# $\mathrm{Cp}_{2}$ TiCl－catalyzed highly stereoselective intramolecular epoxide allylation using allyl carbonates $\dagger$ 

Irene R．Márquez，Alba Millán，Araceli G．Campaña＊and Juan M．Cuerva＊

A useful method for the diastereoselective synthesis of vinyl substituted carbo－and heterocycles is described．Highly functionalized structures difficult to achieve by other methodologies are obtained in a single step by this procedure．

Epoxides are highly versatile functional groups in organic syn－ thesis owing to the fact that their manipulation yields many attractive final products．Thus，for example，diverse carbon nucleophiles，such as Grignard and organolithium reagents or organocuprates，have been used in ring－opening reactions to install a new C－C bond．${ }^{1,2}$ The intramolecular version of this reaction would allow the preparation of different carbo－and heterocycles with different sizes and functionalities．Neverthe－ less，the synthesis of suitable polyfunctionalized starting materials is not simple taking into account the chemical incompatibilities between the required reactive partners．In this context，neutral pronucleophiles like olefins or allylsilanes （ $\mathrm{I}, \mathrm{LG}=\mathrm{SiR}_{3}$ ，Scheme 1）are more convenient since they allow better control of the reaction and functional group compatibil－ ity．${ }^{3}$ A valuable advantage of the reactions of epoxides with allylsilanes，compared with alkenes，is their ability to stabilize $\beta$－carbocations（III，Scheme 1），thereby controlling which carbon of the alkene is the nucleophilic carbon．${ }^{4}$ Moreover the allylsilane can control the direction of the final elimination acting as a good leaving group that stabilizes the generated positive charge（IV，Scheme 1）．On the other hand，its main drawback is related to the electrophilic character of the reac－ tion，which implies the use of Lewis acids，such as $\mathrm{TiCl}_{4}$ ，and strict control over the temperature．Another disadvantage of allylsilanes relative to simple alkenes is that extra synthetic steps are necessary because they are generally prepared from oxygenated－allyl groups．Therefore，the direct employment of allylic oxygenated functionalities in epoxide ring－opening reac－ tions retaining the favourable characteristics of allyl silane

[^0]

Radical pathway
Scheme 1 Working hypothesis．
analogues using very mild reaction conditions would represent an important advance in organic synthesis．

The limitation of this approach is that the corresponding $\beta$－carbocations（Scheme 1，III，LG＝OCOR）would not be stabi－ lized and the control of the direction of elimination would remain a challenge due to the lack of a carbocation stabilizing group and also a good leaving group．As a result，a cationic pathway can be discarded in this case，and an alternative reac－ tion pathway based on carbon－centered radicals was con－ sidered． $\mathrm{Cp}_{2} \mathrm{TiCl}^{5}$－mediated homolytic epoxide opening is a well－known reaction，${ }^{6-19}$ which has allowed many remarkable transformations，including a highly successful bioinspired approach to different natural products．${ }^{20-26}$ Epoxyallylcarboxy－ lates I（LG＝OCOR，Scheme 1）are expected to react with $\mathrm{Cp}_{2} \mathrm{TiCl}$ ，yielding radical intermediate type－v．After the
homolytic opening of the epoxide, the $\beta$-titanoxy radical generated $\mathbf{V}$ would undergo further radical cyclization generating a carbon-centered radical VI. At this point, we expected that an oxygenated function in the $\beta$-position would act as a good leaving group, thus directing the final elimination towards IV assisted by $\mathrm{Cp}_{2} \mathrm{TiCl}$ as the Lewis acid. ${ }^{27,28}$ In fact, we had previously observed the $\mathrm{Cp}_{2} \mathrm{TiCl}$-mediated radical fragmentation of $\beta$-acetoxy alkyl radicals toward the corresponding alkenes. ${ }^{21,29}$

In this alternative radical pathway, $\mathrm{Cp}_{2} \mathrm{TiCl}$ would play a crucial dual role in the intramolecular epoxide allylation with oxygenated-allyl groups: (i) starting the reaction by homolytic opening of the oxirane ring and (ii) controlling the final product obtained by radical fragmentation.

Here we wish to communicate that epoxides can formally be allylated intramolecularly in a highly diastereoselective manner under smooth reaction conditions using easily prepared and handled allylic carbonates as allylation reagents. This approach also allows the preparation of different carboand heterocycles with different functionalities.

Due to the known oxophilic character of Ti (III), our initial studies began testing different allyl pronucleophiles 1a-d and 3, including different oxygenated functional groups such as carbonate, acetate, benzoate, methoxyl or hydroxyl groups. Moreover, an epoxyallylsilane 6 was also tested in order to compare the observed results with oxygenated functions. Remarkably, the new developments in titanocene(iII)-regenerating agents now allow the use of substoichiometric amounts of $\mathrm{Cp}_{2} \mathrm{TiCl}_{2}$ as a precatalyst. In this context, the combination of $2,4,6$-collidine and trimethylsilyl chloride developed in our lab ${ }^{30}$ has been extensively used, and it was the choice in this case.

Treatment of compounds $\mathbf{1 a} \mathbf{- d}$ with $\mathrm{Cp}_{2} \mathbf{T i C l}$ led to the expected cyclic compound 2 with variable yields from 50 to $85 \%$ (Scheme 2). It is noteworthy that compound 2 was obtained as a single diastereomer in all cases. NOE-diff. experiments (see the Experimental section) showed a cis relationship between the hydroxyl group at C-3 and the vinyl group at C-5.

When epoxyallylic alcohol 3 was treated with $\mathrm{Cp}_{2} \mathrm{TiCl}$, cyclic compounds 4 and 5 were isolated in a $2 / 1$ ratio (Scheme 3). In this case, the lack of a better leaving group resulted in a different final process. After homolytic oxirane-opening and subsequent cyclization, $\mathrm{Ti}($ (II) -mediated hydrogen abstraction

Scheme 2 Ti(III)-mediated cyclization of model compounds 1a-d. Reaction conditions: (i) $1 \mathrm{a}-\mathrm{d}(1.0 \mathrm{mmol}) \mathrm{Cp}_{2} \mathrm{TiCl}_{2}(0.2 \mathrm{mmol}), \mathrm{Mn}$ $(8.0 \mathrm{mmol}), \mathrm{Me}_{3} \mathrm{SiCl}(4.0 \mathrm{mmol}), 2,4,6$-collidine ( 6.0 mmol ), THF, RT, 16 h . Isolated yields after column chromatography.

Scheme $3 \mathrm{Ti}($ III)-mediated cyclization of compound 3. Reaction conditions: (i) 3 ( 1.0 mmol ) $\mathrm{Cp}_{2} \mathrm{TiCl}_{2}(0.2 \mathrm{mmol}), \mathrm{Mn}(8.0 \mathrm{mmol}), \mathrm{Me} \mathrm{S}_{3} \mathrm{SiCl}$ ( 4.0 mmol ), 2,4,6-collidine ( 6.0 mmol ), THF, RT, 16 h . Isolated yields after column chromatography.
in the radical intermediate yields aldehyde 4 (Scheme 3, process a). ${ }^{31}$ Besides, the radical intermediate can abstract a hydrogen-atom from the solvent (THF) leading to reduced product 5 (Scheme 3, process b). ${ }^{32}$

Silyl derivative 6 was assayed under the same reaction conditions, leading to a mixture of trimethylsilyl containing compounds 7 and 8 in a $1 / 0.6$ ratio (Scheme 4). ${ }^{23}$ These two compounds were obtained by similar hydrogen-atom abstractions mentioned above. Ethyl carbonate derivative 1a (85\% yield, Scheme 2) resulted in the best yield and therefore ethyl carbonate was the leaving group of choice for the following reactions.

With the optimized conditions in hand, we explored substrates with different linkers, functionalities and substitution patterns. The results are summarized in Table 1.

The reaction successfully gave different five- and six-membered carbo- and heterocycles with excellent diastereoselectivities in almost all the tested substrates. Titanium-induced cyclization of compound $E-\mathbf{1 a}$ (Table 1, entry 1) led to compound 2 as $Z-1$ a (Scheme 2), revealing the stereoconvergent nature of the process. Additionally, the reaction proved to be compatible with different functional groups, including esters (Table 1, entries 1-7 and 11-12), sulfones (Table 1, entry 10), sulphonamides (Table 1, entries 8 and 9) or free hydroxyl groups (Table 1, entry 11), and permitted different substitution patterns in the oxirane ring (Table 1, entries 1-4) as well as in the involved alkene (Table 1, entries 5 and 11).

Scheme 4 Ti(III)-mediated cyclization of compound 6. Reaction conditions: (i) $6(1.0 \mathrm{mmol}) \mathrm{Cp}_{2} \mathrm{TiCl}_{2}(0.2 \mathrm{mmol}), \mathrm{Mn}(8.0 \mathrm{mmol}), \mathrm{Me} 3 \mathrm{SiCl}$ $(4.0 \mathrm{mmol}), 2,4,6-$ collidine $(6.0 \mathrm{mmol})$, THF, RT, 16 h . Isolated yield after column chromatography. Compounds 7 and 8 were not separated.

${ }^{a}$ Isolated yield after column chromatography. ${ }^{b}$ 7/3 mixture of cis/trans diastereoisomers. ${ }^{c}$ Compounds 14 and 15 were obtained in a $1 / 1$ ratio. Both compounds were obtained as diastereomeric mixture in $2 / 1 \mathrm{dr}$. ${ }^{d}$ Additional $12 \%$ of cyclic compound $\mathbf{S 4 3}$ in which the carbonate group is eliminated was also obtained (see ESI for further details). ${ }^{e} 1 / 1$ mixture of cis/trans diastereoisomers. ${ }^{f}$ Additional $15 \%$ of cyclic compound $\mathbf{S 4 4}$ in which the carbonate moiety is eliminated was also obtained (see ESI for further details).

The regiochemistry of the radical epoxide opening mainly depends upon the substitution pattern ${ }^{33}$ and controls the size of the obtained final cycle (Table 1, entries 1 vs. 2 and entries $8 v s .9$ ). As shown in entry 4, treatment of compound 13 with $\mathrm{Cp}_{2} \mathrm{TiCl}$ led to the formation of a $1 / 1$ mixture of five- and sixmembered rings, as expected from a 1,2-disubstituted oxirane ring. ${ }^{8,9}$ However in compound 18 electronic effects control the homolytic epoxide opening, thus only affording the six-membered ring 19. Stereoconvergency was further demonstrated, as diastereomeric mixture 28 (entry 11) gave rise to a single cyclic diastereomer 29. It is also noteworthy that the stereoselectivity
of this cyclization allows the setting up of two stereocenters in six-membered and notably five-membered rings (entries 2 and 9). When the stereocenters are located in 1,3-relative positions a cis stereochemistry between the hydroxyl group at C-3 and the vinyl group at $\mathrm{C}-5$ is observed as in the case of compounds 2,17 and 23 (entries 1, 5 and 8). On the other hand, compounds presenting contiguous stereocenters showed a trans (entries 2, 7, 9 and 12) or cis relationship (entry 3) between the vinyl and hydroxymethyl groups depending on the substitution pattern of the intermediate radical. Interestingly, in more functionalized substrates even three stereocenters can be allocated stereoselectively (entries 6 and 11). In the case of 1,3-relative positions, cis stereochemistry between the hydroxyl group at C-3 and the vinyl group at C-5 is preserved. The additional stereocenter at C-4 presents a trans stereochemistry with respect to the other two stereocenters.

All these stereochemical findings can be rationalized invoking the Beckwith-Houk rules. ${ }^{34,35}$ cis Substituted five-membered rings are expected for 5 -exo-trig cyclizations (entry 3). Trisubstituted radicals proceed disposing the bulkier substituent ( $\mathrm{R}_{2}$ in Scheme 5a) in a pseudoequatorial position (Scheme 5) thus yielding the observed cyclopentanes 10 and 25 (entries 2 and 9).

Although cyclizations of 6 -heptenyl radicals are less studied, a similar reasoning explains the experimental results. In the chair-like transition states all the bulkier substituents ( $\mathrm{R}_{1}$ and $\mathrm{R}_{3}$ in Scheme 6) are disposed in the equatorial positions. Additional template effects cannot be ruled out in cyclization of compound 28 (entry 11). ${ }^{20-23}$

In the case of entries 4 and 10, the structures of compounds 13 and 26 do not follow these stereochemical trends and

mixtures of diastereoisomers are obtained. The intrinsic reactivity of a 1,2-disubstituted epoxide in compound 13 (entry 4) precludes a clear analysis of its stereoselectivity. In compound 26 (entry 10), the transition state may be affected by bulky phenyl sulphonyl groups avoiding a clear chair-like transition state and leading to the formation of both isomers.

## Conclusions

A useful method for the diastereoselective synthesis of vinyl substituted carbo- and heterocycles is presented. The protocol is based on the radical opening of an epoxide and subsequent intramolecular addition to an allyl carbonate. Formally, the reaction yields similar products as the allylation of epoxides by the appropriate nucleophile but with several significant advantages. Firstly, the polyfunctionalized substrates required are very easily obtained and handled. Secondly, the cyclization reaction occurs at room temperature and under very smooth conditions highly compatible with diverse functional groups. And lastly, the diastereoselectivity observed is quite remarkable giving rise in most of the cases to a single diastereomer even when three stereogenic centres are generated in the final product. Highly functionalized structures difficult to achieve by other methodologies are obtained in a single step by this procedure. Thus, this method is an interesting tool in the context of organic synthesis.

## Experimental section

## General remarks

Unless otherwise stated, all reagents and solvents $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right.$, $\mathrm{Et}_{2} \mathrm{O}, \mathrm{MeCN}, \mathrm{EtOAc}$, hexane, DMF, and MeOH) were purchased from commercial sources and used without further purification. Dry THF was freshly distilled over $\mathrm{Na} /$ benzophenone. Flash column chromatography was carried out using Silica Gel 60 (230-400 mesh, Scharlab, Spain) as the stationary phase. Analytical TLC was performed on aluminium sheets coated with silica gel with the fluorescent indicator $\mathrm{UV}_{254}$ (Alugram SIL G/UV ${ }_{254}$, Mackerey-Nagel, Germany) and observed under UV light ( 254 nm ) and/or staining with Ce/Mo reagent or phosphomolybdic acid solution and subsequent heating. All ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra were recorded on Varian 300, 400 or 500 MHz spectrometers at a constant temperature of 298 K . Chemical shifts are reported in ppm and referenced to residual solvent. Coupling constants $(J)$ are reported in hertz (Hz). Standard abbreviations indicating multiplicity were used as follows: $\mathrm{m}=$ multiplet, quint. $=$ quintet, $\mathrm{q}=$ quartet, $\mathrm{t}=$ triplet, $d=$ doublet, $s=$ singlet, $b=$ broad. Assignment of the ${ }^{13} \mathrm{C}$ NMR multiplicities was accomplished by DEPT techniques.

## General procedure for the intramolecular epoxide allylation

Rigorously deoxygenated dry THF ( 10 mL ) was added to a previously deoxygenated mixture of $\mathrm{Cp}_{2} \mathrm{TiCl}_{2}(0.2 \mathrm{mmol})$ and Mn ( 8.0 mmol ) under an Ar atmosphere, and the suspension was stirred at room temperature until it turned green (about 10 min ). A solution of the previously synthesized polyfunctionalized substrate ( 1.0 mmol ) in THF ( 2 mL ), $\mathrm{Me}_{3} \mathrm{SiCl}$ ( 4.0 mmol ) and $2,4,6$-collidine ( 6.0 mmol ) was then added. The reaction mixture was stirred at room temperature for 16 h and then diluted with EtOAc, washed with HCl (10\%), dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and the solvent removed. The residue was subjected to flash column chromatography $\left(\mathrm{SiO}_{2}, \mathrm{EtOAc}-\right.$ hexane mixtures) to give the corresponding cyclic products.

Characterization data of cyclic products $2,4,5,7,8,10,12,14$, $15,17,19,21,23,25,27,29$, and 31
(See ESI $\dagger$ for numbering and copies of ${ }^{1} \mathrm{H}-\mathrm{NMR}$ and ${ }^{13} \mathrm{C}-\mathrm{NMR}$ spectra.)

31 K. V. Bhaskar and L. N. Mander, Tetrahedron Lett., 1996, 37, 719-722.
32 It is known that in the presence of a better H -atom source the reduction process yielding alcohols is favored: (a) J. Justicia, J. E. Oltra, A. F. Barrero, A. Guadaño, A. González-Coloma and J. M. Cuerva, Eur. J. Org. Chem., 2005, 712-718; (b) T. Jiménez, A. G. Campaña, B. Bazdi, M. Paradas, D. Arráez-Román, A. Segura-Carretero, A. Fernández-Gutiérrez, J. E. Oltra, R. Robles, J. Justicia and J. M. Cuerva, Eur. J. Org. Chem., 2010, 4288-4295. Nevertheless, in this case the reduction process can take place on intermediate radicals type-V (Scheme 1), thus competing with the desired cyclization reaction.
