions in top decays. F_0 is the fraction of longitudinal and F_+ the fraction of right-handed W bosons. F_{V+A} is the fraction of $V\!+\!A$ current in top decays. The effective Lagrangian (cited by ABAZOV 08AI) has terms \mathfrak{f}_1^L and \mathfrak{f}_1^R for V-A and V+A couplings, f_2^L and f_2^R for tensor couplings with \mathbf{b}_R and \mathbf{b}_L respectively.

- $^1\,\mathrm{Based}$ on 5.4 fb $^{-1}$ of data. For each value of the form factor quoted the other two are assumed to have their SM value. Their Fig. 4 shows two-dimensional posterior probability density distributions for the anomalous couplings.
- 2 Results are based on 5.4 fb $^{-1}$ of data in $p\overline{p}$ collisions at 1.96 TeV, including those of ABAZOV 08B. Under the SM constraint of $f_0=0.698$ (for $m_t=173.3$ GeV, $m_W=80.399$ GeV), $f_+=0.010\pm0.022\pm0.030$ is obtained.
- ³ Results are based on 2.7 fb⁻¹ of data in $p\bar{p}$ collisions at $\sqrt{s}=1.96$ TeV. F_0 result is obtained by assuming $F_+=0$, while F_+ result is obtained for $F_0=0.70$, the SM value. Model independent fits for the two fractions give $F_0=0.88\pm0.11\pm0.06$ and $F_+=-0.15\pm0.07\pm0.06$ with correlation coefficient of -0.59. The results are for $m_t=175$ GeV.
- 4 Results are based on 1.9 fb $^{-1}$ of data in $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV. F_0 result is obtained assuming $F_+=0$, while F_+ result is obtained for $F_0=0.70$, the SM values. Model independent fits for the two fractions give $F_0=0.66\pm0.16\pm0.05$ and $F_+=0.00$
- $-0.03\pm0.06\pm0.03$. 5 Based on 1 fb $^{-1}$ of data at $p\overline{p}$ collisions $\sqrt{s}=1.96$ TeV. Combined result of the W helicity measurement in $t\overline{t}$ events (ABAZOV 08B) and the search for anomalous tb Wcouplings in the single top production (ABAZOV 08AI). Constraints when ${
 m f}_{1}^{L}$ and one of the anomalous couplings are simultaneously allowed to vary are given in their Fig. 1 and
- 1301e 1. 6 Result is based on $0.9~{\rm fb}^{-1}$ of data at $\sqrt{s}=1.96~{\rm TeV}$. Single top quark production events are used to measure the Lorentz structure of the tb W coupling. The upper bounds on the non-standard couplings are obtained when only one non-standard coupling is allowed to be present together with the SM one, $\mathbf{f}_1^L = \mathbf{V}_{t\,b}^*$
- 7 Based on 1 fb $^{-1}$ at $\sqrt{s}=1.96$ TeV.
- ⁸ Based on 370 pb $^{-1}$ of data at $\sqrt{s}=1.96$ TeV, using the ℓ + jets and dilepton decay channels. The result assumes $F_0=0.70$, and it gives $F_+<0.23$ at 95% CL.
- 9 Based on 700 pb $^{-1}$ of data at $\sqrt{s}=$ 1.96 TeV.
- $^{10}\,\mathrm{Based}$ on 318 pb $^{-1}$ of data at $\sqrt{s}=$ 1.96 TeV.
- 11 Based on 200 pb $^{-1}$ of data at $\sqrt{s}=$ 1.96 TeV. $t \to ~Wb \to ~\ell \nu b~(\ell = {\rm e~or}~\mu)$. The errors are stat + syst.
- 12 ABAZOV 05G studied the angular distribution of leptonic decays of W bosons in $t\bar{t}$ candidate events with lepton + jets final states, and obtained the fraction of Posette 135 polarized W under the constraint of no right-handed current, $F_+=0$. Based on 125 pb $^{-1}$ of data at $\sqrt{s}=$ 1.8 TeV.
- 13 ABAZOV 05L studied the angular distribution of leptonic decays of W bosons in $t\bar{t}$ events, where one of the W's from t or \bar{t} decays into e or μ and the other decays

- hadronically. The fraction of the "+" helicity W boson is obtained by assuming F_0 = 0.7, which is the generic prediction for any linear combination of V and A currents. Based on 230 \pm 15 pb $^{-1}$ of data at $\sqrt{s}=1.96$ TeV.
- Based on 230 \pm 13 pb of data at \sqrt{s} = 1.78 fc. 14 ACOSTA 05D measures the m_ℓ^2 $\pm b$ distribution in tT production events where one or both W's decay leptonically to ℓ = e or μ , and finds a bound on the V+A coupling of the tbW vertex. By assuming the SM value of the longitudinal W fraction $F_0 = B(t \rightarrow W_0 b) = 0.70$, the bound on F_+ is obtained. If the results are combined with those of AFFOLDER 00B, the bounds become $F_{V+A}<0.61$ (95% CL) and $F_+<0.18$ (95% CL), respectively. Based on 109 \pm 7 pb $^{-1}$ of data at $\sqrt{s}=1.8$ TeV (run I).
- 15 AFFOLDER 00B studied the angular distribution of leptonic decays of $\it W$ bosons in $\it t$ Wb events. The ratio F_0 is the fraction of the helicity zero (longitudinal) W bosons in the decaying top quark rest frame. B($t \rightarrow W_+ b$) is the fraction of positive helicity (right-handed) positive charge W bosons in the top quark decays. It is obtained by assuming the Standard Model value of F_0 .

Spin Correlation in $t\bar{t}$ Production

C is the correlation strength parameter, f is the ratio of events with correlated t and \overline{t} spins (SM prediction: f=1), and κ is the spin correlation coefficient. See "The Top iew for more informatio

- Based on 2.3 fb⁻¹ of data in $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV. Upper limit of single top quark production cross section 0.20 pb and 0.27 pb via FCNC t-u-g and t-c-g couplings, respectively, lead to the bounds without assuming the absence of the other coupling. B($t \rightarrow u + g$) < 2.0×10^{-4} and B($t \rightarrow c + g$) < 3.9×10^{-3} follow. 2 Based on 2.2 fb⁻¹ of data in $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV. Upper limit of single top quark production cross section $\sigma(u(c)+g \rightarrow t) < 1.8$ pb (95% CL) via FCNC t-u-g
- and t-c-g couplings lead to the bounds. B(t \rightarrow u + g) < 3.9 \times 10⁻⁴ and B(t \rightarrow $(c + g) < 5.7 \times 10^{-3}$ follow.
- ³ Result is based on 230 pb $^{-1}$ of data at $\sqrt{s}=1.96$ TeV. Absence of single top quark production events via FCNC t-u-g and t-c-g couplings lead to the upper bounds on the dimensioned couplings, κ^{utg}/Λ and κ^{ctg}/Λ , respectively.

- 1 Based on 5.4 fb $^{-1}$ of data and for $m_t=172.5$ GeV. The error is statistical + systematic combined. Results for other m_t values are given in Table III of ABAZOV 11AD. The result is obtained by assuming the SM ratio between tb (s-channel) and $t\,q\,b$ (t-channel) productions, and gives $|\mathsf{V}_{tb}|\,f^L|=1.02^{+}_{-0.11}$, or $|\mathsf{V}_{tb}|\,>0.79$ at 95% CL for a flat prior within $0<|\mathsf{V}_{vb}|^2<1$
- prior within $0 < |V_{tb}|^2 < 1$.
 ² Based on 3.2 fb⁻¹ of data. Events with isolated $\ell + \not\!\!\! E_T$ + jets with at least one b-tag are analyzed and s- and t-channel single top events are selected by using the likelihood function, matrix element, neural-network, boosted decision tree, likelihood function optimized for s-channel process, and neural-networked based analysis of events with $\not\!\!\! E_T$ that has sensitivity for $W \to \tau \nu$ decays. The result is for $m_t = 175$ GeV, and the mean value decreases by 0.02 pb/GeV for smaller m_t . The signal has 5.0 sigma significance. The result gives $|V_{tb}| = 0.91 \pm 0.11$ (stat+syst) ± 0.07 (theory), or $|V_{tb}| > 0.71$ at 95% CL.
- 3 Based on 5.4 fb $^{-1}$ of data. The error is statistical + systematic combined. The results are for $m_t=172.5$ GeV. Results for other m_t values are given in Table 2 of ABAZOV 11AA.
- ABAZOV 11AA. 4 Based on 3.2 fb $^{-1}$ of data. For combined s- + t-channel result see AALTONEN 09AT. 5 Result is based on 2.1 fb $^{-1}$ of data. Events with large missing E_T and jets with at least one b-jet without identified electron or muon are selected. Result is obtained when observed 2.1 σ excess over the background originates from the signal for $m_t = 175$ GeV, giving $|V_{t+1}| = 1.24 \pm 0.34 \pm 0.07$ (theory).
- giving $|V_{tb}|=1.24^{+0.34}_{-0.29}\pm0.07$ (theory). ⁶ Result is based on 2.3 fb $^{-1}$ of data. Events with isolated $\ell+E_T+2$,3,4 jets with one or two b-tags are selected. The analysis assumes $m_t=170$ GeV.
- 7 Result is based on 4.8 fb $^{-1}$ of data. Events with an isolated reconstructed tau lepton, missing E_T + 2, 3 jets with one or two b-tags are selected. When combined with ABAZOV 09z result for e+ μ channels, the s- and t-channels combined cross section is 3.84 $^{+0.89}_{-0.83}$ pb.
- ⁸ Based on 2.3 fb⁻¹ of data. Events with isolated $\ell+E_T+\geq 2$ jets with 1 or 2 b-tags are analyzed and s- and t-channel single top events are selected by using boosted decision tree, Bayesian neural networks and the matrix element method. The signal has 5.0 sigma significance. The result gives $|V_{tb}|=1.07\pm0.12$, or $|V_{tb}|>0.78$ at 95% CL. The analysis assumes $m_t=170$ GeV.
- 9 Result is based on $^2.2~{\rm fb^{-1}}$ of data. Events with isolated $\ell+\not\!\!E_T+2$, 3 jets with at least one b-tag are selected, and s- and r-channel single top events are selected by using likelihood, matrix element, and neural network discriminants. The result can be interpreted as $|V_{tb}|=0.88^{+0.13}_{-0.12}({\rm stat+syst})\pm 0.07({\rm theory}),$ and $|V_{tb}|>0.66~(95\%$ CL) under the $|V_{tb}|<1$ constraint.
- 10 Result is based on $0.9~{\rm fb^{-1}}$ of data. Events with isolated $\ell+E_T+2$, 3, 4 jets with one or two b-vertex-tag are selected, and contributions from W+ jets, $t\overline{t}$, s- and t-channel single top events are identified by using boosted decision trees, Bayesian neural networks, and matrix element analysis. The result can be interpreted as the measurement of the CKM matrix element $|V_{tb}|=1.31^{+0.25}_{-0.21},$ or $|V_{tb}|>0.68~(95\%~{\rm CL})$ under the $|V_{tb}|<1$ constraint.
- 11 Result is based on 0.9 fb $^{-1}$ of data. This result constrains V_{tb} to 0.68 $<|V_{tb}|\le 1$ at 95% CL.
- 12 ÅBAZOV 05P bounds single top-quark production from either the s-channel W-exchange process, $q'\overline{q} \to t\overline{b}$, or the t-channel W-exchange process, $q'g \to qt\overline{b}$, based on $\sim 230~{\rm pb}^{-1}$ of data.
- $^{13}\text{ACOSTA}$ 05N bounds single top-quark production from the t-channel W-exchange process ($q'g\to qt\bar{b}$), the s-channel W-exchange process ($q'\overline{q}\to t\overline{b}$), and from the combined cross section of t- and s-channel. Based on $\sim 162~\text{pb}^{-1}$ of data.

| | | | | | |

- 1 AARON 09A looked for single top production via FCNC in $e^\pm p$ collisions at HERA with 474 pb $^{-1}$ of data at $\sqrt{s}=301$ –319 GeV. The result supersedes that of AKTAS 04.
- 2 AKTAS 04 looked for single top production via FCNC in e^\pm collisions at HERA with $118.3~{\rm pb}^{-1}$, and found 5 events in the e or μ channels while 1.31 ± 0.22 events are expected from the Standard Model background. No excess was found for the hadronic channel. The observed cross section of $\sigma(e\,p\,\rightarrow\,e\,t\,X)=0.29^{+0.15}_{-0.14}$ pb at $\sqrt{s}=319$ GeV gives the quoted upper bound if the observed events are due to statistical fluctuation.
- THUCTURATION: 3 CHEKANOV 03 looked in 130.1 pb $^{-1}$ of data at $\sqrt{s}=$ 301 and 318 GeV. The limit is for $\sqrt{s}=$ 318 GeV and assumes $m_t=$ 175 GeV.

$t\,\overline{t}$ production cross section in $p\,\overline{p}$ collisions at $\sqrt{s}=$ 1.8 TeV

041 CDF di-lepton + jets + missing ET

- 1 Based on 1.12 fb $^{-1}$ and assumes $m_{\,t}\,=\,$ 175 GeV, where the cross section changes by ± 0.1 pb for every ∓ 1 GeV shift in $m_{\tilde{t}}.$ AALTONEN 11D fits simultaneously the $t\,\overline{t}$ production cross section and the b-tagging efficiency and find improvements in both measurements.
- Based on 2.7 fb $^{-1}$. The first error is from statistics and systematics, the second is from luminosity. The result is for $m_t=175\,$ GeV. AALTONEN 11w fits simultaneously a jet flavor discriminator between b-, c-, and light-quarks, and find significant reduction in the systematic error.
- 3 Based on 2.2 fb $^{-1}$. The result is for $m_t=172.5$ GeV. AALTONEN 11Y selects multi-jet events with large $\not\!\!E_T$, and vetoes identified electrons and muons. 4 Based on 5.3 fb $^{-1}$. The error is statistical + systematic + luminosity combined. The
- = 172.5 GeV. The results for other $m_{ extbf{\emph{t}}}$ values are given in Table XII and result is for $m_t = 172.5 \text{ G}$ eq.(10) of ABAZOV 11E.
- ⁵ Combination of a dilepton measurement presented in ABAZOV 11z (based on 5.4 fb⁻¹), which yields $7.36^{+0.90}_{-0.79}$ (stat+syst) pb, and the lepton + jets measurement of ABAZOV 11E. The result is for $m_t=172.5$ GeV. The results for other m_t values is given by eq.(5) of ABAZOV 11A.
- $^6\mathrm{Based}$ on 2.8 fb $^{-1}$. The result is for $m_t=175$ GeV.
- $^7\,\mathrm{Based}$ on 2.9 fb $^{-1}.$ Result is obtained from the fraction of signal events in the top quark mass measurement in the all hadronic decay channel.
- 8 Based on 1.7 fb $^{-1}$. The result is for $m_t=175$ GeV. AALTONEN 10v uses soft electrons from b-hadron decays to suppress W+jets background events.
- g Based on 4.6 fb $^{-1}$. The result is for $m_t=$ 172.5 GeV. The ratio $\sigma(t\,\overline{t}\to\ell+{
 m jets})$ / $\sigma(Z/\gamma^* o \ \ell\ell)$ is measured and then multiplied by the theoretical $Z/\gamma^* o \ \ell\ell$ cross
- section of $\sigma(Z/\gamma^* \to \ell\ell)=251.3\pm5.0$ pb, which is free from the luminosity error. 10 Based on 1 fb $^{-1}$. The result is for $m_t=175$ GeV. 7.9 ± 2.3 pb is found for $m_t=170$ GeV. ABAZOV 10i uses a likelihood discriminant to separate signal from background,
- where the background model was created from lower jet-multiplicity data. 11 Based on 1 fb $^{-1}$. The result is for $m_t=$ 170 GeV. For $m_t=$ 175 GeV, the result is $6.3^{+1.2}_{-1.1}(\text{stat}) \pm 0.7(\text{syst}) \pm 0.4(\text{lumi})$ pb. Cross section of $t\overline{t}$ production has been measured in the $t\,\overline{t} o au_h + ext{ jets topology, where } au_h ext{ denotes hadronically decaying } au$ leptons. The result for the cross section times the branching ratio is $\sigma(t\,\overline{t})\cdot \mathsf{B}(t\,\overline{t} \to t)$ au_h + jets) = 0.60 $^+$ 0.23 $^+$ 0.15 $^+$ 0.04 pb for m_t = 170 GeV.
- 12 Based on 1.1 fb $^{-1}$. The result is for B(W $\rightarrow \ell \nu)=10.8\%$ and $m_t=175$ GeV; the mean value is 9.8 for $m_t=172.5$ GeV and 10.1 for $m_t=170$ GeV. AALTONEN 09AD used high p_T e or μ with an isolated track to select t7 decays into dileptons including ℓ
- = τ . The result is based on the candidate event samples with and without vertex b-tag. 13 Based on 2 fb $^{-1}$. The result is for $m_t=175$ GeV; the mean value is 3% higher for m_t = 170 GeV and 4% lower for $m_{ extit{t}} = 180$ GeV.
- 14 Result is based on 1 fb $^{-1}$ of data. The result is for $m_t=170$ GeV, and the mean value decreases with increasing m_t ; see their Fig. 2. The result is obtained after combining ℓ + jets, $\ell\ell_{\rm c}$ and $\ell\tau$ final states, and the ratios of the extracted cross sections are R $^{\ell\ell/\ell j}=0.86^{+}_{-0.17}^{+0.19}$ and R $^{\ell\tau/\ell\ell-\ell j}=0.97^{+0.32}_{-0.29}$, consistent with the SM expectation of R = 1. This leads to the upper bound of B($t o bH^+$) as a function of m_{H^+} . Results are shown in their Fig. 1 for B($H^+ \to \tau \nu$) = 1 and B($H^+ \to c\bar{s}$) = 1 cases. Comparison of the m_t dependence of the extracted cross section and a partial NNLO prediction gives $m_t = 169.1 {+} 5.9_{-5.2} \text{ GeV}.$
- 15 Result is based on 1 fb $^{-1}$ of data. The result is for $m_t=170$ GeV, and the mean value changes by $-0.07\ [m_t({\rm GeV})-170]$ pb near the reference m_t value. Comparison of the m_t dependence of the extracted cross section and a partial NNLO QCD prediction gives $m_t=171.5^{+9.9}_{-8.8}$ GeV. The ℓau channel alone gives $7.6^{+4.9}_{-4.3}+\frac{3.5}{3.4}+\frac{1.4}{0.9}$ pb and the $\ell\ell$
- than el gives 7.5 + 1.2 + 0.7 + 0.7 pb. 16 Result is based on 0.9 fb-1 of data. The first error is from stat + syst, while the latter error is from luminosity. The result is for m_t =175 GeV, and the mean value changes by
- -0.09 pb[m_t (GeV)-175]. 17 Result is based on 0.9 fb $^{-1}$ of data. The cross section is obtained from the $\ell+\geq 3$ jet event rates with 1 or 2 b-tag, and also from the kinematical likelihood analysis of the $\ell+3$, 4 jet events. The result is for $m_t=172.6$ GeV, and its m_t dependence shown in Fig. 3 leads to the constraint $m_t=170\pm7$ GeV when compared to the SM prediction.
- $^{18}\,\mathrm{Result}$ is based on 360 pb $^{-1}$ of data. Events with high p_T oppositely charged dileptons $\ell^+\ell^-$ ($\ell=e,\mu$) are used to obtain cross sections for $t\bar{t}$, W^+W^- , and $Z\to\tau^+\tau^-$ production processes simultaneously. The other cross sections are given in Table IV. 19 Based on 1.02 fb $^{-1}$ of data. Result is for $m_t=175$ GeV. Secondary vertex b-tag and neural network selections are used to achieve a signal-to-background ratio of about 1/2.
- 20 Based on 425 pb $^{-1}$ of data. Result is for $m_{t}=175$ GeV. For $m_{t}=170.9$ GeV,
- 7.8 \pm 1.8(stat + syst) pb is obtained. ²¹ Based on 405 \pm 25 pb $^{-1}$ of data. Result is for $m_t=175\,$ GeV. The last error is for luminosity. Secondary vertex b-tag and neural network are used to separate the signal
- events from the background. 22 Based on 425 pb $^{-1}$ of data. Assumes $m_{\,t}=$ 175 GeV.
- ²³ Based on ⁴²⁵ pb ⁻¹ of data. Assumes $m_t = 1/5$ GeV. The first error is combined statistical and systematic, the second one is luminosity. ²⁴ Based on ~ 318 pb ⁻¹. Assuming $m_t = 178$ GeV. The cross section changes by ± 0.08 pb for each ∓ 1 GeV change in the assumed m_t . Result is for at least one b-tags per jets of significance greater than 5σ is found, and the cross section is $10.1 \pm 1.6 \pm 2.0$ pb for $m_t = 178$ GeV. For $m_t = 175$ GeV, the result is $6.0 \pm 1.2 \pm 0.9$ This is the first CDE massurement without lepton identification, and
- $6.0\pm1.2^{+0.9}_{-0.7}$. This is the first CDF measurement without lepton identification, and hence it has sensitivity to the $W \rightarrow \tau \nu$ mode.
- 26 ABULENCIA,A 06E measures the $t\overline{t}$ production cross section in the all hadronic decay mode by selecting events with 6 to 8 jets and at least one b-jet. $S/B\,=\,1/5$ has been achieved. Based on 311 pb $^{-1}$. Assuming $m_{\,t}=$ 178 GeV.
- 27 Based on \sim 318 pb $^{-1}$. Assuming $m_t=$ 178 GeV. Result is for at least one b-tag. For at least two *b*-tagged jets, the cross section is 11.1 + 2.3 + 2.5 pb.
- 28 ABAZOV 05Q measures the top-quark pair production cross section with \sim 230 pb $^{-1}$ of data, based on the analysis of W plus n-jet events where W decays into e or μ

- plus neutrino, and at least one of the jets is b-jet like. The first error is statistical and systematic, and the second accounts for the luminosity uncertainty. The result assumes $m_t=175\,$ GeV; the mean value changes by $(175-m_t({\rm GeV}))\times 0.06\,$ pb in the mass range 160 to 190 GeV
- 29 ABAZOV 05R measures the top-quark pair production cross section with 224–243 pb $^{-1}$ of data, based on the analysis of events with two charged leptons in the final state. The result assumes $m_t=175$ GeV; the mean value changes by $(175-m_t({\rm GeV}))\times 0.08$ pb in the mass range 160 to 190 GeV. 30 Based on 230 pb $^{-1}$. Assuming $m_t=175$ GeV.
- $^{31}\,\mathrm{Based}$ on 194 pb^{-1} . Assuming $m_{\,t}=$ 175 GeV.
- $^{32}\,\mathrm{Based}$ on 194 \pm 11 pb $^{-1}$. Assuming $m_t=$ 175 GeV.
- $^{33}\,\mathrm{Based}$ on $162\pm10~\mathrm{pb}^{-1}$. Assuming $m_{\,t}^{\,}=175~\mathrm{GeV}.$
- 34 ACOSTA 05v measures the top-quark pair production cross section with \sim 162 pb $^{-1}$ data, based on the analysis of W plus n-jet events where W decays into e or μ plus neutrino, and at least one of the jets is b-jet like. Assumes $m_t=175$ GeV.
- 35 ACOSTA $\,$ 041 measures the top-quark pair production cross section with 197 ± 12 pb $^{-1}$ data, based on the analysis of events with two charged leptons in the final state. Assumes $m_t = 175 \text{ GeV}.$

Ratio of the production cross sections of $t\bar{t}\gamma$ to $t\bar{t}$ at $\sqrt{s}=1.96$ TeV

DOCUMENT ID TECN COMMENT • • • We do not use the following data for averages, fits, limits, etc. • • • $^{1}\,\mathrm{AALTONEN}$ $\,$ 11z CDF $\,$ $\,$ $E_{\,T}(\gamma) >$ 10 GeV, $\left|\eta(\gamma)\right| <$ 1.0 $\,$ $\left|$ 0.024 ± 0.009 1 Based on 6.0 fb $^{-1}$ of data. The error is statistical and systematic combined. Events with lepton + E_T + \geq 3 jets(\geq 1b) with and without central, high E_T photon are measured. The result is consistent with the SM prediction of 0.024 \pm 0.005. The absolute production cross section is measured to be 0.18 \pm 0.08 fb. The statistical significance is 2.2 the statistical significance is

$t\bar{t}$ production cross section in pp collisions at $\sqrt{s}=7$ TeV

3.0 standard deviations.

Unless otherwise noted the first quoted error is from statistics, the second from systematic uncertainties, and the third from luminosity. If only two errors are quoted the luminosity is included in the systematic uncertainties.

Quark Particle Listings

†

 1 Based on 5.3 fb $^{-1}$ of data. The error is statistical and systematic combined. Events with lepton $+\not\!\!E_T + \ge 4 \mathrm{jets}(\ge 1b)$ are used. AALTONEN 11F also measures the asymmetry as a function of the rapidity difference $|\mathsf{y}_t - \mathsf{y}_{\overline{t}}|.$ The NLO QCD predictions [MCFM] are $(4.0\pm 0.6)\%$ and $(8.8\pm 1.3)\%$ for $m_{t\overline{t}} < 450$ and > 450 GeV, respectively.

[MCFM] are (4.0 \pm 0.0)% and (0.0 \pm 1.0)% for $m_{t\bar{t}}$ and systematic combined. The quoted asymmetry is obtained after unfolding to be compared with the MC@NLO prediction of (5.0 \pm 0.1)%. No significant difference between the $m_{t\bar{t}}$ < 450 and > 450 GeV data samples is found. A corrected asymmetry based on the lepton from a top quark decay of (15.2 \pm 4.0)% is measured to be compared to the MC@NLO prediction of (2.1 \pm 0.1)%.

 3 Result is based on 1.9 fb $^{-1}$ of data. The FB asymmetry in the $t\overline{t}$ events has been measured in the $\ell+$ jets mode, where the lepton charge is used as the flavor tag. The asymmetry in the $p\overline{p}$ frame is defined in terms of $\cos(\theta)$ of hadronically decaying t-quark momentum, whereas that in the $t\overline{t}$ frame is defined in terms of the t and \overline{t} rapidity difference. The results are consistent ($\leq 2~\sigma$) with the SM predictions.

 4 Result is based on 0.9 fb $^{-1}$ of data. The asymmetry in the number of $t\overline{t}$ events with $y_t>y_{\overline{t}}$ and those with $y_t<y_{\overline{t}}$ has been measured in the lepton + jets final state. The observed value is consistent with the SM prediction of 0.8% by MC@NLO, and an upper bound on the $Z'\to t\overline{t}$ contribution for the SM Z-like couplings is given in in Fig. 2 for 350 GeV $< m_{Z'}<1$ TeV.

t-Quark Electric Charge

VALUE <u>DOCUMENT ID</u> TECN COMMENT

• • • We do not use the following data for averages, fits, limits, etc. • • •

 $\begin{array}{cccc} \frac{1}{2}\,\mathsf{AALTONEN} & \mathsf{10s} & \mathsf{CDF} \\ 2\,\mathsf{ABAZOV} & \mathsf{07c} & \mathsf{D0} & \mathsf{fraction} \ \mathsf{of} \ |\mathsf{q}| \!\!=\! \! \mathsf{4e/3} \ \mathsf{pair} \end{array}$

 1 AALTONEN 10s excludes the charge -4/3 assignment for the top quark [CHANG 99] at 95%CL, using $2.7~{\rm fb}^{-1}$ of data in $\rho\overline{\rho}$ collisions at $\sqrt{s}=1.96$ TeV. Result is obtained by reconstructing $t\overline{t}$ events in the lepton + jets final state, where b-jet charges are tagged by the SLT (soft lepton tag) algorithm.

2ABAZOV 07C reports an upper limit $\rho<0.80$ (90% CL) on the fraction ρ of exotic quark pairs $Q\overline{Q}$ with electric charge $|{\bf q}|=4{\bf e}/3$ in $t\overline{t}$ candidate events with high p_T lepton, missing E_T and ≥ 4 jets. The result is obtained by measuring the fraction of events in which the quark pair decays into W^-+b and $W^++\overline{b}$, where b and \overline{b} jets are discriminated by using the charge and momenta of tracks within the jet cones. The maximum CL at which the model of CHANG 99 can be excluded is 92%. Based on 370 pb $^{-1}$ of data at $\sqrt{s}=1.96$ TeV.

- 1 Based on 4.8 fb $^{-1}$ of data in $p\overline{p}$ collisions at 1.96 TeV. AALTONEN 11J looked for events with $\ell+\not\!\!E_T+\ \geq$ 5j (≥ 1 b or c). No signal is observed and the bound $\sigma(b'\overline{b}')$
- < 30 fb for $m_{b'}>$ 375 GeV is found for B($b'\to t\,W)=1.$ 2 Based on 34 pb $^{-1}$ of data in pp collisions at 7 TeV. CHATRCHYAN 11L looked for multijet events with trileptons or same-sign dileptons. No excess above the SM background excludes $m_{b'}$ between 255 and 361 GeV at 95% CL for B($b' \rightarrow t W$) = 1.
- 3 Result is based on 1.1 fb $^{-1}$ of data. No signal is found for the search of long-lived particles which decay into final states with two electrons or photons, and upper bound on the cross section times branching fraction is obtained for $2 < c\tau < 7000$ mm; see Fig.
- 3. 95% CL excluded region of b' lifetime and mass is shown in Fig. 4. ⁴ Result is based on 1.06 fb⁻¹ of data. No excess from the SM Z+jet events is found when Z decays into ee or $\mu\mu$. The $m_{b'}$ bound is found by comparing the resulting upper bound on $\sigma(b'b')$ [1-(1-B($b' \to bZ$))²] and the LO estimate of the b' pair production cross section shown in Fig. 38 of the article.

 5 HUANG 08 reexamined the b' mass lower bound of 268 GeV obtained in AALTONEN 07c that assumes B($b' \to bZ$) = 1, which does not hold for $m_{b'} > 255$ GeV. The lower
- mass bound is given in the plane of $\sin^2(\theta_{t\,b'})$ and $m_{b'}$
- ⁶ACOSTA 03 looked for long-lived fourth generation quarks in the data sample of 90 pb⁻¹ of \sqrt{s} =1.8 TeV $p\bar{p}$ collisions by using the muon-like penetration and anomalously high ionization energy loss signature. The corresponding lower mass bound for the charge (2/3)e quark (t') is 220 GeV. The t' bound is higher than the b' bound because t' is more likely to produce charged hadrons than b^\prime . The 95% CL upper bounds for the production cross sections are given in their Fig. 3. ⁷ ABACHI 95F bound on the top-quark also applies to b^\prime and t^\prime quarks that decay pre-
- dominantly into W. See FROGGATT 97. 8 Based on 2.7 fb $^{-1}$ of data in $p\overline{p}$ collisions at $\sqrt{s}=1.96$ TeV. AALTONEN 10H looked for pair production of heavy quarks which decay into $t\,W^-$ or $t\,W^+$, in events with same sign dileptons (e or μ), several jets and large missing E_T . The result is obtained for b' which decays into tW^- . For the charge 5/3 quark ($T_{5/3}$) which decays into $t\,W^+$, $m_{T_5/3}>365$ GeV (95% CL) is found when it has the charge -1/3 partner B of the same mass.
- 9 FLACCO 10 result is obtained from AALTONEN 10H result of $m_{\,b'} >$ 338 GeV, by relaxing the condition B(b'
 ightarrow t W) = 100% when $m_{b'} > m_{t'}$.
- 10 AFFOLDER 00 looked for b' that decays in to b+Z. The signal searched for is $b\,b\,Z\,Z$ events where one Z decays into $e^+\,e^-$ or $\mu^+\,\mu^-$ and the other Z decays hadronically. The bound assumes B(b' o b Z)= 100%. Between 100 GeV and 199 GeV, the 95%CL upper bound on $\sigma(b' \to \overline{b'}) \times B^2(b' \to bZ)$ is also given (see their Fig. 2).
- 11 ABE 98N looked for $Z
 ightarrow e^+e^-$ decays with displaced vertices. Quoted limit assumes B($b'
 ightarrow b\,Z)\!=\!1$ and $c\, au_{b'}\!=\!1\,\mathrm{cm}$. The limit is lower than $m_{Z}\!+\!m_{b}$ (\sim 96 GeV) if $c\, au>$ 22 cm or $c\, au<$ 0.009 cm. See their Fig. 4.
- 12 ABACHI 97D searched for b^\prime that decays mainly via FCNC. They obtained 95%CL upper bounds on B($b'\overline{b'} \to \gamma + 3$ jets) and B($b'\overline{b'} \to 2\gamma + 2$ jets), which can be interpreted as the lower mass bound $m_{b'} > m_Z + m_b$.
- 13 MUKHOPADHYAYA 93 analyze CDF dilepton data of ABE 92g in terms of a new quark decaying via flavor-changing neutral current. The above limit assumes $\mathsf{B}(b'$ – $b\,\ell^+\,\ell^-)\!=\!1\%.$ For an exotic quark decaying only via virtual Z [B($\!b\,\ell^+\,\ell^-)=3\%$], the limit is 85 GeV.
- 14 Imit is 85 GeV.

 14 Imit is 85 GeV.

 15 ABE 92 dilepton analysis limit of >85 GeV at CL=95% also applies to b' quarks, as discussed in ABE 908. ABE 908 exclude the region 28–72 GeV.

 15 ABE 908 exclude the region 28–72 GeV.
- 16 AKESSON 90 searched for events having an electron with $p_{T}~>12$ GeV, missing momentum > 15 GeV, and a jet with $E_{T}>$ 10 GeV, $\left|\eta\right|$ < 2.2, and excluded $m_{B'}$ between 30 and 69 GeV.

- 15 between 30 and 69 GeV.

 17 For the reduction of the limit due to non-charged-current decay modes, see Fig. 19 of ALBAJAR 908.

 18 ALBAJAR 80 study events at $E_{\rm cm} = 546$ and 630 GeV with a muon or isolated electron, accompanied by one or more jets and find agreement with Monte Carlo predictions for the production of charm and bottom, without the need for a new quark. The lower mass limit is obtained by using a conservative estimate for the $b^{\prime}\overline{b^{\prime}}$ production cross section and by assuming that it cannot be produced in W decays. The value quoted here is revised using the full $O(\alpha_s^3)$ cross section of ALTARELLI 88.

b' mass limits from single production in $p\overline{p}$ and pp collisions

 19 Based on 5.4 fb $^{-1}$ of data in ppbar collisions at 1.96 TeV. ABAZOV 11F looked for single production of b' via the W or Z coupling to the first generation up or down quarks, respectively. Model independent cross section limits for the single production processes $p\overline{p} \to b'q \to Wuq$, and $p\overline{p} \to b'q \to Zdq$ are given in Figs. 3 and 4, respectively, and the mass limits are obtained for the model of ATRE 09 with degenerate bi-doublets of vector-like quarks.

MASS LIMITS for b' (4th Generation) Quark or Hadron in e^+e^- Collisions

Search for hadrons containing a fourth-generation -1/3 quark denoted b'.

The last column specifies the assumption for the decay mode (CC denotes the conventional charged-current decay) and the event signature which is looked for.

- $^{20}\,\mathrm{DECAMP}$ 90F looked for isolated charged particles, for isolated photons, and for four-jet final states. The modes $b'\to bg$ for B($b'\to bg$) >65% $b'\to b\gamma$ for B($b'\to b\gamma$) >5% are excluded. Charged Higgs decay were not discussed.
- ²¹ABDALLAH 07 searched for b' pair production at $E_{
 m cm} = 196$ –209 GeV, with 420 pb $^{-1}$. No signal leads to the 95% CL upper limits on B(b' o bZ) and B(b' o cW) for $m_{b'}$
- = 96 to 103 GeV. 22 ADRIANI 93G search for vector quarkonium states near Z and give limit on quarkonium-Z mixing parameter $\delta m^2 < (10{\text -}30) \; {\rm GeV}^2$ (95%CL) for the mass 88–94.5 GeV. Using Richardson potential, a 1S $(b'\overline{b'})$ state is excluded for the mass range 87.7–94.7 GeV. This range depends on the potential choice
- $^{23}\,\mathrm{ABREU}$ 90D assumed $m_{\ensuremath{H^-}} < m_{\ensuremath{b^\prime}} 3$ GeV.
- 24 Superseded by ABREU 91F.
- $_{25}^{25}$ AKRAWY 90B search was restricted to data near the Z peak at $E_{
 m cm}=91.26$ GeV at LEP. The excluded region is between 23.6 and 41.4 GeV if no H^+ decays exist. For charged Higgs decays the excluded regions are between $(m_{H^+}\ +\ 1.5\ {\rm GeV})$ and 45.5
- 26 AKRAWY 90J search for isolated photons in hadronic Z decay and derive $B(Z \to b' \overline{b}') \cdot B(b' \to \gamma X)/B(Z \to hadrons) < 2.2 \times 10^{-3}$. Mass limit assumes $B(b' \rightarrow \gamma X) > 10\%$
- $27\,\text{ABE 895}$ search at $E_{Cm}=56\text{--}57$ GeV at TRISTAN for multihadron events with a spherical shape (using thrust and acoplanarity) or containing isolated leptons.
- $^{28}\,\mathrm{ABE}$ 89G search was at $E_\mathrm{cm} = 55\text{--}60.8$ GeV at TRISTAN.
- ²⁹ If the photonic decay mode is large (B($b' \to b \gamma$) > 25%), the ABRAMS 89c limit is 45.4 GeV. The limit for for Higgs decay ($b' \to cH^-, H^- \to \overline{c}s$) is 45.2 GeV.
- 30 ADACHI 89c search was at $E_{
 m cm}=56.5$ –60.8 GeV at TRISTAN using multi-hadron events accompanying muons.
- 31 ADACHI 89c also gives limits for any mixture of $\it CC$ and $\it bg$ decays.
- 32 ENO 89 search at $E_{\rm cm} = 50$ –60.8 at TRISTAN.
- 33 ENO 89 considers arbitrary mixture of the charged current, bg, and $b\gamma$ decays.
- 34 IGARASHI 88 searches for leptons in low-thrust events and gives $\Delta R(b') < 0.26$ (95% CL) assuming charged current decay, which translates to $m_{h'} > 24.4~{\rm GeV}$.

Quark Particle Listings

b' (Fourth Generation) Quark, t' (Fourth Generation) Quark, Free Quark Searches

- 35 SAGAWA 88 set limit $\sigma(top) < 6.1$ pb at CL=95% for top-flavored hadron production from event shape analyses at $E_{\rm cm} = 52$ GeV. By using the quark parton model cross-section formula near threshold, the above limit leads to lower mass bounds of 23.8 GeV for charge -1/3 quarks.
- 36 ADEVA 86 give 95%CL upper bound on an excess of the normalized cross section, ΔR , as a function of the minimum c.m. energy (see their figure 3). Production of a pair of 1/3 charge quarks is excluded up to $E_{
 m CM}=45.4$ GeV.
- 37 ALTHOFF 84C narrow state search sets limit $\Gamma(e^+e^-)$ B(hadrons) <2.4 keV CL = 95% and heavy charge 1/3 quark pair production m > 21 GeV, CL = 95%.
- $^{36} \rm ALTHOFF$ 84! exclude heavy quark pair production for 7 $<\!m<\!19$ GeV (1/3 charge) using aplanarity distributions (CL = 95%).

- 1 Based on 1.04 fb $^{-1}$ of data in pp collisions at 7 TeV. AAD 12c looked for $t'\bar{t}'$ production followed by t^\prime decaying into a top quark and X, an invisible particle, in a final state with an isolated high-P $_T$ lepton, four or more jets, and a large missing transverse energy. No excess over the SM ttbar production gives the upper limit on $t' \bar t'$ production cross section as a function of $m_{\,t'}$ and $m_{\,X}$. The result is obtained for B($t'
 ightarrow t \, W$) = 1.
- 2 Based on 5.6 fb $^{-1}$ of data in ppbar collisions at 1.96 TeV. AALTONEN 11AL looked for $\ell + \geq$ 4j events and set upper limits on $\sigma(\,t'\,\overline{t}')$ as functions of $m_{_{t'}}$
- 3 Based on 5.7 fb $^{-1}$ of data in $p\overline{p}$ collisions at 1.96 TeV. AALTONEN 11AH looked for $t'\overline{t'}$ production followed by t' decaying into a top quark and X, an invisible particle, in the all hadronic decay mode of $t\overline{t}$. No excess over the SM tibar production gives the upper limit on $t'\overline{t}'$ production cross section as a function of $m_{t'}$ and $m_{X'}$. The result is obtained for $B(t' \rightarrow tX) = 1$.
- ⁴ Based on 4.8 fb⁻¹ of data in $p\overline{p}$ collisions at 1.96 TeV. AALTONEN 110 looked for $t'\overline{t}'$ production signal when t' decays into a top quark and X, an invisible particle, in ℓ $+
 ot\!\!\!E_T + ext{jets channel}$. No excess over the SM ttbar production gives the upper limit on $t'\overline{t}'$ production cross section as a function of $m_{t'}$ and m_X . The result is obtained for $B(t' \rightarrow tX) = 1$
- 5 Based on 5.3 fb $^{-1}$ of data in $p\overline{p}$ collisions at 1.96 TeV. ABAZOV 11Q looked for ℓ +
- 6 Searches for pair production of a new heavy top-like quark t^\prime decaying to a W boson and another quark by fitting the observed spectrum of total transverse energy and reconstructed t' mass in the lepton + jets events.

 7 HUANG 08 reexamined the t' mass lower bound of 256 GeV obtained in AALTONEN 08H that assumes B($b' \rightarrow qZ$) = 1 for q = u, c which does not hold when $m_{b'} < m_{t'} - m_W$ or the mixing $\sin^2(\theta_{h\,t'})$ is so tiny that the decay occurs outside of the vertex detector. Fig. 1 gives that lower bound on $m_{t'}$ in the plane of $\sin^2(\theta_{h\,t'})$ and $m_{h'}$.

t' mass limits from single production in $p\overline{p}$ and pp collisions

Free Quark Searches

FREE QUARK SEARCHES

The basis for much of the theory of particle scattering and hadron spectroscopy is the construction of the hadrons from a set of fractionally charged constituents (quarks). A central but unproven hypothesis of this theory, Quantum Chromodynamics, is that quarks cannot be observed as free particles but are confined to mesons and baryons.

Experiments show that it is at best difficult to "unglue" quarks. Accelerator searches at increasing energies have produced no evidence for free quarks, while only a few cosmic-ray and matter searches have produced uncorroborated events.

This compilation is only a guide to the literature, since the quoted experimental limits are often only indicative. Reviews can be found in Refs. 1–4.

| 10 HHEN | TR | IIP 96 quote | 95% CL lin | nits for | production | of | fragments with char | σe diff | erin o |

- 10 HUENTRUP 96 quote 95% CL limits for production of fragments with charge differing by as much as $\pm 1/3$ (in units of e) for charge $6 \le Z \le 10$.
- 11 BUSKULIC 93c limits for inclusive quark production are more conservative if the ALEPH hadronic fragmentation function is assumed.
- nadronic fragmentation function is assumed. 21 CECCHNI) 93 limit at 90%CL for 23/3 \leq Z \leq 40/3, for 16A GeV O, 14.5A Si, and 200A S incident on Cu target. Other limits are 2.3×10^{-4} for $17/3\leq$ Z \leq 20/3 and 1.2×10^{-4} for $20/3\leq$ Z \leq 23/3.
- 13 GHOSH 92 reports measurement of spallation fragment charge based on ionization in emulsion. Out of 650 measured tracks, 2 were consistent with charge 5e/3, and 4 with 7e/3.
- 14 Hadronic quark.
- ¹⁵ Leptonic quark.
- 16 HE 91 limits are for charges of the form $N\pm 1/3$ from 23/3 to 38/3, and correspond to cross-section limits of $380\mu b$ (Pb) and $320\mu b$ (Cu).

 17 The limits apply to projectile fragment charges of 17, 19, 20, 22, 23 in units of e/3.
- The limits apply to projectile fragment charges of 16, 17, 19, 20, 22, 23 in units of e/3.
- 19 Flux limits and mass range depend on charge.
- 20 Bound to nuclei. 21 Quark lifetimes $> 1 \times 10^{-8}$ s.
- 22 One candidate m < 0.17 GeV.

Quark Flux — Cosmic Ray Searches

Shielding values followed with an asterisk indicate altitude in km. Shielding values not followed with an asterisk indicate sea level in kg/cm².

²⁵ With telescope axis at zenith angle 40° to the south.

²⁶ Leptonic quarks.

27 Lifetime > 10⁻⁸ s; charge ±0.70, 0.68, 0.42; and mass >4.4, 4.8, and 20 GeV, respectively.

28 Time delayed air shower search.

²⁹ Prompt air shower search. 30 Also e/4 and e/6 charges.

³⁵ Note that in PHILLIPS 88 these authors report a subtle magnetic effect which could account for the apparent fractional charges.
36 Limit inferred by JONES 77B.
