<b>&lt;1 × 10<sup>-6</sup></b>	90	77 BABUSCI	13B	KLOE $1.02 e^+e^- \rightarrow \eta e^+e^-$

1 Combined analysis of the CMD-2 data on  $\phi \rightarrow K^+K^-, K_L^0 K_L^0, \pi^+\pi^-\pi^0, \eta\gamma$  assuming that the sum of their branching fractions is 0.99741 ± 0.00007.

2 Using  $B(\phi \rightarrow e^+e^-) = (2.93 \pm 0.14) \times 10^{-4}$ .

3 Theoretical analysis of BRAMON 00 taking into account phase-space difference, electromagnetic radiative corrections, as well as isospin breaking, predicts 0.62. FLOREZ-BAEZ 08 predicts 0.63 considering also structure-dependent radiative corrections. FIS-CHBAOZ 02 calculates additional corrections caused by the close threshold and predicts 0.68. See also BENAYOUN 01 and DUBYNSKIY 07. BENAYOUN 12 obtains 0.71 ± 0.01 in the HLS model.

4 Using  $B(\phi \rightarrow e^+e^-) = (2.99 \pm 0.08) \times 10^{-4}$ .

5 Using  $\Gamma(\phi) = 4.1$  MeV. If interference between the  $\rho\pi$  and  $3\pi$  modes is neglected, the fraction of the  $\rho\pi$  is more than 80% at the 90% confidence level.

6 From a fit without limitations on charged and neutral  $\pi$  masses and widths.

7 Adding the direct and  $\omega\pi$  contributions and considering the interference between the  $\rho\pi$  and  $\pi^+\pi^-\pi^0$ .

8 Neglecting the interference between the  $\rho\pi$  and  $\pi^+\pi^-\pi^0$ .

9 Using  $B(\phi \rightarrow e^+e^-) = (2.99 \pm 0.08) \times 10^{-4}$  and  $B(\eta \rightarrow 3\pi^0) = (32.2 \pm 0.4) \times 10^{-2}$ .

10 From  $\pi^+\pi^-\pi^0$  decay mode of  $\eta$ .

11 From  $2\gamma$  decay mode of  $\eta$ .

12 From  $3\pi^0$  decay mode of  $\eta$ .

13 ACHASOV 07b reports  $[\Gamma(\phi(1020) \rightarrow \eta\gamma)/\Gamma_{total}] \times [B(\phi(1020) \rightarrow e^+e^-)] = (4.050 \pm 0.067 \pm 0.118) \times 10^{-6}$  which we divide by our best value  $B(\phi(1020) \rightarrow e^+e^-) = (2.954 \pm 0.030) \times 10^{-4}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value. Supersedes ACHASOV 00b and ACHASOV 06a.

14 Using  $B(\phi \rightarrow e^+e^-) = (2.98 \pm 0.04) \times 10^{-4}$  and  $B(\eta \rightarrow \gamma\gamma) = 39.43 \pm 0.26\%$ .

15 Not independent of the corresponding  $\Gamma(e^+e^-) \times \Gamma(\eta\gamma)/\Gamma_{total}^2$ .

16 Using  $B(\phi \rightarrow e^+e^-) = (2.99 \pm 0.08) \times 10^{-4}$  and  $B(\eta \rightarrow 3\pi^0) = (32.24 \pm 0.29) \times 10^{-2}$ .

17 The combined fit from 600 to 1380 MeV taking into account  $\rho(770), \omega(782), \phi(1020)$ , and  $\rho(1450)$  (mass and width fixed at 1450 MeV and 310 MeV respectively).

18 From the  $\eta \rightarrow 2\gamma$  decay and using  $B(\phi \rightarrow e^+e^-) = (2.99 \pm 0.08) \times 10^{-4}$ .

19 From  $\pi^+\pi^-\pi^0$  decay mode of  $\eta$  and using  $B(\phi \rightarrow e^+e^-) = (2.99 \pm 0.08) \times 10^{-4}$ .

20 Reanalysis of DRUZHININ 84, DOLINSKY 89, and DOLINSKY 91 taking into account a triangle anomaly contribution.

21 Using  $B(\phi \rightarrow e^+e^-) = (2.98 \pm 0.04) \times 10^{-4}$ .

22 Not independent of the corresponding  $\Gamma(e^+e^-) \times \Gamma(\pi^0\gamma)/\Gamma_{total}^2$ .

23 From the  $\pi^0 \rightarrow 2\gamma$  decay and using  $B(\phi \rightarrow e^+e^-) = (2.99 \pm 0.08) \times 10^{-4}$ .

24 From the combined fit assuming that the total  $\phi(1020)$  production cross section is saturated by those of  $K^+K^-, K_S^0 K_L^0, \pi^+\pi^-\pi^0$ , and  $\eta\gamma$  decays modes and using ACHASOV 00b for the  $\eta\gamma$  decay mode.

25 Using total width 4.2 MeV. They detect  $3\pi$  mode and observe significant interference with  $\omega$  tail. This is accounted for in the result quoted above.

26 Neglecting interference between resonance and continuum.

27 Using  $B(\phi \rightarrow e^+e^-) = (2.91 \pm 0.07) \times 10^{-4}$ .

28 Recalculated by us using  $B(\phi \rightarrow e^+e^-) = (2.99 \pm 0.08) \times 10^{-4}$ .

29 Using  $B(\eta \rightarrow \gamma\gamma) = (39.25 \pm 0.32)\%$ ,  $B(\phi \rightarrow \eta\gamma) = (1.26 \pm 0.06)\%$ , and  $B(\phi \rightarrow e^+e^-) = (3.00 \pm 0.06) \times 10^{-4}$ .

30 The average of the branching ratios separately obtained from the  $\eta \rightarrow \gamma\gamma, 3\pi^0, \pi^+\pi^-\pi^0$  decays.

31 From  $\eta \rightarrow \gamma\gamma$  decays and using  $B(\eta \rightarrow \gamma\gamma) = (39.33 \pm 0.25) \times 10^{-2}$ ,  $B(\eta \rightarrow \pi^+\pi^-\pi^0) = (4.75 \pm 11) \times 10^{-2}$ , and  $B(\phi \rightarrow \eta\gamma) = (1.297 \pm 0.033) \times 10^{-2}$ .

- 32 From  $\eta \rightarrow 3\pi^0$  decays and using  $B(\pi^0 \rightarrow \gamma\gamma) = (98.798 \pm 0.033) \times 10^{-2}$ ,  $B(\eta \rightarrow 3\pi^0) = (32.24 \pm 0.29) \times 10^{-2}$ ,  $B(\eta \rightarrow \pi^+\pi^-\gamma) = (4.75 \pm 0.11) \times 10^{-2}$ , and  $B(\phi \rightarrow \eta\gamma) = (1.297 \pm 0.033) \times 10^{-2}$ .
- 33 From  $\eta \rightarrow \pi^+\pi^-\pi^0$  decays and using  $B(\pi^0 \rightarrow \gamma\gamma) = (98.798 \pm 0.033) \times 10^{-2}$ ,  $B(\pi^0 \rightarrow e^+e^-\gamma) = (1.198 \pm 0.032) \times 10^{-2}$ ,  $B(\eta \rightarrow \pi^+\pi^-\pi^0) = (23.0 \pm 0.4) \times 10^{-2}$ ,  $B(\phi \rightarrow \pi^+\pi^-\pi^0) = (15.5 \pm 0.6) \times 10^{-2}$ , and  $B(\phi \rightarrow \eta\gamma) = (1.297 \pm 0.033) \times 10^{-2}$ .
- 34 Using the 1996 and 1998 data.
- 35  $(2.3 \pm 0.3)\%$  correction for other decay modes of the  $\omega(782)$  applied.
- 36 Not independent of the corresponding  $\Gamma(\omega\pi^0) \times \Gamma(e^+e^-) / \Gamma^2(\text{total})$ .
- 37 Using the 1996 data.
- 38 Using the 1998 data.
- 39 Supersedes AKHMETSHIN 97c.
- 40 For  $E_\gamma > 20$  MeV and assuming that  $B(\phi(1020) \rightarrow f_0(980)\gamma)$  is negligible. Supersedes AKHMETSHIN 97c.
- 41 For  $E_\gamma > 20$  MeV and assuming that  $B(\phi(1020) \rightarrow f_0(980)\gamma)$  is negligible.
- 42 Obtained by the authors taking into account the  $\pi^+\pi^-$  decay mode. Includes a component due to  $\pi\pi$  production via the  $f_0(500)$  meson. Supersedes ALOISIO 02d.
- 43 From the combined fit of the photon spectra in the reactions  $e^+e^- \rightarrow \pi^+\pi^-\gamma$ ,  $\pi^0\pi^0\gamma$ .
- 44 From the negative interference with the  $f_0(500)$  meson of AITALA 01B using the ACHASOV 89 parameterization for the  $f_0(980)$ , a Breit-Wigner for the  $f_0(500)$ , and ACHASOV 01f for the  $\rho\pi$  contribution. Superseded by AMBROSINO 07.
- 45 Assuming that the  $\pi^0\pi^0\gamma$  final state is completely determined by the  $f_0\gamma$  mechanism, neglecting the decay  $B(\phi \rightarrow K\bar{K}\gamma)$  and using  $B(f_0 \rightarrow \pi^+\pi^-) = 2B(f_0 \rightarrow \pi^0\pi^0)$ .
- 46 Using the value  $B(\phi \rightarrow \eta\gamma) = (1.338 \pm 0.053) \times 10^{-2}$ .
- 47 For  $E_\gamma > 20$  MeV. Supersedes AKHMETSHIN 97c.
- 48 Neglecting other intermediate mechanisms ( $\rho\pi, \sigma\gamma$ ).
- 49 A narrow pole fit taking into account  $f_0(980)$  and  $f_0(1200)$  intermediate mechanisms.
- 50 For destructive interference with the Bremsstrahlung process
- 51 For constructive interference with the Bremsstrahlung process
- 52 Supersedes ALOISIO 02d.
- 53 Supersedes ACHASOV 98b. Excluding  $\omega\pi^0$ .
- 54 Using various branching ratios from the 2000 Edition of this Review (PDG 00).
- 55 Using  $B(\pi^0 \rightarrow \gamma\gamma) = 0.98798 \pm 0.00032$ ,  $B(\phi \rightarrow \eta\gamma) = (1.297 \pm 0.033) \times 10^{-2}$ , and  $B(\eta \rightarrow \pi^+\pi^-\gamma) = (4.75 \pm 0.11) \times 10^{-2}$ .
- 56 Combined results of  $\eta \rightarrow \gamma\gamma$  and  $\eta \rightarrow \pi^+\pi^-\pi^0$  decay modes measurements.
- 57 From the decay mode  $\eta \rightarrow \gamma\gamma$ .
- 58 From the decay mode  $\eta \rightarrow \pi^+\pi^-\pi^0$ .
- 59 Supersedes ACHASOV 98b.
- 60 Using  $B(\phi \rightarrow \eta\gamma) = (1.304 \pm 0.025)\%$ ,  $B(\eta \rightarrow 3\pi^0) = (32.56 \pm 0.23)\%$ , and  $B(\eta \rightarrow \gamma\gamma) = (39.31 \pm 0.20)\%$ .
- 61 Using  $B(\phi \rightarrow \eta\gamma) = (1.304 \pm 0.025)\%$ ,  $B(\eta \rightarrow 3\pi^0) = (32.56 \pm 0.23)\%$ , and  $B(\eta \rightarrow \pi^+\pi^-\pi^0) = (22.73 \pm 0.28)\%$ .
- 62 Using  $M_{\phi_0(980)} = 984.8$  MeV and assuming  $a_0(980)\gamma$  dominance.
- 63 Assuming  $a_0(980)\gamma$  dominance in the  $\eta\pi^0\gamma$  final state.
- 64 Using data of ACHASOV 00f.
- 65 Using results of ALOISIO 02d and assuming that  $f_0(980)$  decays into  $\pi\pi$  only and  $a_0(980)$  into  $\eta\pi$  only.
- 66 AMBROSINO 07a reports  $[\Gamma(\phi(1020) \rightarrow \eta(958)\gamma) / \Gamma_{\text{total}}] / [B(\phi(1020) \rightarrow \eta\gamma)] = (4.77 \pm 0.09 \pm 0.19) \times 10^{-3}$  which we multiply by our best value  $B(\phi(1020) \rightarrow \eta\gamma) = (1.309 \pm 0.024) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.
- 67 Averaging AULCHENKO 03b with AULCHENKO 99.
- 68 Using  $B(\phi \rightarrow \eta\gamma) = (1.297 \pm 0.033)\%$ .
- 69 Using the value  $B(\phi \rightarrow \eta\gamma) = (1.26 \pm 0.06) \times 10^{-2}$ .
- 70 Using  $B(\phi \rightarrow K_S^0 K_S^0) = (33.8 \pm 0.6)\%$ .
- 71 Averaging AKHMETSHIN 00b with AKHMETSHIN 00f.
- 72 Using the value  $B(\eta' \rightarrow \eta\pi^+\pi^-) = (43.7 \pm 1.5) \times 10^{-2}$  and  $B(\eta \rightarrow \gamma\gamma) = (39.25 \pm 0.31) \times 10^{-2}$ .
- 73 Using various branching ratios of  $K_S^0, K_L^0, \eta, \eta'$  from the 2000 edition (The European Physical Journal **C15** 1 (2000)) of this Review.
- 74 From the decay mode  $\eta' \rightarrow \eta\pi^+\pi^-, \eta \rightarrow \gamma\gamma$ .
- 75 Superseded by AKHMETSHIN 00b.
- 76 For  $E_\gamma > 20$  MeV.
- 77 For a narrow vector  $U$  with mass between 5 and 470 MeV, from the combined analysis of  $\eta \rightarrow \pi^+\pi^-\pi^0$  and  $\eta \rightarrow \pi^0\pi^0\pi^0$  from ARCHILLI 12. Measured 90% CL limits as a function of  $m_U$  range from  $2.2 \times 10^{-8}$  to  $10^{-6}$ .

## CONSTRAINED FIT INFORMATION

An overall fit to the total width, 4 partial widths, a combination of partial widths obtained from integrated cross sections, and 6 branching ratios uses 44 measurements and one constraint to determine 8 parameters. The overall fit has a  $\chi^2 = 81.8$  for 37 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$ , in percent, from the fit to parameters  $p_i$ , including the branching fractions,  $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

2.84 $\pm 0.35$		BOGLIONE 99	RVUE	$\gamma\gamma \rightarrow \pi^+ \pi^-, \pi^0 \pi^0$
2.93 $\pm 0.23 \pm 0.32$		26 YABUKI 95	VNS	
2.58 $\pm 0.13 \pm 0.36$		27 BEHREND 92	CELL	$e^+ e^- \rightarrow e^+ e^- \pi^+ \pi^-$
3.10 $\pm 0.35 \pm 0.35$		28 BLINOV 92	MD1	$e^+ e^- \rightarrow e^+ e^- \pi^+ \pi^-$
2.27 $\pm 0.47 \pm 0.11$		ADACHI 90D	TOPZ	$e^+ e^- \rightarrow e^+ e^- \pi^+ \pi^-$

The value of this width depends on the theoretical model used. Unitary approaches with scalars typically (with exception of PENNINGTON 08) give values clustering around 2.6 keV; without an S-wave contribution, values are systematically higher (typically around 3 keV).

- 21 From a partial-wave analysis of data using a K-matrix formalism with 5 poles.  
 22 From analysis of L3 data at 91 and 183–209 GeV and using SU(3) relations.  
 23 Solution A (preferred solution based on  $\chi^2$ -analysis).  
 24 Dispersion theory based amplitude analysis of BOYER 90, MARSISKE 90, BEHREND 92, and MORI 07.  
 25 Solution B (worse than solution A; still acceptable when systematic uncertainties are included).  
 26 With a narrow scalar state around 1220 MeV.  
 27 Using a unitarized model with a 300 - 500 keV wide scalar at 1100 MeV.  
 28 Using the unitarized model of LYTH 85.  
 29 Error includes spread of different solutions. Data of MARK2 and CRYSTAL BALL used in the analysis. Authors report strong correlations with  $\gamma\gamma$  width of  $f_0(1370)$ :  $\Gamma(f_2) + 1/4 \Gamma(f_0) = 3.6 \pm 0.3$  KeV.  
 30 Radiative corrections modify the partial widths; for instance the COURAU 84 value becomes  $2.66 \pm 0.21$  in the calculation of LANDRO 86.  
 31 Using the MENNESSIER 83 model.  
 32 Superseded by BOYER 90.  
 33 If helicity = 2 assumption is not made.  
 34 Using mass, width and  $B(f_2(1270) \rightarrow 2\pi)$  from PDG 78.

 $f_2(1270) \Gamma(i) \Gamma(\gamma\gamma) / \Gamma(\text{total})$  $\Gamma(K\bar{K}) \times \Gamma(\gamma\gamma) / \Gamma_{\text{total}}$  $\Gamma_3 \Gamma_7 / \Gamma$

1 Using the  $2\pi^+2\pi^-$  and  $\pi^+\pi^-\eta$  modes of  $f_1(1285)$  decay.2 The selected process is  $J/\psi \rightarrow \omega a_0(980)\pi$ .

3 Supersedes ABATZIS 94, ARMSTRONG 89e.

4 From partial wave analysis of  $K^+ \bar{K}^0 \pi^-$  system.

5 No systematic error given.

6 From a unitarized quark-model calculation.

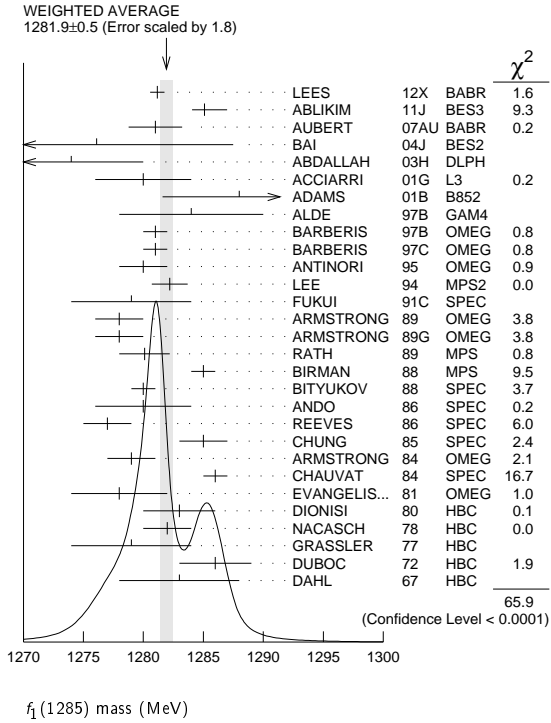

7 From phase shift analysis of  $\eta\pi^+\pi^-$  system.

8 Seen in the missing mass spectrum.

See key on page 547

## CONSTRAINED FIT INFORMATION

An overall fit to 7 branching ratios uses 16 measurements and one constraint to determine 5 parameters. The overall fit has a  $\chi^2 = 24.7$  for 12 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

## CONSTRAINED FIT INFORMATION

An overall fit to 5 branching ratios uses 18 measurements and one constraint to determine 4 parameters. The overall fit has a  $\chi^2 = 9.3$  for 15 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

29 KARSHON 74 suggest an additional  $I = 0$  state strongly coupled to  $\omega\pi\pi$  which could explain discrepancies in branching ratios and masses. We use a central value and a systematic spread.

- Another pole is found at  $(1510 \pm 130) - i(800 \pm 100)_{-150} \text{ MeV}$ .
- Coupled channel analysis of  $\pi^+ \pi^- \pi^0, K^+ K^- \pi^0$ , and  $K^\pm K_S^0 \pi^\mp$ .
- Average between  $\pi^+ \pi^- 2\pi^0$  and  $2(\pi^+ \pi^-)$ .
- T-matrix pole on sheet ---.
- Supersedes ANISOVICH 94.
- Coupled-channel analysis of  $\bar{p}p \rightarrow 3\pi^0, \pi^0 \eta \eta$ , and  $\pi^0 \pi^0 \eta$  on sheet IV. Demonstrates explicitly that  $f_0(500)$  and  $f_0(1370)$  are two different poles.
- Analysis of data from FALVARD 88.
- The pole is on Sheet III. Demonstrates explicitly that  $f_0(500)$  and  $f_0(1370)$  are two different poles.
- Uses data from BEIER 72b, OCHS 73, HYAMS 73, GRAYER 74, ROSSELET 77, CASON 83, ASTON 88, and ARMSTRONG 91b. Coupled channel analysis with flavor symmetry and all light two-pseudoscalars systems.
- Reanalysis of ANISOVICH 94 data.
- T-matrix pole on sheet III.
- Analysis of data from OCHS 73, GRAYER 74, BECKER 79, and CASON 83.

 $\eta(1405)$ 

$$I^G(J^{PC}) = 0^+(0^{-+})$$

THE  $\eta(1405)$ ,  $\eta(1475)$ ,  $f_1(1420)$ , AND  $f_1(1510)$ 

Revised November 2013 by C. Amsler (Bern) and A. Masoni (INFN Cagliari).

The first observation of the  $\eta(1440)$  was made in  $p\bar{p}$  annihilation at rest into  $\eta(1440)\pi^+\pi^-$ ,  $\eta(1440) \rightarrow K\bar{K}\pi$  [1]. This state was reported to decay through  $a_0(980)\pi$  and  $K^*(892)\bar{K}$  with roughly equal contributions. The  $\eta(1440)$  was also observed in radiative  $J/\psi(1S)$  decay into  $K\bar{K}\pi$  [2–4] and  $\gamma\rho$  [5]. There is evidence for the existence of two pseudoscalars in this mass region, the  $\eta(1405)$  and  $\eta(1475)$ . The former decays mainly through  $a_0(980)\pi$  (or direct  $K\bar{K}\pi$ ) and the latter mainly to  $K^*(892)\bar{K}$ .

The simultaneous observation of two pseudoscalars is reported in three production mechanisms:  $\pi^- p$  [6,7]; radiative  $J/\psi(1S)$  decay [8,9]; and  $p\bar{p}$  annihilation at rest [10–13]. All of them give values for the masses, widths, and decay modes in reasonable agreement. However, Ref. 9 favors a state decaying into  $K^*(892)\bar{K}$  at a lower mass than the state decaying into  $a_0(980)\pi$ . In  $J/\psi(1S)$  radiative decay, the  $\eta(1405)$  decays into  $K\bar{K}\pi$  through  $a_0(980)\pi$ , and hence a signal is also expected in the  $\eta\pi\pi$  mass spectrum. This was indeed observed by MARK III in  $\eta\pi^+\pi^-$  [14], which reports a mass of 1400 MeV, in line with the existence of the  $\eta(1405)$  decaying into  $a_0(980)\pi$ .

BES [15] reports an enhancement in  $K^+K^-\pi^0$  around 1.44 GeV in  $J/\psi(1S)$  decay, recoiling against an  $\omega$  (but not a  $\phi$ ) without resolving the presence of two states nor performing a spin-parity analysis, due to low statistics. This state could also be the  $f_1(1420)$  (see below). On the other hand, BES observes  $\eta(1405) \rightarrow \eta\pi\pi$  in  $J/\psi(1S)$  decay, recoiling against an  $\omega$  [16].

The  $\eta(1405)$  is also observed in  $p\bar{p}$  annihilation at rest into  $\eta\pi^+\pi^-\pi^0\pi^0$ , where it decays into  $\eta\pi\pi$  [17]. The intermediate  $a_0(980)\pi$  accounts for roughly half of the  $\eta\pi\pi$  signal, in agreement with MARK III [14] and DM2 [4].

However, the issue remains controversial as to whether two pseudoscalar mesons really exist. According to Ref. 18

# Meson Particle Listings

## $\eta(1405)$

the splitting of a single state could be due to nodes in the decay amplitudes which differ in  $\eta\pi\pi$  and  $K^*(892)\bar{K}$ . Based on the isospin violating decay  $J/\psi(1S) \rightarrow \gamma 3\pi$  observed by BES [19] the splitting could also be due to a triangular singularity mixing  $\eta\pi\pi$  and  $K^*(892)\bar{K}$  [20–21]. However, in a further paper [22], using the approach of [20], the authors concluded that the BES results can be reproduced either with the  $\eta(1405)$  or the  $\eta(1475)$  or by a mixture of the two states.

The  $\eta(1295)$  has been observed by four  $\pi^-p$  experiments [7,23–25], and evidence is reported in  $\bar{p}p$  annihilation [26–28]. In  $J/\psi(1S)$  radiative decay, an  $\eta(1295)$  signal is evident in the  $0^{-+}$   $\eta\pi\pi$  wave of the DM2 data [9]. Also BaBar [29] reports evidence for a signal around 1295 MeV in  $B$  decays into  $\eta\pi\pi K$ . However, the existence of the  $\eta(1295)$  is questioned in Refs. [18] and [30]. The authors claim a single pseudoscalar meson in the 1400 MeV region. This conclusion is based on properties of the wave functions in the  $^3P_0$  model (and on an unpublished analysis of the annihilation  $\bar{p}p \rightarrow 4\pi\eta$ ). The pseudoscalar signal around 1400 MeV is then attributed to the first radial excitation of the  $\eta$ .

Assuming establishment of the  $\eta(1295)$ , the  $\eta(1475)$  could be the first radial excitation of the  $\eta'$ , with the  $\eta(1295)$  being the first radial excitation of the  $\eta$ . Ideal mixing, suggested by the  $\eta(1295)$  and  $\pi(1300)$  mass degeneracy, would then imply that the second isoscalar in the nonet is mainly  $s\bar{s}$ , and hence couples to  $K^*\bar{K}$ , in agreement with properties of the  $\eta(1475)$ . Also, its width matches the expected width for the radially excited  $s\bar{s}$  state [31,32]. A study of radial excitations of pseudoscalar mesons [33] favors the  $s\bar{s}$  interpretation of the  $\eta(1475)$ . However, due to the strong kinematical suppression the data are not sufficient to exclude a sizeable  $s\bar{s}$  admixture also in the  $\eta(1405)$ .

The  $K\bar{K}\pi$  and  $\eta\pi\pi$  channels were studied in  $\gamma\gamma$  collisions by L3 [34]. The analysis led to a clear  $\eta(1475)$  signal in  $K\bar{K}\pi$ , decaying into  $K^*\bar{K}$ , very well identified in the untagged data sample, where contamination from spin 1 resonances is not allowed. At the same time, L3 [34] did not observe the  $\eta(1405)$ , neither in  $K\bar{K}\pi$  nor in  $\eta\pi\pi$ . The observation of the  $\eta(1475)$ , combined with the absence of an  $\eta(1405)$  signal, strengthens the two-resonances hypothesis. Since gluonium production is presumably suppressed in  $\gamma\gamma$  collisions, the L3 results [34] suggest that  $\eta(1405)$  has a large gluonic content (see also Refs. [35] and [36]).

The L3 result is somewhat in disagreement with that of CLEO-II, which did not observe any pseudoscalar signal in  $\gamma\gamma \rightarrow \eta(1475) \rightarrow K_S^0 K^\pm \pi^\mp$  [37]. However, more data are required. Moreover, after the CLEO-II result, L3 performed a further analysis with full statistics [38], confirming their previous evidence for the  $\eta(1475)$ . The CLEO upper limit [37] for  $\Gamma_{\gamma\gamma}(\eta(1475))$ , and the L3 results [38], are consistent with the world average for the  $\eta(1475)$  width.

BaBar [29] also reports the  $\eta(1475)$  in  $B$  decays into  $K\bar{K}^*$  recoiling against a  $K$ , but upper limits only are given for the  $\eta(1405)$ . As mentioned above, in  $B$  decays into  $\eta\pi\pi K$  the

$\eta(1295) \rightarrow \eta\pi\pi$  is observed while only upper limits are given for the  $\eta(1405)$ . The  $f_1(1420)$  (and the  $f_1(1285)$ ) are not seen.

The gluonium interpretation for the  $\eta(1405)$  is not favored by lattice gauge theories which predict the  $0^{-+}$  state above 2 GeV [39,40] (see also the article on the “Quark model” in this issue of the Review). However, the  $\eta(1405)$  is an excellent candidate for the  $0^{-+}$  glueball in the fluxtube model [41]. In this model, the  $0^{++}$   $f_0(1500)$  glueball is also naturally related to a  $0^{-+}$  glueball with mass degeneracy broken in QCD. Also, Ref. [42] shows that the pseudoscalar glueball could lie at a lower mass than predicted from lattice calculation. In this model the  $\eta(1405)$  appears as the natural glueball candidate, see also Refs. [43–45]. A detailed review of the experimental situation is available in Ref. 46.

Let us now deal with  $1^{++}$  isoscalars. The  $f_1(1420)$ , decaying into  $K^*\bar{K}$ , was first reported in  $\pi^-p$  reactions at 4 GeV/c [47]. However, later analyses found that the 1400–1500 MeV region was far more complex [48–50]. A reanalysis of the MARK III data in radiative  $J/\psi(1S)$  decay into  $K\bar{K}\pi$  [8] shows the  $f_1(1420)$  decaying into  $K^*\bar{K}$ . Also, a  $C=+1$  state is observed in tagged  $\gamma\gamma$  collisions (*e.g.*, Ref. 51).

In  $\pi^-p \rightarrow \eta\pi\pi n$  charge-exchange reactions at 8–9 GeV/c the  $\eta\pi\pi$  mass spectrum is dominated by the  $\eta(1440)$  and  $\eta(1295)$  [23,52], and at 100 GeV/c Ref. [24] reports the  $\eta(1295)$  and  $\eta(1440)$  decaying into  $\eta\pi^0\pi^0$  with a weak  $f_1(1285)$  signal, and no evidence for the  $f_1(1420)$ .

Axial ( $1^{++}$ ) mesons are not observed in  $\bar{p}p$  annihilation at rest in liquid hydrogen, which proceeds dominantly through  $S$ -wave annihilation. However, in gaseous hydrogen,  $P$ -wave annihilation is enhanced and, indeed, Ref. 11 reports  $f_1(1420)$  decaying into  $K^*\bar{K}$ . The  $f_1(1420)$ , decaying into  $K\bar{K}\pi$ , is also seen in  $pp$  central production, together with the  $f_1(1285)$ . The latter decays via  $a_0(980)\pi$ , and the former only via  $K^*\bar{K}$ , while the  $\eta(1440)$  is absent [53,54]. The  $K_S^0 K_S^0 \pi^0$  decay mode of the  $f_1(1420)$  establishes unambiguously  $C=+1$ . On the other hand, there is no evidence for any state decaying into  $\eta\pi\pi$  around 1400 MeV, and hence the  $\eta\pi\pi$  mode of the  $f_1(1420)$  must be suppressed [55].

We now turn to the experimental evidence for the  $f_1(1510)$ . Two states, the  $f_1(1420)$  and  $f_1(1510)$ , decaying into  $K^*\bar{K}$ , compete for the  $s\bar{s}$  assignment in the  $1^{++}$  nonet. The  $f_1(1510)$  was seen in  $K^-p \rightarrow \Lambda K\bar{K}\pi$  at 4 GeV/c [56], and at 11 GeV/c [57]. Evidence is also reported in  $\pi^-p$  at 8 GeV/c, based on the phase motion of the  $1^{++}$   $K^*\bar{K}$  wave [50]. A somewhat broader  $1^{++}$  signal is also observed in  $J/\psi(1S) \rightarrow \gamma\eta\pi^+\pi^-$  [58] as well as a small signal in  $J/\psi(1S) \rightarrow \gamma\eta'\pi^+\pi^-$ , attributed to the  $f_1(1510)$  [59].

The absence of  $f_1(1420)$  in  $K^-p$  [57] argues against the  $f_1(1420)$  being the  $s\bar{s}$  member of the  $1^{++}$  nonet. However, the  $f_1(1420)$  was reported in  $K^-p$  but not in  $\pi^-p$  [60], while two experiments do not observe the  $f_1(1510)$  in  $K^-p$  [60,61]. The latter is also not seen in central collisions [54], or  $\gamma\gamma$  collisions [62], although, surprisingly for an  $s\bar{s}$  state, a

signal is reported in  $4\pi$  decays [63]. These facts lead to the conclusion that  $f_1(1510)$  is not well established [64].

Assigning the  $f_1(1420)$  to the  $1^{++}$  nonet, one finds a nonet mixing angle of  $\sim 50^\circ$  [64]. However, arguments favoring the  $f_1(1420)$  being a hybrid  $q\bar{q}g$  meson, or a four-quark state, were put forward in Refs. [65] and [66], respectively, while Ref. 67 argued for a molecular state formed by the  $\pi$  orbiting in a  $P$ -wave around an  $S$ -wave  $K^*\bar{K}$  state. The  $f_1(1420)$  could also be an isoscalar  $K^*\bar{K}$  molecule. It is interesting to note that evidence for an isovector  $1^{++}$  partner,  $a_1(1420)$  decaying into  $f_0(980)\pi$ , was reported recently by the COMPASS experiment in  $\pi^-p \rightarrow (3\pi)^-p$  with 190 GeV/c pions [68].

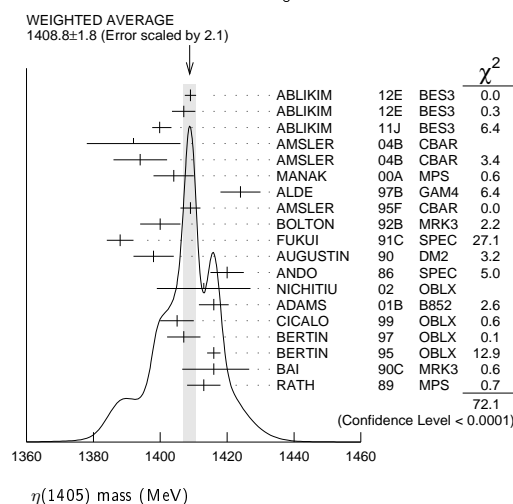

Summarizing, there is convincing evidence for the  $f_1(1420)$  decaying into  $K^*\bar{K}$ , and for two pseudoscalars in the  $\eta(1440)$  region, the  $\eta(1405)$  and  $\eta(1475)$ , decaying into  $a_0(980)\pi$  and  $K^*\bar{K}$ , respectively. Alternatively, these two structures could originate from a single pole. Doubts have been expressed on the existence of the  $\eta(1295)$ . The  $f_1(1510)$  is not well established.

- The selected process is  $J/\psi \rightarrow \omega a_0(980)\pi$ .
- From fit to the  $a_0(980)\pi 0^-+$  partial wave.
- Best fit with a single Breit Wigner.
- Decaying dominantly directly to  $K^+K^-\pi^0$ .
- Decaying into  $(K\bar{K})_S\pi$ ,  $(K\pi)_S\bar{K}$ , and  $a_0(980)\pi$ .
- From fit to the  $a_0(980)\pi 0^-+$  partial wave. Cannot rule out a  $a_0(980)\pi 1^++$  partial wave.
- Excluded from averaging because averaging would be meaningless.
- Best fit with a single Breit Wigner.
- This peak in the  $\gamma\rho$  channel may not be related to the  $\eta(1405)$ .
- Estimated by us from various fits.
- These experiments identify only one pseudoscalar in the 1400–1500 range. Data could also refer to  $\eta(1475)$ .
- Systematic uncertainty not evaluated.
- From best fit of  $0^-+$  partial wave, 50%  $K^*(892)K$ , 50%  $a_0(980)\pi$ .

80 ± 10	800	22,24 BAILLON	67	HBC	$0.0 \bar{p} p \rightarrow K\bar{K}\pi\pi\pi$

14 The selected process is  $J/\psi \rightarrow \omega a_0(980)\pi$ .  
 15 From fit to the  $a_0(980)\pi$   $0^-+$  partial wave.  
 16 From  $\eta\pi^+\pi^-$  mass distribution - mainly  $a_0(980)\pi$  - no spin-parity determination available.  
 17 Decaying dominantly directly to  $K^+K^-\pi^0$ .  
 18 Decaying into  $(K\bar{K})_S\pi$ ,  $(K\pi)_S\bar{K}$ , and  $a_0(980)\pi$ .  
 19 From fit to the  $a_0(980)\pi$   $0^-+$  partial wave, but  $a_0(980)\pi$   $1^++$  cannot be excluded.  
 20 This peak in the  $\gamma\rho$  channel may not be related to the  $\eta(1405)$ .  
 21 Estimated by us from various fits.  
 22 These experiments identify only one pseudoscalar in the 1400–1500 range. Data could also refer to  $\eta(1475)$ .  
 23 Systematic uncertainty not evaluated.  
 24 From best fit to  $0^-+$  partial wave, 50%  $K^*(892)K$ , 50%  $a_0(980)\pi$ .

<sup>1</sup> Using the KUHN 90 parametrization of the pion form factor, neglecting  $\rho$ - $\omega$  interference.

<sup>2</sup> Using the GOUNARIS 68 parametrization of the pion form factor leaving the masses and widths of the  $\rho(1450)$ ,  $\rho(1700)$ , and  $\rho(2150)$  resonances as free parameters of the fit.

<sup>3</sup> From the GOUNARIS 68 parametrization of the pion form factor.

<sup>4</sup>  $|F_\pi(0)|^2$  fixed to 1.

<sup>5</sup> From the combined fit of the  $\tau^-$  data from ANDERSON 00A and SCHAEEL 05C and  $e^+ e^-$  data from the compilation of BARKOV 85, AKHMETSHIN 04, and ALOISIO 05.

<sup>6</sup>  $\rho(1700)$  mass and width fixed at 1713 MeV and 235 MeV, respectively. Supersedes BARATE 97M.

<sup>7</sup>  $\rho(1700)$  mass and width fixed at 1700 MeV and 235 MeV, respectively.

<sup>8</sup>  $\rho(1700)$  mass and width fixed at 1780 MeV and 275 MeV, respectively.

<sup>9</sup> T-matrix pole.

<sup>10</sup> Using for  $\rho(1700)$  mass and width 1600 ± 20 and 300 ± 10 MeV respectively.

### CONSTRAINED FIT INFORMATION

An overall fit to 6 branching ratios uses 10 measurements and one constraint to determine 5 parameters. The overall fit has a  $\chi^2 = 11.4$  for 6 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

$x_4$	-83

## Meson Particle Listings

 $f_2'(1525)$ 

## CONSTRAINED FIT INFORMATION

An overall fit to the total width, 2 partial widths, a combination of partial widths obtained from integrated cross sections, and 3 branching ratios uses 17 measurements and one constraint to determine 5 parameters. The overall fit has a  $\chi^2 = 14.3$  for 13 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$ , in percent, from the fit to parameters  $p_i$ , including the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

	$x_1$	$x_2$	$x_3$	$x_8$
$x_2$	-100			
$x_3$	-6	-1		
$x_8$	-6	6	1	
$\Gamma$	-23	23	-1	-56

Mode	Rate (MeV)
$\Gamma_1$ $K\bar{K}$	$65 \begin{smallmatrix} +5 \\ -4 \end{smallmatrix}$
$\Gamma_2$ $\eta\eta$	$7.6 \pm 1.8$
$\Gamma_3$ $\pi\pi$	$0.60 \pm 0.12$
$\Gamma_8$ $\gamma\gamma$	$(8.1 \pm 0.9) \times 10^{-5}$

## CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 6 measurements and one constraint to determine 4 parameters. The overall fit has a  $\chi^2 = 1.9$  for 3 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

## CONSTRAINED FIT INFORMATION

An overall fit to 5 branching ratios uses 10 measurements and one constraint to determine 4 parameters. The overall fit has a  $\chi^2 = 14.7$  for 7 degrees of freedom.The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

 **$\rho(1700)$** 

$$I^G(J^{PC}) = 1^+(1^-)$$

**THE  $\rho(1450)$  AND THE  $\rho(1700)$** 

Updated May 2010 by S. Eidelman (Novosibirsk) and G. Venanzoni (Frascati).

In our 1988 edition, we replaced the  $\rho(1600)$  entry with two new ones, the  $\rho(1450)$  and the  $\rho(1700)$ , because there was emerging evidence that the 1600-MeV region actually contains two  $\rho$ -like resonances. Erkal [1] had pointed out this possibility with a theoretical analysis on the consistency of  $2\pi$  and  $4\pi$  electromagnetic form factors and the  $\pi\pi$  scattering length. Donnachie [2], with a full analysis of data on the  $2\pi$  and  $4\pi$  final states in  $e^+e^-$  annihilation and photoproduction reactions, had also argued that in order to obtain a consistent picture, two resonances were necessary. The existence of  $\rho(1450)$  was supported by the analysis of  $\eta\rho^0$  mass spectra obtained in photoproduction and  $e^+e^-$  annihilation [3], as well as that of  $e^+e^- \rightarrow \omega\pi$  [4].

The analysis of [2] was further extended by [5,6] to include new data on  $4\pi$ -systems produced in  $e^+e^-$  annihilation, and in  $\tau$ -decays ( $\tau$  decays to  $4\pi$ , and  $e^+e^-$  annihilation to  $4\pi$  can be related by the Conserved Vector Current assumption). These systems were successfully analyzed using interfering contributions from two  $\rho$ -like states, and from the tail of the  $\rho(770)$  decaying into two-body states. While specific conclusions on  $\rho(1450) \rightarrow 4\pi$  were obtained, little could be said about the  $\rho(1700)$ .

Independent evidence for two  $1^-$  states is provided by [7] in  $4\pi$  electroproduction at  $\langle Q^2 \rangle = 1$  (GeV/c)<sup>2</sup>, and by [8] in a high-statistics sample of the  $\eta\pi\pi$  system in  $\pi^-p$  charge exchange.

This scenario with two overlapping resonances is supported by other data. Bisello [9] measured the pion form factor in the interval 1.35–2.4 GeV, and observed a deep minimum around 1.6 GeV. The best fit was obtained with the hypothesis of  $\rho$ -like resonances at 1420 and 1770 MeV, with widths of about 250 MeV. Antonelli [10] found that the  $e^+e^- \rightarrow \eta\pi^+\pi^-$  cross section is better fitted with two fully interfering Breit-Wigners, with parameters in fair agreement with those of [2] and [9]. These results can be considered as a confirmation of the  $\rho(1450)$ .

Decisive evidence for the  $\pi\pi$  decay mode of both  $\rho(1450)$  and  $\rho(1700)$  comes from  $\bar{p}p$  annihilation at rest [11]. It has been shown that these resonances also possess a  $K\bar{K}$

decay mode [12–14]. High-statistics studies of the decays  $\tau \rightarrow \pi\pi\nu_\tau$  [15,16], and  $\tau \rightarrow 4\pi\nu_\tau$  [17] also require the  $\rho(1450)$ , but are not sensitive to the  $\rho(1700)$ , because it is too close to the  $\tau$  mass. A recent very-high-statistics study of the  $\tau \rightarrow \pi\pi\nu_\tau$  decay performed at Belle [18] reports the first observation of both  $\rho(1450)$  and  $\rho(1700)$  in  $\tau$  decays.

The structure of these  $\rho$  states is not yet completely clear. Barnes [19] and Close [20] claim that  $\rho(1450)$  has a mass consistent with radial  $2S$ , but its decays show characteristics of hybrids, and suggest that this state may be a  $2S$ -hybrid mixture. Donnachie [21] argues that hybrid states could have a  $4\pi$  decay mode dominated by the  $a_1\pi$ . Such behavior has been observed by [22] in  $e^+e^- \rightarrow 4\pi$  in the energy range 1.05–1.38 GeV, and by [17] in  $\tau \rightarrow 4\pi$  decays. Alexander [23] observes the  $\rho(1450) \rightarrow \omega\pi$  decay mode in  $B$ -meson decays, however, does not find  $\rho(1700) \rightarrow \omega\pi^0$ . A similar conclusion is made by [24], who studied the process  $e^+e^- \rightarrow \omega\pi^0$ . Various decay modes of the  $\rho(1450)$  and  $\rho(1700)$  are observed in  $\bar{p}n$  and  $\bar{p}p$  annihilation [25,26], but no definite conclusions can be drawn. More data should be collected to clarify the nature of the  $\rho$  states, particularly in the energy range above 1.6 GeV.

We now list under a separate entry the  $\rho(1570)$ , the  $\phi\pi$  state with  $J^{PC} = 1^{--}$  earlier observed by [27] (referred to as  $C(1480)$ ) and recently confirmed by [28]. While [29] shows that it may be a threshold effect, [5] and [30] suggest two independent vector states with this decay mode. The  $C(1480)$  has not been seen in the  $\bar{p}p$  [31] and  $e^+e^-$  [32,33] experiments. However, the sensitivity of the two latter is an order of magnitude lower than that of [28]. Note that [28] can not exclude that their observation is due to an OZI-suppressed decay mode of the  $\rho(1700)$ .

Several observations on the  $\omega\pi$  system in the 1200-MeV region [34–40] may be interpreted in terms of either  $J^P = 1^-$   $\rho(770) \rightarrow \omega\pi$  production [41], or  $J^P = 1^+$   $b_1(1235)$  production [39,40]. We argue that no special entry for a  $\rho(1250)$  is needed. The LASS amplitude analysis [42] showing evidence for  $\rho(1270)$  is preliminary and needs confirmation. For completeness, the relevant observations are listed under the  $\rho(1450)$ .

Recently [43] reported a very broad  $1^{--}$  resonance-like  $K^+K^-$  state in  $J/\psi \rightarrow K^+K^-\pi^0$  decays. Its pole position corresponds to mass of 1576 MeV and width of 818 MeV. [44–46] suggest its exotic structure (molecular or multiquark), while [47] and [48] explain it by the interference between the  $\rho(1450)$  and  $\rho(1700)$ . We quote [43] as  $X(1575)$  in the section “Further States.”

Evidence for  $\rho$ -like mesons decaying into  $6\pi$  states was first noted by [49] in the analysis of  $6\pi$  mass spectra from  $e^+e^-$  annihilation [50,51] and diffractive photoproduction [52]. Clegg [49] argued that two states at about 2.1 and 1.8 GeV exist: while the former is a candidate for the  $\rho(2150)$ , the latter could be a manifestation of the  $\rho(1700)$  distorted by threshold effects. BaBar reported observations of the new decay modes of the  $\rho(2150)$  in the channels  $\eta'(958)\pi^+\pi^-$  and  $f_1(1285)\pi^+\pi^-$

## Meson Particle Listings

 $\rho(1700)$ 

[53]. The relativistic quark model [54] predicts the  $2^3D_1$  state with  $J^{PC} = 1^{--}$  at 2.15 GeV which can be identified with the  $\rho(2150)$ .

The E687 Collaboration at Fermilab reported an observation of a narrow-dip structure at 1.9 GeV in the  $3\pi^+3\pi^-$  diffractive photoproduction [55]. A similar effect of the dip in the cross section of  $e^+e^- \rightarrow 6\pi$  around 1.9 GeV has been earlier reported by DM2 [51], where  $6\pi$  included both  $3\pi^+3\pi^-$  and  $2\pi^+2\pi^-2\pi^0$ . Later the dip in the  $R$  value (the total cross section of  $e^+e^- \rightarrow$  hadrons divided by the cross section of  $e^+e^- \rightarrow \mu^+\mu^-$ ) was observed by [56], again around 1.9 GeV. This energy is close to the  $N\bar{N}$  threshold, which hints at the possible relation between the dip and  $N\bar{N}$ , *e.g.*, the frequently discussed narrow  $N\bar{N}$  resonance or just a threshold effect. Such behaviour is also characteristic of exotic objects like vector  $q\bar{q}$  hybrids. Note that [57] failed to find this state in the reaction  $\bar{n}p \rightarrow 3\pi^+2\pi^-\pi^0$ . A reanalysis of the E687 data by [58] shows that a dip may arise due to interference of a narrow object with a broad  $\rho(1700)$  independently of the nature of the former. BaBar studied the processes  $e^+e^- \rightarrow 3\pi^+3\pi^-$  and  $e^+e^- \rightarrow 2\pi^+2\pi^-2\pi^0$  using the radiative return, and observed a structure around 1.9 GeV in both final states [59]. The data are not well described by a single Breit-Wigner state, and a good fit is achieved while taking into account the interference of such a structure with a Jacob-Slansky amplitude for continuum. The mass of this state obtained by BaBar is consistent with [56] and [55], but the width is substantially larger. Recently [28] observed a structure at 1.9 GeV in the radiative return to the  $\phi\pi$  final state, with a much smaller width of  $48 \pm 17$  MeV consistent with that of [56,58]. We list these observations under a separate particle  $\rho(1900)$ , which needs confirmation.

<sup>1</sup> In the SU(3) based model with a specific interference pattern of the  $f_2(1270)$ ,  $a_2^0(1320)$ , and  $f_2'(1525)$  mesons incoherently added to the  $f_0(1710)$  and non-resonant background.

<sup>2</sup> This state may be different from  $f_0(1710)$ , see CLOSE 05.

<sup>3</sup>  $J^P = 0^+$ .

<sup>4</sup> T-matrix pole.

<sup>5</sup> Supersedes BARBERIS 99 and BARBERIS 99b.

<sup>6</sup>  $J^P = 0^+$ , supersedes by ARMSTRONG 89d.

<sup>7</sup>  $N_p J^{PC}$  determination.

<sup>8</sup>  $J^P = 2^+$ .

<sup>9</sup> Breit-Wigner mass.

<sup>10</sup> Systematic errors not estimated.

<sup>11</sup> K-matrix pole, assuming  $J^P = 0^+$ , from combined analysis of  $\pi^- p \rightarrow \pi^0 \pi^0 n$ ,  $\pi^- p \rightarrow K \bar{K} n$ ,  $\pi^+ \pi^- \rightarrow \pi^+ \pi^-$ ,  $\bar{p}p \rightarrow \pi^0 \pi^0 \pi^0$ ,  $\pi^0 \eta \eta$ ,  $\pi^0 \pi^0 \eta$ ,  $\pi^+ \pi^- \pi^0$ ,  $K^+ K^- \pi^0$ ,  $K_S^0 K_S^0 \pi^0$ ,  $K^+ K_S^0 \pi^-$  at rest,  $\bar{p}n \rightarrow \pi^- \pi^- \pi^+$ ,  $K_S^0 K^- \pi^0$ ,  $K_S^0 K_S^0 \pi^-$  at rest.

<sup>12</sup> Decaying to  $f_0(1370) \pi \pi$ .

<sup>13</sup>  $J^P = 0^+$ .

<sup>14</sup> Not seen by AMSLER 02.

<sup>15</sup> T-matrix pole, assuming  $J^P = 0^+$ .

<sup>16</sup> No  $J^{PC}$  determination.

<sup>17</sup> No  $J^{PC}$  determination, width not determined.

<sup>18</sup> From a fit to the  $0^+$  partial wave.

<sup>19</sup> ALDE 92d combines all the GAMS-2000 data.

<sup>20</sup>  $J^P = 2^+$ , superseded by FRENCH 99.

<sup>21</sup> From an analysis ignoring interference with  $f_2'(1525)$ .

<sup>22</sup> From an analysis including interference with  $f_2'(1525)$ .

<sup>23</sup> Superseded by ALDE 92d.

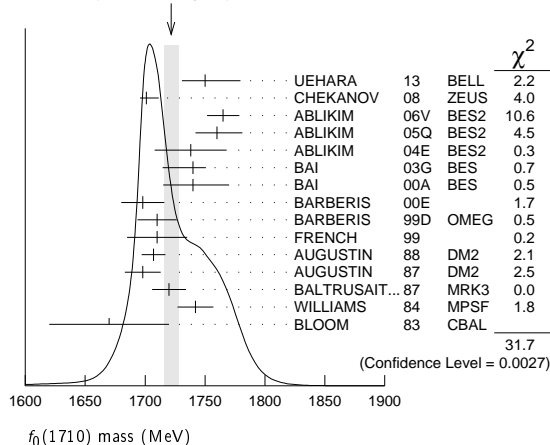

<sup>24</sup> Uses MRK3 data. From a partial-wave analysis of data using a K-matrix formalism with 5 poles, but assuming spin 2. Fit with constrained inelasticity.

<sup>25</sup>  $J^P = 2^+$  preferred.

<sup>26</sup> From fit neglecting nearby  $f_2'(1525)$ . Replaced by BLOOM 83.

<sup>27</sup> Superseded by LONGACRE 86.

<sup>28</sup> In the SU(3) based model with a specific interference pattern of the  $f_2(1270)$ ,  $a_2^0(1320)$ , and  $f_2'(1525)$  mesons incoherently added to the  $f_0(1710)$  and non-resonant background.

<sup>29</sup> Breit-Wigner width.

<sup>30</sup>  $J^P = 0^+$ .

<sup>31</sup> T-matrix pole.

<sup>32</sup> Supersedes BARBERIS 99 and BARBERIS 99b.

<sup>33</sup>  $J^P = 0^+$ , superseded by ARMSTRONG 89d.

<sup>34</sup>  $N_p J^{PC}$  determination.

<sup>35</sup>  $J^P = 2^+$ .

<sup>36</sup> No  $J^{PC}$  determination.

<sup>37</sup> Systematic errors not estimated.

<sup>38</sup> This state may be different from  $f_0(1710)$ , see CLOSE 05.

<sup>39</sup> (Solution I)

<sup>40</sup> K-matrix pole, assuming  $J^P = 0^+$ , from combined analysis of  $\pi^- p \rightarrow \pi^0 \pi^0 n$ ,  $\pi^- p \rightarrow K \bar{K} n$ ,  $\pi^+ \pi^- \rightarrow \pi^+ \pi^-$ ,  $\bar{p}p \rightarrow \pi^0 \pi^0 \pi^0$ ,  $\pi^0 \eta \eta$ ,  $\pi^0 \pi^0 \eta$ ,  $\pi^+ \pi^- \pi^0$ ,  $K^+ K^- \pi^0$ ,  $K_S^0 K_S^0 \pi^0$ ,  $K^+ K_S^0 \pi^-$  at rest,  $\bar{p}n \rightarrow \pi^- \pi^- \pi^+$ ,  $K_S^0 K^- \pi^0$ ,  $K_S^0 K_S^0 \pi^-$  at rest.

<sup>41</sup> (Solution I)

<sup>42</sup> Decaying to  $f_0(1370) \pi \pi$ .

<sup>43</sup>  $J^P = 0^+$ .

<sup>44</sup> Not seen by AMSLER 02.

<sup>45</sup> T-matrix pole, assuming  $J^P = 0^+$ .

<sup>46</sup> No  $J^{PC}$  determination.

<sup>47</sup> From a fit to the  $0^+$  partial wave.

<sup>48</sup> ALDE 92d combines all the GAMS-2000 data.

<sup>49</sup>  $J^P = 2^+$ , ( $0^+$  excluded).

<sup>50</sup> From an analysis ignoring interference with  $f_2'(1525)$ .

<sup>51</sup> From an analysis including interference with  $f_2'(1525)$ .

<sup>52</sup> Uses MRK3 data. From a partial-wave analysis of data using a K-matrix formalism with 5 poles, but assuming spin 2. Fit with constrained inelasticity.

<sup>53</sup>  $J^P = 2^+$  preferred.

<sup>54</sup> From fit neglecting nearby  $f_2'(1525)$ . Replaced by BLOOM 83.

<sup>55</sup> From an amplitude analysis of the  $K_S^0 K_S^0$  system, superseded by LONGACRE 86.

## $f_2(1910)$

$$I^G(J^{PC}) = 0^+(2^{++})$$

OMITTED FROM SUMMARY TABLE

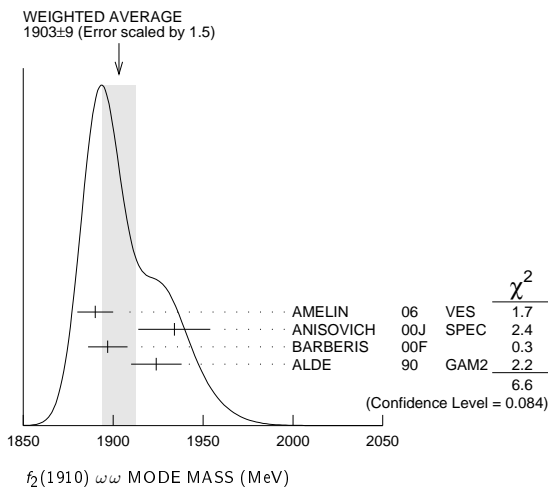

We list here three different peaks with close masses and widths seen in the mass distributions of  $\omega\omega$ ,  $\eta\eta'$ , and  $K^+K^-$  final states. ALDE 91B argues that they are of different nature.

### $f_2(1910)$ MASS

#### $f_2(1910) \omega\omega$ MODE

VALUE (MeV)	DOCUMENT ID	TECN	COMMENT
<b><math>1903 \pm 9</math> OUR AVERAGE</b>	Error includes scale factor of 1.5. See the ideogram below.		
$1890 \pm 10$	<sup>1</sup> AMELIN	06	VES $36\pi^-p \rightarrow \omega\omega n$
$1934 \pm 20$	ANISOVICH	00j	SPEC
$1897 \pm 11$	BARBERIS	00f	$450 pp \rightarrow p_f\omega\omega p_S$
$1924 \pm 14$	ALDE	90	GAM2 $38\pi^-p \rightarrow \omega\omega n$

<sup>1</sup>Supersedes BELADIDZE 92b.

~ 2150	<sup>7</sup> MARTIN	80C	RVUE
~ 2150	<sup>8</sup> DULUDE	78B	OSPK 1-2 $\bar{p}p \rightarrow \pi^0\pi^0$

<sup>5</sup> OAKDEN 94 makes an amplitude analysis of LEAR data on  $\bar{p}p \rightarrow \pi\pi$  using a method based on Barrelet zeros. This is solution A. The amplitude analysis of HASAN 94 includes earlier data as well, and assume that the data can be parametrized in terms of towers of nearly degenerate resonances on the leading Regge trajectory. See also KLOET 96 and MARTIN 97 who make related analyses.

<sup>6</sup> From solution B of amplitude analysis of data on  $\bar{p}p \rightarrow \pi\pi$ .

<sup>7</sup>  $I(J^P) = 0(2^+)$  from simultaneous analysis of  $p\bar{p} \rightarrow \pi^-\pi^+$  and  $\pi^0\pi^0$ .

<sup>8</sup>  $I^G(J^P) = 0^+(2^+)$  from partial-wave amplitude analysis.

2170±30	ALDE 92C	GAM4	100 $\pi^-p \rightarrow \omega\pi^0 n$

- Using the GOUNARIS 68 parametrization of the pion form factor leaving the masses and widths of the  $\rho(1450)$ ,  $\rho(1700)$ , and  $\rho(2150)$  resonances as free parameters of the fit.
- Includes ATKINSON 85.
- See however KLOET 96 who fit  $\pi^+\pi^-$  only and find waves only up to  $J = 3$  to be important but not significantly resonant.
- $I(J^P) = 1(1^-)$  from simultaneous analysis of  $p\bar{p} \rightarrow \pi^-\pi^+$  and  $\pi^0\pi^0$ .
- From the combined analysis of ANISOVICH 00J, ANISOVICH 01D, ANISOVICH 01E, and ANISOVICH 02.
- Isospins 0 and 1 not separated.
- From a fit to the total elastic cross section.
- Referred to as  $T$  or  $T$  region by ALSPECTOR 73.
- Seen as bump in  $l = 1$  state. See also COOPER 68. PEASLEE 75 confirm  $\bar{p}p$  results of ABRAMS 70, no narrow structure.

## Meson Particle Listings

 $K^\pm$ 

**STRANGE MESONS**  
**( $S = \pm 1, C = B = 0$ )**

$K^+ = u\bar{s}, K^0 = d\bar{s}, \bar{K}^0 = \bar{d}s, K^- = \bar{u}s,$  similarly for  $K^{*}$ 's

 $K^\pm$  $I(J^P) = \frac{1}{2}(0^-)$ **THE CHARGED KAON MASS**

Revised 1994 by T.G. Trippe (LBNL).

The average of the six charged kaon mass measurements which we use in the Particle Listings is

$$m_{K^\pm} = 493.677 \pm 0.013 \text{ MeV } (S = 2.4), \quad (1)$$

where the error has been increased by the scale factor  $S$ . The large scale factor indicates a serious disagreement between different input data. The average before scaling the error is

$$m_{K^\pm} = 493.677 \pm 0.005 \text{ MeV}, \quad (2)$$

$$\chi^2 = 22.9 \text{ for } 5 \text{ D.F.}, \text{ Prob.} = 0.04\%,$$

where the high  $\chi^2$  and correspondingly low  $\chi^2$  probability further quantify the disagreement.

The main disagreement is between the two most recent and precise results,

$$m_{K^\pm} = 493.696 \pm 0.007 \text{ MeV} \quad \text{DENISOV 91}$$

$$m_{K^\pm} = 493.636 \pm 0.011 \text{ MeV } (S = 1.5) \quad \text{GALL 88}$$

$$\text{Average} = 493.679 \pm 0.006 \text{ MeV}$$

$$\chi^2 = 21.2 \text{ for } 1 \text{ D.F.}, \text{ Prob.} = 0.0004\%, \quad (3)$$

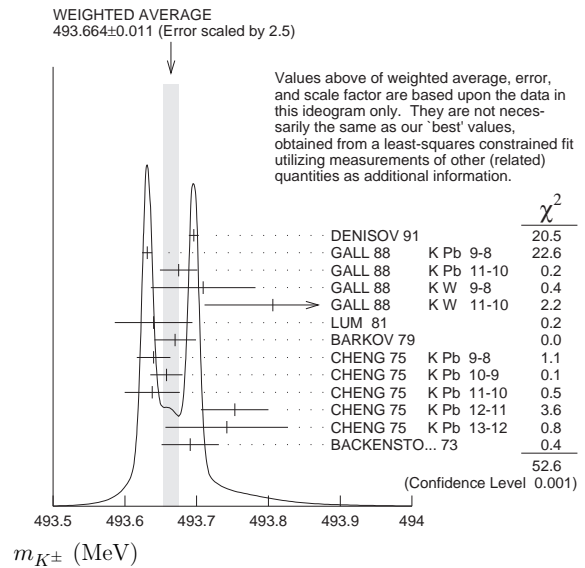

both of which are measurements of x-ray energies from kaonic atoms. Comparing the average in Eq. (3) with the overall average in Eq. (2), it is clear that DENISOV 91 and GALL 88 dominate the overall average, and that their disagreement is responsible for most of the high  $\chi^2$ .

The GALL 88 measurement was made using four different kaonic atom transitions,  $K^- \text{Pb } (9 \rightarrow 8)$ ,  $K^- \text{Pb } (11 \rightarrow 10)$ ,  $K^- \text{W } (9 \rightarrow 8)$ , and  $K^- \text{W } (11 \rightarrow 10)$ . The  $m_{K^\pm}$  values they obtain from each of these transitions is shown in the Particle Listings and in Fig. 1. Their  $K^- \text{Pb } (9 \rightarrow 8)$   $m_{K^\pm}$  is below and somewhat inconsistent with their other three transitions. The average of their four measurements is

$$m_{K^\pm} = 493.636 \pm 0.007,$$

$$\chi^2 = 7.0 \text{ for } 3 \text{ D.F.}, \text{ Prob.} = 7.2\%. \quad (4)$$

This is a low but acceptable  $\chi^2$  probability so, to be conservative, GALL 88 scaled up the error on their average by  $S=1.5$  to obtain their published error  $\pm 0.011$  shown in Eq. (3) above and used in the Particle Listings average.

**Figure 1:** Ideogram of  $m_{K^\pm}$  mass measurements. GALL 88 and CHENG 75 measurements are shown separately for each transition they measured.

The ideogram in Fig. 1 shows that the DENISOV 91 measurement and the GALL 88  $K^- \text{Pb } (9 \rightarrow 8)$  measurement yield two well-separated peaks. One might suspect the GALL 88  $K^- \text{Pb } (9 \rightarrow 8)$  measurement since it is responsible both for the internal inconsistency in the GALL 88 measurements and the disagreement with DENISOV 91.

To see if the disagreement could result from a systematic problem with the  $K^- \text{Pb } (9 \rightarrow 8)$  transition, we have separated the CHENG 75 data, which also used  $K^- \text{Pb}$ , into its separate transitions. Figure 1 shows that the CHENG 75 and GALL 88  $K^- \text{Pb } (9 \rightarrow 8)$  values are consistent, suggesting the possibility of a common effect such as contaminant nuclear  $\gamma$  rays near the  $K^- \text{Pb } (9 \rightarrow 8)$  transition energy, although the CHENG 75 errors are too large to make a strong conclusion. The average of all 13 measurements has a  $\chi^2$  of 52.6 as shown in Fig. 1 and the first line of Table 1, yielding an unacceptable  $\chi^2$  probability of 0.00005%. The second line of Table 1 excludes both the GALL 88 and CHENG 75 measurements of the  $K^- \text{Pb } (9 \rightarrow 8)$  transition and yields a  $\chi^2$  probability of 43%. The third [fourth] line of Table 1 excludes only the GALL 88  $K^- \text{Pb } (9 \rightarrow 8)$  [DENISOV 91] measurement and yields a  $\chi^2$  probability of 20% [8.6%]. Table 1 shows that removing both measurements of the  $K^- \text{Pb } (9 \rightarrow 8)$  transition produces the most consistent set of data, but that excluding only the GALL 88  $K^- \text{Pb } (9 \rightarrow 8)$  transition or DENISOV 91 also produces acceptable probabilities.

**Table 1:**  $m_{K^\pm}$  averages for some combinations of Fig. 1 data.

$m_{K^\pm}$ (MeV)	$\chi^2$	D.F.	Prob. (%)	Measurements used
$493.664 \pm 0.004$	52.6	12	0.00005	all 13 measurements
$493.690 \pm 0.006$	10.1	10	43	no $K^-$ Pb(9→8)
$493.687 \pm 0.006$	14.6	11	20	no GALL 88 $K^-$ Pb(9→8)
$493.642 \pm 0.006$	17.8	11	8.6	no DENISOV 91

Yu.M. Ivanov, representing DENISOV 91, has estimated corrections needed for the older experiments because of improved  $^{192}\text{Ir}$  and  $^{198}\text{Au}$  calibration  $\gamma$ -ray energies. He estimates that CHENG 75 and BACKENSTOSS 73  $m_{K^\pm}$  values could be raised by about 15 keV and 22 keV, respectively. With these estimated corrections, Table 1 becomes Table 2. The last line of Table 2 shows that if such corrections are assumed, then GALL 88  $K^-$  Pb (9 → 8) is inconsistent with the rest of the data even when DENISOV 91 is excluded. Yu.M. Ivanov warns that these are rough estimates. Accordingly, we do not use Table 2 to reject the GALL 88  $K^-$  Pb (9 → 8) transition, but we note that a future reanalysis of the CHENG 75 data could be useful because it might provide supporting evidence for such a rejection.

**Table 2:**  $m_{K^\pm}$  averages for some combinations of Fig. 1 data after raising CHENG 75 and BACKENSTOSS 73 values by 0.015 and 0.022 MeV respectively.

$m_{K^\pm}$ (MeV)	$\chi^2$	D.F.	Prob. (%)	Measurements used
$493.666 \pm 0.004$	53.9	12	0.00003	all 13 measurements
$493.693 \pm 0.006$	9.0	10	53	no $K^-$ Pb(9→8)
$493.690 \pm 0.006$	11.5	11	40	no GALL 88 $K^-$ Pb(9→8)
$493.645 \pm 0.006$	23.0	11	1.8	no DENISOV 91

The GALL 88 measurement uses a Ge semiconductor spectrometer which has a resolution of about 1 keV, so they run the risk of some contaminant nuclear  $\gamma$  rays. Studies of  $\gamma$  rays following stopped  $\pi^-$  and  $\Sigma^-$  absorption in nuclei (unpublished) do not show any evidence for contaminants according to GALL 88 spokesperson, B.L. Roberts. The DENISOV 91 measurement uses a crystal diffraction spectrometer with a resolution of 6.3 eV for radiation at 22.1 keV to measure the 4f-3d transition in  $K^-$   $^{12}\text{C}$ . The high resolution and the light nucleus reduce the probability for overlap by contaminant  $\gamma$  rays, compared with the measurement of GALL 88. The DENISOV 91 measurement is supported by their high-precision measurement of the 4d-2p transition energy in  $\pi^-$   $^{12}\text{C}$ , which is good agreement with the calculated energy.

While we suspect that the GALL 88  $K^-$  Pb (9 → 8) measurements could be the problem, we are unable to find clear grounds for rejecting it. Therefore, we retain their measurement in the average and accept the large scale factor until further information can be obtained from new measurements and/or from reanalysis of GALL 88 and CHENG 75 data.

We thank B.L. Roberts (Boston Univ.) and Yu.M. Ivanov (Petersburg Nuclear Physics Inst.) for their extensive help in understanding this problem.

More recent bounds for a short lived pseudoscalar  $X^0$  decaying to muons or photons are  $B(K_L \rightarrow \pi^0 \pi^0 \mu^+ \mu^-) < 1 \times 10^{-10}$  [25] and  $B(K_L \rightarrow \pi^0 \pi^0 \gamma \gamma) < 2.4 \times 10^{-7}$  [26].

### C. Measurements of Standard Model parameters:

In the SM, the decay  $K^+ \rightarrow \pi^+ \nu \bar{\nu}$  is dominated by one-loop diagrams with top-quark intermediate states and long-distance contributions are known to be quite small [2,27]. This permits a precise calculation of this rate in terms of SM parameters. Studies of this process are thus motivated by the possibility of detecting non-SM physics when comparing with the results of global fits [28,29].

BNL-787 observed two candidate events [30,31] in the clean high  $\pi^+$  momentum and one event [32] in the low-momentum region. The successor experiment BNL-949 observed one more in the high-momentum region [24] and three more in the low-momentum region [33] yielding a branching ratio of  $(1.73^{+1.15}_{-1.05}) \times 10^{-10}$  [34]. A subsequent experiment, NA62, with a sensitivity goal of  $\sim 10^{-12}$ /event was proposed [35] at CERN in 2005. It was approved and ran with a partial detector in autumn 2012. Physics running is scheduled to start in the fall of 2014. A new experiment, ORKA [36], received Stage 1 approval from Fermilab in December 2011. It proposes to collect  $O(1000)$  events in five years of running by studying kaon decays at rest. In contrast, the NA62 experiment will be performed with kaon decays in flight. In the future, this mode may provide grounds for precision tests of flavor dynamics [37]. The branching ratio can be written in a compact form that exhibits the different ingredients that go into the calculation [38],

$$B(K^+ \rightarrow \pi^+ \nu \bar{\nu}(\gamma)) = \kappa_+(1 + \Delta_{EM}) \left[ \left( \frac{\text{Im}(V_{ts}^* V_{td})}{\lambda^5} X_t \right)^2 + \left( \frac{\text{Re}(V_{cs}^* V_{cd})}{\lambda} (P_c + \delta P_{c,u}) + \frac{\text{Re}(V_{ts}^* V_{td})}{\lambda^5} X_t \right)^2 \right]. \quad (1)$$

The parameters in Eq. (1) incorporate the *a priori* unknown hadronic matrix element in terms of the very well-measured  $K_{e3}$  rate [2] in  $\kappa_+$ ; long distance QED corrections in  $\Delta_{EM}$  [39]; the Inami-Lim function for the short distance top-quark contribution [40] including NLO QCD corrections [41] and the two-loop electroweak correction [38], all in  $X_t$ ; and the charm-quark contributions due to short distance effects including NNLO QCD corrections [42] and NLO electroweak corrections via  $P_c$  [43], as well as certain long distance effects via  $\delta P_{c,u}$  [44]. An interesting approximate way to cast this result in terms of the CKM parameters  $\lambda$ ,  $V_{cb}$ ,  $\bar{\rho}$  and  $\bar{\eta}$  (see our Section on “The Cabibbo-Kobayashi-Maskawa mixing matrix”) [11] is:

$$B(K^+ \rightarrow \pi^+ \nu \bar{\nu}) \approx 1.6 \times 10^{-5} |V_{cb}|^4 [\sigma \bar{\eta}^2 + (\rho_c - \bar{\rho})^2], \quad (2)$$

where  $\rho_c \approx 1.45$  and  $\sigma \equiv 1/(1 - \frac{1}{2}\lambda^2)^2$ . Thus,  $B(K^+ \rightarrow \pi^+ \nu \bar{\nu})$  determines an ellipse in the  $\bar{\rho}$ ,  $\bar{\eta}$  plane with center  $(\rho_c, 0)$  and semiaxes  $\approx \frac{1}{|V_{cb}|^2} \sqrt{\frac{B(K^+ \rightarrow \pi^+ \nu \bar{\nu})}{1.6 \times 10^{-5}}}$  and  $\frac{1}{\sigma |V_{cb}|^2} \sqrt{\frac{B(K^+ \rightarrow \pi^+ \nu \bar{\nu})}{1.6 \times 10^{-5}}}$ . The latest numerical study leads to a predicted branching ratio  $(7.81^{+0.80}_{-0.71} \pm 0.29) \times 10^{-11}$  [38], near the lower end of the measurement of BNL-787 and 949.

Modes with an extra pion,  $K \rightarrow \pi \pi \nu \bar{\nu}$ , could also be used in the extraction of CKM parameters as they are also dominated by short distance contributions [45]. However, they occur at much lower rates with branching ratios of order  $10^{-13}$ , and the current best bound from KEK-391a is  $B(K_L \rightarrow \pi^0 \pi^0 \nu \bar{\nu}) < 8.1 \times 10^{-7}$  at 90% CL [46]. There is also an older bound of  $B(K^+ \rightarrow \pi^+ \pi^0 \nu \bar{\nu}) < 4.3 \times 10^{-5}$  at 90% CL [47] from BNL-787.

The decay  $K_L \rightarrow \mu^+ \mu^-$  also has a short distance contribution sensitive to the CKM parameter  $\bar{\rho}$ , given by [11]:

$$B_{SD}(K_L \rightarrow \mu^+ \mu^-) \approx 2.7 \times 10^{-4} |V_{cb}|^4 (\rho'_c - \bar{\rho})^2 \quad (3)$$

where  $\rho'_c$  depends on the charm quark mass and is approximately 1.2. This decay, however, is dominated by a long-distance contribution from a two-photon intermediate state. The absorptive (imaginary) part of the long-distance component is determined by the measured rate for  $K_L \rightarrow \gamma \gamma$  to be  $B_{\text{abs}}(K_L \rightarrow \mu^+ \mu^-) = (6.64 \pm 0.07) \times 10^{-9}$ ; and it almost completely saturates the observed rate  $B(K_L \rightarrow \mu^+ \mu^-) = (6.84 \pm 0.11) \times 10^{-9}$  [48]. The difference between the observed rate and the absorptive component can be attributed to the (coherent) sum of the short-distance amplitude and the real part of the long-distance amplitude. The latter cannot be derived directly from experiment [49], but can be estimated with certain assumptions [50,51].

The decay  $K_L \rightarrow e^+ e^-$  is completely dominated by long distance physics and is easier to estimate. The result,  $B(K_L \rightarrow e^+ e^-) \sim 9 \times 10^{-12}$  [49,52], is in good agreement with the BNL-871 measurement,  $(8.7^{+5.7}_{-4.1}) \times 10^{-12}$  [53].

The mode  $K_S \rightarrow \mu^+ \mu^-$  also has a short distance contribution proportional to the square of the CKM parameter  $\bar{\eta}$  entering at the  $10^{-13}$  level [15] as well as long distance contributions which arise in this case from a two photon intermediate state and result in a rate  $B(K_S \rightarrow \mu^+ \mu^-)_{LD} = 5.1 \times 10^{-12}$  [15]. A 95% (90%) c.l. limit  $B(K_S \rightarrow \mu^+ \mu^-) < 11(9) \times 10^{-9}$  has recently been obtained by LHCb [54].

**D. Searches for direct CP violation:** The mode  $K_L \rightarrow \pi^0 \nu \bar{\nu}$  is dominantly *CP*-violating and free of hadronic uncertainties [2,55,56]. In the Standard Model, this mode is dominated by an intermediate top-quark state and does not suffer from the small uncertainty associated with the charm-quark intermediate state that affects the mode  $K^+ \rightarrow \pi^+ \nu \bar{\nu}$ . The branching ratio is given by Ref. 11:

$$B(K_L \rightarrow \pi^0 \nu \bar{\nu}) = \kappa_L \left( \frac{\text{Im}(V_{ts}^* V_{td})}{\lambda^5} X_t \right)^2 \approx 7.6 \times 10^{-5} |V_{cb}|^4 \bar{\eta}^2. \quad (4)$$

The hadronic matrix element can be related to that measured in  $K_{e3}$  decay and is parameterized in  $\kappa_L$ . The latest numerical evaluation leads to a predicted branching ratio  $(2.43^{+0.40}_{-0.37} \pm 0.06) \times 10^{-11}$  [38]. The 90% CL bound on  $K^+ \rightarrow \pi^+ \nu \bar{\nu}$  provides a nearly model-independent bound  $B(K_L \rightarrow \pi^0 \nu \bar{\nu}) < 1.46 \times 10^{-9}$  [57]. KEK-391a, which took data in 2004 and 2005, has published a 90% CL upper bound of  $B(K_L \rightarrow \pi^0 \nu \bar{\nu}) \leq$

## $K^\pm$

$2.6 \times 10^{-8}$  [58]. The KOTO experiment at J-PARC [59], whose initial goal is to reach the  $10^{-11}$ /event level had a short physics run in the spring of 2013 and is expected to resume in 2014.

There has been much theoretical work on possible contributions to rare  $K$  decays beyond the SM. A comprehensive discussion of these can be found in Refs. [14] and [60].

The decay  $K_L \rightarrow \pi^0 e^+ e^-$  also has sensitivity to the CKM parameter  $\eta$  through its  $CP$ -violating component. There are both direct and indirect  $CP$ -violating amplitudes that can interfere. The direct  $CP$ -violating amplitude is short distance dominated and has been calculated in detail within the SM [8]. The indirect  $CP$ -violating amplitude can be inferred from a measurement of  $K_S \rightarrow \pi^0 e^+ e^-$ . The complete  $CP$ -violating contribution to the rate can be written as [61,62]:

$$B_{\text{CPV}} \approx 10^{-12} \left[ 15.7 |a_S|^2 \pm 1.4 \left( \frac{|V_{cb}|^2 \eta}{10^{-4}} \right) |a_S| + 0.12 \left( \frac{|V_{cb}|^2 \eta}{10^{-4}} \right)^2 \right] \quad (5)$$

where the three terms correspond to the indirect  $CP$  violation, the interference, and the direct  $CP$  violation respectively. The parameter  $a_S$  has been extracted by NA48 from a measurement of the decay  $K_S \rightarrow \pi^0 e^+ e^-$  with the result  $|a_S| = 1.06^{+0.26}_{-0.21} \pm 0.07$  [63], as well as from a measurement of the decay  $K_S \rightarrow \pi^0 \mu^+ \mu^-$  with the result  $|a_S| = 1.54^{+0.40}_{-0.32} \pm 0.06$  [64]. With current constraints on the CKM parameters, and assuming a positive sign for the interference term [62,65], this implies that  $B_{\text{CPV}}(K_L \rightarrow \pi^0 e^+ e^-) \approx (3.1 \pm 0.9) \times 10^{-11}$ , and that the indirect  $CP$  violation is larger than the direct  $CP$  violation. The complete  $CP$  violating amplitude for the related mode  $K_L \rightarrow \pi^0 \mu^+ \mu^-$  is predicted to be  $B_{\text{CPV}}(K_L \rightarrow \pi^0 \mu^+ \mu^-) \approx (1.4 \pm 0.5) \times 10^{-11}$  [66,15].

$K_L \rightarrow \pi^0 \gamma \gamma$  also has a  $CP$ -conserving component dominated by a two-photon intermediate state. This component can be decomposed into an absorptive and a dispersive part. The absorptive part can be extracted from the measurement of the low  $m_{\gamma\gamma}$  region of the  $K_L \rightarrow \pi^0 \gamma \gamma$  spectrum. The rate and the shape of the distribution  $d\Gamma/dm_{\gamma\gamma}$  in  $K_L \rightarrow \pi^0 \gamma \gamma$  are well described in chiral perturbation theory in terms of three (*a priori*) unknown parameters [67,68].

Both KTeV and NA48 have studied the mode  $K_L \rightarrow \pi^0 \gamma \gamma$ , reporting similar results. KTeV finds  $B(K_L \rightarrow \pi^0 \gamma \gamma) = (1.29 \pm 0.03_{\text{stat}} \pm 0.05_{\text{sys}}) \times 10^{-6}$  [69], while NA48 finds  $B(K_L \rightarrow \pi^0 \gamma \gamma) = (1.36 \pm 0.03_{\text{stat}} \pm 0.03_{\text{sys}} \pm 0.03_{\text{norm}}) \times 10^{-6}$  [70]. Both experiments are consistent with a negligible rate in the low  $m_{\gamma\gamma}$  region, suggesting a very small  $CP$ -conserving component  $B_{\text{CP}}(K_L \rightarrow \pi^0 e^+ e^-) \sim \mathcal{O}(10^{-13})$  [62,68,70]. There remains some model dependence in the estimate of the dispersive part of the  $CP$ -conserving  $K_L \rightarrow \pi^0 e^+ e^-$  [62].

The related process,  $K_L \rightarrow \pi^0 \gamma e^+ e^-$ , is potentially an additional background in some region of phase space [71]. This process has been observed with a branching ratio of  $(1.62 \pm 0.14_{\text{stat}} \pm 0.09_{\text{sys}}) \times 10^{-8}$  [72].

The decay  $K_L \rightarrow \gamma \gamma e^+ e^-$  constitutes the dominant background to  $K_L \rightarrow \pi^0 e^+ e^-$ . It was first observed by BNL-845 [73], and subsequently confirmed with a much larger sample by KTeV [74]. It has been estimated that this background will enter at about the  $10^{-10}$  level [75,76], comparable to or larger than the signal level. Because of this, the observation of  $K_L \rightarrow \pi^0 e^+ e^-$  at the SM level will depend on background subtraction with good statistics. Possible alternative strategies are discussed in Ref. 62 and references cited therein.

The 90% CL upper bound for the process  $K_L \rightarrow \pi^0 e^+ e^-$  is  $2.8 \times 10^{-10}$  [76]. For the closely related muonic process, the published upper bound is  $B(K_L \rightarrow \pi^0 \mu^+ \mu^-) \leq 3.8 \times 10^{-10}$  [77], compared with the SM prediction of  $(1.5 \pm 0.3) \times 10^{-11}$  [66] (assuming positive interference between the direct- and indirect- $CP$  violating components).

A study of  $K_L \rightarrow \pi^0 \mu^+ \mu^-$  has indicated that it might be possible to extract the direct  $CP$ -violating contribution by a joint study of the Dalitz plot variables and the components of the  $\mu^+$  polarization [78]. The latter tends to be quite substantial so that large statistics may not be necessary.

Combined information from the two  $K_L \rightarrow \pi^0 \ell^+ \ell^-$  modes complements the  $K \rightarrow \pi \nu \bar{\nu}$  measurements in constraining physics beyond the SM [79].

### ***E. Other long distance dominated modes:***

The decays  $K^+ \rightarrow \pi^+ \ell^+ \ell^-$  ( $\ell = e$  or  $\mu$ ) have received considerable attention. The rate and spectrum have been measured for both the electron and muon modes [80,81,20]. Ref. 61 has proposed a parametrization inspired by chiral perturbation theory, which provides a successful description of data but indicates the presence of large corrections beyond leading order. More work is needed to fully understand the origin of these large corrections. NA62 has now also observed the mode  $K^+ \rightarrow \pi^+ \pi^0 e^+ e^-$  [82].

The decay  $K^+ \rightarrow \pi^+ \gamma \gamma$  can be predicted in terms of one unknown parameter to leading order in  $\chi$ PT resulting in a correlation between the rate and the diphoton mass spectrum [83]. Certain important corrections at the next order are also known [84]. The rate was first measured by E787 [85] and more recently NA48/2 [86] has obtained a more precise result with 6% error along with the corresponding spectrum fits.

Much information has been recorded by KTeV and NA48 on the rates and spectrum for the Dalitz pair conversion modes  $K_L \rightarrow \ell^+ \ell^- \gamma$  [87,88], and  $K_L \rightarrow \ell^+ \ell^- \ell'^+ \ell'^-$  for  $\ell, \ell' = e$  or  $\mu$  [19,89–91]. All these results are used to test hadronic models and could further our understanding of the long distance component in  $K_L \rightarrow \mu^+ \mu^-$ .

[a] See the Particle Listings below for the energy limits used in this measurement.

[b] Most of this radiative mode, the low-momentum  $\gamma$  part, is also included in the parent mode listed without  $\gamma$ 's.

[c] Structure-dependent part.

[d] See the "Note on  $\pi^\pm \rightarrow \ell^\pm \nu \gamma$  and  $K^\pm \rightarrow \ell^\pm \nu \gamma$  Form Factors" in the  $\pi^\pm$  Particle Listings for definitions and details.

[e] Direct-emission branching fraction.

[f] Derived from an analysis of neutrino-oscillation experiments.

[g] Violates angular-momentum conservation.

## CONSTRAINED FIT INFORMATION

An overall fit to the mean life, a decay rate, and 13 branching ratios uses 32 measurements and one constraint to determine 8 parameters. The overall fit has a  $\chi^2 = 51.8$  for 25 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$ , in percent, from the fit to parameters  $p_i$ , including the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

Mode	Rate ( $10^8 \text{ s}^{-1}$ )	Scale factor
$\Gamma_2 \mu^+ \nu_\mu$	$0.5133 \pm 0.0013$	1.5

<sup>31</sup>BATLEY 12 uses data collected in 2003-2004. The result is inclusive of  $K^\pm \rightarrow \pi^+ \pi^- e^\pm \nu_\gamma$  decays. Using PDG 12 value for  $\Gamma(\pi^+ \pi^- \pi^+)/\Gamma = (5.59 \pm 0.04) \times 10^{-2}$ . BATLEY 12 obtains  $B(\pi^+ \pi^- e \nu) = (4.257 \pm 0.004 \pm 0.035) \times 10^{-5}$  where the syst. error is dominated by the error on the normalization mode.

<sup>32</sup>PISLAK 01 reports  $\Gamma(\pi^+ \pi^- e^+ \nu_e)/\Gamma_{total} = (4.109 \pm 0.008 \pm 0.110) \times 10^{-5}$  using the PDG 00 value  $\Gamma(\pi^+ \pi^+ \pi^-)/\Gamma_{total} = (5.59 \pm 0.05) \times 10^{-2}$ . We divide by the PDG value and unfold its error from the systematic error. PISLAK 03 and PISLAK 10A give additional details on the branching ratio measurement and give improved errors on the S-wave  $\pi$ - $\pi$  scattering length:  $a_0^0 = 0.235 \pm 0.013$  and  $a_0^2 = -0.0410 \pm 0.0027$ .

## Hadronic modes with photons

 $\Gamma(\pi^+ \pi^0 \gamma(\text{INT}))/\Gamma_{\text{total}}$   $\Gamma_{21}/\Gamma$ 

The  $K^+ \rightarrow \pi^+ \pi^0 \gamma$  differential decay rate can be described in terms of  $T_{\pi^+}$ , the charged pion kinetic energy, and  $W^2 = (P_K \cdot P_\gamma) (P_{\pi^+} \cdot P_\gamma) / (m_K m_{\pi^+})^2$ ; then we can write  $d^2\Gamma(K^+ \rightarrow \pi^+ \pi^0 \gamma) / (dT_{\pi^+} dW^2) = d^2\Gamma(K^+ \rightarrow \pi^+ \pi^0 \gamma)_{IB} / (dT_{\pi^+} dW^2) [1 + 2 \cos(\pm\phi + \delta_1^1 - \delta_0^2) m_\pi^2 m_K^2 W^2 X_E + m_\pi^4 m_K^4 (X_E^2 + X_M^2) W^4]$ . The IB differential and total branching ratios are expressed in terms of the non-radiative experimental width  $\Gamma(K^+ \rightarrow \pi^+ \pi^0)$  by Low's theorem. Using PDG 10  $B(K^+ \rightarrow \pi^+ \pi^0) = 0.2066 \pm 0.0008$ , one obtains respectively  $B(K^+ \rightarrow \pi^+ \pi^0 \gamma)_{IB} (55 < T_{\pi^+} < 90 \text{ MeV}) = 2.55 \times 10^{-4}$  and  $B(K^+ \rightarrow \pi^+ \pi^0 \gamma)_{IB} (0 < T_{\pi^+} < 80 \text{ MeV}) = 1.80 \times 10^{-4}$ . Fitting respectively the piece proportional to  $W^2$  and the piece proportional to  $W^4$ , the interference contribution (INT), proportional to  $X_E$ , and the direct contribution (DE) proportional to  $X_E^2 + X_M^2$  are extracted.

59 BATLEY 14 uses data collected in 2003 and 2004. Branching ratio is obtained by determining the parameter  $\tilde{c} = 1.41 \pm 0.38 \pm 0.11$  and integrating the  $O(p^6)$  chiral spectrum. A model independent value for the branching ratio is also obtained ( $8.77 \pm 0.87 \pm 0.17$ )  $\times 10^{-7}$  for kinematic range  $(m_{\gamma\gamma}/m_K)^2 > 0.2$ .

60 KITCHING 97 is extrapolated from their model-independent branching fraction ( $6.0 \pm 1.5 \pm 0.7$ )  $\times 10^{-7}$  for  $100 \text{ MeV}/c < P_{\pi^+} < 180 \text{ MeV}/c$  using Chiral Perturbation Theory.

61 ARTAMONOV 05 limit assumes ChPT with  $\tilde{c} = 1.8$  with unitarity corrections. With  $\tilde{c} = 1.6$  and no unitarity corrections they obtain  $< 2.3 \times 10^{-8}$  at 90% CL. This partial branching ratio is predicted to be  $6.10 \times 10^{-9}$  and  $0.49 \times 10^{-9}$  for the cases with and without unitarity correction.

$< 23$	90	ATIYA	89	B787	+	

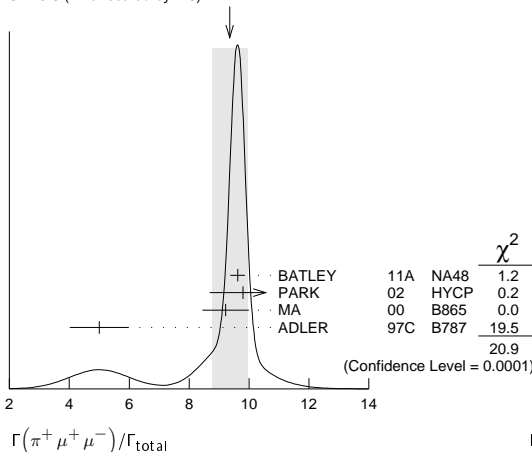

<sup>69</sup>BATLEY 11A also studies the form factor  $f(z)$  dependence of the decay, described via single photon exchange: i) assuming a linear form factor,  $f(z) = f_0(1 + \delta z)$ ,  $z = (M_{\mu\mu}/m_K)^2$ , finding  $f_0 = 0.470 \pm 0.040$  and  $\delta = 3.11 \pm 0.57$  and ii) assuming a linear form factor including  $\pi-\pi$  rescattering,  $W_{\pi\pi}$ , as in DAMBROSI 98A, finding  $f(z) = G_F m_K^2 (a_+ + b_+ z) + W_{\pi\pi}(z)$ ,  $a_+ = -0.575 \pm 0.039$ ,  $b_+ = -0.813 \pm 0.145$ .

<sup>70</sup>PARK 02 "±" result comes from combining  $K^+ \rightarrow \pi^+ \mu^+ \mu^-$  and  $K^- \rightarrow \pi^- \mu^+ \mu^-$ , assuming CP is conserved.

<sup>71</sup>MA 00 establishes vector nature of this decay and determines form factor  $f(z) = f_0(1 + \delta z)$ ,  $z = (M_{\mu\mu}/m_K)^2$ ,  $\delta = 2.45 \pm 1.30 - 0.95$ .

<sup>72</sup>ADLER 97c gives systematic error  $0.7 \times 10^{-8}$  and theoretical uncertainty  $0.6 \times 10^{-8}$ , which we combine in quadrature to obtain our second error.

Revised 1999 by T.G. Trippe (LBNL).

The Dalitz plot distribution for  $K^\pm \rightarrow \pi^\pm \pi^\pm \pi^\mp$ ,  $K^\pm \rightarrow \pi^0 \pi^0 \pi^\pm$ , and  $K_L^0 \rightarrow \pi^+ \pi^- \pi^0$  can be parameterized by a series expansion such as that introduced by Weinberg [1]. We use the form

$$\begin{aligned}
 |M|^2 \propto & 1 + g \frac{(s_3 - s_0)}{m_{\pi^+}^2} + h \left[ \frac{s_3 - s_0}{m_{\pi^+}^2} \right]^2 \\
 & + j \frac{(s_2 - s_1)}{m_{\pi^+}^2} + k \left[ \frac{s_2 - s_1}{m_{\pi^+}^2} \right]^2 \\
 & + f \frac{(s_2 - s_1)(s_3 - s_0)}{m_{\pi^+}^2 m_{\pi^+}^2} + \dots, \quad (1)
 \end{aligned}$$

where  $m_{\pi^+}^2$  has been introduced to make the coefficients  $g$ ,  $h$ ,  $j$ , and  $k$  dimensionless, and

$$s_i = (P_K - P_i)^2 = (m_K - m_i)^2 - 2m_K T_i, \quad i = 1, 2, 3,$$

$$s_0 = \frac{1}{3} \sum_i s_i = \frac{1}{3} (m_K^2 + m_1^2 + m_2^2 + m_3^2).$$

Here the  $P_i$  are four-vectors,  $m_i$  and  $T_i$  are the mass and kinetic energy of the  $i^{\text{th}}$  pion, and the index 3 is used for the odd pion.

The coefficient  $g$  is a measure of the slope in the variable  $s_3$  (or  $T_3$ ) of the Dalitz plot, while  $h$  and  $k$  measure the quadratic dependence on  $s_3$  and  $(s_2 - s_1)$ , respectively. The coefficient  $j$  is related to the asymmetry of the plot and must be zero if  $CP$  invariance holds. Note also that if  $CP$  is good,  $g$ ,  $h$ , and  $k$  must be the same for  $K^+ \rightarrow \pi^+ \pi^+ \pi^-$  as for  $K^- \rightarrow \pi^- \pi^- \pi^+$ .

Since different experiments use different forms for  $|M|^2$ , in order to compare the experiments we have converted to  $g$ ,  $h$ ,  $j$ , and  $k$  whatever coefficients have been measured. Where such conversions have been done, the measured coefficient  $a_y$ ,  $a_t$ ,  $a_u$ , or  $a_v$  is given in the comment at the right. For definitions of these coefficients, details of this conversion, and discussion of the data, see the April 1982 version of this note [2].

<sup>106</sup> BATLEY 07E includes data from BATLEY 06A. Uses quadratic parametrization and PDG 06 value  $g = 0.626 \pm 0.007$  to obtain  $g_+ - g_- = (2.2 \pm 2.1 \pm 0.7) \times 10^{-4}$ . Neglects any possible charge asymmetries in higher order slope parameters  $h$  or  $k$ .

<sup>107</sup> Asymmetry obtained assuming that  $g_+ + g_- = 2 \times 0.652$  (PDG 02) and that asymmetries in  $h$  and  $k$  are zero.

<sup>108</sup> Linear and quadratic slopes from PDG 04 are used. Any possible charge asymmetries in higher order slope parameters  $h$  or  $k$  are neglected.

ALTERNATIVE PARAMETRIZATIONS OF  $K^\pm \rightarrow \pi^\pm \pi^0 \pi^0$  DALITZ PLOT

The following functional form for the matrix element suggested by  $\pi\pi$  rescattering in  $K^+ \rightarrow \pi^+ \pi^+ \pi^- \rightarrow \pi^+ \pi^0 \pi^0$  is used for this fit (CABIBBO 04A, CABIBBO 05): Matrix element =  $M_0 + M_1$  where  $M_0 = 1 + (1/2)g_0 u + (1/2)h' u^2 + (1/2)k_0 v^2$  with  $u = (s_3 - s_0) / (m_\pi)^2$ ,  $v = (s_2 - s_1) / (m_\pi)^2$  and where  $M_1$  takes into account the non-analytic piece due to  $\pi\pi$  rescattering amplitudes  $a_0$  and  $a_2$ ; The parameters  $g_0$  and  $h'$  are related to the parameters  $g$  and  $h$  of the matrix element squared given in the previous section by the approximations  $g_0 \sim g^{PDG}$  and  $h' \sim h^{PDG} - (g/2)^2$  and  $k_0 \sim k^{PDG}$ .

In addition, we also consider the effective field theory framework of COLANGELO 06A and BISSEGGER 09 to extract  $g_{BB}$  and  $h'_{BB}$ .

## $K_{\ell 3}^\pm$ AND $K_{\ell 3}^0$ FORM FACTORS

Updated September 2013 by T.G. Trippe (LBNL) and C.-J. Lin (LBNL).

Assuming that only the vector current contributes to  $K \rightarrow \pi \ell \nu$  decays, we write the matrix element as

$$M \propto f_+(t) [(P_K + P_\pi)_\mu \bar{\ell} \gamma_\mu (1 + \gamma_5) \nu] + f_-(t) [m_\ell \bar{\ell} (1 + \gamma_5) \nu], \quad (1)$$

where  $P_K$  and  $P_\pi$  are the four-momenta of the  $K$  and  $\pi$  mesons,  $m_\ell$  is the lepton mass, and  $f_+$  and  $f_-$  are dimensionless form factors which can depend only on  $t = (P_K - P_\pi)^2$ , the square of the four-momentum transfer to the leptons. If time-reversal invariance holds,  $f_+$  and  $f_-$  are relatively real.  $K_{\mu 3}$  experiments, discussed immediately below, measure  $f_+$  and  $f_-$ , while  $K_{e 3}$  experiments, discussed further below, are sensitive only to  $f_+$  because the small electron mass makes the  $f_-$  term negligible.

**$K_{\mu 3}$  Experiments.** Analyses of  $K_{\mu 3}$  data frequently assume a linear dependence of  $f_+$  and  $f_-$  on  $t$ , *i.e.*,

$$f_\pm(t) = f_\pm(0) [1 + \lambda_\pm(t/m_{\pi^+}^2)]. \quad (2)$$

Most  $K_{\mu 3}$  data are adequately described by Eq. (2) for  $f_+$  and a constant  $f_-$  (*i.e.*,  $\lambda_- = 0$ ).

There are two equivalent parametrizations commonly used in these analyses:

(1)  **$\lambda_+, \xi(0)$  parametrization.** Older analyses of  $K_{\mu 3}$  data often introduce the ratio of the two form factors

$$\xi(t) = f_-(t)/f_+(t). \quad (3)$$

The  $K_{\mu 3}$  decay distribution is then described by the two parameters  $\lambda_+$  and  $\xi(0)$  (assuming time reversal invariance and  $\lambda_- = 0$ ).

(2)  **$\lambda_+, \lambda_0$  parametrization.** More recent  $K_{\mu 3}$  analyses have parametrized in terms of the form factors  $f_+$  and  $f_0$ , which are associated with vector and scalar exchange, respectively, to the lepton pair.  $f_0$  is related to  $f_+$  and  $f_-$  by

$$f_0(t) = f_+(t) + [t/(m_K^2 - m_\pi^2)] f_-(t). \quad (4)$$

Here  $f_0(0)$  must equal  $f_+(0)$  unless  $f_-(t)$  diverges at  $t = 0$ . The earlier assumption that  $f_+$  is linear in  $t$  and  $f_-$  is constant leads to  $f_0$  linear in  $t$ :

$$f_0(t) = f_0(0) [1 + \lambda_0(t/m_{\pi^+}^2)]. \quad (5)$$

With the assumption that  $f_0(0) = f_+(0)$ , the two parametrizations,  $(\lambda_+, \xi(0))$  and  $(\lambda_+, \lambda_0)$  are equivalent as long as correlation information is retained.  $(\lambda_+, \lambda_0)$  correlations tend to be less strong than  $(\lambda_+, \xi(0))$  correlations.

Since the 2006 edition of the *Review* [4], we no longer quote results in the  $(\lambda_+, \xi(0))$  parametrization. We have removed many older low statistics results from the Listings. See the 2004 version of this note [5] for these older results, and the 1982 version [6] for additional discussion of the  $K_{\mu 3}^0$  parameters, correlations, and conversion between parametrizations.

**Quadratic Parametrization.** More recent high-statistics experiments have included a quadratic term in the expansion of  $f_+(t)$ ,

$$f_+(t) = f_+(0) \left[ 1 + \lambda'_+(t/m_{\pi^+}^2) + \frac{\lambda''_+}{2} (t/m_{\pi^+}^2)^2 \right]. \quad (6)$$

If there is a non-vanishing quadratic term, then  $\lambda_+$  of Eq. (2) represents the average slope, which is then different from  $\lambda'_+$ . Our convention is to include the factor  $\frac{1}{2}$  in the quadratic term, and to use  $m_{\pi^+}$  even for  $K_{e 3}^+$  and  $K_{\mu 3}^+$  decays. We have converted other's parametrizations to match our conventions, as noted in the beginning of the " $K_{\ell 3}^\pm$  and  $K_{\ell 3}^0$  Form Factors" sections of the Listings.

**Pole Parametrization:** The pole model describes the  $t$ -dependence of  $f_+(t)$  and  $f_0(t)$  in terms of the exchange of the lightest vector and scalar  $K^*$  mesons with masses  $M_v$  and  $M_s$ , respectively:

$$f_+(t) = f_+(0) \left[ \frac{M_v^2}{M_v^2 - t} \right], \quad f_0(t) = f_0(0) \left[ \frac{M_s^2}{M_s^2 - t} \right]. \quad (7)$$

**Dispersive Parametrization** [7,8]. This approach uses dispersive techniques and the known low-energy  $K-\pi$  phases to parametrize the vector and scalar form factors:

$$f_+(t) = f_+(0) \exp \left[ \frac{t}{m_\pi^2} (\Lambda_+ + H(t)) \right]; \quad (8)$$

$$f_+(t) = f_+(0) \exp \left[ \frac{t}{(m_K^2 - m_\pi^2)} (\ln[C] - G(t)) \right], \quad (9)$$

where  $\Lambda_+$  is the slope of the vector form factor, and  $\ln[C] = \ln[f_0(m_K^2 - m_\pi^2)]$  is the logarithm of the scalar form factor at the Callan-Treiman point. The functions  $H(t)$  and  $G(t)$  are dispersive integrals.

**$K_{e3}$  Experiments:** Analysis of  $K_{e3}$  data is simpler than that of  $K_{\mu 3}$  because the second term of the matrix element assuming a pure vector current [Eq. (1) above] can be neglected. Here  $f_+$  can be assumed to be linear in  $t$ , in which case the linear coefficient  $\lambda_+$  of Eq. (2) is determined, or quadratic, in which case the linear coefficient  $\lambda'_+$  and quadratic coefficient  $\lambda''_+$  of Eq. (6) are determined.

If we remove the assumption of a pure vector current, then the matrix element for the decay, in addition to the terms in Eq. (1), would contain

$$+2m_K f_S \bar{\ell}(1 + \gamma_5) \nu \\ + (2f_T/m_K)(P_K)_\lambda (P_\pi)_\mu \bar{\ell} \sigma_{\lambda\mu} (1 + \gamma_5) \nu, \quad (10)$$

where  $f_S$  is the scalar form factor, and  $f_T$  is the tensor form factor. In the case of the  $K_{e3}$  decays where the  $f_-$  term can be neglected, experiments have yielded limits on  $|f_S/f_+|$  and  $|f_T/f_+|$ .

**Fits for  $K_{\ell 3}$  Form Factors.** For  $K_{e3}$  data, we determine best values for the three parametrizations: linear ( $\lambda_+$ ), quadratic ( $\lambda'_+$ ,  $\lambda''_+$ ) and pole ( $M_V$ ). For  $K_{\mu 3}$  data, we determine best values for the three parametrizations: linear ( $\lambda_+$ ,  $\lambda_0$ ), quadratic ( $\lambda'_+$ ,  $\lambda''_+$ ,  $\lambda_0$ ) and pole ( $M_V$ ,  $M_S$ ). We then assume  $\mu - e$  universality so that we can combine  $K_{e3}$  and  $K_{\mu 3}$  data, and again determine best values for the three parametrizations: linear ( $\lambda_+$ ,  $\lambda_0$ ), quadratic ( $\lambda'_+$ ,  $\lambda''_+$ ,  $\lambda_0$ ), and pole ( $M_V$ ,  $M_S$ ). When there is more than one parameter, fits are done including input correlations. Simple averages suffice in the two  $K_{e3}$  cases where there is only one parameter: linear ( $\lambda_+$ ) and pole ( $M_V$ ).

Both KTeV and KLOE see an improvement in the quality of their fits relative to linear fits when a quadratic term is introduced, as well as when the pole parametrization is used. The quadratic parametrization has the disadvantage that the quadratic parameter  $\lambda''_+$  is highly correlated with the linear parameter  $\lambda'_+$ , in the neighborhood of 95%, and that neither parameter is very well determined. The pole fit has the same number of parameters as the linear fit, but yields slightly better fit probabilities, so that it would be advisable for all experiments to include the pole parametrization as one of their choices [9].

The “Kaon Particle Listings” show the results with and without assuming  $\mu - e$  universality. The “Meson Summary Tables” show all of the results assuming  $\mu - e$  universality, but most results not assuming  $\mu - e$  universality are given only in the Listings.

## $K_{e3}^\pm$ FORM FACTORS

In the form factor comments, the following symbols are used.

$f_+$  and  $f_-$  are form factors for the vector matrix element.

$f_S$  and  $f_T$  refer to the scalar and tensor term.

$f_0 = f_+ + f_- t/(m_{K^+}^2 - m_{\pi^0}^2)$ .

$t$  = momentum transfer to the  $\pi$ .

$\lambda_+$  and  $\lambda_0$  are the linear expansion coefficients of  $f_+$  and  $f_0$ :

$f_+(t) = f_+(0) (1 + \lambda_+ t/m_{\pi^+}^2)$

For quadratic expansion

$f_+(t) = f_+(0) (1 + \lambda'_+ t/m_{\pi^+}^2 + \lambda''_+ t^2/m_{\pi^+}^4)$

as used by KTeV. If there is a non-vanishing quadratic term, then  $\lambda_+$  represents an average slope, which is then different from  $\lambda'_+$ .

NA48 and ISTRA quadratic expansion coefficients are converted with  $\lambda'_+{}^{PDG} = \lambda_+{}^{NA48}$  and  $\lambda''_+{}^{PDG} = 2\lambda'_+{}^{NA48}$

$\lambda_+{}^{PDG} = (\frac{m_{\pi^\pm}}{m_{\pi^0}})^2 \lambda_+{}^{ISTRA}$  and

$\lambda''_+{}^{PDG} = 2(\frac{m_{\pi^\pm}}{m_{\pi^0}})^4 \lambda''_+{}^{ISTRA}$

ISTRA linear expansion coefficients are converted with

$\lambda_+{}^{PDG} = (\frac{m_{\pi^\pm}}{m_{\pi^0}})^2 \lambda_+{}^{ISTRA}$  and  $\lambda_0{}^{PDG} = (\frac{m_{\pi^\pm}}{m_{\pi^0}})^2 \lambda_0{}^{ISTRA}$

The pole parametrization is

$f_+(t) = f_+(0) (\frac{M_V^2}{M_V^2 - t})$

$f_0(t) = f_0(0) (\frac{M_S^2}{M_S^2 - t})$

where  $M_V$  and  $M_S$  are the vector and scalar pole masses.

The following abbreviations are used:

DP = Dalitz plot analysis.

PI =  $\pi$  spectrum analysis.

MU =  $\mu$  spectrum analysis.

POL =  $\mu$  polarization analysis.

BR =  $K_{\mu 3}^\pm/K_{e3}^\pm$  branching ratio analysis.

E = positron or electron spectrum analysis.

RC = radiative corrections.

## $\lambda_+$ (LINEAR ENERGY DEPENDENCE OF $f_+$ IN $K_{e3}^\pm$ DECAY)

These results are for a linear expansion only. See the next section for fits including a quadratic term. For radiative correction of the  $K_{e3}^\pm$  Dalitz plot, see GINSBERG 67, BECHERRAWY 70, CIRIGLIANO 02, CIRIGLIANO 04, and ANDRE 07. Results labeled OUR FIT are discussed in the review “ $K_{e3}^\pm$  and  $K_{\mu 3}^\pm$  Form Factors” above. For earlier, lower statistics results, see the 2004 edition of this review, Physics Letters **B592** 1 (2004).

 $K_{\mu 4}^\pm$  FORM FACTORS

Based on the parametrizations of AMOROS 99, the  $K_{\mu 4}^\pm$  form factors can be expressed as

$$F_S = f_S + f'_S q^2 + f''_S q^4 + f'_e S_e / 4m_\pi^2$$

$$F_P = f_P$$

$$G_P = g_P + g'_P q^2$$

$$H_P = h_P$$

where  $q^2 = (S_\pi / 4m_\pi^2) - 1$ ,  $S_\pi$  is the invariant mass squared of the dipion, and  $S_e$  is the invariant mass squared of the dilepton.

140 PISLAK 03 B865 +

139 BATLEY 12 uses data collected in 2003-2004. The result is obtained from a measurement of  $\Gamma(\pi^+ \pi^- e \nu) / \Gamma(\pi^+ \pi^- \pi^+) / \Gamma = (5.59 \pm 0.04) \times 10^{-2}$ .

140 Radiative corrections included. Using Roy equations and not including isospin breaking, PISLAK 03 obtains the following  $\pi\pi$  scattering lengths  $a_0^0 = 0.228 \pm 0.012 \pm 0.004 \pm 0.012$  (theor.) and  $a_0^2 = -0.0365 \pm 0.0023 \pm 0.0008 \pm 0.0031$  (theor.).

DECAY FORM FACTOR FOR  $K^\pm \rightarrow \pi^0 \pi^0 e^\pm \nu$ 

Given in BOLOTOV 86b, BARMIN 88b, and SHIMIZU 04.

 $K^\pm \rightarrow \ell^\pm \nu \gamma$  FORM FACTORS

For definitions of the axial-vector  $F_A$  and vector  $F_V$  form factor, see the "Note on  $\pi^\pm \rightarrow \ell^\pm \nu \gamma$  and  $K^\pm \rightarrow \ell^\pm \nu \gamma$  Form Factors" in the  $\pi^\pm$  section. In the kaon literature, often different definitions  $a_K = F_A/m_K$  and  $v_K = F_V/m_K$  are used.

 $F_A + F_V$ , SUM OF AXIAL-VECTOR AND VECTOR FORM FACTOR FOR  $K \rightarrow e \nu e \gamma$ 

VALUE	EVTS	DOCUMENT ID	TECN	COMMENT
<b>0.133 ± 0.008 OUR AVERAGE</b>				Error includes scale factor of 1.3. See the ideogram below.

<b><math>6.6 \pm 1.3 \pm 1.0</math></b>	640k	1 ANGELOPO...	98E CPLR

<sup>1</sup> ANGELOPOULOS 98E measures the asymmetry  $A_T = [\Gamma(\bar{K}_{t=0}^0 \rightarrow e^+ \pi^- \nu_{t=\tau}) - \Gamma(K_{t=0}^0 \rightarrow e^- \pi^+ \bar{\nu}_{t=\tau})] / [\Gamma(\bar{K}_{t=0}^0 \rightarrow e^+ \pi^- \nu_{t=\tau}) + \Gamma(K_{t=0}^0 \rightarrow e^- \pi^+ \bar{\nu}_{t=\tau})]$  as a function of the neutral-kaon eigentime  $\tau$ . The initial strangeness of the neutral kaon is tagged by the charge of the accompanying charged kaon in the reactions  $p\bar{p} \rightarrow K^- \pi^+ K^0$  and  $p\bar{p} \rightarrow K^+ \pi^- \bar{K}^0$ . The strangeness at the time of the decay is tagged by the lepton charge. The reported result is the average value of  $A_T$  over the interval  $1\tau_S < \tau < 20\tau_S$ . From this value of  $A_T$  ANGELOPOULOS 01B, assuming  $CPT$  invariance in the  $e\nu$  decay amplitude, determine the  $T$ -violating  $\Delta S = \Delta S$  conserving parameter (for its definition, see Review below)  $4\text{Re}(\epsilon) = (6.2 \pm 1.4 \pm 1.0) \times 10^{-3}$ .

## CPT INVARIANCE TESTS IN NEUTRAL KAON DECAY

Updated October 2013 by M. Antonelli (LNF-INFN, Frascati) and G. D'Ambrosio (INFN Sezione di Napoli).

$CPT$  theorem is based on three assumptions: quantum field theory, locality, and Lorentz invariance, and thus it is a fundamental probe of our basic understanding of particle physics. Strangeness oscillation in  $K^0 - \bar{K}^0$  system, described by the equation

$$i \frac{d}{dt} \begin{bmatrix} K^0 \\ \bar{K}^0 \end{bmatrix} = [M - i\Gamma/2] \begin{bmatrix} K^0 \\ \bar{K}^0 \end{bmatrix},$$

where  $M$  and  $\Gamma$  are hermitian matrices (see PDG review [1], references [2,3], and KLOE paper [5] for notations and previous literature), allows a very accurate test of  $CPT$  symmetry; indeed since  $CPT$  requires  $M_{11} = M_{22}$  and  $\Gamma_{11} = \Gamma_{22}$ , the mass and width eigenstates,  $K_{S,L}$ , have a  $CPT$ -violating piece,  $\delta$ , in addition to the usual  $CPT$ -conserving parameter  $\epsilon$ :

$$K_{S,L} = \frac{1}{\sqrt{2(1 + |\epsilon_{S,L}|^2)}} \left[ (1 + \epsilon_{S,L}) K^0 + (1 - \epsilon_{S,L}) \bar{K}^0 \right]$$

$$\epsilon_{S,L} = \frac{-i\Im(M_{12}) - \frac{1}{2}\Im(\Gamma_{12}) \mp \frac{1}{2} \left[ M_{11} - M_{22} - \frac{i}{2}(\Gamma_{11} - \Gamma_{22}) \right]}{m_L - m_S + i(\Gamma_S - \Gamma_L)/2}$$

$$\equiv \epsilon \pm \delta. \quad (1)$$

Using the phase convention  $\Im(\Gamma_{12}) = 0$ , we determine the phase of  $\epsilon$  to be  $\varphi_{SW} \equiv \arctan \frac{2(m_L - m_S)}{\Gamma_S - \Gamma_L}$ . Imposing unitarity to an arbitrary combination of  $K^0$  and  $\bar{K}^0$  wave functions, we obtain the Bell-Steinberger relation [4] connecting  $CP$  and  $CPT$  violation in the mass matrix to  $CP$  and  $CPT$  violation in the decay; in fact, neglecting  $\mathcal{O}(\epsilon)$  corrections to the coefficient of the  $CPT$ -violating parameter,  $\delta$ , we can write [5]

$$\left[ \frac{\Gamma_S + \Gamma_L}{\Gamma_S - \Gamma_L} + i \tan \phi_{SW} \right] \left[ \frac{\Re(\epsilon)}{1 + |\epsilon|^2} - i\Im(\delta) \right] = \frac{1}{\Gamma_S - \Gamma_L} \sum_f A_L(f) A_S^*(f), \quad (2)$$

where  $A_{L,S}(f) \equiv A(K_{L,S} \rightarrow f)$ . We stress that this relation is phase-convention-independent. The advantage of the neutral kaon system is that only a few decay modes give significant contributions to the r.h.s. in Eq. (2); in fact, defining for the hadronic modes

$$\alpha_i \equiv \frac{1}{\Gamma_S} \langle A_L(i) A_S^*(i) \rangle = \eta_i B(K_S \rightarrow i),$$

$$i = \pi^0 \pi^0, \pi^+ \pi^- (\gamma), 3\pi^0, \pi^0 \pi^+ \pi^- (\gamma), \quad (3)$$

the recent data from CPLEAR, KLOE, KTeV, and NA48 have led to the following determinations (the analysis described in Ref. 5 has been updated by using the recent measurements of  $K_L$  branching ratios from KTeV [6,7], NA48 [8,9], and the results described in the  $CP$  violation in  $K_L$  decays minireview, and the recent KLOE result [10])

$$\alpha_{\pi^+ \pi^-} = ((1.112 \pm 0.010) + i(1.061 \pm 0.010)) \times 10^{-3},$$

$$\alpha_{\pi^0 \pi^0} = ((0.493 \pm 0.005) + i(0.471 \pm 0.005)) \times 10^{-3},$$

$$\alpha_{\pi^+ \pi^- \pi^0} = ((0 \pm 2) + i(0 \pm 2)) \times 10^{-6},$$

$$|\alpha_{\pi^0 \pi^0 \pi^0}| < 1.5 \times 10^{-6} \text{ at } 95\% \text{ CL}. \quad (4)$$

The semileptonic contribution to the right-handed side of Eq. (2) requires the determination of several observables: we define [2,3]

$$\mathcal{A}(K^0 \rightarrow \pi^- l^+ \nu) = \mathcal{A}_0(1 - y),$$

$$\mathcal{A}(K^0 \rightarrow \pi^+ l^- \nu) = \mathcal{A}_0^*(1 + y^*)(x_+ - x_-)^*,$$

$$\mathcal{A}(\bar{K}^0 \rightarrow \pi^+ l^- \nu) = \mathcal{A}_0^*(1 + y^*),$$

$$\mathcal{A}(\bar{K}^0 \rightarrow \pi^- l^+ \nu) = \mathcal{A}_0(1 - y)(x_+ + x_-), \quad (5)$$

where  $x_+$  ( $x_-$ ) describes the violation of the  $\Delta S = \Delta Q$  rule in  $CPT$ -conserving (violating) decay amplitudes, and  $y$  parametrizes  $CPT$  violation for  $\Delta S = \Delta Q$  transitions. Taking advantage of their tagged  $K^0(\bar{K}^0)$  beams, CPLEAR has measured  $\Im(x_+)$ ,  $\Re(x_-)$ ,  $\Im(\delta)$ , and  $\Re(\delta)$  [11]. These determinations have been improved in Ref. 5 by including the information  $A_S - A_L = 4[\Re(\delta) + \Re(x_-)]$ , where  $A_{L,S}$  are the  $K_L$  and  $K_S$  semileptonic charge asymmetries, respectively, from the PDG [12] and KLOE [13]. Here we are also including the  $T$ -violating asymmetry measurement from CPLEAR [14].

**Table 1:** Values, errors, and correlation coefficients for  $\Re(\delta)$ ,  $\Im(\delta)$ ,  $\Re(x_-)$ ,  $\Im(x_+)$ , and  $A_S + A_L$  obtained from a combined fit, including KLOE [5] and CPLEAR [14].

	value	Correlations coefficients			
$\Re(\delta)$	$(3.0 \pm 2.3) \times 10^{-4}$	1			
$\Im(\delta)$	$(-0.66 \pm 0.65) \times 10^{-2}$	-0.21	1		
$\Re(x_-)$	$(-0.30 \pm 0.21) \times 10^{-2}$	-0.21	-0.60	1	
$\Im(x_+)$	$(0.02 \pm 0.22) \times 10^{-2}$	-0.38	-0.14	0.47	1
$A_S + A_L$	$(-0.40 \pm 0.83) \times 10^{-2}$	-0.10	-0.63	0.99	0.43

The value  $A_S + A_L$  in Table 1 can be directly included in the semileptonic contributions to the Bell Steinberger relations in Eq. (2)

$$\begin{aligned} & \sum_{\pi\ell\nu} \langle \mathcal{A}_L(\pi\ell\nu) \mathcal{A}_S^*(\pi\ell\nu) \rangle \\ &= 2\Gamma(K_L \rightarrow \pi\ell\nu) (\Re(\epsilon) - \Re(y) - i(\Im(x_+) + \Im(\delta))) \\ &= 2\Gamma(K_L \rightarrow \pi\ell\nu) ((A_S + A_L)/4 - i(\Im(x_+) + \Im(\delta))) . \end{aligned} \quad (6)$$

Defining

$$\alpha_{\pi\ell\nu} \equiv \frac{1}{\Gamma_S} \sum_{\pi\ell\nu} \langle \mathcal{A}_L(\pi\ell\nu) \mathcal{A}_S^*(\pi\ell\nu) \rangle + 2i \frac{\tau_{K_S}}{\tau_{K_L}} \mathcal{B}(K_L \rightarrow \pi\ell\nu) \Im(\delta) , \quad (7)$$

we find:

$$\alpha_{\pi\ell\nu} = ((-0.2 \pm 0.5) + i(0.1 \pm 0.5)) \times 10^{-5} .$$

Inserting the values of the  $\alpha$  parameters into Eq. (2), we find

$$\begin{aligned} \Re(\epsilon) &= (161.1 \pm 0.5) \times 10^{-5} , \\ \Im(\delta) &= (-0.7 \pm 1.4) \times 10^{-5} . \end{aligned} \quad (8)$$

The complete information on Eq. (8) is given in Table 2.

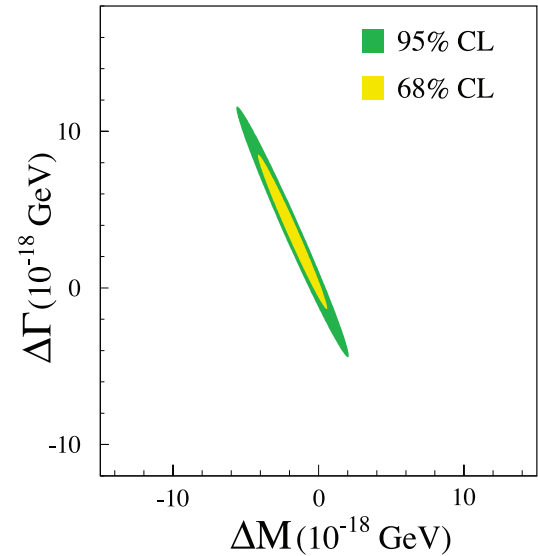

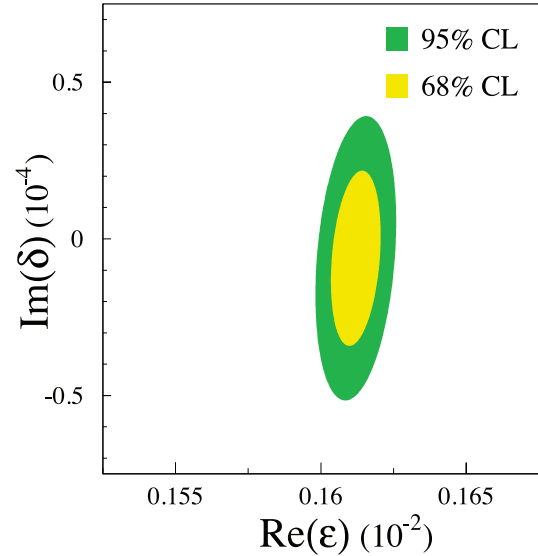

**Table 2:** Summary of results: values, errors, and correlation coefficients for  $\Re(\epsilon)$ ,  $\Im(\delta)$ ,  $\Re(\delta)$ , and  $\Re(x_-)$ .

	value	Correlations coefficients			
$\Re(\epsilon)$	$(161.1 \pm 0.5) \times 10^{-5}$	+1			
$\Im(\delta)$	$(-0.7 \pm 1.4) \times 10^{-5}$	+0.09	1		
$\Re(\delta)$	$(2.4 \pm 2.3) \times 10^{-4}$	+0.08	-0.12	1	
$\Re(x_-)$	$(-4.1 \pm 1.7) \times 10^{-3}$	+0.14	0.22	-0.43	1

Now the agreement with  $CPT$  conservation,  $\Im(\delta) = \Re(\delta) = \Re(x_-) = 0$ , is at 18% C.L.

The allowed region in the  $\Re(\epsilon) - \Im(\delta)$  plane at 68% CL and 95% C.L. is shown in the top panel of Fig. 1.

The process giving the largest contribution to the size of the allowed region is  $K_L \rightarrow \pi^+ \pi^-$ , through the uncertainty on  $\phi_{+-}$ .

**Figure 1:** Top: allowed region at 68% and 95% C.L. in the  $\Re(\epsilon)$ ,  $\Im(\delta)$  plane. Bottom: allowed region at 68% and 95% C.L. in the  $\Delta M$ ,  $\Delta\Gamma$  plane.

The limits on  $\Im(\delta)$  and  $\Re(\delta)$  can be used to constrain the  $K^0 - \bar{K}^0$  mass and width difference

$$\delta = \frac{i(m_{K^0} - m_{\bar{K}^0}) + \frac{1}{2}(\Gamma_{K^0} - \Gamma_{\bar{K}^0})}{\Gamma_S - \Gamma_L} \cos \phi_{SW} e^{i\phi_{SW}} [1 + \mathcal{O}(\epsilon)] .$$

The allowed region in the  $\Delta M = (m_{K^0} - m_{\bar{K}^0})$ ,  $\Delta\Gamma = (\Gamma_{K^0} - \Gamma_{\bar{K}^0})$  plane is shown in the bottom panel of Fig. 1. As a result, we improve on the previous limits (see for instance, P. Bloch in Ref. 12) and in the limit  $\Gamma_{K^0} - \Gamma_{\bar{K}^0} = 0$  we obtain

$$-4.0 \times 10^{-19} \text{ GeV} < m_{K^0} - m_{\bar{K}^0} < 4.0 \times 10^{-19} \text{ GeV} \quad \text{at } 95 \% \text{ C.L.}$$

<sup>3</sup> LAI 05A values are obtained through unitarity (Bell-Steinberger relations), improving determination of  $\eta_{000}$  and combining other data from PDG 04 and APOSTOLAKIS 99B.

## CPT-VIOLATION PARAMETERS

In  $K^0$ - $\bar{K}^0$  mixing, if *CP*-violating interactions include a *T* conserving part then

$$|K_S\rangle = [|K_1\rangle + (\epsilon + \delta)|K_2\rangle] / \sqrt{1 + |\epsilon + \delta|^2}$$

$$|K_L\rangle = [|K_2\rangle + (\epsilon - \delta)|K_1\rangle] / \sqrt{1 + |\epsilon - \delta|^2}$$

where

$$|K_1\rangle = [|K^0\rangle + |\bar{K}^0\rangle] / \sqrt{2}$$

$$|K_2\rangle = [|K^0\rangle - |\bar{K}^0\rangle] / \sqrt{2}$$

and

$$|\bar{K}^0\rangle = CP|K^0\rangle.$$

The parameter  $\delta$  specifies the *CPT*-violating part.

Estimates of  $\delta$  are given below assuming the validity of the  $\Delta S = \Delta Q$  rule. See also THOMSON 95 for a test of *CPT*-symmetry conservation in  $K^0$  decays using the Bell-Steinberger relation.

REAL PART OF  $\delta$ 

A nonzero value violates *CPT* invariance.

2 ± 13 ± 3	650k	ANGELOPO...	98F CPLR	Strangeness tagged

<sup>17</sup> AMBROSINO 06H uses Bell-Steinberger relations with the following measurements:  $B(K_L^0 \rightarrow \pi^+ \pi^-)$  in AMBROSINO 06F,  $B(K_S^0 \rightarrow \pi^0 \pi^0 \pi^0)$  in AMBROSINO 05B, the  $K_S^0$ -semileptonic charge asymmetry in AMBROSINO 06E, and  $K^0$ -semileptonic results in ANGELOPOULOS 98F.

<sup>18</sup> Uses PDG 04 for the  $K_L^0$  semileptonic charge asymmetry and  $\text{Re}(\delta)$  from CPLEAR, ANGELOPOULOS 98F.

<sup>19</sup> Constrained by Bell-Steinberger (or unitarity) relation.

$$|m_{K^0} - m_{\bar{K}^0}| / m_{\text{average}}$$

A test of *CPT* invariance. “Our Evaluation” is described in the “Tests of Conservation Laws” section. It assumes *CPT* invariance in the decay and neglects some contributions from decay channels other than  $\pi\pi$ .

VALUE	CL%	DOCUMENT ID	TECN
<b>&lt;6 × 10<sup>-19</sup></b>	90	PDG	12

(-3 ± 4) × 10 <sup>-18</sup>		<sup>20</sup> ANGELOPO...	99B RVUE
------------------------------	--	---------------------------	----------

<sup>20</sup> ANGELOPOULOS 99B assumes only unitarity and combines CPLEAR and other results.

See key on page 547

# Meson Particle Listings

$K^0, K_S^0$

$$(\Gamma_{K^0} - \Gamma_{\bar{K}^0})/m_{\text{average}}$$

A test of *CPT* invariance.

VALUE	DOCUMENT ID	TECN
$(7.8 \pm 8.4) \times 10^{-18}$	21 ANGELOPO... 99B	RVUE

<sup>21</sup> ANGELOPOULOS 99B assumes only unitarity and combines CPLEAR with other results. Correlated with  $(m_{K^0} - m_{\bar{K}^0})/m_{\text{average}}$  with a correlation coefficient of  $-0.95$ .

## TESTS OF $\Delta S = \Delta Q$ RULE

Re( $x_+$ )

A non-zero value would violate the  $\Delta S = \Delta Q$  rule in *CPT* conserving transitions.  $x_+$  is defined above in the Re( $x_-$ ) section.

VALUE (units $10^{-3}$ )	EVTs	DOCUMENT ID	TECN
$-0.9 \pm 3.0$	<b>OUR AVERAGE</b>		
$-2 \pm 10$		22 BATLEY 07D	NA48
$-0.5 \pm 3.6$	13k	23 AMBROSINO 06E	KLOE
$-1.8 \pm 6.1$		24 ANGELOPO... 98D	CPLR

<sup>22</sup> Result obtained from the measurement  $\Gamma(K_S^0 \rightarrow \pi e \nu) / \Gamma(K_L^0 \rightarrow \pi e \nu) = 0.993 \pm 0.34$ , neglecting possible *CPT* non-invariance and using PDG 06 values of  $B(K_L^0 \rightarrow \pi e \nu) = 0.4053 \pm 0.0015$ ,  $\tau_L = (5.114 \pm 0.021) \times 10^{-8}$  s and  $\tau_S = (0.8958 \pm 0.0005) \times 10^{-10}$  s. <sup>23</sup> Re( $x_+$ ) can be shown to be equal to the following combination of rates:

$$\text{Re}(x_+) = \frac{1}{2} \frac{\Gamma(K_S^0 \rightarrow \pi e \nu) - \Gamma(K_L^0 \rightarrow \pi e \nu)}{\Gamma(K_S^0 \rightarrow \pi e \nu) + \Gamma(K_L^0 \rightarrow \pi e \nu)}$$

which is valid up to first order in terms violating *CPT* and/or the  $\Delta S = \Delta Q$  rule.

<sup>24</sup> Obtained neglecting *CPT* violating amplitudes.

## $K_S^0$ MEAN LIFE

For earlier measurements, beginning with BOLDT 58B, see our 1986 edition, Physics Letters **170B** 130 (1986).

OUR FIT is described in the note on "*CP* violation in  $K_L^0$  decays" in the  $K^0$  Particle Listings. The result labeled "OUR FIT Assuming *CPT*" ["OUR FIT Not assuming *CPT*"] includes all measurements except those with the comment "Not assuming *CPT*" ["Assuming *CPT*"]. Measurements with neither comment do not assume *CPT* and enter both fits.

VALUE ( $10^{-10}$ s)	EVTs	DOCUMENT ID	TECN	COMMENT

0.872 ± 0.009	20000	9,10 HILL 68	DBC	

<sup>1</sup> The two ABOUZAIID 11 values use the same full KTeV dataset from 1996, 1997, and 1999. The first enters the "assuming *CPT*" fit and the second enters the "not assuming *CPT*" fit.

<sup>2</sup> ABOUZAIID 11 fit has  $\Delta m$ ,  $\tau_S$ ,  $\phi_e$ ,  $\text{Re}(e'/e)$ , and  $\text{Im}(e'/e)$  as free parameters. See  $\text{Im}(e'/e)$  in the " $K_L^0$  *CP* violation" section for correlation information.

<sup>3</sup> ABOUZAIID 11 fit has  $\Delta m$  and  $\tau_S$  free but constrains  $\phi_e$  to the Superweak value, i.e. assumes *CPT*. This  $\tau_S$  value is correlated with their  $\Delta m = m_{K_L^0} - m_{K_S^0}$  measurement in the  $K_L^0$  listings. The correlation coefficient  $\rho(\tau_S, \Delta m) = -0.670$ .

<sup>4</sup> Fit to the proper time distribution.

<sup>5</sup> This ALAVI-HARATI 03 fit has  $\Delta m$  and  $\tau_S$  free but constrains  $\phi_{+-}$  to the Superweak value, i.e. assumes *CPT*. This  $\tau_S$  value is correlated with their  $\Delta m = m_{K_L^0} - m_{K_S^0}$  measurement in the  $K_L^0$  listings. The correlation coefficient  $\rho(\tau_S, \Delta m) = -0.396$ .

<sup>6</sup> Superseded by ABOUZAIID 11.

<sup>7</sup> This ALAVI-HARATI 03 fit has  $\Delta m$ ,  $\phi_{+-}$ , and  $\tau_{K_S}$  free. See  $\phi_{+-}$  in the " $K_L$  *CP* violation" section for correlation information. Superseded by ABOUZAIID 11.

<sup>8</sup> ARONSON 82 find that  $K_S^0$  mean life may depend on the kaon energy.

<sup>9</sup> CARITHERS 75 measures the  $\Delta m$  dependence of the total decay rate (inverse mean life) to be  $\Gamma(K_S^0) = [(1.122 \pm 0.004) + 0.16(\Delta m - 0.5348)/\Delta m] 10^{10}/s$ , or, in terms of mean life, CARITHERS 75 measures  $\tau_S = (0.8913 \pm 0.0032) - 0.238 [\Delta m - 0.5348] (10^{-10} \text{ s})$ . We have adjusted the measurement to use our best values of  $(\Delta m = 0.5293 \pm 0.0009) (10^{10} \text{ h s}^{-1})$ . Our first error is their experiment's error and our second error is the systematic error from using our best values.

<sup>10</sup> HILL 68 has been changed by the authors from the published value  $(0.865 \pm 0.009)$  because of a correction in the shift due to  $\eta_{+-}$ . SKJEGGESTAD 72 and HILL 68 give detailed discussions of systematics encountered in this type of experiment.

<sup>11</sup> Pre-1971 experiments are excluded from the average because of disagreement with later more precise experiments.

## $K_S^0$ DECAY MODES

Mode	Fraction ( $\Gamma_i/\Gamma$ )	Scale factor/ Confidence level
<b>Hadronic modes</b>

 $K_S^0$ 

## CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 5 measurements and one constraint to determine 4 parameters. The overall fit has a  $\chi^2 = 0.1$  for 2 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

3.9 <sup>+5.4+0.9</sup> <sub>-1.8-0.7</sub>		24 THOMSON 94	E621	Sup. by ZOU 96
20 BATLEY 05 is obtained by measuring the interference parameters in $K_S, K_L \rightarrow \pi^+ \pi^- \pi^0$ . $\text{Re}(\lambda) = 0.038 \pm 0.008 \pm 0.006$ and $\text{Im}(\lambda) = -0.013 \pm 0.005 \pm 0.004$ ; the correlation coeff. between $\text{Re}(\lambda)$ and $\text{Im}(\lambda)$ is 0.66 (statistical only).				
21 ADLER 97B find the CP-conserving parameters $\text{Re}(\lambda) = (28 \pm 7 \pm 3) \times 10^{-3}$ , $\text{Im}(\lambda) = (-10 \pm 8 \pm 2) \times 10^{-3}$ . They estimate $B(K_S^0 \rightarrow \pi^+ \pi^- \pi^0)$ from $\text{Re}(\lambda)$ and the $K_L^0$ decay parameters. See also ANGELOPOULOS 98c.				
22 ZOU 96 is from the the measured quantities $ \rho_{+-0}  = 0.039 \pm 0.009 \pm 0.005$ and $\phi_\rho = (-9 \pm 18)^\circ$ .				
23 ADLER 96E is from the measured quantities $\text{Re}(\lambda) = 0.036 \pm 0.010 \pm 0.003$ and $\text{Im}(\lambda) = (-10 \pm 8 \pm 2) \times 10^{-3}$ . Note that the quantity $\lambda$ is the same as $\rho_{+-0}$ used in other footnotes.				
24 THOMSON 94 calculates this branching ratio from their measurements $ \rho_{+-0}  = 0.035 \pm 0.019 \pm 0.004$ and $\phi_\rho = (-59 \pm 48)^\circ$ where $ \rho_{+-0}  e^{i\phi_\rho} = A(K_S^0 \rightarrow \pi^+ \pi^- \pi^0, l = 2) / A(K_L^0 \rightarrow \pi^+ \pi^- \pi^0)$ .

• • • We do not use the following data for averages, fits, limits, etc. • • •

$7.2 \pm 1.4$  75 AKHMETSHIN 99 CMD2 Tagged  $K_S^0$  using  $\phi \rightarrow K_L^0 K_S^0$

<sup>36</sup>Reconstructed from  $K^0(\bar{K}^0)(t) \rightarrow \pi e \nu$  distributions using PDG values of  $B(K_L^0 \rightarrow \pi e \nu) = 0.4053 \pm 0.0015$ ,  $\tau_L = (5.114 \pm 0.021) \times 10^{-8}$  s and  $\tau_S = (0.8958 \pm 0.0005) \times 10^{-10}$  s.

<sup>37</sup>Uses the PDG 00 value for  $B(K_S^0 \rightarrow \pi^+ \pi^-)$ .

<sup>38</sup>Obtained by imposing  $\sum_i B(K_S^0 \rightarrow i) = 1$ , where  $i$  runs over all the four branching ratios  $\pi^+ \pi^-$ ,  $\pi^0 \pi^0$ ,  $\pi e \nu$ , and  $\pi \mu \nu$ . Input value of  $B(K_S^0 \rightarrow \pi^+ \pi^-) / B(K_S^0 \rightarrow \pi^0 \pi^0)$  from AMBROSINO 06c is used. To derive  $\Gamma(K_S^0 \rightarrow \pi^+ \mu \nu) / \Gamma(K_S^0 \rightarrow \pi^+ e \nu)$ , lepton universality is assumed, radiative corrections from ANDRE 07 are used, and phase space integrals are taken from KTeV, ALEXOPOULOS 04A. This branching fraction enters our fit via their  $\Gamma(\pi^\pm e^\mp \nu_e) / \Gamma(\pi^+ \pi^-)$  branching ratio measurement.

$\Gamma(\pi^\pm \mu^\mp \nu_\mu)/\Gamma_{\text{total}}$   $\Gamma_9/\Gamma$

The PDG 06 value below has not been measured but is computed to be 0.666 times the  $K_S \rightarrow \pi^\pm e^\mp \nu_e$  branching fraction. It is included in the fit that constrains the four branching ratios  $\pi^+ \pi^-$ ,  $\pi^0 \pi^0$ ,  $\pi e \nu$ , and  $\pi \mu \nu$  to sum to 1. This treatment, used by AMBROSINO 06E, is preferable to our previous practice of constraining the  $\pi^+ \pi^-$  and  $\pi^0 \pi^0$  modes to sum to 1. The 0.666 factor is obtained from AMBROSINO 06E and assumes lepton universality, radiative corrections from ANDRE 07, and phase space integrals from KTeV, ALEXOPOULOS 04A.

### $K_S^0$ FORM FACTORS

For discussion, see note on  $K_{f3}$  form factors in the  $K^\pm$  section of the Particle Listings above. Because the semileptonic branching fraction is smaller in  $K_S^0$  than  $K_L^0$  by the ratio of the mean lives, the  $K_S^0$  semileptonic form factor has so far been measured only in the  $K_{e3}$  mode using the linear expansion  $f_+(t) = f_+(0) (1 + \lambda_+ t / m_\pi^2)$ , which gives the vector form factor  $f_+(t)$  relative to its value at  $t = 0$ .

### CP VIOLATION IN $K_S \rightarrow 3\pi$

Written 1996 by T. Nakada (Paul Scherrer Institute) and L. Wolfenstein (Carnegie-Mellon University).

The possible final states for the decay  $K^0 \rightarrow \pi^+ \pi^- \pi^0$  have isospin  $I = 0, 1, 2$ , and 3. The  $I = 0$  and  $I = 2$  states have  $CP = +1$  and  $K_S$  can decay into them without violating  $CP$  symmetry, but they are expected to be strongly suppressed by centrifugal barrier effects. The  $I = 1$  and  $I = 3$  states, which have no centrifugal barrier, have  $CP = -1$  so that the  $K_S$  decay to these requires  $CP$  violation.

In order to see  $CP$  violation in  $K_S \rightarrow \pi^+ \pi^- \pi^0$ , it is necessary to observe the interference between  $K_S$  and  $K_L$  decay, which determines the amplitude ratio

$$\eta_{+0} = \frac{A(K_S \rightarrow \pi^+ \pi^- \pi^0)}{A(K_L \rightarrow \pi^+ \pi^- \pi^0)} \quad (1)$$

## Meson Particle Listings

 $K_S^0$ 

If  $\eta_{+-0}$  is obtained from an integration over the whole Dalitz plot, there is no contribution from the  $I = 0$  and  $I = 2$  final states and a nonzero value of  $\eta_{+-0}$  is entirely due to  $CP$  violation.

Only  $I = 1$  and  $I = 3$  states, which are  $CP = -1$ , are allowed for  $K^0 \rightarrow \pi^0\pi^0\pi^0$  decays and the decay of  $K_S^0$  into  $3\pi^0$  is an unambiguous sign of  $CP$  violation. Similarly to  $\eta_{+-0}$ ,  $\eta_{000}$  is defined as

$$\eta_{000} = \frac{A(K_S^0 \rightarrow \pi^0\pi^0\pi^0)}{A(K_L^0 \rightarrow \pi^0\pi^0\pi^0)}. \quad (2)$$

If one assumes that  $CPT$  invariance holds and that there are no transitions to  $I = 3$  (or to nonsymmetric  $I = 1$  states), it can be shown that

$$\begin{aligned} \eta_{+-0} &= \eta_{000} \\ &= \epsilon + i \frac{\text{Im } a_1}{\text{Re } a_1}. \end{aligned} \quad (3)$$

With the Wu-Yang phase convention,  $a_1$  is the weak decay amplitude for  $K^0$  into  $I = 1$  final states;  $\epsilon$  is determined from  $CP$  violation in  $K_L \rightarrow 2\pi$  decays. The real parts of  $\eta_{+-0}$  and  $\eta_{000}$  are equal to  $\text{Re}(\epsilon)$ . Since currently-known upper limits on  $|\eta_{+-0}|$  and  $|\eta_{000}|$  are much larger than  $|\epsilon|$ , they can be interpreted as upper limits on  $\text{Im}(\eta_{+-0})$  and  $\text{Im}(\eta_{000})$  and so as limits on the  $CP$ -violating phase of the decay amplitude  $a_1$ .

CP-VIOLATION PARAMETERS IN  $K_S^0$  DECAY

$A_S = [ \Gamma(K_S^0 \rightarrow \pi^- e^+ \nu_e) - \Gamma(K_S^0 \rightarrow \pi^+ e^- \bar{\nu}_e) ] / \text{SUM}$   
Such asymmetry violates  $CP$ . If  $CPT$  is assumed then  $A_S = 2 \text{Re}(\epsilon)$ .

$-0.05 \pm 0.12 \pm 0.05$	17300	<sup>54</sup> ANGELOPO...	98B	CPLR Assumes $CPT$

<sup>53</sup> LAI 05A assumes  $\text{Re}(\eta_{000}) = \text{Re}(\epsilon) = 1.66 \times 10^{-3}$ . The equivalent limit is  $|\eta_{000}|_{CPT} < 0.025$  at 90% CL. Without assuming  $CPT$  invariance, they obtain  $\text{Re}(\eta_{000}) = -0.002 \pm 0.011 \pm 0.015$  and  $\text{Im}(\eta_{000}) = -0.003 \pm 0.013 \pm 0.017$  with a statistical correlation coefficient of 0.77 and an overall correlation coefficient of 0.57 between imaginary and real part. The equivalent limit is  $|\eta_{000}| < 0.045$  at 90% CL.

<sup>54</sup> ANGELOPOULOS 98B assumes  $\text{Re}(\eta_{000}) = \text{Re}(\epsilon) = 1.635 \times 10^{-3}$ . Without assuming  $CPT$  invariance, they obtain  $\text{Re}(\eta_{000}) = 0.18 \pm 0.14 \pm 0.06$  and  $\text{Im}(\eta_{000}) = 0.15 \pm 0.20 \pm 0.03$ .

$|\eta_{000}| = |A(K_S^0 \rightarrow 3\pi^0)/A(K_L^0 \rightarrow 3\pi^0)|$

A non-zero value violates  $CP$  invariance.

DECAY-PLANE ASYMMETRY IN  $\pi^+\pi^-e^+e^-$  DECAYS

This is the  $CP$ -violating asymmetry

$$A = \frac{N_{\sin\phi\cos\phi>0.0} - N_{\sin\phi\cos\phi<0.0}}{N_{\sin\phi\cos\phi>0.0} + N_{\sin\phi\cos\phi<0.0}}$$

where  $\phi$  is the angle between the  $e^+e^-$  and  $\pi^+\pi^-$  planes in the  $K_S^0$  rest frame.

$CP$  asymmetry  $A$  in  $K_S^0 \rightarrow \pi^+\pi^-e^+e^-$

$$I(J^P) = \frac{1}{2}(0^-)$$

$$m_{K_L^0} - m_{K_S^0}$$

For earlier measurements, beginning with GOOD 61 and FITCH 61, see our 1986 edition, Physics Letters **170B** 132 (1986).

OUR FIT is described in the note on "CP violation in  $K_L$  decays" in the  $K_L^0$  Particle Listings. The result labeled "OUR FIT Assuming  $CPT$ " ["OUR FIT Not assuming  $CPT$ "] includes all measurements except those with the comment "Not assuming  $CPT$ " ["Assuming  $CPT$ "]. Measurements with neither comment do not assume  $CPT$  and enter both fits.

- The two ABOUZAIID 11 values use the same data. The first enters the "assuming  $CPT$ " fit and the second enters the "not assuming  $CPT$ " fit.
- ABOUZAIID 11 fit has  $\Delta m$ ,  $\tau_S$ ,  $\phi_c$ ,  $\text{Re}(e'/\epsilon)$ , and  $\text{Im}(e'/\epsilon)$  as free parameters. See  $\text{Im}(e'/\epsilon)$  in the " $K_L^0$  CP violation" section for correlation information.
- ABOUZAIID 11 fit has  $\Delta m$  and  $\tau_S$  free but constrains  $\phi_c$  to the Superweak value, i.e. assumes  $CPT$ . See " $K_S^0$  Mean Life" section for correlation information.
- Fits  $\Delta m$  and  $\phi_{+-}$  simultaneously. GIBBONS 93c systematic error is from B. Winstein via private communication. 20-160 GeV  $K$  beams.
- GIBBONS 93 value assume  $\phi_{+-} = \phi_{00} = \phi_{SW} = (43.7 \pm 0.2)^\circ$ , i.e. assumes  $CPT$ . 20-160 GeV  $K$  beams.
- These two experiments have a common systematic error due to the uncertainty in the momentum scale, as pointed out in WAHL 89.
- GJESDAL 74 uses charge asymmetry in  $K_{L3}^0$  decays.
- ALAVI-HARATI 03 fit  $\Delta m$  and  $\tau_{K_S^0}$  simultaneously.  $\phi_{+-}$  is constrained to the Superweak value, i.e.  $CPT$  is assumed. See " $K_S^0$  Mean Life" section for correlation information. Superseded by ABOUZAIID 11.
- ALAVI-HARATI 03 fit  $\Delta m$ ,  $\phi_{+-}$ , and  $\tau_{K_S^0}$  simultaneously. See  $\phi_{+-}$  in the " $K_L$  CP violation" section for correlation information. Superseded by ABOUZAIID 11.
- ANGELOPOULOS 01 uses strong interactions strangeness tagging at two different times.
- Uses  $\bar{K}_{e3}^0$  and  $K_{e3}^0$  strangeness tagging at production and decay. Assumes  $CPT$  conservation on  $\Delta S = -\Delta Q$  transitions.
- ADLER 96c is the result of a fit which includes nearly the same data as entered into the "OUR FIT" value above.
- ARONSON 82 find that  $\Delta m$  may depend on the kaon energy.
- ARONSON 70 and CARNEGIE 71 use  $K_S^0$  mean life =  $(0.862 \pm 0.006) \times 10^{-10}$  s. We have not attempted to adjust these values for the subsequent change in the  $K_S^0$  mean life or in  $\eta_{+-}$ .

$K_L^0$  MEAN LIFE

VALUE ( $10^{-8}$ s)	EVTS	DOCUMENT ID	TECN	COMMENT	
<b>5.116 ± 0.021 OUR FIT</b>	Error includes scale factor of 1.1.				
<b>5.099 ± 0.021 OUR AVERAGE</b>					
5.072 ± 0.011 ± 0.035	13M	<sup>1</sup> AMBROSINO 06	KLOE	$\sum_i B_i = 1$	
5.092 ± 0.017 ± 0.025	15M	AMBROSINO 05c	KLOE		
5.154 ± 0.044	0.4M	VOSBURGH 72	CNTR		
••• We do not use the following data for averages, fits, limits, etc. •••					
5.15 ± 0.14		DEVLIN 67	CNTR		
<sup>1</sup> AMBROSINO 06 uses $\phi \rightarrow K_L K_S$ with $K_L$ tagged by $K_S \rightarrow \pi^+\pi^-$ . The four major $K_L$ BR's are measured, the small remainder ( $\pi^+\pi^-\pi^0, \pi^0\pi^0, \gamma\gamma$ ) is taken from PDG 04. This KLOE $K_L$ lifetime is obtained by imposing $\sum_i B_i = 1$ . The correlation matrix among the four measured $K_L$ BR's and this $K_L$ lifetime is					
	$K_{e3}$	$K_{\mu 3}$	$3\pi^0$	$\pi^+\pi^-\pi^0$	$\tau_{K_L}$
	1	-0.25	-0.56	-0.07	0.25
		1	-0.43	-0.20	0.33
			1	-0.39	-0.21
				1	-0.39
					1

These correlations are taken into account in our fit. The average of this KLOE mean life measurement and the independent KLOE measurement in AMBROSINO 05c is  $(5.084 \pm 0.023) \times 10^{-8}$  s.

$\Gamma_{37}$	$\pi^0\pi^0\mu^\pm e^\mp$	LF	$< 1.7 \times 10^{-10}$	CL=90%

[a] The value is for the sum of the charge states or particle/antiparticle states indicated.

[b] This mode includes gammas from inner bremsstrahlung but not the direct emission mode  $K_L^0 \rightarrow \pi^+\pi^-\gamma$  (DE).

[c] See the Particle Listings below for the energy limits used in this measurement.

[d] Most of this radiative mode, the low-momentum  $\gamma$  part, is also included in the parent mode listed without  $\gamma$ 's.

[e] Allowed by higher-order electroweak interactions.

[f] Violates CP in leading order. Test of direct CP violation since the indirect CP-violating and CP-conserving contributions are expected to be suppressed.

## CONSTRAINED FIT INFORMATION

An overall fit to the mean life and 15 branching ratios uses 27 measurements and one constraint to determine 11 parameters. The overall fit has a  $\chi^2 = 37.4$  for 17 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients  $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$ , in percent, from the fit to parameters  $p_i$ , including the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

**$V_{ud}$ ,  $V_{us}$ , THE CABIBBO ANGLE, AND CKM UNITARITY**

Updated September 2013 by E. Blucher (Univ. of Chicago) and W.J. Marciano (BNL).

The Cabibbo-Kobayashi-Maskawa (CKM) [1,2] three-generation quark mixing matrix written in terms of the Wolfenstein parameters ( $\lambda$ ,  $A$ ,  $\rho$ ,  $\eta$ ) [3] nicely illustrates the orthonormality constraint of unitarity and central role played by  $\lambda$ .

$$V_{\text{CKM}} = \begin{pmatrix} V_{ud} & V_{us} & V_{ub} \\ V_{cd} & V_{cs} & V_{cb} \\ V_{td} & V_{ts} & V_{tb} \end{pmatrix} = \begin{pmatrix} 1 - \lambda^2/2 & \lambda & A\lambda^3(\rho - i\eta) \\ -\lambda & 1 - \lambda^2/2 & A\lambda^2 \\ A\lambda^3(1 - \rho - i\eta) & -A\lambda^2 & 1 \end{pmatrix} + \mathcal{O}(\lambda^4). \quad (1)$$

That cornerstone is a carryover from the two-generation Cabibbo angle,  $\lambda = \sin(\theta_{\text{Cabibbo}}) = V_{us}$ . Its value is a critical ingredient in determinations of the other parameters and in tests of CKM unitarity.

Until about 10 years ago, the precise value of  $\lambda$  was somewhat controversial, with kaon decays suggesting [4]  $\lambda \simeq 0.220$ , while indirect determinations via nuclear  $\beta$ -decays implied a somewhat larger  $\lambda \simeq 0.225 - 0.230$ . This difference resulted in a 2 – 2.5 sigma deviation from the unitarity requirement

$$|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 1, \quad (2)$$

a potential signal [6] for new physics effects. Below, we discuss the current status of  $V_{ud}$ ,  $V_{us}$ , and their associated unitarity test in Eq. (2). (Since  $|V_{ub}|^2 \simeq 1 \times 10^{-5}$  is negligibly small, it is ignored in this discussion.) Although current measurements show no deviation from unitarity, Eq. (2) remains the most stringent test of unitarity in the CKM matrix.

 **$V_{ud}$** 

The value of  $V_{ud}$  has been obtained from superallowed nuclear, neutron, and pion decays. Currently, the most precise determination of  $V_{ud}$  comes from superallowed nuclear beta-decays [6] ( $0^+ \rightarrow 0^+$  transitions). Measuring their half-lives,  $t$ , and  $Q$  values that give the decay rate factor,  $f$ , leads to a precise determination of  $V_{ud}$  via the master formula [7–9]

$$|V_{ud}|^2 = \frac{2984.48(5) \text{ sec}}{ft(1 + \text{RC})}, \quad (3)$$

where RC denotes the entire effect of electroweak radiative corrections, nuclear structure, and isospin violating nuclear effects. RC is nucleus-dependent, ranging from about +3.0% to +3.6% for the best measured superallowed decays. The most recent analysis of Hardy and Towner [10, 11] gives a weighted average of

$$V_{ud} = 0.97425(8)_{\text{exp.}(10)}_{\text{nucl.dep.}(18)}_{\text{RC (superallowed)}}, \quad (4)$$

which, assuming unitarity, corresponds to  $\lambda = 0.2255(10)$ . The average value of  $V_{ud}$  shifted upward compared to our 2007 value of 0.97418(27) primarily because of improvements in the experimental  $ft$  values and nuclear isospin breaking corrections

employed. We note, however, that the possibility of additional nuclear coulombic corrections has been raised [12].

Combined measurements of the neutron lifetime,  $\tau_n$ , and the ratio of axial-vector/vector couplings,  $g_A \equiv G_A/G_V$ , via neutron decay asymmetries can also be used to determine  $V_{ud}$ :

$$|V_{ud}|^2 = \frac{4908.7(1.9) \text{ sec}}{\tau_n(1 + 3g_A^2)}, \quad (5)$$

where the error stems from uncertainties in the electroweak radiative corrections [8] due to hadronic loop effects. Those effects were updated and their error was reduced by about a factor of 2 [9], leading to a  $\pm 0.0002$  theoretical uncertainty in  $V_{ud}$  (common to all  $V_{ud}$  extractions). Using the world averages from this *Review*

$$\begin{aligned} \tau_n^{\text{ave}} &= 880.0(0.9) \text{ sec} \quad (\times 1.4 \text{ PDG scale factor}) \\ g_A^{\text{ave}} &= 1.2701(25) \quad (\times 1.9 \text{ PDG scale factor}) \end{aligned} \quad (6)$$

leads to

$$V_{ud} = 0.9774(5)_{\tau_n(16)}_{g_A(2)_{\text{RC}}} \quad (7)$$

with the error dominated by  $g_A$  uncertainties. The new shorter neutron lifetime average now leads to a value of  $V_{ud}$  that is inconsistent with the superallowed nuclear beta decay result in Eq. (4) by about 2 sigma. That disagreement suggests that a shift of  $g_A$  to about 1.275 (consistent with more modern day measurements [14]) or movement back to a longer neutron lifetime ( $\sim 886$  sec) is likely. Future neutron studies are expected to resolve these inconsistencies and significantly reduce the uncertainties in  $g_A$  and  $\tau_n$ , potentially making them the best way to determine  $V_{ud}$ .

The PIBETA experiment at PSI measured the very small ( $\mathcal{O}(10^{-8})$ ) branching ratio for  $\pi^+ \rightarrow \pi^0 e^+ \nu_e$  with about  $\pm 1/2\%$  precision. Their result gives [15]

$$V_{ud} = 0.9749(26) \left[ \frac{BR(\pi^+ \rightarrow e^+ \nu_e(\gamma))}{1.2352 \times 10^{-4}} \right]^{\frac{1}{2}} \quad (8)$$

which is normalized using the very precisely determined theoretical prediction for  $BR(\pi^+ \rightarrow e^+ \nu_e(\gamma)) = 1.2352(5) \times 10^{-4}$  [7], rather than the experimental branching ratio from this *Review* of  $1.230(4) \times 10^{-4}$  which would lower the value to  $V_{ud} = 0.9728(30)$ . Theoretical uncertainties in that determination are very small; however, much higher statistics would be required to make this approach competitive with others.

 **$V_{us}$** 

$|V_{us}|$  may be determined from kaon decays, hyperon decays, and tau decays. Previous determinations have most often used  $K\ell 3$  decays:

$$\Gamma_{K\ell 3} = \frac{G_F^2 M_K^5}{192\pi^3} S_{EW} (1 + \delta_K^\ell + \delta_{SU2}) C^2 |V_{us}|^2 f_+^2(0) I_K^\ell. \quad (9)$$

Here,  $\ell$  refers to either  $e$  or  $\mu$ ,  $G_F$  is the Fermi constant,  $M_K$  is the kaon mass,  $S_{EW}$  is the short-distance radiative correction,  $\delta_K^\ell$  is the mode-dependent long-distance radiative correction,  $f_+(0)$  is the calculated form factor at zero momentum transfer

## Meson Particle Listings

 $K_L^0$ 

for the  $\ell\nu$  system, and  $I_K^\ell$  is the phase-space integral, which depends on measured semileptonic form factors. For charged kaon decays,  $\delta_{SU2}$  is the deviation from one of the ratio of  $f_+(0)$  for the charged to neutral kaon decay; it is zero for the neutral kaon.  $C^2$  is 1 (1/2) for neutral (charged) kaon decays. Most early determinations of  $|V_{us}|$  were based solely on  $K \rightarrow \pi e \nu$  decays;  $K \rightarrow \pi \mu \nu$  decays were not used because of large uncertainties in  $I_K^\mu$ . The experimental measurements are the semileptonic decay widths (based on the semileptonic branching fractions and lifetime) and form factors (allowing calculation of the phase space integrals). Theory is needed for  $S_{EW}$ ,  $\delta_K^\ell$ ,  $\delta_{SU2}$ , and  $f_+(0)$ .

Many measurements during the last decade have resulted in a significant shift in  $V_{us}$ . Most importantly, recent measurements of the  $K \rightarrow \pi e \nu$  branching fractions are significantly different than earlier PDG averages, probably as a result of inadequate treatment of radiation in older experiments. This effect was first observed by BNL E865 [16] in the charged kaon system and then by KTeV [17,18] in the neutral kaon system; subsequent measurements were made by KLOE [19–22], NA48 [23–25], and ISTRA+ [26]. Current averages (*e.g.*, by the PDG [27] or Flavianet [28]) of the semileptonic branching fractions are based only on recent, high-statistics experiments where the treatment of radiation is clear. In addition to measurements of branching fractions, new measurements of lifetimes [29] and form factors [31–35], have resulted in improved precision for all of the experimental inputs to  $V_{us}$ . Precise measurements of form factors for  $K_{\mu 3}$  decay make it possible to use both semileptonic decay modes to extract  $V_{us}$ .

Following the analysis of Moulson [30] and the Flavianet group [28], one finds, after including the isospin violating up-down mass difference effect, the values of  $|V_{us}|f_+(0)$  in Table 1. The average of these measurements gives

$$f_+(0)|V_{us}| = 0.2163(5). \quad (10)$$

Figure 1 shows a comparison of these results with the PDG evaluation from 2002 [36], as well as  $f_+(0)(1 - |V_{ud}|^2 - |V_{ub}|^2)^{1/2}$ , the expectation for  $f_+(0)|V_{us}|$  assuming unitarity, based on  $|V_{ud}| = 0.9742 \pm 0.0003$ ,  $|V_{ub}| = (3.6 \pm 0.7) \times 10^{-3}$ , and the lattice calculation of  $f_+(0) = 0.960_{-0.006}^{+0.005}$  [37] (Lattice calculations of  $f_+(0)$  have improved significantly in recent years, and therefore replace the classic calculation of Leutwyler and Roos [38].) Combining the result in Eq. (10) with the above value of  $f_+(0)$  gives

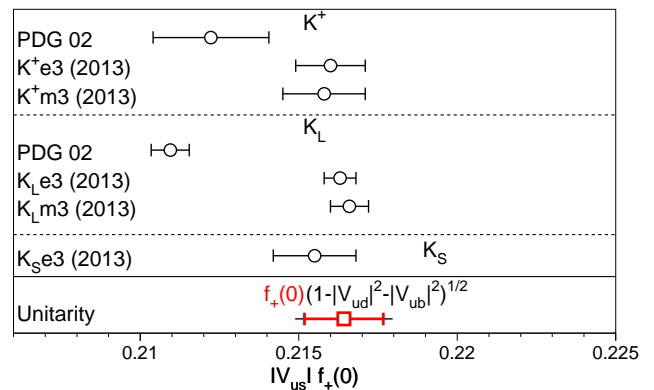

$$|V_{us}| = \lambda = 0.2253 \pm 0.0014. \quad (11)$$

A value of  $V_{us}$  can also be obtained from a comparison of the radiative inclusive decay rates for  $K \rightarrow \mu\nu(\gamma)$  and  $\pi \rightarrow \mu\nu(\gamma)$  combined with a lattice gauge theory calculation of  $f_K/f_\pi$  via [43]

$$\frac{|V_{us}|f_K}{|V_{ud}|f_\pi} = 0.23922(25) \left[ \frac{\Gamma(K \rightarrow \mu\nu(\gamma))}{\Gamma(\pi \rightarrow \mu\nu(\gamma))} \right]^{\frac{1}{2}} \quad (12)$$

**Table 1:**  $|V_{us}|f_+(0)$  from  $K_{\ell 3}$ .

Decay Mode	$ V_{us} f_+(0)$
$K^\pm e 3$	$0.2160 \pm 0.0011$
$K^\pm \mu 3$	$0.2158 \pm 0.0013$
$K_L e 3$	$0.2163 \pm 0.0005$
$K_L \mu 3$	$0.2166 \pm 0.0006$
$K_S e 3$	$0.2155 \pm 0.0013$
Average	$0.2163 \pm 0.0005$

**Figure 1:** Comparison of determinations of  $|V_{us}|f_+(0)$  from this review (labeled 2013), from the PDG 2002, and with the prediction from unitarity using  $|V_{ud}|$  and the lattice calculation of  $f_+(0) = 0.960_{-0.006}^{+0.005}$  [37]. For  $f_+(0)(1 - |V_{ud}|^2 - |V_{ub}|^2)^{1/2}$ , the inner error bars are from the quoted uncertainty in  $f_+(0)$ ; the total uncertainties include the  $|V_{ud}|$  and  $|V_{ub}|$  errors.

with the small error coming from electroweak radiative corrections and isospin breaking effects. Employing

$$\frac{\Gamma(K \rightarrow \mu\nu(\gamma))}{\Gamma(\pi \rightarrow \mu\nu(\gamma))} = 1.3344(42), \quad (13)$$

which averages in the KLOE result [44],  $B(K \rightarrow \mu\nu(\gamma)) = 63.66(9)(15)\%$  and [45]

$$f_K/f_\pi = 1.1947(45) \quad (14)$$

along with the value of  $V_{ud}$  in Eq. (4) leads to

$$|V_{us}| = 0.2253(4)(9). \quad (15)$$

It should be mentioned that hyperon decay fits suggest [5]

$$|V_{us}| = 0.2250(27) \text{ Hyperon Decays} \quad (16)$$

modulo SU(3) breaking effects that could shift that value up or down. We note that a representative effort [46] that incorporates SU(3) breaking found  $V_{us} = 0.226(5)$ . Strangeness changing tau

decays, averaging both inclusive and exclusive measurements, currently give [47]

$$|V_{us}| = 0.2202(15) \text{ Tau Decays}, \quad (17)$$

which differs by about 3 sigma from the kaon determination discussed above, and would, if combined with  $V_{ud}$  from super-allowed beta decays, lead to a 2.6 sigma deviation from unitarity. This discrepancy results mainly from the inclusive tau decay results that rely on Finite Energy Sum Rule techniques and assumptions. Further investigation of that approach seems to be warranted.

Employing the value of  $V_{ud}$  in Eq. (4) and  $V_{us} = 0.2253(8)$ , the average of the  $K\ell 3$  (Eq. (11)) and  $K\mu 2$  (Eq. (15)) determinations of  $V_{us}$ , leads to the unitarity consistency check

$$|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 0.9999(4)(4). \quad (18)$$

where the first error is the uncertainty from  $|V_{ud}|^2$  and the second error is the uncertainty from  $|V_{us}|^2$ .

### CKM Unitarity Constraints

The current good experimental agreement with unitarity,  $|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 0.9999(6)$ , provides strong confirmation of Standard Model radiative corrections (which range between 3-4% depending on the nucleus used) at better than the 50 sigma level [48]. In addition, it implies constraints on “New Physics” effects at both the tree and quantum loop levels. Those effects could be in the form of contributions to nuclear beta decays,  $K$  decays and/or muon decays, with the last of these providing normalization via the muon lifetime [49], which is used to obtain the Fermi constant,  $G_\mu = 1.1663787(6) \times 10^{-5} \text{ GeV}^{-2}$ .

In the following sections, we illustrate the implications of CKM unitarity for (1) exotic muon decays [50] (beyond ordinary muon decay  $\mu^+ \rightarrow e^+ \nu_e \bar{\nu}_\mu$ ) and (2) new heavy quark mixing  $V_{uD}$  [51]. Other examples in the literature [52,53] include  $Z_\chi$  boson quantum loop effects, supersymmetry, leptoquarks, compositeness etc.

### Exotic Muon Decays

If additional lepton flavor violating decays such as  $\mu^+ \rightarrow e^+ \bar{\nu}_e \nu_\mu$  (wrong neutrinos) occur, they would cause confusion in searches for neutrino oscillations at, for example, muon storage rings/neutrino factories or other neutrino sources from muon decays. Calling the rate for all such decays  $\Gamma(\text{exotic } \mu \text{ decays})$ , they should be subtracted before the extraction of  $G_\mu$  and normalization of the CKM matrix. Since that is not done and unitarity works, one has (at one-sided 95% CL)

$$|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 1 - BR(\text{exotic } \mu \text{ decays}) \geq 0.9989 \quad (19)$$

or

$$BR(\text{exotic } \mu \text{ decays}) < 0.001. \quad (20)$$

This bound is a factor of 10 better than the direct experimental bound on  $\mu^+ \rightarrow e^+ \bar{\nu}_e \nu_\mu$ .

### New Heavy Quark Mixing

Heavy  $D$  quarks naturally occur in fourth quark generation models and some heavy quark “new physics” scenarios such as  $E_6$  grand unification. Their mixing with ordinary quarks gives rise to  $V_{ud}$  which is constrained by unitarity (one sided 95% CL)

$$\begin{aligned} |V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 &= 1 - |V_{uD}|^2 > 0.9989 \\ |V_{uD}| &< 0.03. \end{aligned} \quad (21)$$

A similar constraint applies to heavy neutrino mixing and the couplings  $V_{\mu N}$  and  $V_{eN}$ .

<sup>1</sup>Quadratic dependence required by some experiments. (See sections on "QUADRATIC COEFFICIENT  $h$ " and "QUADRATIC COEFFICIENT  $k$ " below.) Correlations prevent us from averaging results of fits not including  $g$ ,  $h$ , and  $k$  terms.

<sup>2</sup>BISI 74 value comes from quadratic fit with quad. term consistent with zero.  $g$  error is thus larger than if linear fit were used.

<sup>3</sup>BUCHANAN 70 result revised by BUCHANAN 75 to include radiative correlations and to use more reliable  $K_L^0$  momentum spectrum of second experiment (had same beam).

-3.3 ± 1.1 ± 0.7	5M	<sup>2,3</sup> SOMALWAR 92	E731

- <sup>1</sup> Result obtained using C13p1 model of CABIBBO 05 to include  $\pi\pi$  rescattering effects. The systematic error includes an external error of  $1.06 \times 10^{-3}$  from the parametrization input of  $(a_0 - a_2) m_{\pi^+} = 0.268 \pm 0.017$  from BATLEY 06b.
- <sup>2</sup> LAI 01B and SOMALWAR 92 results do not include  $\pi\pi$  final state rescattering effects.
- <sup>3</sup> SOMALWAR 92 chose  $m_{\pi^+}$  as normalization to make it compatible with the Particle Data Group  $K_L^0 \rightarrow \pi^+ \pi^- \pi^0$  definitions.

**$K_L^0$  FORM FACTORS**

For discussion, see note on form factors in the  $K^\pm$  section of the Particle Listings above.

In the form factor comments, the following symbols are used.

- $f_+$  and  $f_-$  are form factors for the vector matrix element.
- $f_S$  and  $f_T$  refer to the scalar and tensor term.
- $f_0(t) = f_+(t) + f_-(t) t / (m_{K^0}^2 - m_{\pi^+}^2)$ .
- $t =$  momentum transfer to the  $\pi$ .
- $\lambda_+$  and  $\lambda_0$  are the linear expansion coefficients of  $f_+$  and  $f_0$ :
- $f_+(t) = f_+(0) (1 + \lambda_+ t / m_{\pi^+}^2)$
- For quadratic expansion
- $f_+(t) = f_+(0) (1 + \lambda'_+ t / m_{\pi^+}^2 + \frac{\lambda''_+}{2} t^2 / m_{\pi^+}^4)$
- as used by KTeV. If there is a non-vanishing quadratic term, then  $\lambda_+$  represents an average slope, which is then different from  $\lambda'_+$ .
- NA48 ( $K_{e3}$ ) and ISTRA quadratic expansion coefficients are converted with  $\lambda'_+ PDG = \lambda_{NA48}$  and  $\lambda''_+ PDG = 2 \lambda'_{NA48}$
- $\lambda'_+ PDG = (\frac{m_{\pi^+}}{m_{\pi^0}})^2 \lambda_+ ISTRA$  and
- $\lambda''_+ PDG = 2 (\frac{m_{\pi^+}}{m_{\pi^0}})^4 \lambda'_+ ISTRA$
- ISTRA linear expansion coefficients are converted with  $\lambda_+ PDG = (\frac{m_{\pi^+}}{m_{\pi^0}})^2 \lambda_+ ISTRA$  and  $\lambda_0 PDG = (\frac{m_{\pi^+}}{m_{\pi^0}})^2 \lambda_0 ISTRA$

The pole parametrization is

$$f_+(t) = f_+(0) \left( \frac{M_V^2}{M_V^2 - t} \right)$$

$$f_0(t) = f_0(0) \left( \frac{M_S^2}{M_S^2 - t} \right)$$

where  $M_V$  and  $M_S$  are the vector and scalar pole masses.

The dispersive parametrization is

$$f_+(t) = f_+(0) \exp\left[ \frac{t}{m_{\pi^+}^2} (\Lambda_+ + H(t)) \right];$$

$$f_0(t) = f_+(0) \exp\left[ \frac{t}{m_K^2 - m_{\pi^+}^2} (\ln[C] - G(t)) \right],$$

where  $\Lambda_+$  is the slope parameter and  $\ln[C] = \ln[f_0(m_K^2 - m_{\pi^+}^2)]$  is the logarithm of the scalar form factor at the Callan-Treiman point.

$H(t)$  and  $G(t)$  are dispersive integrals.

The following abbreviations are used:

- DP = Dalitz plot analysis.
- PI =  $\pi$  spectrum analysis.
- MU =  $\mu$  spectrum analysis.
- POL =  $\mu$  polarization analysis.
- BR =  $K_{\mu 3}^0 / K_{e 3}^0$  branching ratio analysis.
- E = positron or electron spectrum analysis.
- RC = radiative corrections.

**$\lambda_+$  (LINEAR ENERGY DEPENDENCE OF  $f_+$  IN  $K_{e 3}^0$  DECAY)**

For radiative correction of  $K_{e 3}^0$  DP, see GINSBERG 67, BECHERRAWY 70, CIRIGLIANO 02, CIRIGLIANO 04, and ANDRE 07. Results labeled OUR FIT are discussed in the review " $K_{e 3}^0$  and  $K_{\mu 3}^0$  Form Factors" in the  $K^\pm$  Listings. For earlier, lower statistics results, see the 2004 edition of this review, Physics Letters **B592** 1 (2004).

**$\alpha_{K^*}^{\text{eff}}$  DECAY FORM FACTOR FOR  $K_L \rightarrow e^+ e^- e^+ e^-$**

$\alpha_{K^*}^{\text{eff}}$  is the parameter describing the relative strength of an intermediate pseudoscalar decay amplitude and a vector meson decay amplitude in the model of BERGSTROM 83. It takes into account both the radiative effects and the form factor. Since there are two  $e^+ e^-$  pairs here compared with one in  $e^+ e^- \gamma$  decays, a factorized expression is used for the  $e^+ e^- e^+ e^-$  decay form factor.

## CP VIOLATION IN $K_L$ DECAYS

Updated October 2013 by L. Wolfenstein (Carnegie-Mellon University), C.-J. Lin (LBNL), and T.G. Trippe (LBNL).

The symmetries  $C$  (particle-antiparticle interchange) and  $P$  (space inversion) hold for strong and electromagnetic interactions. After the discovery of large  $C$  and  $P$  violation in the weak interactions, it appeared that the product  $CP$  was a good symmetry. In 1964  $CP$  violation was observed in  $K^0$  decays at a level given by the parameter  $\epsilon \approx 2.3 \times 10^{-3}$ .

A unified treatment of  $CP$  violation in  $K$ ,  $D$ ,  $B$ , and  $B_s$  mesons is given in “ $CP$  Violation in Meson Decays” by

D. Kirkby and Y. Nir in this *Review*. A more detailed review including a thorough discussion of the experimental techniques used to determine  $CP$  violation parameters is given in a book by K. Kleinknecht [1]. Here we give a concise summary of the formalism needed to define the parameters of  $CP$  violation in  $K_L$  decays, and a description of our fits for the best values of these parameters.

### 1. Formalism for $CP$ violation in Kaon decay:

$CP$  violation has been observed in the semi-leptonic decays  $K_L^0 \rightarrow \pi^\mp \ell^\pm \nu$ , and in the nonleptonic decay  $K_L^0 \rightarrow 2\pi$ . The experimental numbers that have been measured are

$$A_L = \frac{\Gamma(K_L^0 \rightarrow \pi^- \ell^+ \nu) - \Gamma(K_L^0 \rightarrow \pi^+ \ell^- \nu)}{\Gamma(K_L^0 \rightarrow \pi^- \ell^+ \nu) + \Gamma(K_L^0 \rightarrow \pi^+ \ell^- \nu)} \quad (1a)$$

$$\eta_{+-} = A(K_L^0 \rightarrow \pi^+ \pi^-) / A(K_S^0 \rightarrow \pi^+ \pi^-) = |\eta_{+-}| e^{i\phi_{+-}} \quad (1b)$$

$$\eta_{00} = A(K_L^0 \rightarrow \pi^0 \pi^0) / A(K_S^0 \rightarrow \pi^0 \pi^0) = |\eta_{00}| e^{i\phi_{00}} \quad (1c)$$

$CP$  violation can occur either in the  $K^0 - \bar{K}^0$  mixing or in the decay amplitudes. Assuming  $CPT$  invariance, the mass eigenstates of the  $K^0 - \bar{K}^0$  system can be written

$$|K_S\rangle = p|K^0\rangle + q|\bar{K}^0\rangle, \quad |K_L\rangle = p|K^0\rangle - q|\bar{K}^0\rangle \quad (2)$$

If  $CP$  invariance held, we would have  $q = p$  so that  $K_S$  would be  $CP$ -even and  $K_L$   $CP$ -odd. (We define  $|\bar{K}^0\rangle$  as  $CP|K^0\rangle$ ).  $CP$  violation in  $K^0 - \bar{K}^0$  mixing is then given by the parameter  $\tilde{\epsilon}$  where

$$\frac{p}{q} = \frac{(1 + \tilde{\epsilon})}{(1 - \tilde{\epsilon})} \quad (3)$$

$CP$  violation can also occur in the decay amplitudes

$$A(K^0 \rightarrow \pi\pi(I)) = A_I e^{i\delta_I}, \quad A(\bar{K}^0 \rightarrow \pi\pi(I)) = A_I^* e^{i\delta_I} \quad (4)$$

where  $I$  is the isospin of  $\pi\pi$ ,  $\delta_I$  is the final-state phase shift, and  $A_I$  would be real if  $CP$  invariance held. The  $CP$ -violating observables are usually expressed in terms of  $\epsilon$  and  $\epsilon'$  defined by

$$\eta_{+-} = \epsilon + \epsilon', \quad \eta_{00} = \epsilon - 2\epsilon' \quad (5a)$$

One can then show [2]

$$\epsilon = \tilde{\epsilon} + i (\text{Im } A_0 / \text{Re } A_0), \quad (5b)$$

$$\sqrt{2}\epsilon' = ie^{i(\delta_2 - \delta_0)} (\text{Re } A_2 / \text{Re } A_0) (\text{Im } A_2 / \text{Re } A_2 - \text{Im } A_0 / \text{Re } A_0), \quad (5c)$$

$$A_L = 2\text{Re } \epsilon / (1 + |\epsilon|^2) \approx 2\text{Re } \epsilon \quad (5d)$$

In Eqs. (5a), small corrections [3] of order  $\epsilon' \times \text{Re}(A_2/A_0)$  are neglected, and Eq. (5d) assumes the  $\Delta S = \Delta Q$  rule.

The quantities  $\text{Im } A_0$ ,  $\text{Im } A_2$ , and  $\text{Im } \tilde{\epsilon}$  depend on the choice of phase convention, since one can change the phases of  $K^0$  and  $\bar{K}^0$  by a transformation of the strange quark state  $|s\rangle \rightarrow |s\rangle e^{i\alpha}$ ; of course, observables are unchanged. It is possible by a choice of phase convention to set  $\text{Im } A_0$  or  $\text{Im } A_2$  or  $\text{Im } \tilde{\epsilon}$  to zero, but none of these is zero with the usual phase conventions in the Standard Model. The choice  $\text{Im } A_0 = 0$  is called the

Wu-Yang phase convention [4], in which case  $\epsilon = \tilde{\epsilon}$ . The value of  $\epsilon'$  is independent of phase convention, and a nonzero value demonstrates  $CP$  violation in the decay amplitudes, referred to as direct  $CP$  violation. The possibility that direct  $CP$  violation is essentially zero, and that  $CP$  violation occurs only in the mixing matrix, was referred to as the superweak theory [5].

By applying  $CPT$  invariance and unitarity the phase of  $\epsilon$  is given approximately by

$$\phi_\epsilon \approx \tan^{-1} \frac{2(m_{K_L} - m_{K_S})}{\Gamma_{K_S} - \Gamma_{K_L}} \approx 43.52 \pm 0.05^\circ, \quad (6a)$$

while Eq. (5c) gives the phase of  $\epsilon'$  to be

$$\phi_{\epsilon'} = \delta_2 - \delta_0 + \frac{\pi}{2} \approx 42.3 \pm 1.5^\circ, \quad (6b)$$

where the numerical value is based on an analysis of  $\pi\text{-}\pi$  scattering using chiral perturbation theory [6]. The approximation in Eq. (6a) depends on the assumption that direct  $CP$  violation is very small in all  $K^0$  decays. This is expected to be good to a few tenths of a degree, as indicated by the small value of  $\epsilon'$  and of  $\eta_{+-0}$  and  $\eta_{000}$ , the  $CP$ -violation parameters in the decays  $K_S \rightarrow \pi^+\pi^-\pi^0$  [7], and  $K_S \rightarrow \pi^0\pi^0\pi^0$  [8]. The relation in Eq. (6a) is exact in the superweak theory, so this is sometimes called the superweak-phase  $\phi_{SW}$ . An important point for the analysis is that  $\cos(\phi_{\epsilon'} - \phi_\epsilon) \simeq 1$ . The consequence is that only two real quantities need be measured, the magnitude of  $\epsilon$  and the value of  $(\epsilon'/\epsilon)$ , including its sign. The measured quantity  $|\eta_{00}/\eta_{+-}|^2$  is very close to unity so that we can write

$$|\eta_{00}/\eta_{+-}|^2 \approx 1 - 6\text{Re}(\epsilon'/\epsilon) \approx 1 - 6\epsilon'/\epsilon, \quad (7a)$$

$$\text{Re}(\epsilon'/\epsilon) \approx \frac{1}{3}(1 - |\eta_{00}/\eta_{+-}|). \quad (7b)$$

From the experimental measurements in this edition of the *Review*, and the fits discussed in the next section, one finds

$$|\epsilon| = (2.228 \pm 0.011) \times 10^{-3}, \quad (8a)$$

$$\phi_\epsilon = (43.5 \pm 0.5)^\circ, \quad (8b)$$

$$\text{Re}(\epsilon'/\epsilon) \approx \epsilon'/\epsilon = (1.66 \pm 0.23) \times 10^{-3}, \quad (8c)$$

$$\phi_{+-} = (43.4 \pm 0.5)^\circ, \quad (8d)$$

$$\phi_{00} - \phi_{+-} = (0.34 \pm 0.32)^\circ, \quad (8e)$$

$$A_L = (3.32 \pm 0.06) \times 10^{-3}. \quad (8f)$$

Direct  $CP$  violation, as indicated by  $\epsilon'/\epsilon$ , is expected in the Standard Model. However, the numerical value cannot be reliably predicted because of theoretical uncertainties [9]. The value of  $A_L$  agrees with Eq. (5d). The values of  $\phi_{+-}$  and  $\phi_{00} - \phi_{+-}$  are used to set limits on  $CPT$  violation [see “Tests of Conservation Laws”].

## 2. Fits for $K_L^0$ $CP$ -violation parameters:

In recent years,  $K_L^0$   $CP$ -violation experiments have improved our knowledge of  $CP$ -violation parameters, and their consistency with the expectations of  $CPT$  invariance and unitarity. To determine the best values of the  $CP$ -violation parameters in  $K_L^0 \rightarrow \pi^+\pi^-$  and  $\pi^0\pi^0$  decay, we make two types of fits, one for the phases  $\phi_{+-}$  and  $\phi_{00}$  jointly with  $\Delta m$  and  $\tau_S$ , and the other for the amplitudes  $|\eta_{+-}|$  and  $|\eta_{00}|$  jointly with the  $K_L^0 \rightarrow \pi\pi$  branching fractions.

**Fits to  $\phi_{+-}$ ,  $\phi_{00}$ ,  $\Delta\phi$ ,  $\Delta m$ , and  $\tau_S$  data:** These are joint fits to the data on  $\phi_{+-}$ ,  $\phi_{00}$ , the phase difference  $\Delta\phi = \phi_{00} - \phi_{+-}$ , the  $K_L^0 - K_S^0$  mass difference  $\Delta m$ , and the  $K_S^0$  mean life  $\tau_S$ , including the effects of correlations.

Measurements of  $\phi_{+-}$  and  $\phi_{00}$  are highly correlated with  $\Delta m$  and  $\tau_S$ . Some measurements of  $\tau_S$  are correlated with  $\Delta m$ . The correlations are given in the footnotes of the  $\phi_{+-}$  and  $\phi_{00}$  sections of the  $K_L^0$  Listings, and the  $\tau_S$  section of the  $K_S^0$  Listings.

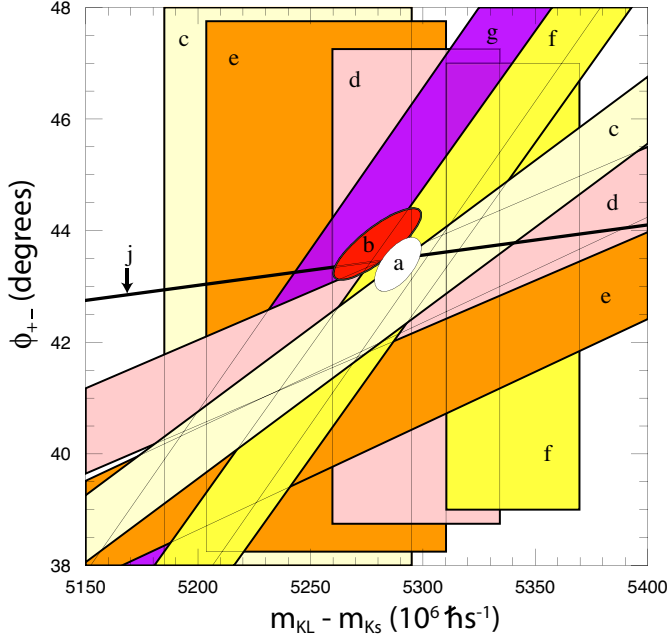

In most cases, the correlations are quoted as 100%, *i.e.*, with the value and error of  $\phi_{+-}$  or  $\phi_{00}$  given at a fixed value of  $\Delta m$  and  $\tau_S$ , with additional terms specifying the dependence of the value on  $\Delta m$  and  $\tau_S$ . These cases lead to diagonal bands in Figs. 1 and 2. The KTeV experiment [10] quotes its results as values of  $\Delta m$ ,  $\tau_S$ ,  $\phi_\epsilon$ ,  $\text{Re}(\epsilon'/\epsilon)$ , and  $\text{Im}(\epsilon'/\epsilon)$  with correlations, leading to the ellipses labeled “b.” The correlations for the KTeV measurements are given in the  $\text{Im}(\epsilon'/\epsilon)$  section of the  $K_L^0$  Listings. For small  $|\epsilon'/\epsilon|$ ,  $\phi_{+-} \approx \phi_\epsilon + \text{Im}(\epsilon'/\epsilon)$ .

**Table 1:** References, Document ID’s, and sources corresponding to the letter labels in the figures. The data are given in the  $\phi_{+-}$  and  $\Delta m$  sections of the  $K_L$  Listings, and the  $\tau_S$  section of the  $K_S$  Listings.

j	this <i>Review</i>	SUPERWEAK 13	

The data on  $\tau_S$ ,  $\Delta m$ , and  $\phi_{+-}$  shown in Figs. 1 and 2 are combined with data on  $\phi_{00}$  and  $\phi_{00} - \phi_{+-}$  in two fits, one without assuming  $CPT$ , and the other with this assumption. The results without assuming  $CPT$  are shown as ellipses labeled “a.” These ellipses are seen to be in good agreement with the superweak phase

$$\phi_{SW} = \tan^{-1} \left( \frac{2\Delta m}{\Delta\Gamma} \right) = \tan^{-1} \left( \frac{2\Delta m \tau_S \tau_L}{\hbar(\tau_L - \tau_S)} \right). \quad (9)$$

**Figure 1:**  $\phi_{+-}$  vs  $\Delta m$  for experiments which do not assume  $CPT$  invariance.  $\Delta m$  measurements appear as vertical bands spanning  $\Delta m \pm 1\sigma$ , cut near the top and bottom to aid the eye. Most  $\phi_{+-}$  measurements appear as diagonal bands spanning  $\phi_{+-} \pm \sigma_\phi$ . Data are labeled by letters: “b”–FNAL KTeV, “c”–CERN CPLEAR, “d”–FNAL E773, “e”–FNAL E731, “f”–CERN, “g”–CERN NA31, and are cited in Table 1. The narrow band “j” shows  $\phi_{SW}$ . The ellipse “a” shows the  $\chi^2 = 1$  contour of the fit result.

In Figs. 1 and 2,  $\phi_{SW}$  is shown as narrow bands labeled “j.”

Table 2 column 2, “Fit w/o  $CPT$ ,” gives the resulting fitted parameters, while Table 3 gives the correlation matrix for this fit. The white ellipses labeled “a” in Fig. 1 and Fig. 2 are the  $\chi^2 = 1$  contours for this fit.

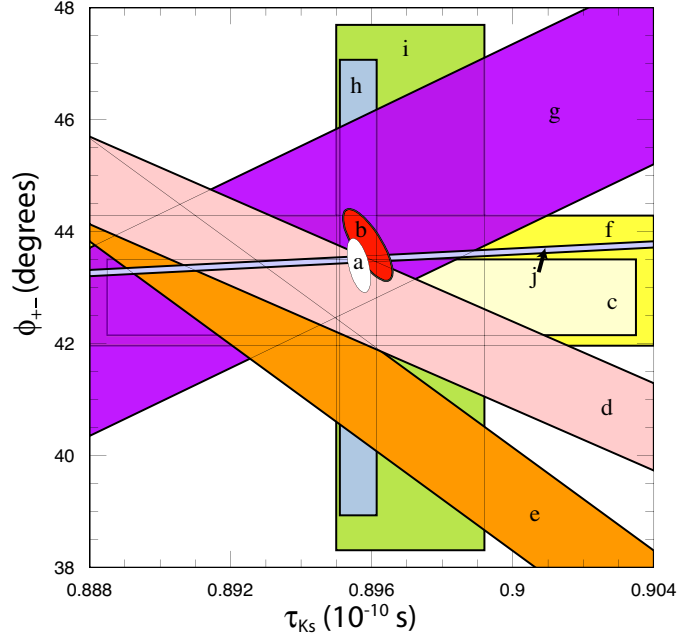

For experiments which have dependencies on unseen fit parameters, that is, parameters other than those shown on the x or y axis of the figure, their band positions are evaluated using the fit results and their band widths include the fitted uncertainty in the unseen parameters. This is also true for the  $\phi_{SW}$  bands.

If  $CPT$  invariance and unitarity are assumed, then by Eq. (6a), the phase of  $\epsilon$  is constrained to be approximately equal to

$$\phi_{SW} = (43.50258 \pm 0.00021)^\circ + 54.1(\Delta m - 0.5289)^\circ + 32.0(\tau_s - 0.89564) \quad (10)$$

where we have linearized the  $\Delta m$  and  $\tau_s$  dependence of Eq. (9). The error  $\pm 0.00021$  is due to the uncertainty in  $\tau_L$ . Here  $\Delta m$  has units  $10^{10} \hbar s^{-1}$  and  $\tau_s$  has units  $10^{-10} s$ .

If in addition we use the observation that  $Re(\epsilon'/\epsilon) \ll 1$  and  $\cos(\phi_{\epsilon'} - \phi_\epsilon) \simeq 1$ , as well as the numerical value of  $\phi_{\epsilon'}$  given in

**Figure 2:**  $\phi_{+-}$  vs  $\tau_s$ .  $\tau_s$  measurements appear as vertical bands spanning  $\tau_s \pm 1\sigma$ , some of which are cut near the top and bottom to aid the eye. Most  $\phi_{+-}$  measurements appear as diagonal or horizontal bands spanning  $\phi_{+-} \pm \sigma_\phi$ . Data are labeled by letters: “b”–FNAL KTeV, “c”–CERN CPLEAR, “d”–FNAL E773, “e”–FNAL E731, “f”–CERN, “g”–CERN NA31, “h”–CERN NA48, “i”–CERN NA31, and are cited in Table 1. The narrow band “j” shows  $\phi_{SW}$ . The ellipse “a” shows the fit result’s  $\chi^2 = 1$  contour.

**Table 2:** Fit results for  $\phi_{+-}$ ,  $\Delta m$ ,  $\tau_s$ ,  $\phi_{00}$ ,  $\Delta\phi = \phi_{00} - \phi_{+-}$ , and  $\phi_\epsilon$  without and with the  $CPT$  assumption.

Quantity(units)	Fit w/o $CPT$	Fit w/ $CPT$
$\phi_{+-}(\circ)$	$43.4 \pm 0.5$ (S=1.2)	$43.51 \pm 0.05$ (S=1.2)
$\Delta m(10^{10} \hbar s^{-1})$	$0.5289 \pm 0.0010$	$0.5293 \pm 0.0009$ (S=1.3)
$\tau_s(10^{-10}s)$	$0.89564 \pm 0.00033$	$0.8954 \pm 0.0004$ (S=1.1)
$\phi_{00}(\circ)$	$43.7 \pm 0.6$ (S=1.2)	$43.52 \pm 0.05$ (S=1.3)
$\Delta\phi(\circ)$	$0.34 \pm 0.32$	$0.006 \pm 0.014$ (S=1.7)
$\phi_\epsilon(\circ)$	$43.5 \pm 0.5$ (S=1.3)	$43.52 \pm 0.05$ (S=1.2)
$\chi^2$	16.4	20.0
# Deg. Free.	14	16

Eq. (6b), then Eqs. (5a), which are sketched in Fig. 3, lead to the constraint

$$\begin{aligned} \phi_{00} - \phi_{+-} &\approx -3 \operatorname{Im} \left( \frac{\epsilon'}{\epsilon} \right) \\ &\approx -3 \operatorname{Re} \left( \frac{\epsilon'}{\epsilon} \right) \tan(\phi_{\epsilon'} - \phi_\epsilon) \\ &\approx 0.006^\circ \pm 0.008^\circ, \end{aligned} \quad (11)$$

so that  $\phi_{+-} \approx \phi_{00} \approx \phi_\epsilon \approx \phi_{SW}$ .

In the fit assuming  $CPT$ , we constrain  $\phi_\epsilon = \phi_{SW}$  using the linear expression in Eq. (10), and constrain  $\phi_{00} - \phi_{+-}$  using Eq. (11). These constraints are inserted into the Listings with the Document ID of SUPERWEAK 13. Some additional data for which the authors assumed  $CPT$  are added to this fit or substitute for other less precise data for which the authors did not make this assumption. See the Listings for details.

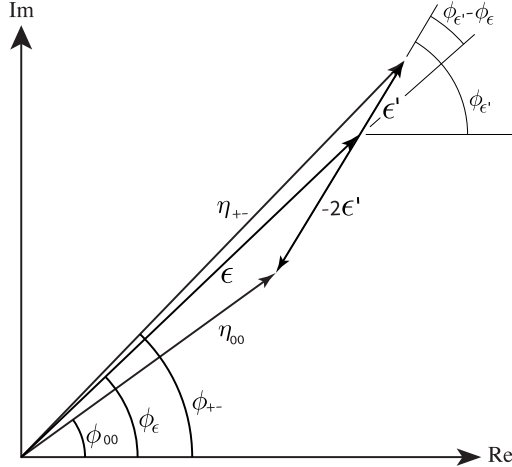

Figure 3: Sketch of Eqs. (5a). Not to scale.

The results of this fit are shown in Table 2, column 3, “Fit w/ $CPT$ ,” and the correlation matrix is shown in Table 4. The  $\Delta m$  precision is improved by the  $CPT$  assumption.

Table 3: Correlation matrix for the results of the fit without the  $CPT$  assumption

	$\phi_{+-}$	$\Delta m$	$\tau_S$	$\phi_{00}$	$\Delta\phi$	$\phi_\epsilon$

### Fits for $\epsilon'/\epsilon$ , $|\eta_{+-}|$ , $|\eta_{00}|$ , and $B(K_L \rightarrow \pi\pi)$

We list measurements of  $|\eta_{+-}|$ ,  $|\eta_{00}|$ ,  $|\eta_{00}/\eta_{+-}|$ , and  $\epsilon'/\epsilon$ . Independent information on  $|\eta_{+-}|$  and  $|\eta_{00}|$  can be obtained from measurements of the  $K_L^0$  and  $K_S^0$  lifetimes ( $\tau_L$ ,  $\tau_S$ ), and branching ratios (B) to  $\pi\pi$ , using the relations

$$|\eta_{+-}| = \left[ \frac{B(K_L^0 \rightarrow \pi^+\pi^-)}{\tau_L} \frac{\tau_S}{B(K_S^0 \rightarrow \pi^+\pi^-)} \right]^{1/2}, \quad (12a)$$

$$|\eta_{00}| = \left[ \frac{B(K_L^0 \rightarrow \pi^0\pi^0)}{\tau_L} \frac{\tau_S}{B(K_S^0 \rightarrow \pi^0\pi^0)} \right]^{1/2}. \quad (12b)$$

For historical reasons, the branching ratio fits and the  $CP$ -violation fits are done separately, but we want to include the influence of  $|\eta_{+-}|$ ,  $|\eta_{00}|$ ,  $|\eta_{00}/\eta_{+-}|$ , and  $\epsilon'/\epsilon$  measurements on  $B(K_L^0 \rightarrow \pi^+\pi^-)$  and  $B(K_L^0 \rightarrow \pi^0\pi^0)$  and vice versa. We approximate a global fit to all of these measurements by first performing two independent fits: 1) BRFIT, a fit to the  $K_L^0$  branching ratios, rates, and mean life, and 2) ETAFIT, a fit to the  $|\eta_{+-}|$ ,  $|\eta_{00}|$ ,  $|\eta_{+-}/\eta_{00}|$ , and  $\epsilon'/\epsilon$  measurements. The results from fit 1, along with the  $K_S^0$  values from this edition, are used to compute values of  $|\eta_{+-}|$  and  $|\eta_{00}|$ , which are included as measurements in the  $|\eta_{00}|$  and  $|\eta_{+-}|$  sections with a document ID of BRFIT 13. Thus, the fit values of  $|\eta_{+-}|$  and  $|\eta_{00}|$  given in this edition include both the direct measurements and the results from the branching ratio fit.

The process is reversed in order to include the direct  $|\eta|$  measurements in the branching ratio fit. The results from fit 2 above (before including BRFIT 13 values) are used along with the  $K_L^0$  and  $K_S^0$  mean lives and the  $K_S^0 \rightarrow \pi\pi$  branching fractions to compute the  $K_L^0$  branching ratio  $\Gamma(K_L^0 \rightarrow \pi^0\pi^0)/\Gamma(K_L^0 \rightarrow \pi^+\pi^-)$ . This branching ratio value is included as a measurement in the branching ratio section with a document ID of ETAFIT 12. Thus, the  $K_L^0$  branching ratio fit values in this edition include the results of the direct measurement of  $|\eta_{00}/\eta_{+-}|$  and  $\epsilon'/\epsilon$ . Most individual measurements of  $|\eta_{+-}|$  and  $|\eta_{00}|$  enter our fits directly via the corresponding measurements of  $\Gamma(K_L^0 \rightarrow \pi^+\pi^-)/\Gamma(\text{total})$  and  $\Gamma(K_L^0 \rightarrow \pi^0\pi^0)/\Gamma(\text{total})$ , and those that do not have too large errors to have any influence on the fitted values of these branching ratios. A more detailed discussion of these fits is given in the 1990 edition of this *Review* [20].

CP-VIOLATION PARAMETERS IN  $K_L^0$  DECAYSCHARGE ASYMMETRY IN  $K_{e3}^0$  DECAYSSuch asymmetry violates CP. It is related to  $\text{Re}(\epsilon)$ . $A_L$  = weighted average of  $A_L(\mu)$  and  $A_L(e)$ In previous editions and in the literature the symbol used for this asymmetry was  $\delta_L^{\pm}$  or  $\delta$ . We use  $A_L$  for consistency with  $B^0$  asymmetry notation and with recent  $K_S^0$  notation.

$$\eta_{+-} = A(K_L^0 \rightarrow \pi^+ \pi^-) / A(K_S^0 \rightarrow \pi^+ \pi^-)$$

$$\eta_{00} = A(K_L^0 \rightarrow \pi^0 \pi^0) / A(K_S^0 \rightarrow \pi^0 \pi^0)$$

The fitted values of  $|\eta_{+-}|$  and  $|\eta_{00}|$  given below are the results of a fit to  $|\eta_{+-}|$ ,  $|\eta_{00}|$ ,  $|\eta_{00}/\eta_{+-}|$ , and  $\text{Re}(\epsilon'/\epsilon)$ . Independent information on  $|\eta_{+-}|$  and  $|\eta_{00}|$  can be obtained from the fitted values of the  $K_L^0 \rightarrow \pi\pi$  and  $K_S^0 \rightarrow \pi\pi$  branching ratios and the  $K_L^0$  and  $K_S^0$  lifetimes. This information is included as data in the  $|\eta_{+-}|$  and  $|\eta_{00}|$  sections with a Document ID "BRFIT." See the note "CP violation in  $K_L$  decays" above for details.

$$|\eta_{00}| = |A(K_L^0 \rightarrow 2\pi^0) / A(K_S^0 \rightarrow 2\pi^0)|$$

<sup>1</sup> Value obtained from the NA48 measurements of  $\Gamma(K_L^0 \rightarrow \pi^+ \pi^-)/\Gamma(K_L^0 \rightarrow \pi e \nu_e)$  and  $\tau_{K_S^0}$  and KLOE measurements of  $B(K_S^0 \rightarrow \pi^+ \pi^-)$  and  $\tau_{K^0}$ .  $\Gamma(K_L^0 \rightarrow \pi^+ \pi^-)$

is defined to include the inner bremsstrahlung component  $\Gamma(K_L^0 \rightarrow \pi^+ \pi^- \gamma(\text{IB}))$  but exclude the direct emission component  $B(K_S^0 \rightarrow \pi^+ \pi^- (\text{DE}))$ . Their  $|\eta_{+-}|$  value is not directly used in our fit, but enters the fit via their branching ratio and lifetime measurements.

<sup>2</sup> AMBROSINO 06F uses KLOE branching ratios and  $\tau_L$  together with  $\tau_S$  from PDG 04. Their  $|\eta_{+-}|$  value is not directly used in our fit, but enters the fit via their branching ratio and lifetime measurements.

<sup>3</sup> ALEXOPOULOS 04  $|\eta_{+-}|$  uses their  $K_L^0 \rightarrow \pi\pi$  branching fractions,  $\tau_S = (0.8963 \pm 0.0005) \times 10^{-10}$  s from the average of KTeV and NA48  $\tau_S$  measurements, and assumes that  $\Gamma(K_S^0 \rightarrow \pi e \nu_e) = \Gamma(K_L^0 \rightarrow \pi e \nu_e)$  giving  $B(K_S^0 \rightarrow \pi e \nu_e) = 0.118\%$ . Their  $\eta_{+-}$  is not directly used in our fit, but enters our fit via their branching ratio measurements.

<sup>4</sup> APOSTOLAKIS 99C report  $(2.264 \pm 0.023 \pm 0.026 + 9.1[\tau_S - 0.8934]) \times 10^{-3}$ . We evaluate for our 2006 best value  $\tau_S = (0.8958 \pm 0.0005) \times 10^{-10}$  s.

<sup>5</sup> ADLER 95B report  $(2.312 \pm 0.043 \pm 0.030 - 1[\Delta m - 0.5274] + 9.1[\tau_S - 0.8926]) \times 10^{-3}$ . We evaluate for our 1996 best values  $\Delta m = (0.5304 \pm 0.0014) \times 10^{-10} \text{ ns}^{-1}$  and  $\tau_S = (0.8927 \pm 0.0009) \times 10^{-10}$  s. Superseded by APOSTOLAKIS 99C.

$$|\epsilon| = (2|\eta_{+-}| + |\eta_{00}|)/3$$

This expression is a very good approximation, good to about one part in  $10^{-4}$  because of the small measured value of  $\phi_{00} - \phi_{+-}$  and small theoretical ambiguities.

0.9939 ± 0.0013 ± 0.0015	1M	<sup>1</sup> BARR	93D	NA31
0.9899 ± 0.0020 ± 0.0025		<sup>1</sup> BURKHARDT	88	NA31

<sup>1</sup> This is the square root of the ratio R given by BURKHARDT 88 and BARR 93D.

<sup>2</sup> This is the combined results from BARR 93D and BURKHARDT 88, taking into account a common systematic uncertainty of 0.0014.

<sup>3</sup> We calculate  $|\eta_{00}/\eta_{+-}| = 1 - 3(\epsilon'/\epsilon)$  from WOODS 88 ( $\epsilon'/\epsilon$ ) value.

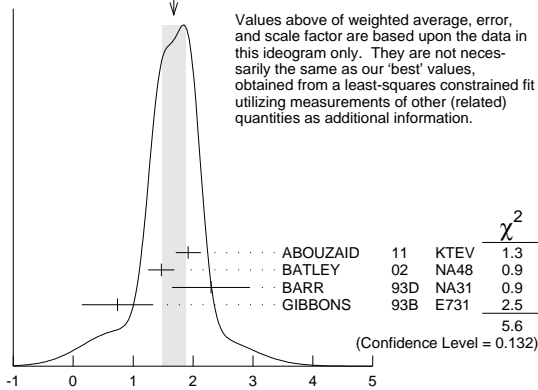

**Re( $\epsilon'/\epsilon$ ) = (1- $|\eta_{00}/\eta_{+-}|$ )/3**

We have neglected terms of order  $\omega \cdot \text{Re}(\epsilon'/\epsilon)$ , where  $\omega = \text{Re}(A_2)/\text{Re}(A_0) \simeq 1/22$ . If included, this correction would lower  $\text{Re}(\epsilon'/\epsilon)$  by about  $0.04 \times 10^{-3}$ . See SOZZI 04.

- The two ABOUZAID 11 values use the same data. The fits are performed with and without *CPT* invariance requirement.
- These values are derived from  $|\eta_{00}/\eta_{+-}|$  measurements. They enter the average in this section but enter the fit via the  $|\eta_{00}/\eta_{+-}|$  only.
- This is the combined results from BARR 93D and BURKHARDT 88, taking into account their common systematic uncertainty.
- We use ABOUZAID 11  $\text{Re}(\epsilon'/\epsilon)$  value with *CPT* assumption in our fits for  $|\eta_{+-}|$ ,  $|\eta_{00}|$ , and  $\text{Re}(\epsilon'/\epsilon)$ .
- These values are derived from  $|\eta_{00}/\eta_{+-}|$  measurements.

WEIGHTED AVERAGE  
1.68±0.20 (Error scaled by 1.4)

$\text{Re}(\epsilon'/\epsilon) = (1-|\eta_{00}/\eta_{+-}|)/3$

**$\phi_{+-}$ , PHASE OF  $\eta_{+-}$**

The dependence of the phase on  $\Delta m$  and  $\tau_S$  is given for each experiment in the comments below, where  $\Delta m$  is the  $K_L^0 - K_S^0$  mass difference in units  $10^{10} \text{ h s}^{-1}$  and  $\tau_S$  is the  $K_S$  mean life in units  $10^{-10} \text{ s}$ . We also give the regeneration phase  $\phi_f$  in the comments below.

OUR FIT is described in the note on "CP violation in  $K_L$  decays" in the  $K_L^0$  Particle Listings. Most experiments in this section are included in both the "Not Assuming *CPT*" and "Assuming *CPT*" fits. In the latter fit, they have little direct influence on  $\phi_{+-}$  because their errors are large compared to that assuming *CPT*, but they influence  $\Delta m$  and  $\tau_S$  through their dependencies on these parameters, which are given in the footnotes.

- APOSTOLAKIS 99c measures  $\phi_{+-} = (43.19 \pm 0.53 \pm 0.28) + 300 [\Delta m - 0.5301] (^\circ)$ . We have adjusted the measurement to use our best values of ( $\Delta m = 0.5293 \pm 0.0009$ ) ( $10^{10} \text{ h s}^{-1}$ ). Our first error is their experiment's error and our second error is the systematic error from using our best values.
- SCHWINGENHEUER 95 measures  $\phi_{+-} = (43.53 \pm 0.76) + 173 [\Delta m - 0.5282] - 275 [\tau_S - 0.8926] (^\circ)$ . We have adjusted the measurement to use our best values of ( $\Delta m = 0.5293 \pm 0.0009$ ) ( $10^{10} \text{ h s}^{-1}$ ), ( $\tau_S = 0.8954 \pm 0.0004$ ) ( $10^{-10} \text{ s}$ ). Our first error is their experiment's error and our second error is the systematic error from using our best values.
- These experiments measure  $\phi_{+-} - \phi_f$  and calculate the regeneration phase from the power law momentum dependence of the regeneration amplitude using analyticity and dispersion relations. SCHWINGENHEUER 95 [GIBBONS 93] includes a systematic error of 0.35° [0.5°] for uncertainties in their modeling of the regeneration amplitude.
- GIBBONS 93 measures  $\phi_{+-} = (42.21 \pm 0.9) + 189 [\Delta m - 0.5257] - 460 [\tau_S - 0.8922] (^\circ)$ . We have adjusted the measurement to use our best values of ( $\Delta m = 0.5293 \pm 0.0009$ ) ( $10^{10} \text{ h s}^{-1}$ ), ( $\tau_S = 0.8954 \pm 0.0004$ ) ( $10^{-10} \text{ s}$ ). Our first error is their experiment's error and our second error is the systematic error from using our best values. This is actually reported in SCHWINGENHEUER 95, footnote 8. GIBBONS 93 reports  $\phi_{+-}$  ( $42.2 \pm 1.4$ )°. They measure  $\phi_{+-} - \phi_f$  and calculate the regeneration phase  $\phi_f$  from the power law momentum dependence of the regeneration amplitude using analyticity. An error of 0.6° is included for possible uncertainties in the regeneration phase.
- CAROSI 90 measures  $\phi_{+-} = (46.9 \pm 1.4 \pm 0.7) + 579 [\Delta m - 0.5351] + 303 [\tau_S - 0.8922] (^\circ)$ . We have adjusted the measurement to use our best values of ( $\Delta m = 0.5293 \pm 0.0009$ ) ( $10^{10} \text{ h s}^{-1}$ ), ( $\tau_S = 0.8954 \pm 0.0004$ ) ( $10^{-10} \text{ s}$ ). Our first error is their experiment's error and our second error is the systematic error from using our best values.
- GEWENIGER 74B measures  $\phi_{+-} = (49.4 \pm 1.0) + 565 [\Delta m - 0.540] (^\circ)$ . We have adjusted the measurement to use our best values of ( $\Delta m = 0.5293 \pm 0.0009$ ) ( $10^{10} \text{ h s}^{-1}$ ). Our first error is their experiment's error and our second error is the systematic error from using our best values.
- Not independent of other phase parameters reported in ABOUZAID 11.
- ALAVI-HARATI 03  $\phi_{+-}$  is correlated with their  $\Delta m = m_{K_L^0} - m_{K_S^0}$  and  $\tau_{K_S}$  measurements in the  $K_L^0$  and  $K_S^0$  sections respectively. The correlation coefficients are  $\rho(\phi_{+-}, \Delta m) = +0.955$ ,  $\rho(\phi_{+-}, \tau_S) = -0.871$ , and  $\rho(\tau_S, \Delta m) = -0.840$ . *CPT* is not assumed. Uses scintillator Pb regenerator. Superseded by ABOUZAID 11.
- ADLER 96c measures  $\phi_{+-} = (43.82 \pm 0.41) + 339 [\Delta m - 0.5307] - 252 [\tau_S - 0.8922] (^\circ)$ . We have adjusted the measurement to use our best values of ( $\Delta m = 0.5293 \pm 0.0009$ ) ( $10^{10} \text{ h s}^{-1}$ ), ( $\tau_S = 0.8954 \pm 0.0004$ ) ( $10^{-10} \text{ s}$ ). Our first error is their experiment's error and our second error is the systematic error from using our best values.
- ADLER 96c is the result of a fit which includes nearly the same data as entered into the "OUR FIT" value in the 1996 edition of this Review (Physical Review **D54** 1 (1996)).
- ADLER 95B measures  $\phi_{+-} = (42.7 \pm 0.9 \pm 0.6) + 316 [\Delta m - 0.5274] + 30 [\tau_S - 0.8926] (^\circ)$ . We have adjusted the measurement to use our best values of ( $\Delta m = 0.5293 \pm 0.0009$ ) ( $10^{10} \text{ h s}^{-1}$ ), ( $\tau_S = 0.8954 \pm 0.0004$ ) ( $10^{-10} \text{ s}$ ). Our first error is their experiment's error and our second error is the systematic error from using our best values.
- ADLER 92B quote separately two systematic errors:  $\pm 0.4$  from their experiment and  $\pm 1.0$  degrees due to the uncertainty in the value of  $\Delta m$ .
- KARLSSON 90 systematic error does not include regeneration phase uncertainty.
- CARITHERS 75 measures  $\phi_{+-} = (45.5 \pm 2.8) + 224 [\Delta m - 0.5348] (^\circ)$ . We have adjusted the measurement to use our best values of ( $\Delta m = 0.5293 \pm 0.0009$ ) ( $10^{10} \text{ h s}^{-1}$ ). Our first error is their experiment's error and our second error is the systematic error from using our best values.  $\phi_f = -40.9 \pm 2.6$ °.

**$\phi_{00}$ , PHASE OF  $\eta_{00}$**

See comment in  $\phi_{+-}$  header above for treatment of  $\Delta m$  and  $\tau_S$  dependence, as well as for the inclusion of data in both the "Assuming *CPT*" and "Not Assuming *CPT*" fits.

OUR FIT is described in the note on "CP violation in  $K_L$  decays" in the  $K_L^0$  Particle Listings.

47.4 ± 1.4 ± 0.9	5 KARLSSON 90	E731	
1 CAROSI 90 measures $\phi_{00} = (47.1 \pm 2.1 \pm 1.0) + 579 [\Delta m - 0.5351] + 252 [\tau_S - 0.8922] (^\circ)$ . We have adjusted the measurement to use our best values of ( $\Delta m = 0.5293 \pm 0.0009$ ) ( $10^{10} \text{ h s}^{-1}$ ), ( $\tau_S = 0.8954 \pm 0.0004$ ) ( $10^{-10} \text{ s}$ ). Our first error is their experiment's error and our second error is the systematic error from using our best values.			
2 Not independent of other phase parameters reported in ABOUZAID 11.			
3 ANGELOPOULOS 98 measures $\phi_{00} = (42.0 \pm 5.6 \pm 1.9) + 240 [\Delta m - 0.5307] (^\circ)$ . We have adjusted the measurement to use our best values of ( $\Delta m = 0.5293 \pm 0.0009$ ) ( $10^{10} \text{ h s}^{-1}$ ). Our first error is their experiment's error and our second error is the systematic error from using our best values. The $\tau_S$ dependence is negligible.			
4 ADLER 96B identified initial neutral kaon individually as being a $K^0$ or a $\bar{K}^0$ . The systematic uncertainty is $\pm 1.5$ ° combined in quadrature with $\pm 0.8$ ° due to $\Delta m$ .			
5 KARLSSON 90 systematic error does not include regeneration phase uncertainty.			

## Meson Particle Listings

 $K_L^0$ 

$$\phi_\epsilon = (2\phi_{+-} + \phi_{00})/3$$

This expression is a very good approximation, good to about  $10^{-3}$  degrees because of the small measured values of  $\phi_{00} - \phi_{+-}$  and  $\text{Re}(e'/\epsilon)$ , and small theoretical ambiguities.

VALUE (%)	DOCUMENT ID	TECN	COMMENT
<b>43.52 ± 0.05 OUR FIT</b>			Error includes scale factor of 1.2. Assuming <i>CPT</i>
<b>43.5 ± 0.5 OUR FIT</b>			Error includes scale factor of 1.3. Not assuming <i>CPT</i>
43.5164 ± 0.0002 ± 0.0518	<sup>1</sup> SUPERWEAK 13		Assuming <i>CPT</i>
43.86 ± 0.63	<sup>2</sup> ABOUZAID 11	KTEV	Not assuming <i>CPT</i>

<sup>1</sup> SUPERWEAK 13 is a fake measurement used to impose the *CPT* or Superweak constraint  $\phi_{+-} = \phi_{SW} = \tan^{-1}[2 \frac{\Delta m}{\hbar} (\frac{\tau_S \tau_L}{\tau_L - \tau_S})]$ . This "measurement" is linearized using values near the PDG 04 edition values of  $\Delta m$ ,  $\tau_S$  and  $\tau_L$ , and then adjusted to our current values as described in the following "measurement". SUPERWEAK 13 measures  $\phi_\epsilon = (43.50258 \pm 0.00021) + 54.1 [\Delta m - 0.5289] + 32.0 [\tau_S - 0.89564]$  (°). We have adjusted the measurement to use our best values of ( $\Delta m = 0.5293 \pm 0.0009$ ) ( $10^{10} \hbar \text{ s}^{-1}$ ), ( $\tau_S = 0.8954 \pm 0.0004$ ) ( $10^{-10} \text{ s}$ ). Our first error is their experiment's error and our second error is the systematic error from using our best values.

<sup>2</sup> ABOUZAID 11 uses the full KTeV dataset collected in 1996, 1997, and 1999. See  $\text{Im}(e'/\epsilon)$  section for correlation information.

$$\text{Im}(e'/\epsilon) = -(\phi_{00} - \phi_{+-})/3$$

For small  $|e'/\epsilon|$ ,  $\text{Im}(e'/\epsilon)$  is related to the phases of  $\eta_{00}$  and  $\eta_{+-}$  by the above expression.

VALUE (%)	DOCUMENT ID	TECN	COMMENT
<b>-0.002 ± 0.005 OUR FIT</b>			Error includes scale factor of 1.7. Assuming <i>CPT</i>

- Not seen by KOPP 01 using 7070 events of  $D^0 \rightarrow K^- \pi^+ \pi^0$ . LINK 02e and LINK 05i show clear evidence for a constant non-resonant scalar amplitude rather than  $K_0^*(800)$  in their high statistics analysis of  $D^+ \rightarrow K^- \pi^+ \mu^+ \nu_\mu$ .
- AUBERT 07t does not find evidence for the charged  $K_0^*(800)$  using 11k events of  $D^0 \rightarrow K^- K^+ \pi^0$ .
- S-matrix pole. Supersedes BUGG 06. Combined analysis of ASTON 88, ABLIKIM 06c, AITALA 06, and LINK 09 using an s-dependent width with couplings to  $K\pi$  and  $K\eta'$ , and the Adler zero near thresholds.
- T-matrix pole.
- A Breit-Wigner mass and width.
- S-matrix pole. Reanalysis of ASTON 88, AITALA 02, and ABLIKIM 06c using for the  $\kappa$  an s-dependent width with an Adler zero near threshold.
- Breit-Wigner parameters. A significant S-wave can be also modeled as a non-resonant contribution.
- Using ASTON 88.
- T-matrix pole. Reanalysis of data from LINGLIN 73, ESTABROOKS 78, and ASTON 88 in the unitarized ChPT model.
- T-matrix pole. Reanalysis of ASTON 88 data.
- Reanalysis of ASTON 88 using interfering Breit-Wigner amplitudes.

$K_0^*(800)$   
OF  $\kappa$

$$J(P) = \frac{1}{2}(0^+)$$

OMITTED FROM SUMMARY TABLE

Needs confirmation. See the mini-review on scalar mesons under  $f_0(500)$  (see the index for the page number).

- The Breit-Wigner parameters from a fit with seven intermediate resonances. The S-matrix pole position is  $(764 \pm 63^{+71}_{-54}) - i(306 \pm 149^{+143}_{-85})$  MeV.
- From a fit including ten additional resonances and energy-independent Breit-Wigner width.
- S-matrix pole.
- S-matrix pole. GUO 06 in a chiral unitary approach report a mass of  $757 \pm 33$  MeV and a width of  $558 \pm 82$  MeV.
- A fit in the  $K_0^*(800) + K^*(892) + K^*(1410)$  model with mass and width of the  $K_0^*(800)$  from ABLIKIM 06c well describes the left slope of the  $K_S^0 \pi^-$  invariant mass spectrum in  $\tau^- \rightarrow K_S^0 \pi^- \nu_\tau$  decay studied by EPIFANOV 07.
- S-matrix pole. Using Roy-Steiner equations (ROY 71) as well as unitarity, analyticity and crossing symmetry constraints.

WEIGHTED AVERAGE  
895.81 ± 0.19 (Error scaled by 1.4)

- <sup>1</sup> Inclusive reaction. Complicated background and phase-space effects.
- <sup>2</sup> Mass errors enlarged by us to  $\Gamma/\sqrt{N}$ . See note.
- <sup>3</sup> Number of events in peak reevaluated by us.
- <sup>4</sup> K-matrix pole.
- <sup>5</sup> From a partial wave amplitude analysis.
- <sup>6</sup> From a fit in the  $K_0^*(800) + K^*(892) + K^*(1410)$  model.
- <sup>7</sup> From the pole position of the  $K\pi$  vector form factor using EPIFANOV 07 and constraints from  $K_{J3}$  decays in ANTONELLI 10.
- <sup>8</sup> Systematic uncertainties not estimated.
- <sup>9</sup> From the pole position of the  $K\pi$  vector form factor in the complex s-plane and using EPIFANOV 07 data.
- <sup>10</sup> Reanalysis of EPIFANOV 07 using resonance chiral theory.
- <sup>11</sup> Calculated by us from the shift by  $4.7 \pm 0.9$  MeV (statistical uncertainty only) reported in BONVICINI 02 with respect to the world average value from PDG 00.
- <sup>12</sup> With mass and width of the  $K^*(1410)$  fixed at 1412 MeV and 227 MeV, respectively.
- <sup>13</sup> Taking into account the  $K^*(892)^0$ , S-wave and P-wave ( $K^*(1410)^0$ ).
- <sup>14</sup> From the isobar model with a complex pole for the  $\kappa$ .
- <sup>15</sup> Fit to  $K\pi$  mass spectrum includes a non-resonant scalar component.
- <sup>16</sup> From pole extrapolation.
- <sup>17</sup> This value comes from a fit with  $\chi^2$  of 178/117.

**$K^*(892)$  MASSES AND MASS DIFFERENCES**

Unrealistically small errors have been reported by some experiments. We use simple “realistic” tests for the minimum errors on the determination of a mass and width from a sample of  $N$  events:

$$\delta_{\min}(m) = \frac{\Gamma}{\sqrt{N}}, \quad \delta_{\min}(\Gamma) = 4 \frac{\Gamma}{\sqrt{N}}. \quad (1)$$

We consistently increase unrealistic errors before averaging. For a detailed discussion, see the 1971 edition of this Note.

### CONSTRAINED FIT INFORMATION

An overall fit to the total width and a partial width uses 13 measurements and one constraint to determine 3 parameters. The overall fit has a  $\chi^2 = 7.8$  for 11 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$ , in percent, from the fit to parameters  $p_i$ , including the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

$\Gamma_2$ $(K\pi)^\pm$	50.7 ± 0.9
$\Gamma_5$ $K^\pm\gamma$	0.050 ± 0.005

### CONSTRAINED FIT INFORMATION

An overall fit to the total width and a partial width uses 22 measurements and one constraint to determine 3 parameters. The overall fit has a  $\chi^2 = 66.8$  for 20 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$ , in percent, from the fit to parameters  $p_i$ , including the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

$x_4$	-100	
$\Gamma$	15	-15
	$x_3$	$x_4$

Mode	Rate (MeV)	Scale factor
$\Gamma_3$ $(K\pi)^0$	47.3 ± 0.6	2.1
$\Gamma_4$ $K^0\gamma$	0.116 ± 0.010

WEIGHTED AVERAGE  
109±5 (Error scaled by 1.9)

8 Errors enlarged by us to  $4\Gamma/\sqrt{N}$ ; see the note with the  $K^*(892)$  mass.

9 Number of events in peak re-evaluated by us.

10 From a partial wave amplitude analysis.

11 From phase shift or partial-wave analysis.

12 Systematic errors not estimated.

13 From pole extrapolation, using world  $K^+p$  data summary tape.

## $K_2^*(1430)$

$$J(J^P) = \frac{1}{2}(2^+)$$

We consider that phase-shift analyses provide more reliable determinations of the mass and width.

CONSTRAINED FIT INFORMATION

An overall fit to the total width, a partial width, and 10 branching ratios uses 31 measurements and one constraint to determine 8 parameters. The overall fit has a  $\chi^2 = 20.2$  for 24 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$ , in percent, from the fit to parameters  $p_i$ , including the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

#### CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 4 measurements and one constraint to determine 3 parameters. The overall fit has a  $\chi^2 = 2.9$  for 2 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

$x_2$	-36	
$x_3$	-39	-72
	$x_1$	$x_2$

- <sup>8</sup> From a partial wave amplitude analysis.
- <sup>9</sup> From a fit to  $Y_6^0$  moment.
- <sup>10</sup> Errors enlarged by us to  $4\Gamma/\sqrt{N}$ ; see the note with the  $K^*(892)$  mass.
- <sup>11</sup> ESTABROOKS 78 find that BRANDENBURG 76D data are consistent with 175 MeV width. Not averaged.

$K_3^*(1780)$  DECAY MODES

Mode	Fraction ( $\Gamma_i/\Gamma$ )	Confidence level
$\Gamma_1$ $K\rho$	(31 ± 9) %	
$\Gamma_2$ $K^*(892)\pi$	(20 ± 5) %	
$\Gamma_3$ $K\pi$	(18.8 ± 1.0) %	
$\Gamma_4$ $K\eta$	(30 ± 13) %	
$\Gamma_5$ $K_2^*(1430)\pi$	< 16 %	95%

CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 4 measurements and one constraint to determine 4 parameters. The overall fit has a  $\chi^2 = 0.0$  for 1 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

**$D^+$  DECAY MODES**

Most decay modes (other than the semileptonic modes) that involve a neutral  $K$  meson are now given as  $K_S^0$  modes, not as  $\bar{K}^0$  modes. Nearly always it is a  $K_S^0$  that is measured, and interference between Cabibbo-allowed and doubly Cabibbo-suppressed modes can invalidate the assumption that  $2\Gamma(K_S^0) = \Gamma(\bar{K}^0)$ .

Mode	Fraction ( $\Gamma_i/\Gamma$ )	Scale factor/ Confidence level
<b>Inclusive modes</b>		
$\Gamma_1$ $D^+ \rightarrow e^+$ semileptonic	(16.07 ± 0.30) %	
$\Gamma_2$ $D^+ \rightarrow \mu^+$ anything	(17.6 ± 3.2) %

$\Gamma_{135}$	Unaccounted decay modes	$(51.2 \pm 1.0) \%$			
[a] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers.					
[b] These subfractions of the $K^- 2\pi^+$ mode are uncertain: see the Particle Listings.					
[c] Submodes of the $D^+ \rightarrow K^- 2\pi^+ \pi^0$ and $K_S^0 2\pi^+ \pi^-$ modes were studied by ANJOS 92C and COFFMAN 92B, but with at most 142 events for the first mode and 229 for the second – not enough for precise results. With nothing new for 18 years, we refer to our 2008 edition, Physics Letters <b>B667</b> 1 (2008), for those results.					
[d] The unseen decay modes of the resonances are included.					
[e] This is <i>not</i> a test for the $\Delta C=1$ weak neutral current, but leads to the $\pi^+ \ell^+ \ell^-$ final state.					
[f] This mode is not a useful test for a $\Delta C=1$ weak neutral current because both quarks must change flavor in this decay.					
<b>CONSTRAINED FIT INFORMATION</b>					
An overall fit to 22 branching ratios uses 31 measurements and one constraint to determine 15 parameters. The overall fit has a $\chi^2 = 32.0$ for 17 degrees of freedom.					
The following <i>off-diagonal</i> array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the $x_i$ whose labels appear in this array to sum to one.

<b>1.460 ± 0.040 ± 0.035</b>	2023 ± 54	<sup>1</sup> HE 08	CLEO	$e^+ e^-$ at $\psi(3770)$

<sup>1</sup> The difference of CLEO  $D^+ \rightarrow K_S^0 \pi^+$  and  $K_L^0 \pi^+$  branching fractions over the sum (DOBBS 07 and HE 08) is  $+0.022 \pm 0.016 \pm 0.018$ .

 $\Gamma(K^- 2\pi^+)/\Gamma_{\text{total}}$   $\Gamma_{40}/\Gamma$ 

VALUE (units $10^{-2}$ )	EVTS	DOCUMENT ID	TECN	COMMENT
<b>9.13 ± 0.19 OUR FIT</b>				
<b>9.14 ± 0.10 ± 0.17</b>		<sup>1</sup> DOBBS 07	CLEO	$e^+ e^-$ at $\psi(3770)$
• • • We do not use the following data for averages, fits, limits, etc. • • •				
9.5 ± 0.2 ± 0.3	15.1k ± 130	<sup>1</sup> HE 05	CLEO	See DOBBS 07
9.3 ± 0.6 ± 0.8	1502	<sup>2</sup> BALEST 94	CLEO	$e^+ e^- \approx \Upsilon(4S)$
6.4 <sup>+1.5</sup> <sub>-1.4</sub>		<sup>3</sup> BARLAG 92c	ACCM	$\pi^-$ Cu 230 GeV
9.1 ± 1.3 ± 0.4	1164	ADLER 88c	MRK3	$e^+ e^- 3.77$ GeV
9.1 ± 1.9	239	<sup>4</sup> SCHINDLER 81	MRK2	$e^+ e^- 3.771$ GeV

<sup>1</sup> DOBBS 07 and HE 05 use single- and double-tagged events in an overall fit. DOBBS 07 supersedes HE 05.

<sup>2</sup> BALEST 94 measures the ratio of  $D^+ \rightarrow K^- \pi^+ \pi^+$  and  $D^0 \rightarrow K^- \pi^+$  branching fractions to be  $2.35 \pm 0.16 \pm 0.16$  and uses their absolute measurement of the  $D^0 \rightarrow K^- \pi^+$  fraction (AKERIB 93).

<sup>3</sup> BARLAG 92c computes the branching fraction by topological normalization.

<sup>4</sup> SCHINDLER 81 (MARK-2) measures  $\sigma(e^+ e^- \rightarrow \psi(3770)) \times$  branching fraction to be  $0.38 \pm 0.05$  nb. We use the MARK-3 (ADLER 88c) value of  $\sigma = 4.2 \pm 0.6 \pm 0.3$  nb.

 $\Gamma((K^- \pi^+)_{S\text{-wave}} \pi^+)/\Gamma(K^- 2\pi^+)$   $\Gamma_{41}/\Gamma_{40}$ 

This is the "fit fraction" from the Dalitz-plot analysis. The  $K^- \pi^+$  S-wave includes a broad scalar  $\kappa$  ( $\bar{K}_0^*(800)$ ), the  $\bar{K}_0^*(1430)^0$ , and non-resonant background.

0.8323 ± 0.0150 ± 0.0008	<sup>3</sup> LINK 07B	FOCS	See LINK 09

<sup>1</sup> This LINK 09 model-independent partial-wave analysis of the  $K^- \pi^+$  S-wave slices the  $K^- \pi^+$  mass range into 39 bins.

<sup>2</sup> The BONVICINI 08A QMIPWA (quasi-model-independent partial-wave analysis) of the  $K^- \pi^+$  S-wave amplitude slices the  $K^- \pi^+$  mass range into 26 bins but keeps the Breit-Wigner  $\bar{K}_0^*(1430)^0$ .

<sup>3</sup> This LINK 07B fit uses a K matrix. The  $K^- \pi^+$  S-wave fit fraction given above breaks down into  $(207.3 \pm 25.5 \pm 12.4)\%$  isospin-1/2 and  $(40.5 \pm 9.6 \pm 3.2)\%$  isospin-3/2 — with large interference between the two. The isospin-1/2 component includes the  $\kappa$  (or  $\bar{K}_0^*(800)^0$ ) and  $\bar{K}_0^*(1430)^0$ .

 $\Gamma(\bar{K}_0^*(800)^0 \pi^+, \bar{K}_0^*(800) \rightarrow K^- \pi^+)/\Gamma(K^- 2\pi^+)$   $\Gamma_{42}/\Gamma_{40}$ 

This is the "fit fraction" from the Dalitz-plot analysis.

WEIGHTED AVERAGE  
0.25 ± 0.04 (Error scaled by 2.4) $\Gamma(\pi^+ (\pi^+ \pi^-)_{S\text{-wave}})/\Gamma(2\pi^+ \pi^-)$   $\Gamma_{68}/\Gamma_{66}$ 

This is the "fit fraction" from the Dalitz-plot analysis. See also the next three data blocks.

VALUE	DOCUMENT ID	TECN	COMMENT
<b>0.5600 ± 0.0324 ± 0.0214</b>	1 LINK	04	FOCS Dalitz fit, 1527 ± 51 evts

<sup>1</sup>LINK 04 borrows a K-matrix parametrization from ANISOVICH 03 of the full  $\pi-\pi$  S-wave isoscalar scattering amplitude to describe the  $\pi^+ \pi^-$  S-wave component of the  $\pi^+ \pi^+ \pi^-$  state. The fit fraction given above is a sum over five  $f_0$  mesons, the  $f_0(980)$ ,  $f_0(1300)$ ,  $f_0(1200-1600)$ ,  $f_0(1500)$ , and  $f_0(1750)$ . See LINK 04 for details and discussion.

 $\Gamma(\sigma \pi^+, \sigma \rightarrow \pi^+ \pi^-)/\Gamma(2\pi^+ \pi^-)$   $\Gamma_{69}/\Gamma_{66}$ 

This is the "fit fraction" from the Dalitz-plot analysis.

$D^\pm$

## $D^+-D^-$ T-VIOLATING DECAY-RATE ASYMMETRIES

### $A_{T\text{hol}}(K_S^0 K^\pm \pi^+ \pi^-)$ in $D^\pm \rightarrow K_S^0 K^\pm \pi^+ \pi^-$

$C_T \equiv \bar{p}_{K^+} \cdot (\bar{p}_{\pi^+} \times \bar{p}_{\pi^-})$  is a parity-odd correlation of the  $K^+$ ,  $\pi^+$ , and  $\pi^-$  momenta for the  $D^+$ .  $\bar{C}_T \equiv \bar{p}_{K^-} \cdot (\bar{p}_{\pi^-} \times \bar{p}_{\pi^+})$  is the corresponding quantity for the  $D^-$ . Then  
 $A_T \equiv [\Gamma(C_T > 0) - \Gamma(C_T < 0)] / [\Gamma(C_T > 0) + \Gamma(C_T < 0)]$ , and  
 $\bar{A}_T \equiv [\Gamma(-\bar{C}_T > 0) - \Gamma(-\bar{C}_T < 0)] / [\Gamma(-\bar{C}_T > 0) + \Gamma(-\bar{C}_T < 0)]$ , and  
 $A_{T\text{viol}} \equiv \frac{1}{2}(A_T - \bar{A}_T)$ .  $C_T$  and  $\bar{C}_T$  are commonly referred to as  $T$ -odd moments, because they are odd under  $T$  reversal. However, the  $T$ -conjugate process  $K_S^0 K^\pm \pi^+ \pi^- \rightarrow D^\pm$  is not accessible, while the  $P$ -conjugate process is.

## Meson Particle Listings

 $D^0$ 

enters the fit in the  $D^\pm$  mass, and PERUZZI 77 and SCHINDLER 81 enter in the  $m_{D^\pm} - m_{D^0}$ , below.

<sup>3</sup>Error does not include possible systematic mass scale shift, estimated to be less than 5 MeV.

 $m_{D^\pm} - m_{D^0}$ 

The fit includes  $D^\pm$ ,  $D^0$ ,  $D_s^\pm$ ,  $D^{*\pm}$ ,  $D^{*0}$ ,  $D_s^{*\pm}$ ,  $D_1(2420)^0$ ,  $D_2^*(2460)^0$ , and  $D_{s1}(2536)^\pm$  mass and mass difference measurements.

 $D^0 - \bar{D}^0$  MIXING

Revised May 2014 by D. M. Asner (Pacific Northwest National Laboratory)

The detailed formalism for  $D^0 - \bar{D}^0$  mixing is presented in the note on “ $CP$  Violation in Meson Decays” in this *Review*. For completeness, we present an overview here. The time evolution of the  $D^0 - \bar{D}^0$  system is described by the Schrödinger equation

$$i \frac{\partial}{\partial t} \begin{pmatrix} D^0(t) \\ \bar{D}^0(t) \end{pmatrix} = \left( \mathbf{M} - \frac{i}{2} \mathbf{\Gamma} \right) \begin{pmatrix} D^0(t) \\ \bar{D}^0(t) \end{pmatrix}, \quad (1)$$

where the  $\mathbf{M}$  and  $\mathbf{\Gamma}$  matrices are Hermitian, and  $CPT$  invariance requires that  $M_{11} = M_{22} \equiv M$  and  $\Gamma_{11} = \Gamma_{22} \equiv \Gamma$ . The off-diagonal elements of these matrices describe the dispersive and absorptive parts of the mixing.

Because  $CP$  violation is expected to be quite small here, it is convenient to label the mass eigenstates by the  $CP$  quantum number in the limit of  $CP$  conservation. Thus, we write

$$|D_{1,2}\rangle = p|D^0\rangle \pm q|\bar{D}^0\rangle, \quad (2)$$

where

$$\left( \frac{q}{p} \right)^2 = \frac{M_{12}^* - \frac{i}{2} \Gamma_{12}^*}{M_{12} - \frac{i}{2} \Gamma_{12}}. \quad (3)$$

The normalization condition is  $|p|^2 + |q|^2 = 1$ . Our phase convention is  $CP|D^0\rangle = +|\bar{D}^0\rangle$ , and the sign is chosen so that  $D_1$  has  $CP$  even, or nearly so.

The corresponding eigenvalues are

$$\omega_{1,2} \equiv m_{1,2} - \frac{i}{2} \Gamma_{1,2} = \left( M - \frac{i}{2} \Gamma \right) \pm \frac{q}{p} \left( M_{12} - \frac{i}{2} \Gamma_{12} \right), \quad (4)$$

where  $m_{1,2}$  and  $\Gamma_{1,2}$  are the masses and widths of the  $D_{1,2}$ .

We define dimensionless mixing parameters  $x$  and  $y$  by

$$x \equiv (m_1 - m_2)/\Gamma = \Delta m/\Gamma \quad (5)$$

and

$$y \equiv (\Gamma_1 - \Gamma_2)/2\Gamma = \Delta\Gamma/2\Gamma, \quad (6)$$

where  $\Gamma \equiv (\Gamma_1 + \Gamma_2)/2$ . If  $CP$  is conserved, then  $M_{12}$  and  $\Gamma_{12}$  are real,  $\Delta m = 2M_{12}$ ,  $\Delta\Gamma = 2\Gamma_{12}$ , and  $p = q = 1/\sqrt{2}$ . The signs of  $\Delta m$  and  $\Delta\Gamma$  are to be determined experimentally.

The parameters  $x$  and  $y$  are measured in several ways. The most precise values are obtained using the time dependence of  $D$  decays. Since  $D^0 - \bar{D}^0$  mixing is a small effect, the identifying tag of the initial particle as a  $D^0$  or a  $\bar{D}^0$  must be extremely accurate. The usual tag is the charge of the distinctive slow pion in the decay sequence  $D^{*+} \rightarrow D^0 \pi^+$  or  $D^{*-} \rightarrow \bar{D}^0 \pi^-$ . In current experiments, the probability of mistagging is about 0.1%. The large data samples produced at the  $B$ -factories allow the production flavor to also be determined by fully reconstructing charm on the “other side” of the event—significantly reducing the mistag rate [1]. Another tag of comparable accuracy is identification of one of the  $D$ 's produced from  $\psi(3770) \rightarrow D^0 \bar{D}^0$  decays. Although time-dependent analyses are not possible at symmetric charm-threshold facilities (the  $D^0$  and  $\bar{D}^0$  do not travel far enough), the quantum-coherent  $C = -1$   $\psi(3770) \rightarrow D^0 \bar{D}^0$  state provides time-integrated sensitivity [2,3].

**Time-Dependent Analyses:** We extend the formalism of this *Review*'s note on “ $CP$  Violation in Meson Decays.” In addition to the “right-sign” instantaneous decay amplitudes  $\bar{A}_f \equiv \langle f|H|\bar{D}^0\rangle$  and  $A_{\bar{f}} \equiv \langle \bar{f}|H|D^0\rangle$  for final states  $f = K^+ \pi^-$ , ... and their  $CP$  conjugate  $\bar{f} = K^- \pi^+$ , ..., we include “wrong-sign” amplitudes  $\bar{A}_{\bar{f}} \equiv \langle \bar{f}|H|\bar{D}^0\rangle$  and  $A_f \equiv \langle f|H|D^0\rangle$ .

It is conventional to normalize the wrong-sign decay distributions to the integrated rate of right-sign decays and to express time in units of the precisely measured neutral  $D$ -meson mean lifetime,  $\tau_{D^0} = 1/\Gamma = 2/(\Gamma_1 + \Gamma_2)$ . Starting from a pure  $|D^0\rangle$  or  $|\bar{D}^0\rangle$  state at  $t = 0$ , the time-dependent rates of decay to wrong-sign final states relative to the integrated right-sign decay rates are, to leading order:

$$r(t) \equiv \frac{|\langle f|H|D^0(t)\rangle|^2}{|\bar{A}_f|^2} = \left| \frac{q}{p} \right|^2 \left| g_+(t) \lambda_f^{-1} + g_-(t) \right|^2, \quad (7)$$

and

$$\bar{r}(t) \equiv \frac{|\langle \bar{f}|H|\bar{D}^0(t)\rangle|^2}{|A_{\bar{f}}|^2} = \left| \frac{p}{q} \right|^2 \left| g_+(t) \lambda_{\bar{f}} + g_-(t) \right|^2. \quad (8)$$

where

$$\lambda_f \equiv q \bar{A}_f / p A_f, \quad \lambda_{\bar{f}} \equiv q \bar{A}_{\bar{f}} / p A_{\bar{f}}, \quad (9)$$

and

$$g_{\pm}(t) = \frac{1}{2} (e^{-iz_1 t} \pm e^{-iz_2 t}), \quad z_{1,2} = \frac{\omega_{1,2}}{\Gamma}. \quad (10)$$

Note that a change in the convention for the relative phase of  $D^0$  and  $\bar{D}^0$  would cancel between  $q/p$  and  $\bar{A}_f/A_f$  and leave

$\lambda_f$  unchanged. We expand  $r(t)$  and  $\bar{r}(t)$  to second order in  $x$  and  $y$  for modes in which the ratio of decay amplitudes,  $R_D = |A_f/\bar{A}_f|^2$ , is very small.

**Semileptonic decays:** Consider the final state  $f = K^+\ell^-\bar{\nu}_\ell$ , where  $A_f = \bar{A}_f = 0$  in the Standard Model. The final state  $f$  is only accessible through mixing and  $r(t)$  is

$$r(t) = |g_-(t)|^2 \left| \frac{q}{p} \right|^2 \approx \frac{e^{-t}}{4} (x^2 + y^2) t^2 \left| \frac{q}{p} \right|^2. \quad (11)$$

For  $\bar{r}(t)$   $q/p$  is replaced by  $p/q$ . In the Standard Model,  $CP$  violation in charm mixing is small and  $|q/p| \approx 1$ . In the limit of  $CP$  conservation,  $r(t) = \bar{r}(t)$ , and the time-integrated mixing rate relative to the time-integrated right-sign decay rate for semileptonic decays is

$$R_M = \int_0^\infty r(t) dt = \left| \frac{q}{p} \right|^2 \frac{x^2 + y^2}{2 + x^2 - y^2} \approx \frac{1}{2} (x^2 + y^2). \quad (12)$$

**Table 1:** Results for  $R_M$  in  $D^0$  semileptonic decays.

Year	Exper.	Final state(s)	$R_M (\times 10^{-3})$	90% C.L.
2008	Belle [4]	$K^{(*)+}e^-\bar{\nu}_e$	$0.13 \pm 0.22 \pm 0.20$	$< 0.61 \times 10^{-3}$
2007	BaBar [1]	$K^{(*)+}e^-\bar{\nu}_e$	$0.04^{+0.70}_{-0.60}$	$(-1.3, 1.2) \times 10^{-3}$
2005*	Belle [5]	$K^{(*)+}e^-\bar{\nu}_e$	$0.02 \pm 0.47 \pm 0.14$	$< 1.0 \times 10^{-3}$
2005	CLEO [6]	$K^{(*)+}e^-\bar{\nu}_e$	$1.6 \pm 2.9 \pm 2.9$	$< 7.8 \times 10^{-3}$
2004*	BaBar [7]	$K^{(*)+}e^-\bar{\nu}_e$	$2.3 \pm 1.2 \pm 0.4$	$< 4.2 \times 10^{-3}$
2002*	FOCUS [8]	$K^+\mu^-\bar{\nu}_\mu$	$-0.76^{+0.99}_{-0.93}$	$< 1.01 \times 10^{-3}$
1996	E791 [9]	$K^+\ell^-\bar{\nu}_\ell$	$(1.1^{+3.0}_{-2.7}) \times 10^{-3}$	$< 5.0 \times 10^{-3}$
HFAG [10]			$0.13 \pm 0.27$	

\*These measurements are excluded from the HFAG average. The FOCUS result is unpublished, the statistical correlation of the BaBar result with Ref. 1 has not been established, and the Belle result is superseded by Ref. 4.

Table 1 summarizes results for  $R_M$  from semileptonic decays; the world average from the Heavy Flavor Averaging Group (HFAG) [10] is  $R_M = (1.30 \pm 2.69) \times 10^{-4}$ .

**Wrong-sign decays to hadronic non- $CP$  eigenstates:** Consider the final state  $f = K^+\pi^-$ , where  $A_f$  is doubly Cabibbo-suppressed. The ratio of decay amplitudes is

$$\frac{A_f}{\bar{A}_f} = -\sqrt{R_D} e^{-i\delta_f}, \quad \left| \frac{A_f}{\bar{A}_f} \right| \sim O(\tan^2 \theta_c), \quad (13)$$

where  $R_D$  is the doubly Cabibbo-suppressed (DCS) decay rate relative to the Cabibbo-favored (CF) rate,  $\delta_f$  is the strong phase difference between DCS and CF processes, and  $\theta_c$  is the Cabibbo angle. The minus sign originates from the sign of  $V_{us}$  relative to  $V_{cd}$ .

We characterize the violation of  $CP$  with the real-valued parameters  $A_M$ ,  $A_D$ , and  $\phi$ . We adopt the parametrization (see Refs. 11 and 12)

$$\left| \frac{q}{p} \right|^2 = \sqrt{\frac{1 + A_M}{1 - A_M}}, \quad (14)$$

$$\lambda_f^{-1} \equiv \frac{pA_f}{q\bar{A}_f} = -\sqrt{R_D} \left( \frac{(1 + A_D)(1 - A_M)}{(1 - A_D)(1 + A_M)} \right)^{1/4} e^{-i(\delta_f + \phi)}, \quad (15)$$

$$\lambda_{\bar{f}} \equiv \frac{q\bar{A}_{\bar{f}}}{pA_{\bar{f}}} = -\sqrt{R_D} \left( \frac{(1 - A_D)(1 + A_M)}{(1 + A_D)(1 - A_M)} \right)^{1/4} e^{-i(\delta_f - \phi)}, \quad (16)$$

and  $A_D$  is a measure of direct  $CP$  violation, while  $A_M$  is a measure of  $CP$  violation in mixing. From these relations, we obtain

$$\sqrt{\frac{1 + A_D}{1 - A_D}} = \frac{|A_f/\bar{A}_f|}{|\bar{A}_{\bar{f}}/A_{\bar{f}}|}, \quad (17)$$

The angle  $\phi$  measures  $CP$  violation in interference between mixing and decay. While  $A_M$  is independent of the decay process,  $A_D$  and  $\phi$ , in general, depend on  $f$ .

In general,  $\lambda_{\bar{f}}$  and  $\lambda_f^{-1}$  are independent complex numbers. More detail on  $CP$  violation in meson decays can be found in Ref. 13. To leading order, for  $A_D$  and  $A_M \ll 1$ ,

$$r(t) = e^{-t} \left[ R_D(1 + A_D) + \sqrt{R_D(1 + A_M)(1 + A_D)} y'_- t + \frac{1}{2}(1 + A_M)R_M t^2 \right] \quad (18)$$

and

$$\bar{r}(t) = e^{-t} \left[ R_D(1 - A_D) + \sqrt{R_D(1 - A_M)(1 - A_D)} y'_+ t + \frac{1}{2}(1 - A_M)R_M t^2 \right] \quad (19)$$

Here

$$y'_\pm \equiv y' \cos \phi \pm x' \sin \phi = y \cos(\delta_{K\pi} \mp \phi) - x \sin(\delta_{K\pi} \mp \phi), \quad (20)$$

where

$$x' \equiv x \cos \delta_{K\pi} + y \sin \delta_{K\pi}, \quad y' \equiv y \cos \delta_{K\pi} - x \sin \delta_{K\pi}, \quad (21)$$

and  $R_M = (x^2 + y^2)/2 = (x'^2 + y'^2)/2$  is the mixing rate relative to the time-integrated Cabibbo-favored rate.

The three terms in Eq. (18) and Eq. (19) probe the three fundamental types of  $CP$  violation. In the limit of  $CP$  conservation,  $A_M$ ,  $A_D$ , and  $\phi$  are all zero. Then

$$r(t) = \bar{r}(t) = e^{-t} \left( R_D + \sqrt{R_D} y' t + \frac{1}{2} R_M t^2 \right), \quad (22)$$

and the time-integrated wrong-sign rate relative to the integrated right-sign rate is

$$R = \int_0^\infty r(t) dt = R_D + \sqrt{R_D} y' + R_M. \quad (23)$$

The ratio  $R$  is the most readily accessible experimental quantity. In Table 2 are reported the measurements of  $R$ ,  $R_D$  and  $A_D$  in  $D^0 \rightarrow K^+\pi^-$ , and their HFAG average [24] from a general fit; that allows for both mixing and  $CP$  violation. Typically, the fit parameters are  $R_D$ ,  $x'^2$ , and  $y'$ . Table 3 summarizes the results for  $x'^2$  and  $y'$ . Allowing for  $CP$  violation, the separate contributions to  $R$  can be extracted by fitting the  $D^0 \rightarrow K^+\pi^-$  and  $\bar{D}^0 \rightarrow K^-\pi^+$  decay rates.

## Meson Particle Listings

 $D^0$ **Table 2:** Results for  $R$ ,  $R_D$ , and  $A_D$  in  $D^0 \rightarrow K^+\pi^-$ .

Year	Exper.	$R(\times 10^{-3})$	$R_D(\times 10^{-3})$	$A_D(\%)$
2014	Belle [14]	$3.86 \pm 0.06$	$3.53 \pm 0.13$	—

2006†	Belle [20]	$-2.8 < y' < 2.1$	$< 0.72$ (95% C.L.)
2005*	FOCUS [21]	$-11.2 < y' < 6.7$	$< 8.0$ (95% C.L.)
2000*	CLEO [22]	$-5.8 < y' < 1.0$	$< 0.81$ (95% C.L.)

\*These measurements are excluded from the HFAG average. The CDF result is superseded by Ref. 16 and the LHCb result has been superseded by Ref. 15. The CLEO and FOCUS results are excluded due to poor precision.

† This Belle result allows for  $CP$  violation. HFAG uses this result for the  $CP$ -violation allowed fit. This result is not superseded by Ref. 14.

\*† This Belle result does not allow for  $CP$  violation. HFAG uses this result for the  $CP$ -conserving fit. This result does not supersede Ref. 20.

Extraction of the mixing parameters  $x$  and  $y$  from the results in Table 3 requires knowledge of the relative strong phase

$\delta_{K\pi}$ . An interference effect that provides useful sensitivity to  $\delta_{K\pi}$  arises in the decay chain  $\psi(3770) \rightarrow D^0 \bar{D}^0 \rightarrow (f_{CP})(K^+\pi^-)$ , where  $f_{CP}$  denotes a  $CP$ -even or -odd eigenstate from  $D^0$  decay, such as  $K^+K^-$  or  $K_S^0\pi^0$ , respectively [27]. Here, the amplitude relation

$$\sqrt{2} A(D_{\pm} \rightarrow K^-\pi^+) = A(D^0 \rightarrow K^-\pi^+) \pm A(\bar{D}^0 \rightarrow K^-\pi^+). \quad (24)$$

where  $D_{\pm}$  denotes a  $CP$ -even or -odd eigenstate, implies that

$$\cos \delta_{K\pi} = \frac{|A(D_+ \rightarrow K^-\pi^+)|^2 - |A(D_- \rightarrow K^-\pi^+)|^2}{2\sqrt{R_D} |A(D^0 \rightarrow K^-\pi^+)|^2}. \quad (25)$$

This neglects  $CP$  violation and uses  $\sqrt{R_D} \ll 1$ .

For multibody final states, Eqs. (13)–(23) apply separately to each point in phase-space. Although  $x$  and  $y$  do not vary across the space, knowledge of the resonant substructure is needed to extrapolate the strong phase difference  $\delta$  from point to point to determine  $x$  and  $y$ .

A time-dependent analysis of the process  $D^0 \rightarrow K^+\pi^-\pi^0$  from BaBar [25,26] determines the *relative* strong phase variation across the Dalitz plot and reports  $x'' = (2.61^{+0.57}_{-0.68} \pm 0.39)\%$ , and  $y'' = (-0.06^{+0.55}_{-0.64} \pm 0.34)\%$ , where  $x''$  and  $y''$  are defined as

$$\begin{aligned} x'' &\equiv x \cos \delta_{K\pi\pi^0} + y \sin \delta_{K\pi\pi^0}, \\ y'' &\equiv y \cos \delta_{K\pi\pi^0} - x \sin \delta_{K\pi\pi^0}, \end{aligned} \quad (26)$$

in parallel to  $x'$ ,  $y'$ , and  $\delta_{K\pi}$  of Eq. (21). Here  $\delta_{K\pi\pi^0}$  is the remaining strong phase difference between the DCS  $D^0 \rightarrow K^+\rho^-$  and the CF  $\bar{D}^0 \rightarrow K^+\rho^-$  amplitudes and does not vary across the Dalitz plot. Both strong phases,  $\delta_{K\pi}$  and  $\delta_{K\pi\pi^0}$ , can be determined from time-integrated  $CP$  asymmetries in correlated  $D^0 \bar{D}^0$  produced at the  $\psi(3770)$  [27,28].

Both the sign and magnitude of  $x$  and  $y$  without phase or sign ambiguity may be measured using the time-dependent resonant substructure of multibody  $D^0$  decays [29,30]. In  $D^0 \rightarrow K_S^0\pi^+\pi^-$ , the DCS and CF decay amplitudes populate the same Dalitz plot, which allows direct measurement of the relative strong phases. CLEO [31], Belle [30], and BaBar [32] have measured the relative phase between  $D^0 \rightarrow K^*(892)^-\pi^+$  and  $D^0 \rightarrow K^*(892)^+\pi^-$  to be  $(189 \pm 10 \pm 3^{+15}_-5)^\circ$ ,  $(171.9 \pm 1.3$  (stat. only) $^\circ$ , and  $(177.6 \pm 1.1$  (stat. only) $^\circ$ , respectively. These results are close to the  $180^\circ$  expected from Cabibbo factors and a small strong phase. Table 4 summarizes the results of a time-dependent Dalitz-plot analyses.

In addition, Belle [30] has results for both the relative phase (statistical errors only) and ratio  $R$  (central values only) of the DCS fit fraction relative to the CF fit fractions for  $K^*(892)^+\pi^-$ ,  $K_0^*(1430)^+\pi^-$ ,  $K_2^*(1430)^+\pi^-$ ,  $K^*(1410)^+\pi^-$ , and  $K^*(1680)^+\pi^-$ . The systematic uncertainties on  $R$  must be evaluated. The values for  $R$  in units of  $\tan^4 \theta_c$  are  $2.94 \pm 0.12$ ,  $22.0 \pm 1.6$ ,  $34 \pm 4$ ,  $87 \pm 13$ , and  $500 \pm 500$ , respectively. For  $K^+\pi^-$ , the corresponding value for  $R_D$  is  $(1.28 \pm 0.02) \times \tan^4 \theta_c$ . Similarly, BaBar [32–35] has reported central values for  $R$  for

**Table 4:** Results from time-dependent Dalitz-plot analysis of  $D^0 \rightarrow K_S^0 \pi^+ \pi^-$  (CLEO and Belle) and  $D^0 \rightarrow K_S^0 \pi^+ \pi^-, K_S^0 K^+ K^-$  (BaBar). The errors are statistical, experimental systematic, and decay-model systematic, respectively.

No $CP$ Violation			
Year	Exper.	$x \times 10^{-3}$	$y \times 10^{-3}$
2010	BaBar [32]	$1.6 \pm 2.3 \pm 1.2 \pm 0.8$	$5.7 \pm 2.0 \pm 1.3 \pm 0.7$
2007	Belle [30]	$8.0 \pm 2.9^{+0.9+1.0}_{-0.7-1.4}$	$3.3 \pm 2.4^{+0.8+0.6}_{-1.2-0.8}$
2005	CLEO [29]	$19^{+32}_{-33} \pm 4 \pm 4$	$-14 \pm 24 \pm 8 \pm 4$
HFAG [33]		$4.2 \pm 2.1$	$4.6 \pm 1.9$
With $CP$ Violation			
Year	Exper.	$ q/p $	$\phi$
2007	Belle [30]	$0.86^{+0.30+0.06}_{-0.29-0.03} \pm 0.08$	$(-14^{+16+5+2}_{-18-3-4})^\circ$

$K^*(892)^+ \pi^-$ ,  $K_0^*(1430)^+ \pi^-$ , and  $K_2^*(1430)^+ \pi^-$ . The large differences in  $R$  among these final states could point to an interesting role for hadronic effects.

**Decays to  $CP$  Eigenstates:** When the final state  $f$  is a  $CP$  eigenstate, there is no distinction between  $f$  and  $\bar{f}$ , and  $A_f = A_{\bar{f}}$  and  $\bar{A}_{\bar{f}} = \bar{A}_f$ . We denote final states with  $CP$  eigenvalues  $\pm 1$  by  $f_\pm$  and write  $\lambda_\pm$  for  $\lambda_{f_\pm}$ .

The quantity  $y$  may be measured by comparing the rate for  $D^0$  decays to non- $CP$  eigenstates such as  $K^- \pi^+$  with decays to  $CP$  eigenstates such as  $K^+ K^-$  [12]. If decays to  $K^+ K^-$  have a shorter effective lifetime than those to  $K^- \pi^+$ ,  $y$  is positive.

In the limit of slow mixing ( $x, y \ll 1$ ) and the absence of direct  $CP$  violation ( $A_D = 0$ ), but allowing for small indirect  $CP$  violation ( $|A_M|, |\phi| \ll 1$ ), we can write

$$\lambda_\pm = \left| \frac{q}{p} \right| e^{\pm i\phi}. \quad (27)$$

In this scenario, to a good approximation, the decay rates for states that are initially  $D^0$  and  $\bar{D}^0$  to a  $CP$  eigenstate have exponential time dependence:

$$r_\pm(t) \propto \exp(-t/\tau_\pm), \quad (28)$$

$$\bar{r}_\pm(t) \propto \exp(-t/\bar{\tau}_\pm), \quad (29)$$

where  $\tau$  is measured in units of  $1/\Gamma$ .

The effective lifetimes are given by

$$1/\tau_\pm = 1 \pm \left| \frac{q}{p} \right| (y \cos \phi - x \sin \phi), \quad (30)$$

$$1/\bar{\tau}_\pm = 1 \pm \left| \frac{p}{q} \right| (y \cos \phi + x \sin \phi). \quad (31)$$

The effective decay rate to a  $CP$  eigenstate combining both  $D^0$  and  $\bar{D}^0$  decays is

$$r_\pm(t) + \bar{r}_\pm(t) \propto e^{-(1 \pm y_{CP})t}. \quad (32)$$

\*This measurement is included in the result reported by Ref. 38 and excluded from the HFAG average.

†This measurement is included in the result reported by Ref. 37.

\*† This measurement is unpublished and excluded from the HFAG average.

Here

$$y_{CP} = \frac{1}{2} \left( \left| \frac{q}{p} \right| + \left| \frac{p}{q} \right| \right) y \cos \phi - \frac{1}{2} \left( \left| \frac{q}{p} \right| - \left| \frac{p}{q} \right| \right) x \sin \phi \quad (33)$$

$$\approx y \cos \phi - A_M x \sin \phi. \quad (34)$$

If  $CP$  is conserved,  $y_{CP} = y$ .

All measurements of  $y_{CP}$  are relative to the  $D^0 \rightarrow K^- \pi^+$  decay rate. Table 5 summarizes the current status of measurements. Belle [37], BaBar [38], and LHCb [39] have reported  $y_{CP}$  and the decay-rate asymmetry for  $CP$  even final states (assuming  $A_D = 0$ )

$$A_\Gamma = \frac{\bar{\tau}_+ - \tau_+}{\bar{\tau}_+ + \tau_+} = \frac{(1/\tau_+) - (1/\bar{\tau}_+)}{(1/\tau_+) + (1/\bar{\tau}_+)} \quad (35)$$

$$= \frac{1}{2} \left( \left| \frac{q}{p} \right| - \left| \frac{p}{q} \right| \right) y \cos \phi - \frac{1}{2} \left( \left| \frac{q}{p} \right| + \left| \frac{p}{q} \right| \right) x \sin \phi \quad (36)$$

$$\approx A_M y \cos \phi - x \sin \phi. \quad (37)$$

Belle [41] has also reported  $y_{CP}$  for the final state  $K_S^0 K^+ K^-$  which is dominated by the  $CP$  odd final state  $K_S^0 \phi$ . If  $CP$  is conserved,  $A_\Gamma = 0$ .

Substantial work on the time-integrated  $CP$  asymmetries in decays to  $CP$  eigenstates are summarized in this *Review* [49]. Table 6 summarizes the current status of measurements of the difference in time-integrated  $CP$  asymmetry,  $\Delta A_{CP} = A_{K^-} - A_{\pi^-}$ , between  $D^0 \rightarrow K^- K^+$  and  $D^0 \rightarrow \pi^- \pi^+$ . The HFAG fit is marginally consistent with no  $CP$  violation at the 0.3183% Confidence Level (2.95 $\sigma$ ) [24].

## Meson Particle Listings

**Coherent  $D^0\bar{D}^0$  Analyses:** Measurements of  $R_D$ ,  $\cos\delta_{K\pi}$ ,  $\sin\delta_{K\pi}$ ,  $x$ , and  $y$  can be determined simultaneously from a combined fit to the time-integrated single-tag (ST) and double-tag (DT) yields in correlated  $D^0\bar{D}^0$  produced at the  $\psi(3770)$  [27,28].

Due to quantum correlations in the  $C = -1$  and  $C = +1$   $D^0\bar{D}^0$  pairs produced in the reactions  $e^+e^- \rightarrow D^0\bar{D}^0(\pi^0)$  and  $e^+e^- \rightarrow D^0\bar{D}^0\gamma(\pi^0)$ , respectively, the time-integrated  $D^0\bar{D}^0$  decay rates are sensitive to interference between amplitudes for indistinguishable final states. The size of this interference is governed by the relevant amplitude ratios and can include contributions from  $D^0-\bar{D}^0$  mixing.

The following categories of final states are considered:

**$f$  or  $\bar{f}$ :** Hadronic states accessed from either  $D^0$  or  $\bar{D}^0$  decay but that are not  $CP$  eigenstates. An example is  $K^-\pi^+$ , which results from Cabibbo-favored  $D^0$  transitions or DCS  $\bar{D}^0$  transitions.

**$\ell^+$  or  $\ell^-$ :** Semileptonic or purely leptonic final states, which, in the absence of mixing, tag unambiguously the flavor of the parent  $D^0$ .

**$f_+$  or  $f_-$ :**  $CP$ -even and  $CP$ -odd eigenstates, respectively.

The decay rates for  $D^0\bar{D}^0$  pairs to all possible combinations of the above categories of final states are calculated in Ref. 2, for both  $C = -1$  and  $C = +1$ , reproducing the work of Ref. 3. Such  $D^0\bar{D}^0$  combinations, where both  $D$  final states are specified, are double tags. In addition, the rates for single tags, where either the  $D^0$  or  $\bar{D}^0$  is identified and the other neutral  $D$  decays generically are given in Ref. 2.

CLEO-c has reported results using 818 pb $^{-1}$  of  $e^+e^- \rightarrow \psi(3770)$  data [56–58], where the quantum-coherent  $D^0\bar{D}^0$  pairs are in the  $C = -1$  state. The values of  $y$ ,  $R_M$ ,  $\cos\delta_{K\pi}$ , and  $\sin\delta_{K\pi}$  are determined from a combined fit to the ST (hadronic only) and DT yields. The hadronic final states included are  $K^-\pi^+$  ( $f$ ),  $K^+\pi^-$  ( $\bar{f}$ ),  $K^-K^+$  ( $f_+$ ),  $\pi^+\pi^-$  ( $f_+$ ),  $K_S^0\pi^0\pi^0$  ( $f_+$ ),  $K_L^0\pi^0$  ( $f_+$ ),  $K_L^0\eta$  ( $f_+$ ),  $K_L^0\omega$  ( $f_+$ ),  $K_S^0\pi^0$  ( $f_-$ ),  $K_S^0\eta$  ( $f_-$ ),  $K_S^0\omega$  ( $f_-$ ), and  $K_L^0\pi^0\pi^0$  ( $f_-$ ), and  $K_S^0\pi^+\pi^-$  (mixture of  $f, \bar{f}, f_+$ , and  $f_-$ ). The two flavored final states,  $K^-\pi^+$  and  $K^+\pi^-$ , can be reached via CF or DCS transitions.

Semileptonic DT yields are also included, where one  $D$  is fully reconstructed in one of the hadronic modes listed above, and the other  $D$  is partially reconstructed in either  $D \rightarrow Ke\nu$  or  $D \rightarrow K\mu\nu$ . When the lepton is accompanied by a flavor tag ( $D \rightarrow K^-\pi^+$  or  $K^+\pi^-$ ), both the “right-sign” and “wrong-sign” DT samples are used, where the electron and kaon charges are the same and opposite, respectively.

The main results of the CLEO-c analysis are the determination of  $\cos\delta_{K\pi} = 0.81_{-0.18-0.05}^{+0.22+0.07}$ ,  $\sin\delta_{K\pi} = -0.01 \pm 0.49 \pm 0.04$ , and World Averages for the mixing parameters from an “extended” fit that combines the CLEO-c data with previous mixing and branching-ratio measurements [58]. These fits allow  $\cos\delta_{K\pi}$ ,  $\sin\delta_{K\pi}$  and  $x^2$  to be unphysical. Constraining  $\cos\delta_{K\pi}$  and  $\sin\delta_{K\pi}$  to  $[-1, +1]$ —that is interpreting  $\delta_{K\pi}$  as an angle—yields  $\delta_{K\pi} = (18_{-17}^{+11} \pm 7)^\circ$ . Note that measurements of  $y$  (Table 4 and Table 5) and  $y'$  (Table 3) contribute to the determination of  $\delta_{K\pi}$ .

**Summary of Experimental Results:** Several recent results indicate that charm mixing is at the upper end of the range of Standard Model estimates.

For  $D^0 \rightarrow K^+\pi^-$ , LHCb [15,17], CDF [16], and Belle [14] each exclude the no-mixing hypothesis by more than 5 standard deviations.

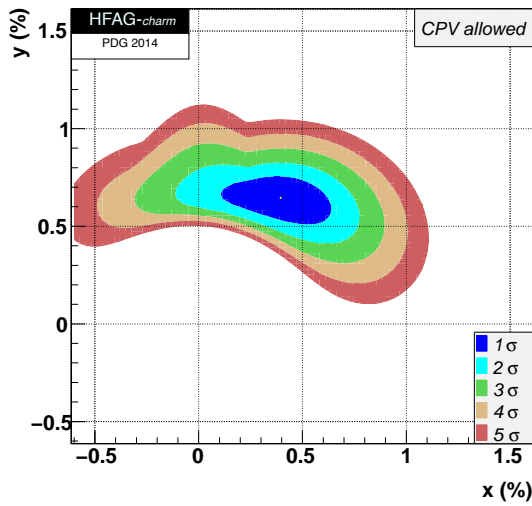

For  $y_{CP}$  in  $D^0 \rightarrow K^+K^-$  and  $\pi^+\pi^-$ , Belle [37] and BaBar [38] find  $4.5\sigma$  and  $3.3\sigma$  effects. The most sensitive measurement of  $x$  and  $y$  is in  $D^0 \rightarrow K_S^0\pi^+\pi^-, K_S^0K^+K^-$  from BaBar [32] and the no mixing solution is only excluded at  $1.9\sigma$ . In a similar analysis, Belle [30] also finds a  $2.4\sigma$  result for  $x$ .

The current situation would benefit from better knowledge of the strong phase difference  $\delta_{K\pi}$  than provided by the current CLEO-c result [58]. This would allow one to unfold  $x$  and  $y$  from the  $D^0 \rightarrow K^+\pi^-$  measurements of  $x'^2$  and  $y'$ , and directly compare them to the  $D^0 \rightarrow K_S^0\pi^+\pi^-$  results.

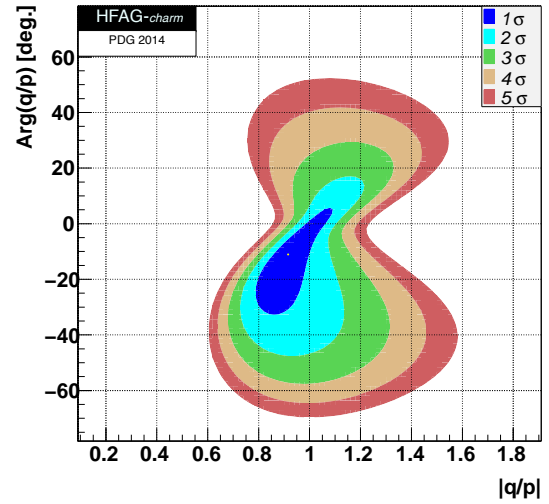

The experimental data consistently indicate that the  $D^0$  and  $\bar{D}^0$  do mix. The mixing is presumably dominated by long-range processes. Under the assumption that the observed mixing is due entirely to non-Standard Model processes, significant constraints on a variety of new physics models are obtained [59]. A serious limitation to the interpretation of charm oscillations in terms of New Physics is the theoretical uncertainty of the Standard Model prediction. The evidence for time integrated  $CP$ -violation,  $\Delta A_{CP} \neq 0$  is intriguing. This result is marginally consistent with Standard Model expectation [60–62].

**HFAG Averaging of Charm Mixing Results:**

The Heavy Flavor Averaging Group (HFAG) has made a global fit to all mixing measurements to obtain values of  $x$ ,  $y$ ,  $\delta_{K\pi}$ ,  $\delta_{K\pi\pi^0}$ ,  $R_D$ ,  $A_D \equiv (R_D^+ - R_D^-)/(R_D^+ + R_D^-)$ ,  $|q/p|$ ,  $\text{Arg}(q/p) \equiv \phi$ , and the time-integrated  $CP$  asymmetries  $A_K$  and  $A_\pi$ . Correlations among observables are taken into account by using the error matrices from the experiments. The measurements of  $D^0 \rightarrow K^{(*)\ell}\bar{\nu}$ ,  $K^+K^-$ ,  $\pi^+\pi^-$ ,  $K^+\pi^-$ ,  $K^+\pi^-\pi^0$ ,  $K^+\pi^-\pi^+\pi^-$ ,  $K_S^0\pi^+\pi^-$ , and  $K_S^0K^+K^-$  decays, as well as CLEO-c results for double-tagged branching fractions measured at the  $\psi(3770)$  are used.

**Figure 1:** Two-dimensional  $1\sigma$ - $5\sigma$  contours for  $(x, y)$  from measurements of  $D^0 \rightarrow K^{(*)+}\ell\nu, h^+h^-, K^+\pi^-, K^+\pi^-\pi^0, K^+\pi^-\pi^+\pi^-, K_S^0\pi^+\pi^-,$  and  $K_S^0K^+K^-$  decays, and double-tagged branching fractions measured at the  $\psi(3770)$  resonance (from HFAG [24]).

**Figure 2:** Two-dimensional  $1\sigma$ - $5\sigma$  contours for  $(|q/p|, \text{Arg}(q/p))$  from measurements of  $D^0 \rightarrow K^{(*)+}\ell\nu, h^+h^-, K^+\pi^-, K^+\pi^-\pi^0, K^+\pi^-\pi^+\pi^-, K_S^0\pi^+\pi^-,$  and  $K_S^0K^+K^-$  decays, and double-tagged branching fractions measured at the  $\psi(3770)$  resonance (from HFAG [24]).

**Table 7:** HFAG Charm Mixing Averages [24].

Parameter	No $CP$	$CP$ Violation	95% C.L. Interval
	Violation	Allowed	
$x(\%)$	$0.53^{+0.16}_{-0.17}$	$0.39^{+0.17}_{-0.18}$	[0.007, 0.803]
$y(\%)$	$0.63 \pm 0.09$	$0.65^{+0.07}_{-0.09}$	[0.464, 0.788]
$R_D(\%)$	$0.350 \pm 0.004$	$0.349 \pm 0.004$	[0.342, 0.357]
$\delta_{K\pi}(\circ)$	$10.0^{+10.0}_{-11.3}$	$9.3^{+10.0}_{-12.0}$	[-17.8, 28.2]
$\delta_{K\pi\pi^0}(\circ)$	$17.4^{+23.2}_{-23.8}$	$25.4^{+25.0}_{-25.1}$	[-24.2, 75.3]
$A_D(\%)$	—	$-0.90 \pm 1.00$	[-2.95, 1.02]
$ q/p $	—	$0.92^{+0.12}_{-0.09}$	[0.76, 1.15]
$\phi(\circ)$	—	$-11.1^{+11.4}_{-13.5}$	[-40.0, 10.9]
$A_K$	—	$-0.14 \pm 0.14$	[-0.41, 0.13]
$A_\pi$	—	$0.19 \pm 0.15$	[-0.11, 0.49]

For the global fit, confidence contours in the two dimensions  $(x, y)$  and  $(|q/p|, \phi)$  are obtained by letting, for any point in the two-dimensional plane, all other fit parameters take their preferred values. Figures 1 and 2 show the resulting 1-to-5  $\sigma$  contours. The fits exclude the no-mixing point ( $x = y = 0$ ) at more than  $12\sigma$ , when  $CP$  violation is allowed. The fits are consistent with no  $CP$  violation at the 50% Confidence Level. The parameters  $x$  and  $y$  differ from zero by  $1.7\sigma$  and  $6.1\sigma$ , respectively. One-dimensional likelihood functions for parameters are obtained by allowing, for any value of the parameter, all other fit parameters to take their preferred values. The resulting likelihood functions give central values, 68.3% C.L. intervals, and 95% C.L. intervals as listed in Table 7.

From the results of the HFAG averaging, the following can be concluded: (1) Since  $CP$  violation is small and  $y_{CP}$  is

positive, the  $CP$ -even state is shorter-lived, as in the  $K^0\bar{K}^0$  system; (2) However, since  $x$  appears to be positive, the  $CP$ -even state is heavier, unlike in the  $K^0\bar{K}^0$  system; (3) The strong phase difference  $\delta_{K\pi}$  is consistent with the SU(3) expectation of zero but large values are not excluded; (4) There is no evidence yet for  $CP$ -violation in  $D^0\bar{D}^0$  mixing. Observing  $CP$ -violation in mixing ( $|q/p| \neq 1$ ) at the current level of sensitivity would indicate new physics.

The author would like to acknowledge helpful input from Bostjan Golob, Marco Gersabeck, and especially Alan Schwartz of the Heavy Flavor Averaging Group.

$$|m_{D_1^0} - m_{D_2^0}| = x \Gamma$$

The  $D_1^0$  and  $D_2^0$  are the mass eigenstates of the  $D^0$  meson, as described in the note on “ $D^0$ - $\bar{D}^0$  Mixing,” above. The experiments usually present  $x \equiv \Delta m/\Gamma$ . Then  $\Delta m = x \Gamma = x \hbar/\tau$ .

“OUR EVALUATION” comes from CPV allowing averages provided by the Heavy Flavor Averaging Group, see the note on “ $D^0$ - $\bar{D}^0$  Mixing.”

<sup>1</sup>Based on  $976 \text{ fb}^{-1}$  of data collected at  $Y(nS)$  resonances. Assumes no *CP* violation. Reported  $x'^2 = (0.09 \pm 0.22) \times 10^{-3}$  and  $y' = (4.6 \pm 3.4) \times 10^{-3}$ , where  $x' = x \cos(\delta) + y \sin(\delta)$ ,  $y' = y \cos(\delta) - x \sin(\delta)$  and  $\delta$  is the strong phase between  $D^0 \rightarrow K^+\pi^-$  and  $\bar{D}^0 \rightarrow K^+\pi^-$ .

<sup>2</sup>Based on  $3 \text{ fb}^{-1}$  of data collected at  $\sqrt{s} = 7, 8 \text{ TeV}$ . Assumes no *CP* violation. Reported  $x'^2 = (5.5 \pm 4.9) \times 10^{-4}$  and  $y' = (4.8 \pm 1.0) \times 10^{-3}$ , where  $x' = x \cos(\delta) + y \sin(\delta)$ ,  $y' = y \cos(\delta) - x \sin(\delta)$  and  $\delta$  is the strong phase between the  $D^0 \rightarrow K^+\pi^-$  and  $\bar{D}^0 \rightarrow K^+\pi^-$ .

<sup>3</sup>Based on  $9.6 \text{ fb}^{-1}$  of data collected at the Tevatron. Assumes no *CP* violation. Reported  $x'^2 = (0.08 \pm 0.18) \times 10^{-3}$  and  $y' = (4.3 \pm 4.3) \times 10^{-3}$ , where  $x' = x \cos(\delta) + y \sin(\delta)$ ,  $y' = y \cos(\delta) - x \sin(\delta)$  and  $\delta$  is the strong phase between the  $D^0 \rightarrow K^+\pi^-$  and  $\bar{D}^0 \rightarrow K^+\pi^-$ .

<sup>4</sup>DEL-AMO-SANCHEZ 10D uses  $540,800 \pm 800 K_S^0 \pi^+ \pi^-$  and  $79,900 \pm 300 K_S^0 K^+ K^-$  events in a time-dependent amplitude analysis of the  $D^0$  and  $\bar{D}^0$  Dalitz plots. No evidence was found for *CP* violation, and the values here assume no such violation.

<sup>5</sup>The ASNER 05 and ZHANG 07B values are from the time-dependent Dalitz-plot analysis of  $D^0 \rightarrow K_S^0 \pi^+ \pi^-$ . Decay-time information and interference on the Dalitz plot are used to distinguish doubly Cabibbo-suppressed decays from mixing and to measure the relative phase between  $D^0 \rightarrow K^* \pi^-$  and  $\bar{D}^0 \rightarrow K^* \pi^-$ . This value allows *CP* violation and is sensitive to the sign of  $\Delta m$ .

<sup>6</sup>Based on  $1 \text{ fb}^{-1}$  of data collected at  $\sqrt{s} = 7 \text{ TeV}$  in 2011. Assumes no *CP* violation. Reported  $x'^2 = (-0.9 \pm 1.3) \times 10^{-4}$  and  $y' = (7.2 \pm 2.4) \times 10^{-3}$ , where  $x' = x \cos(\delta) + y \sin(\delta)$ ,  $y' = y \cos(\delta) - x \sin(\delta)$  and  $\delta$  is the strong phase between the  $D^0 \rightarrow K^+\pi^-$  and  $\bar{D}^0 \rightarrow K^+\pi^-$ .

<sup>7</sup>The AUBERT 09AN values are inferred from the branching ratio  $\Gamma(D^0 \rightarrow K^+\pi^-\pi^0 \text{ via } \bar{D}^0)/\Gamma(D^0 \rightarrow K^-\pi^+\pi^0)$  given near the end of this Listings. Mixing is distinguished from DCS decays using decay-time information. Interference between mixing and DCS is allowed. The phase between  $D^0 \rightarrow K^+\pi^-\pi^0$  and  $\bar{D}^0 \rightarrow K^+\pi^-\pi^0$  is assumed to be small. The width difference here is  $y''$ , which is not the same as  $y_{CP}$  in the note on  $D^0$ - $\bar{D}^0$  mixing.

<sup>8</sup>LOWREY 09 uses quantum correlations in  $e^+e^- \rightarrow D^0\bar{D}^0$  at the  $\psi(3770)$ . See below for coherence factors and average relative strong phases for both  $D^0 \rightarrow K^-\pi^+\pi^0$  and  $D^0 \rightarrow K^-\pi^-\pi^+$ . A fit that includes external measurements of charm mixing parameters gets  $\Delta m = (2.34 \pm 0.61) \times 10^{10} \hbar s^{-1}$ .

<sup>9</sup>The AUBERT 03Z, LI 05A, and ZHANG 06 limits are inferred from the  $D^0$ - $\bar{D}^0$  mixing ratio  $\Gamma(K^+\pi^-\pi^0)/\Gamma(K^-\pi^+\pi^0)$  given near the end of this  $D^0$  Listings. Decay-time information is used to distinguish DCS decays from  $D^0$ - $\bar{D}^0$  mixing. The limit allows interference between the DCS and mixing ratios, and also allows *CP* violation. AUBERT 03Z assumes the strong phase between  $D^0 \rightarrow K^+\pi^-$  and  $\bar{D}^0 \rightarrow K^+\pi^-$ .

- amplitudes is small; if an arbitrary phase is allowed, the limit degrades by 20%. The LI 05A and ZHANG 06 limits are valid for an arbitrary strong phase.
- <sup>10</sup>This LINK 05H limit is inferred from the  $D^0\text{-}\bar{D}^0$  mixing ratio  $\Gamma(K^+\pi^-)$  (via  $\bar{D}^0$ )/ $\Gamma(K^-\pi^+)$  given near the end of this  $D^0$  Listings. Decay-time information is used to distinguish DCS decays from  $D^0\text{-}\bar{D}^0$  mixing. The limit allows interference between the DCS and mixing ratios, and also allows  $CP$  violation. The strong phase between  $D^0 \rightarrow K^+\pi^-$  and  $\bar{D}^0 \rightarrow K^+\pi^-$  is assumed to be small. If an arbitrary relative strong phase is allowed, the limit degrades by 25%.
- <sup>11</sup>This GODANG 00 limit is inferred from the  $D^0\text{-}\bar{D}^0$  mixing ratio  $\Gamma(K^+\pi^-)$  (via  $\bar{D}^0$ )/ $\Gamma(K^-\pi^+)$  given near the end of this  $D^0$  Listings. Decay-time information is used to distinguish DCS decays from  $D^0\text{-}\bar{D}^0$  mixing. The limit allows interference between the DCS and mixing ratios, and also allows  $CP$  violation. The strong phase between  $D^0 \rightarrow K^+\pi^-$  and  $\bar{D}^0 \rightarrow K^+\pi^-$  is assumed to be small. If an arbitrary relative strong phase is allowed, the limit degrades by a factor of two.
- <sup>12</sup>AITALA 98 allows interference between the doubly Cabibbo-suppressed and mixing amplitudes, and also allows  $CP$  violation in this term, but assumes that  $A_{D^0} = A_{\bar{D}^0} = 0$ . See the note on " $D^0\text{-}\bar{D}^0$  Mixing," above.
- <sup>13</sup>This limit is inferred from  $R_M$  for  $f = K^+\pi^-$  and  $f = K^+\pi^-\pi^+$ . See the note on " $D^0\text{-}\bar{D}^0$  Mixing," above. Decay-time information is used to distinguish doubly Cabibbo-suppressed decays from  $D^0\text{-}\bar{D}^0$  mixing.
- <sup>14</sup>This limit is inferred from  $R_M$  for  $f = K^+\ell^-\bar{\nu}_\ell$ . See the note on " $D^0\text{-}\bar{D}^0$  Mixing," above.
- <sup>15</sup>ANJOS 88C assumes that  $y = 0$ . See the note on " $D^0\text{-}\bar{D}^0$  Mixing," above. Without this assumption, the limit degrades by about a factor of two.

$$(\Gamma_{D_1^0} - \Gamma_{D_2^0})/\Gamma = 2y$$

The  $D_1^0$  and  $D_2^0$  are the mass eigenstates of the  $D^0$  meson, as described in the note on " $D^0\text{-}\bar{D}^0$  Mixing," above.

Due to the strong phase difference between  $D^0 \rightarrow K^+\pi^-$  and  $\bar{D}^0 \rightarrow K^+\pi^-$ , we exclude from the average those measurements of  $y'$  that are inferred from the  $D^0\text{-}\bar{D}^0$  mixing ratio  $\Gamma(K^+\pi^-)$  via  $\bar{D}^0$  /  $\Gamma(K^+\pi^-)$  given near the end of this  $D^0$  Listings.

Some early results have been omitted. See our 2006 Review (Journal of Physics (generic for all A,B,E,G) **G33** 1 (2006)).

"OUR EVALUATION" comes from CPV allowing averages provided by the Heavy Flavor Averaging Group, see the note on " $D^0\text{-}\bar{D}^0$  Mixing."

<sup>1</sup>Based on 976  $\text{fb}^{-1}$  of data collected at  $Y(\text{nS})$  resonances. Assumes no  $CP$  violation. Reported  $x'^2 = (0.09 \pm 0.22) \times 10^{-3}$  and  $y' = (4.6 \pm 3.4) \times 10^{-3}$ , where  $x' = x \cos(\delta) + y \sin(\delta)$ ,  $y' = y \cos(\delta) - x \sin(\delta)$  and  $\delta$  is the strong phase between  $D^0 \rightarrow K^+\pi^-$  and  $\bar{D}^0 \rightarrow K^+\pi^-$ .

<sup>2</sup>Based on 3  $\text{fb}^{-1}$  of data collected at  $\sqrt{s} = 7, 8$  TeV. Assumes no  $CP$  violation. Reported  $x'^2 = (5.5 \pm 4.9) \times 10^{-4}$  and  $y' = (4.8 \pm 1.0) \times 10^{-3}$ , where  $x' = x \cos(\delta) + y \sin(\delta)$ ,  $y' = y \cos(\delta) - x \sin(\delta)$  and  $\delta$  is the strong phase between the  $D^0 \rightarrow K^+\pi^-$  and  $\bar{D}^0 \rightarrow K^+\pi^-$ .

<sup>3</sup>Based on 9.6  $\text{fb}^{-1}$  of data collected at the Tevatron. Assumes no  $CP$  violation. Reported  $x'^2 = (0.08 \pm 0.18) \times 10^{-3}$  and  $y' = (4.3 \pm 4.3) \times 10^{-3}$ , where  $x' = x \cos(\delta) + y \sin(\delta)$ ,  $y' = y \cos(\delta) - x \sin(\delta)$  and  $\delta$  is the strong phase between the  $D^0 \rightarrow K^+\pi^-$  and  $\bar{D}^0 \rightarrow K^+\pi^-$ .

<sup>4</sup>Obtained  $y_{CP} = (0.72 \pm 0.18 \pm 0.12)\%$  based on three effective  $D^0$  lifetimes measured in  $K^{\mp}\pi^{\pm}$ ,  $K^{\mp}K^{\pm}$ , and  $\pi^{\mp}\pi^{\pm}$ . We list  $2y_{CP} = \Delta\Gamma/\Gamma$ .

<sup>5</sup>Compared the lifetimes of  $D^0$  decay to the  $CP$  eigenstate  $K^+K^-$  with  $D^0$  decay to  $\pi^+\pi^-$ . The values here assume no  $CP$  violation.

<sup>6</sup>DEL-AMO-SANCHEZ 10D uses 540,800 ± 800  $K_S^0\pi^+\pi^-$  and 79,900 ± 300  $K_S^0K^+K^-$  events in a time-dependent amplitude analyses of the  $D^0$  and  $\bar{D}^0$  Dalitz plots. No evidence was found for  $CP$  violation, and the values here assume no such violation.

<sup>7</sup>ZUPANC 09 uses a method based on measuring the mean decay time of  $D^0 \rightarrow K_S^0K^+K^-$  events for different  $K^+K^-$  mass intervals.

<sup>8</sup>STARIC 07 compares the lifetimes of  $D^0$  decay to the  $CP$  eigenstates  $K^+K^-$  and  $\pi^+\pi^-$  with  $D^0$  decay to  $K^-\pi^+$ .

<sup>9</sup>The ASNER 05 and ZHANG 07B values are from the time-dependent Dalitz-plot analysis of  $D^0 \rightarrow K_S^0\pi^+\pi^-$ . Decay-time information and interference on the Dalitz plot are used to distinguish doubly Cabibbo-suppressed decays from mixing and to measure the relative phase between  $D^0 \rightarrow K^+\pi^-$  and  $\bar{D}^0 \rightarrow K^+\pi^-$ . This limit allows  $CP$  violation.

<sup>10</sup>LINK 00, AITALA 99E, and ABE 02i measure the lifetime difference between  $D^0 \rightarrow K^-K^+$  ( $CP$  even) decays and  $D^0 \rightarrow K^-\pi^+$  ( $CP$  mixed) decays, or  $y_{CP} = [\Gamma(CP^+) - \Gamma(CP^-)] / [\Gamma(CP^+) + \Gamma(CP^-)]$ . We list  $2y_{CP} = \Delta\Gamma/\Gamma$ .

<sup>11</sup>CSORNA 02 measures the lifetime difference between  $D^0 \rightarrow K^-K^+$  and  $\pi^-\pi^+$  ( $CP$  even) decays and  $D^0 \rightarrow K^-\pi^+$  ( $CP$  mixed) decays, or  $y_{CP} = [\Gamma(CP^+) - \Gamma(CP^-)] / [\Gamma(CP^+) + \Gamma(CP^-)]$ . We list  $2y_{CP} = \Delta\Gamma/\Gamma$ .

<sup>12</sup>Based on 1  $\text{fb}^{-1}$  of data collected at  $\sqrt{s} = 7$  TeV in 2011. Assumes no  $CP$  violation. Reported  $x'^2 = (-0.9 \pm 1.3) \times 10^{-4}$  and  $y' = (7.2 \pm 2.4) \times 10^{-3}$ , where  $x' = x \cos(\delta) + y \sin(\delta)$ ,  $y' = y \cos(\delta) - x \sin(\delta)$  and  $\delta$  is the strong phase between the  $D^0 \rightarrow K^+\pi^-$  and  $\bar{D}^0 \rightarrow K^+\pi^-$ .

<sup>13</sup>This combines the  $y_{CP} = (\tau_{K^+\pi^-}/\tau_{K^+K^-}) - 1$  using untagged  $K^-\pi^+$  and  $K^-K^+$  events of AUBERT 09A1 with the disjoint  $y_{CP}$  using tagged  $K^-\pi^+$ ,  $K^-K^+$ , and  $\pi^-\pi^+$  events of AUBERT 08U.

<sup>14</sup>The AUBERT 09AN values are inferred from the branching ratio  $\Gamma(D^0 \rightarrow K^+\pi^-\pi^0)$  via  $\bar{D}^0$  /  $\Gamma(D^0 \rightarrow K^-\pi^+\pi^0)$  given near the end of this Listings. Mixing is distinguished from DCS decays using decay-time information. Interference between mixing and DCS is allowed. The phase between  $D^0 \rightarrow K^+\pi^-\pi^0$  and  $\bar{D}^0 \rightarrow K^+\pi^-\pi^0$  is assumed to be small. The width difference here is  $y''$ , which is not the same as  $y_{CP}$  in the note on  $D^0\text{-}\bar{D}^0$  mixing.

<sup>15</sup>LOWREY 09 uses quantum correlations in  $e^+e^- \rightarrow D^0\bar{D}^0$  at the  $\psi(3770)$ . See below for coherence factors and average relative strong phases for both  $D^0 \rightarrow K^-\pi^+\pi^0$  and  $D^0 \rightarrow K^-\pi^-\pi^+$ . A fit that includes external measurements of charm mixing parameters gets  $2y = (1.62 \pm 0.32) \times 10^{-2}$ .

<sup>16</sup>The GODANG 00, AUBERT 03Z, LINK 05H, LI 05A, ZHANG 06, AUBERT 07W, and AALTONEN 08E limits are inferred from the  $D^0\text{-}\bar{D}^0$  mixing ratio  $\Gamma(K^+\pi^-)$  (via  $\bar{D}^0$ )/ $\Gamma(K^-\pi^+)$  given near the end of this  $D^0$  Listings. Decay-time information is used to distinguish DCS decays from  $D^0\text{-}\bar{D}^0$  mixing. The limits allow interference between the DCS and mixing ratios, and all except AUBERT 07W and AALTONEN 08E also allow  $CP$  violation. The phase between  $D^0 \rightarrow K^+\pi^-$  and  $\bar{D}^0 \rightarrow K^+\pi^-$  is assumed to be small. This is a measurement of  $y'$  and is not the same as the  $y_{CP}$  of our note above on " $D^0\text{-}\bar{D}^0$  Mixing."

<sup>17</sup>This value combines the results of AUBERT 08U and AUBERT 03P.

<sup>18</sup>The ranges of AUBERT 03Z, LINK 05H, LI 05A, and ZHANG 06 measurements are for 95% confidence level.

<sup>19</sup>AUBERT 03P measures  $Y \equiv 2\tau^0 / (\tau^+ + \tau^-) - 1$ , where  $\tau^0$  is the  $D^0 \rightarrow K^-\pi^+$  (and  $\bar{D}^0 \rightarrow K^+\pi^-$ ) lifetime, and  $\tau^+$  and  $\tau^-$  are the  $D^0$  and  $\bar{D}^0$  lifetimes to  $CP$ -even states (here  $K^+K^-$  and  $\pi^+\pi^-$ ). In the limit of  $CP$  conservation,  $Y = \Delta\Gamma / 2\Gamma$  (we list  $2y = \Delta\Gamma/\Gamma$ ). AUBERT 03P also uses  $\tau^+ - \tau^-$  to get  $\Delta Y = -0.008 \pm 0.006 \pm 0.002$ .

### $|q/p|$

The mass eigenstates  $D_1^0$  and  $D_2^0$  are related to the  $C = \pm 1$  states by  $|D_{1,2}^0\rangle = p|D^0\rangle + q|\bar{D}^0\rangle$ . See the note on " $D^0\text{-}\bar{D}^0$  Mixing" above.

"OUR EVALUATION" comes from CPV allowing averages provided by the Heavy Flavor Averaging Group. This would include as-yet-unpublished results, see the note on " $D^0\text{-}\bar{D}^0$  Mixing."

<b>0.92<sup>+0.12</sup><sub>-0.09</sub> OUR EVALUATION</b>			HFAG fit; see the note on " $D^0\text{-}\bar{D}^0$ Mixing."
	1 AAIJ	13CE LHCB	$pp$ at 7, 8 TeV
<b>0.86<sup>+0.30</sup><sub>-0.29</sub> ± 0.10</b>	2 ZHANG	07B BELL	$e^+e^- \approx \Upsilon(4S)$

<sup>1</sup>Based on 3  $\text{fb}^{-1}$  of data collected at  $\sqrt{s} = 7, 8$  TeV. Allowing for  $CP$  violation, the direct  $CP$  violation in mixing is reported  $0.75 < |q/p| < 1.24$  at the 68.3% CL for the  $D^0 \rightarrow K^+\pi^-$  and  $\bar{D}^0 \rightarrow K^+\pi^-$ .

<sup>2</sup>The phase of  $p/q$  is  $(-14^{+16}_{-18} \pm 5)^\circ$ . The ZHANG 07B value is from the time-dependent Dalitz-plot analysis of  $D^0 \rightarrow K_S^0\pi^+\pi^-$ . Decay-time information and interference on the Dalitz plot are used to distinguish doubly Cabibbo-suppressed decays from mixing and to measure the relative phase between  $D^0 \rightarrow K^+\pi^-$  and  $\bar{D}^0 \rightarrow K^+\pi^-$ . This value allows  $CP$  violation.

# Meson Particle Listings

## $D^0$

**$A_F$**   
 $A_F$  is the decay-rate asymmetry for CP-even final states  $A_F = (\bar{\tau}_+ - \tau_+) / (\bar{\tau}_+ + \tau_+)$ .  
 See the note on " $D^0$ - $\bar{D}^0$  Mixing" above.

<b>0.81 +0.22 +0.07 -0.18 -0.05</b>	<sup>1</sup> ASNER	12	CLEO $e^+e^- \rightarrow D^0\bar{D}^0$ , 3.77 GeV
1.03 +0.31 ± 0.06	<sup>2</sup> ASNER	08	CLEO Repl. by ASNER 12

• • • We do not use the following data for averages, fits, limits, etc. • • •

<sup>1</sup> Uses quantum correlations in  $e^+e^- \rightarrow D^0\bar{D}^0$  at the  $\psi(3770)$ , where decay rates of CP-tagged  $K\pi$  final states depend on the strong phases between the decays of  $D^0 \rightarrow K^+\pi^-$  and  $\bar{D}^0 \rightarrow K^+\pi^-$ . The measurements obtained  $\sin(\delta) = -0.01 \pm 0.41 \pm 0.04$  and  $|\delta| = (10^{+28+13}_{-53-00})^\circ$  as well. A fit that includes external measurements of charm mixing parameters finds  $\cos(\delta) = 1.15^{+0.19+0.00}_{-0.17-0.08}$ ,  $\sin(\delta) = 0.56^{+0.32+0.21}_{-0.31-0.20}$ , and  $|\delta| = (18^{+11}_{-17})^\circ$ .

<sup>2</sup> ASNER 08 uses quantum correlations in  $e^+e^- \rightarrow D^0\bar{D}^0$  at the  $\psi(3770)$ , where decay rates of CP-tagged  $K\pi$  final states depend on  $\cos \delta$  because of interfering amplitudes. The above measurement implies  $|\delta| < 75^\circ$  with a confidence level of 95%. A fit that includes external measurements of charm mixing parameters finds  $\cos \delta = 1.10 \pm 0.35 \pm 0.07$ . See also the note on " $D^0$ - $\bar{D}^0$  Mixing" p. 783 in our 2008 Review (PDG 08).

**$D^0 \rightarrow K^-\pi^+\pi^0$  COHERENCE FACTOR  $R_{K\pi\pi^0}$**   
 See the note on " $D^0$ - $\bar{D}^0$  Mixing" for the definition.  $R_{K\pi\pi^0}$  can have any value between 0 and 1. A value near 1 indicates the decay is dominated by a few intermediate states with limited interference.

### $D^0$ DECAY MODES

Most decay modes (other than the semileptonic modes) that involve a neutral  $K$  meson are now given as  $K_S^0$  modes, not as  $\bar{K}^0$  modes. Nearly always it is a  $K_S^0$  that is measured, and interference between Cabibbo-allowed and doubly Cabibbo-suppressed modes can invalidate the assumption that  $2\Gamma(K_S^0) = \Gamma(\bar{K}^0)$ .

4.1 ± 0.6	263 ± 17	<sup>8</sup> SCHINDLER 81	MRK2	$e^+ e^-$ 3.771 GeV
4.3 ± 1.0	130	<sup>9</sup> PERUZZI 77	LGW	$e^+ e^-$ 3.77 GeV

<sup>1</sup> DOBBS 07 and HE 05 use single- and double-tagged events in an overall fit. DOBBS 07 supersedes HE 05.

<sup>2</sup> This combines the CLEO results of ARTUSO 98, COAN 98, and AKERIB 93.

<sup>3</sup> ABACHI 88, DECAMP 91j, AKERIB 93, ALBRECHT 94f, and BARATE 97c use  $D^*(2010)^+ \rightarrow D^0 \pi^+$  decays. The  $\pi^+$  is both slow and of low  $p_T$  with respect to the event thrust axis or nearest jet ( $\approx D^{*+}$  direction). The excess number of such  $\pi^+$ 's over background gives the number of  $D^*(2010)^+ \rightarrow D^0 \pi^+$  events, and the fraction with  $D^0 \rightarrow K^- \pi^+$  gives the  $D^0 \rightarrow K^- \pi^+$  branching fraction.

<sup>4</sup> ARTUSO 98, following ALBRECHT 94, uses  $D^0$  mesons from  $\bar{B}^0 \rightarrow D^*(2010)^+ X \ell^- \bar{\nu}_{\ell}$  decays. Our average uses the CLEO average of this value with the values of COAN 98 and AKERIB 93.

<sup>5</sup> COAN 98 assumes that  $\Gamma(B \rightarrow \bar{D} X \ell^+ \nu)/\Gamma(B \rightarrow X \ell^+ \nu) = 1.0 - 3|V_{ub}/V_{cb}|^2 - 0.010 \pm 0.005$ , the last term accounting for  $\bar{B} \rightarrow D_s^+ K X \ell^- \bar{\nu}$ . COAN 98 is included in the CLEO average in ARTUSO 98.

<sup>6</sup> ALBRECHT 94 uses  $D^0$  mesons from  $\bar{B}^0 \rightarrow D^{*+} \ell^- \bar{\nu}_{\ell}$  decays. This is a different set of events than used by ALBRECHT 94f.

<sup>7</sup> This AKERIB 93 value includes radiative corrections; without them, the value is  $0.0391 \pm 0.0008 \pm 0.0017$ . AKERIB 93 is included in the CLEO average in ARTUSO 98.

<sup>8</sup> SCHINDLER 81 (MARK-2) measures  $\sigma(e^+ e^- \rightarrow \psi(3770)) \times$  branching fraction to be  $0.24 \pm 0.02$  nb. We use the MARK-3 (ADLER 88c) value of  $\sigma = 5.8 \pm 0.5 \pm 0.6$  nb.

<sup>9</sup> PERUZZI 77 (MARK-1) measures  $\sigma(e^+ e^- \rightarrow \psi(3770)) \times$  branching fraction to be  $0.25 \pm 0.05$  nb. We use the MARK-3 (ADLER 88c) value of  $\sigma = 5.8 \pm 0.5 \pm 0.6$  nb.

• • • We do not use the following data for averages, fits, limits, etc. • • •

1 DOBBS 07 and HE 05 use single- and double-tagged events in an overall fit. DOBBS 07 supersedes HE 05.  
 2 ALBRECHT 94 uses  $D^0$  mesons from  $\bar{B}^0 \rightarrow D^{*+} \ell^- \bar{\nu}_\ell$  decays. This is a different set of events than used by ALBRECHT 94F.  
 3 See the footnote on the ALBRECHT 94F measurement of  $\Gamma(K^- \pi^+)/\Gamma_{\text{total}}$  for the method used.  
 4 SCHINDLER 81 (MARK-2) measures  $\sigma(e^+e^- \rightarrow \psi(3770)) \times$  branching fraction to be  $0.68 \pm 0.11$  nb. We use the MARK-3 (ADLER 88c) value of  $\sigma = 5.8 \pm 0.5 \pm 0.6$  nb.  
 5 PERUZZI 77 (MARK-1) measures  $\sigma(e^+e^- \rightarrow \psi(3770)) \times$  branching fraction to be  $0.36 \pm 0.10$  nb. We use the MARK-3 (ADLER 88c) value of  $\sigma = 5.8 \pm 0.5 \pm 0.6$  nb.

6.7 +1.6 -1.7	1	BARLAG	92c	ACCM $\pi^-$ Cu 230 GeV
------------------	---	--------	-----	-------------------------

<sup>1</sup> BARLAG 92c computes the branching fraction using topological normalization.

 $\Gamma(K_S^0 \pi^+ \pi^- \pi^0) / \Gamma(K_S^0 \pi^+ \pi^-)$   $\Gamma_{76} / \Gamma_{35}$ 

Branching fractions for submodes of this mode with narrow resonances (the  $\eta$ ,  $\omega$ ,  $\eta'$ ) are fairly well determined (see below). COFFMAN 92B gives fractions of  $K^*$  and  $\rho$  submodes, but with only 140 ± 28 events above background could not determine them with much accuracy. We omit those measurements here; they are in our 2008 Review (Physics Letters **B667** 1 (2008)).

10.59 ± 0.06 ± 0.13	60k ± 343	AUBERT,B	06x	BABR $e^+e^- \approx \gamma(4S)$

$$\Gamma(\rho^+\pi^-)/\Gamma(\pi^+\pi^-\pi^0) \quad \Gamma_{135}/\Gamma_{134}$$

This is the "fit fraction" from the Dalitz-plot analysis, with interference. See GASPERO 08 and BHATTACHARYA 10A for isospin decompositions of the  $D^0 \rightarrow \pi^+\pi^0\pi^-$  Dalitz plot, both based on the amplitudes of AUBERT 07BJ. They quantify the conclusion that the final state is dominantly isospin 0.

<b><math>&lt; 6.1 \times 10^{-4}</math></b>	90	1 BITENC	08 BELL	$e^+ e^-$ , 10.58 GeV
$< 50 \times 10^{-4}$	90	2 AITALA	96c E791	$\pi^-$ nucleus, 500 GeV

• • • We do not use the following data for averages, fits, limits, etc. • • •

1 The BITENC 08 right-sign sample includes about 15% of  $D^0 \rightarrow K^- \pi^0 \ell^+ \nu_\ell$  and other decays.

2 AITALA 96c uses  $D^{*+} \rightarrow D^0 \pi^+$  (and charge conjugate) decays to identify the charm at production and  $D^0 \rightarrow K^- \ell^+ \nu_\ell$  (and charge conjugate) decays to identify the charm at decay.

$\Gamma(K^+ \text{ or } K^*(892)^+ e^- \bar{\nu}_e \text{ via } \bar{D}^0) / [\Gamma(K^- e^+ \nu_e) + \Gamma(K^*(892)^- e^+ \nu_e)]$		$\Gamma_{221} / (\Gamma_{18} + \Gamma_{20})$		
--	--	--	--	--

This is a limit on  $R_M$  without the complications of possible doubly Cabibbo-suppressed decays that occur when using hadronic modes. The experiments use  $D^{*+} \rightarrow D^0 \pi^+$  (and charge conjugate) decays to identify the charm at production and the charge of the  $e$  to identify the charm at decay. These limits do not allow  $CP$  violation. For the limits on  $|m_1 - m_2|$  and  $(\Gamma_1 - \Gamma_2) / \Gamma$  that come from the best mixing limit, see near the beginning of these  $D^0$  Listings.

$\Gamma(K^+ \pi^-) / \Gamma(K^- \pi^+)$		$\Gamma_{222} / \Gamma_{31}$		
---	--	------------------------------	--	--

This is  $R$ , the time-integrated wrong-sign rate compared to the right-sign rate. See the note on " $D^0$ - $\bar{D}^0$  Mixing," near the start of the  $D^0$  Listings.

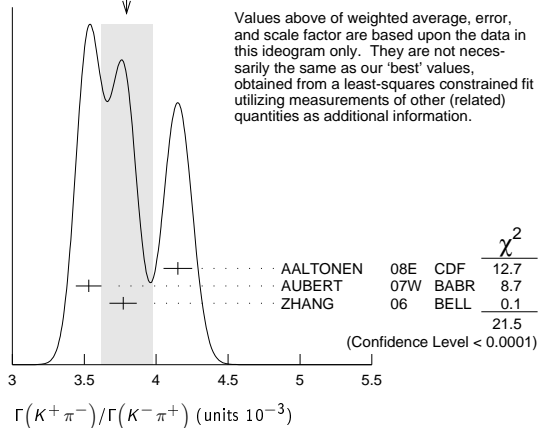

The experiments here use the charge of the pion in  $D^*(2010)^\pm \rightarrow (D^0 \text{ or } \bar{D}^0) \pi^\pm$  decay to tell whether a  $D^0$  or a  $\bar{D}^0$  was born. The  $D^0 \rightarrow K^+ \pi^-$  decay can occur directly by doubly Cabibbo-suppressed (DCS) decay, or indirectly by  $D^0 \rightarrow \bar{D}^0$  mixing followed by  $\bar{D}^0 \rightarrow K^+ \pi^-$  decay. Some of the experiments can use the decay-time information to disentangle the two mechanisms. Here, we list the experimental branching ratio, which if there is no mixing is the DCS ratio. See the next data block for values of the DCS ratio  $R_D$ , and the following data block for limits on the mixing ratio  $R_M$ . See the section on  $CP$ -violating asymmetries near the end of this  $D^0$  Listing for values of  $A_D$ , and the note on " $D^0$ - $\bar{D}^0$  Mixing" for limits on  $x'$  and  $y'$ .

Some early limits have been omitted from this Listing; see our 1998 edition (The European Physical Journal **C3** 1 (1998)) and our 2006 edition (Journal of Physics (generic for all A,B,E,G) **G33** 1 (2006)).

A test of baryon- and lepton-number conservation.

VALUE	CL%	DOCUMENT ID	TECN	COMMENT
$<1.1 \times 10^{-5}$	90	1 RUBIN	09	CLEO $e^+ e^-$ at $\psi(3770)$

<sup>1</sup>This RUBIN 09 limit is for either  $D^0 \rightarrow \bar{\rho} e^+$  or  $\bar{D}^0 \rightarrow \bar{\rho} e^+$  decay.

 $D^0$  CP-VIOLATING DECAY-RATE ASYMMETRIES

This is the difference between  $D^0$  and  $\bar{D}^0$  partial widths for these modes divided by the sum of the widths. The  $D^0$  and  $\bar{D}^0$  are distinguished by the charge of the parent  $D^*$ :  $D^{*+} \rightarrow D^0 \pi^+$  and  $D^{*-} \rightarrow \bar{D}^0 \pi^-$ .

$A_{CP}(K^+ K^-)$  in  $D^0, \bar{D}^0 \rightarrow K^+ K^-$

 $D^0$  CP-VIOLATING ASYMMETRY DIFFERENCES $\Delta A_{CP} = A_{CP}(K^+K^-) - A_{CP}(\pi^+\pi^-)$ 

CP violation in these modes can come from the decay amplitudes (direct) and/or from mixing or interference of mixing and decay (indirect). The difference  $\Delta A_{CP}$  is primarily sensitive to the direct component, and only retains a second-order dependence on the indirect component for measurements where the mean decay time of the  $K^+K^-$  and  $\pi^+\pi^-$  samples are not identical. The results below are averaged assuming the indirect component can be neglected.

<sup>1</sup> Calculated from the AUBERT 08M values of  $A_{CP}(K^+K^-)$  and  $A_{CP}(\pi^+\pi^-)$ . The systematic error here combines the systematic errors in quadrature, and therefore somewhat over-estimates it.

WEIGHTED AVERAGE  
 $-0.46 \pm 0.25$  (Error scaled by 1.8)

$\Delta A_{CP} = A_{CP}(K^+K^-) - A_{CP}(\pi^+\pi^-)$  (%)

 $D^0, \bar{D}^0$  T-VIOLATING DECAY-RATE ASYMMETRIES

The CP-sensitive P-odd (T-odd) correlation in  $D^0, \bar{D}^0 \rightarrow K^+K^-\pi^+\pi^-$  decays.  $D^0$  and  $\bar{D}^0$  are distinguished by the charge of the parent  $D^*$ :  $D^{*+} \rightarrow D^0\pi^+$  and  $D^{*-} \rightarrow \bar{D}^0\pi^-$ .

 $A_{Tviol}(K^+K^-\pi^+\pi^-)$  in  $D^0, \bar{D}^0 \rightarrow K^+K^-\pi^+\pi^-$ 

$C_T \equiv \bar{p}_{K^+} \cdot (\bar{p}_{\pi^+} \times \bar{p}_{\pi^-})$  is a parity-odd correlation of the  $K^+$ ,  $\pi^+$ , and  $\pi^-$  momenta (evaluated in the  $D^0$  rest frame) for the  $D^0$ .  $\bar{C}_T \equiv \bar{p}_{K^-} \cdot (\bar{p}_{\pi^-} \times \bar{p}_{\pi^+})$  is the corresponding quantity for the  $\bar{D}^0$ . Then  $A_T \equiv [\Gamma(C_T > 0) - \Gamma(C_T < 0)] / [\Gamma(C_T > 0) + \Gamma(C_T < 0)]$ , and  $\bar{A}_T \equiv [\Gamma(-\bar{C}_T > 0) - \Gamma(-\bar{C}_T < 0)] / [\Gamma(-\bar{C}_T > 0) + \Gamma(-\bar{C}_T < 0)]$ , and  $A_{Tviol} \equiv \frac{1}{2}(A_T - \bar{A}_T)$ .  $C_T$  and  $\bar{C}_T$  are commonly referred to as T-odd moments, because they are odd under T reversal. However, the T-conjugate process  $K^+K^-\pi^+\pi^- \rightarrow D^0$  is not accessible, while the P-conjugate process is.

$+10 \pm 57 \pm 37$	828 ± 46	LINK	05E FOCS	$\gamma A, \bar{E}_{\gamma} \approx 180$ GeV

 $D^0$  CPT-VIOLATING DECAY-RATE ASYMMETRIES $A_{CPT}(K^{\mp}\pi^{\pm})$  in  $D^0 \rightarrow K^-\pi^+, \bar{D}^0 \rightarrow K^+\pi^-$ 

$A_{CPT}(t)$  is defined in terms of the time-dependent decay probabilities  $P(D^0 \rightarrow K^-\pi^+)$  and  $\bar{P}(\bar{D}^0 \rightarrow K^+\pi^-)$  by  $A_{CPT}(t) = (\bar{P} - P) / (\bar{P} + P)$ . For small mixing parameters  $x \equiv \Delta m / \Gamma$  and  $y \equiv \Delta \Gamma / 2\Gamma$  (as is the case), and times  $t, A_{CPT}(t)$  reduces to  $[y \operatorname{Re} \xi - x \operatorname{Im} \xi] / \Gamma t$ , where  $\xi$  is the CPT-violating parameter.

The following is actually  $y \operatorname{Re} \xi - x \operatorname{Im} \xi$ .

## $D^{*0}(2007)^0$

$$J(P^J) = \frac{1}{2}(1^-)$$

$I, J, P$  need confirmation.

$J$  consistent with 1, value 0 ruled out (NGUYEN 77).

### $D^{*0}(2007)^0$ MASS

The fit includes  $D^{\pm}, D^0, D_s^{\pm}, D^{*\pm}, D^{*0}, D_s^{*\pm}, D_1(2420)^0, D_2^*(2460)^0$ , and  $D_{s1}(2536)^{\pm}$  mass and mass difference measurements.

VALUE (MeV)	DOCUMENT ID	TECN	COMMENT
<b>2006.96 ± 0.10 OUR FIT</b>

### $D^{*0}(2007)^0$ DECAY MODES

$\bar{D}^{*0}(2007)^0$  modes are charge conjugates of modes below.

Mode	Fraction ( $\Gamma_i/\Gamma$ )
$\Gamma_1 D^0 \pi^0$	(61.9 ± 2.9) %
$\Gamma_2 D^0 \gamma$	(38.1 ± 2.9) %

### CONSTRAINED FIT INFORMATION

An overall fit to a branching ratio uses 3 measurements and one constraint to determine 2 parameters. The overall fit has a  $\chi^2 = 0.5$  for 2 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i/\Gamma_{total}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

$$x_2 \begin{bmatrix} -100 \\ x_1 \end{bmatrix}$$

$\Gamma_6/\Gamma_1$

$D_1(2420)^0$  POLARIZATION AMPLITUDE  $A_{D_1}$

A polarization amplitude  $A_{D_1}$  is a parameter that depends on the initial polarization of the  $D_1$  and is sensitive to a possible S-wave contribution to its decay. For  $D_1$  decays the helicity angle,  $\theta_h$ , distribution varies like  $1 + A_{D_1} \cos^2 \theta_h$ , where  $\theta_h$  is the angle in the  $D^*$  rest frame between the two pions emitted by the  $D_1 \rightarrow D^* \pi$  and the  $D^* \rightarrow D \pi$ .

Unpolarized  $D_1$  decaying purely via D-wave is predicted to give  $A_{D_1} = 3$ .

$D_s^\pm$

## CHARMED, STRANGE MESONS ( $C = S = \pm 1$ )

$$D_s^+ = c\bar{s}, D_s^- = \bar{c}s, \text{ similarly for } D_s^{*\prime}s$$

$D_s^\pm$

$$J(P) = 0(0^-)$$

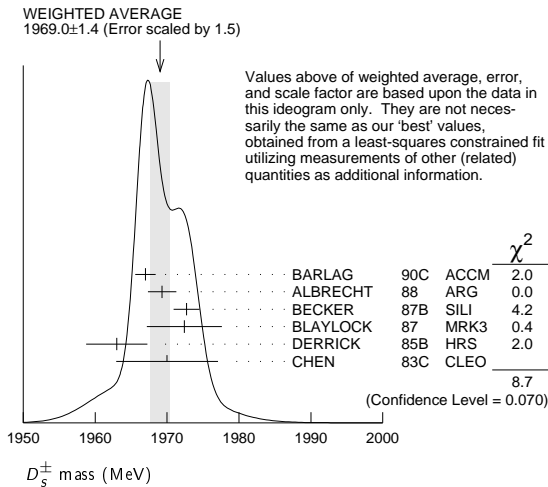

The angular distributions of the decays of the  $\phi$  and  $\bar{K}^*(892)^0$  in the  $\phi\pi^+$  and  $K^+\bar{K}^*(892)^0$  modes strongly indicate that the spin is zero. The parity given is that expected of a  $c\bar{s}$  ground state.

### $D_s^\pm$ MASS

The fit includes  $D_s^\pm, D^0, D_s^\pm, D^{*\pm}, D^{*0}, D_s^{*\pm}, D_1(2420)^0, D_2^*(2460)^0$ , and  $D_{s1}(2536)^\pm$  mass and mass difference measurements. Measurements of the  $D_s^\pm$  mass with an error greater than 10 MeV are omitted from the fit and average. A number of early measurements have been omitted altogether.

<sup>1</sup> BONVICINI 99 obtains  $1.19 \pm 0.04$  for the ratio of  $D_s^\pm$  to  $D^0$  lifetimes.

### $D_s^\pm$ DECAY MODES

Unless otherwise noted, the branching fractions for modes with a resonance in the final state include all the decay modes of the resonance.  $D_s^\pm$  modes are charge conjugates of the modes below.

Mode	Fraction ( $\Gamma_i/\Gamma$ )	Scale factor / Confidence level
<b>Inclusive modes</b>		
$\Gamma_1$ $e^+$ semileptonic	[a] ( 6.5 ± 0.4 ) %	
$\Gamma_2$ $\pi^+$ anything	(119.3 ± 1.4) %	
$\Gamma_3$ $\pi^-$ anything	( 43.2 ± 0.9 ) %	
$\Gamma_4$ $\pi^0$ anything	(123 ± 7) %	
$\Gamma_5$ $K^-$ anything	( 18.7 ± 0.5 ) %	
$\Gamma_6$ $K^+$ anything	( 28.9 ± 0.7 ) %	
$\Gamma_7$ $K_S^0$ anything	( 19.0 ± 1.1 ) %	
$\Gamma_8$ $\eta$ anything	[b] ( 29.9 ± 2.8 ) %	
$\Gamma_9$ $\omega$ anything	( 6.1 ± 1.4 ) %	
$\Gamma_{10}$ $\eta'$ anything	[c] ( 11.7 ± 1.8 ) %	
$\Gamma_{11}$ $f_0(980)$ anything, $f_0 \rightarrow \pi^+\pi^-$	< 1.3 %	CL=90%
$\Gamma_{12}$ $\phi$ anything	( 15.7 ± 1.0 ) %	
$\Gamma_{13}$ $K^+K^-$ anything	( 15.8 ± 0.7 ) %	
$\Gamma_{14}$ $K_S^0 K^+$ anything	( 5.8 ± 0.5 ) %	
$\Gamma_{15}$ $K_S^0 K^-$ anything	( 1.9 ± 0.4 ) %	
$\Gamma_{16}$ $2K_S^0$ anything	( 1.70 ± 0.32 ) %	
$\Gamma_{17}$ $2K^+$ anything	< 2.6 × 10 <sup>-3</sup>	CL=90%
$\Gamma_{18}$ $2K^-$ anything	< 6 × 10 <sup>-4</sup>	CL=90%
<b>Leptonic and semileptonic modes</b>		
$\Gamma_{19}$ $e^+ \nu_e$	< 8.3 × 10 <sup>-5</sup>	CL=90%
$\Gamma_{20}$ $\mu^+ \nu_\mu$	( 5.56 ± 0.25 ) × 10 <sup>-3</sup>	
$\Gamma_{21}$ $\tau^+ \nu_\tau$	( 5.54 ± 0.24 ) %	
$\Gamma_{22}$ $K^+ K^- e^+ \nu_e$	—	
$\Gamma_{23}$ $\phi e^+ \nu_e$	[d] ( 2.49 ± 0.14 ) %	
$\Gamma_{24}$ $\eta e^+ \nu_e + \eta'(958) e^+ \nu_e$	[d] ( 3.66 ± 0.37 ) %	
$\Gamma_{25}$ $\eta e^+ \nu_e$	[d] ( 2.67 ± 0.29 ) %	S=1.1
$\Gamma_{26}$ $\eta'(958) e^+ \nu_e$	[d] ( 9.9 ± 2.3 ) × 10 <sup>-3</sup>	
$\Gamma_{27}$ $\omega e^+ \nu_e$	[e] < 2.0 × 10 <sup>-3</sup>	CL=90%
$\Gamma_{28}$ $K^0 e^+ \nu_e$	( 3.7 ± 1.0 ) × 10 <sup>-3</sup>	
$\Gamma_{29}$ $K^*(892)^0 e^+ \nu_e$	[d] ( 1.8 ± 0.7 ) × 10 <sup>-3</sup>	
$\Gamma_{30}$ $f_0(980) e^+ \nu_e, f_0 \rightarrow \pi^+\pi^-$	( 2.00 ± 0.32 ) × 10 <sup>-3</sup>

[a] This is the purely  $e^+$  semileptonic branching fraction: the  $e^+$  fraction from  $\tau^+$  decays has been subtracted off. The sum of our (non- $\tau$ )  $e^+$  exclusive fractions — an  $e^+ \nu_e$  with an  $\eta, \eta', \phi, K^0, K^{*0},$  or  $f_0(980)$  — is  $7.0 \pm 0.4$  %

[b] This fraction includes  $\eta$  from  $\eta'$  decays.

[c] Two times (to include  $\mu$  decays) the  $\eta' e^+ \nu_e$  branching fraction, plus the  $\eta' \pi^+, \eta' \rho^+,$  and  $\eta' K^+$  fractions, is  $(18.6 \pm 2.3)$ %, which considerably exceeds the inclusive  $\eta'$  fraction of  $(11.7 \pm 1.8)$ %. Our best guess is that the  $\eta' \rho^+$  fraction,  $(12.5 \pm 2.2)$ %, is too large.

[d] This branching fraction includes all the decay modes of the final-state resonance.

[e] A test for  $u\bar{u}$  or  $d\bar{d}$  content in the  $D_s^+$ . Neither Cabibbo-favored nor Cabibbo-suppressed decays can contribute, and  $\omega-\phi$  mixing is an unlikely explanation for any fraction above about  $2 \times 10^{-4}$ .

[f] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers.

[g] We decouple the  $D_s^+ \rightarrow \phi \pi^+$  branching fraction obtained from mass projections (and used to get some of the other branching fractions) from the  $D_s^+ \rightarrow \phi \pi^+, \phi \rightarrow K^+ K^-$  branching fraction obtained from the Dalitz-plot analysis of  $D_s^+ \rightarrow K^+ K^- \pi^+$ . That is, the ratio of these two branching fractions is not exactly the  $\phi \rightarrow K^+ K^-$  branching fraction 0.491.

[h] This is the average of a model-independent and a  $K$ -matrix parametrization of the  $\pi^+ \pi^-$  S-wave and is a sum over several  $f_0$  mesons.

[i] This mode is not a useful test for a  $\Delta C=1$  weak neutral current because both quarks must change flavor in this decay.

[j] This is *not* a test for the  $\Delta C=1$  weak neutral current, but leads to the  $\pi^+ \ell^+ \ell^-$  final state.

## CONSTRAINED FIT INFORMATION

An overall fit to 16 branching ratios uses 19 measurements and one constraint to determine 12 parameters. The overall fit has a  $\chi^2 = 5.7$  for 8 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

 $D_s^+$  BRANCHING FRACTIONS

Written April 2010 by J.L. Rosner (University of Chicago) and C.G. Wohl (LBNL).

More than a dozen papers on the  $D_s^+$ , most of them from the CLEO experiment, have been published since the 2008 Review. We now know enough to attempt an overview of the branching fractions. Figure 1 shows a partial breakdown of the fractions. The rest of this note is about how the figure was constructed. The values shown make heavy use of CLEO measurements of inclusive branching fractions [1]. For other data and references cited in the following, see the Listings.

**Modes with leptons:** The bottom  $(20.0 \pm 0.9)\%$  of Fig. 1 shows the fractions for the exclusive modes that include leptons. Measured  $e^+\nu_e$  fractions have been doubled to get the semileptonic  $\ell^+\nu$  fractions. The sum of the exclusive  $e^+\nu_e$  fractions is  $(6.9 \pm 0.4)\%$ , consistent with an inclusive semileptonic  $e^+\nu_e$  measurement of  $(6.5 \pm 0.4)\%$ . There seems to be little missing here.

**Inclusive hadronic  $K\bar{K}$  fractions:** The Cabibbo-favored  $c \rightarrow s$  decay in  $D_s^+$  decay produces a final state with both an  $s$  and an  $\bar{s}$ ; and thus decay modes with a  $K\bar{K}$  pair or with an  $\eta$ ,  $\omega$ ,  $\eta'$ , or  $\phi$  predominate (see, for example, in Fig. 1 the fractions with leptons). We consider the  $K\bar{K}$  modes first. A complete picture of the exclusive  $K\bar{K}$  charge modes is not yet possible, because branching fractions for more than half of those modes have yet to be measured. However, CLEO has measured the inclusive  $K^+$ ,  $K^-$ ,  $K_S^0$ ,  $K^+K^-$ ,  $K^+K_S^0$ ,  $K^-K_S^0$ , and  $2K_S^0$  fractions (which include modes with leptons) [1]. And each of these inclusive fractions  $f$  with a  $K_S^0$  is equal to the corresponding fraction with a  $K_L^0$ :  $f(K^+K_L^0) = f(K^+K_S^0)$ ,  $f(2K_L^0) = f(2K_S^0)$ , etc. Therefore, of all inclusive fractions pairing a  $K^+$ ,  $K_S^0$ , or  $K_L^0$  with a  $K^-$ ,  $K_S^0$ , or  $K_L^0$ , we know all but  $f(K_S^0K_L^0)$ .

**Figure 1:** A partial breakdown of  $D_s^+$  branching fractions. Shading indicates parts of bins allotted to as-yet unmeasured exclusive modes. The inclusive hadronic  $\phi$  fraction is spread over three bins. See the text for further explanations.

We can get that fraction. The total  $K_S^0$  fraction is

$$f(K_S^0) = f(K^+K_S^0) + f(K^-K_S^0) + 2f(2K_S^0) + f(K_S^0K_L^0) + f(\text{single } K_S^0),$$

where  $f(\text{single } K_S^0)$  is the sum of the branching fractions for modes such as  $K_S^0\pi^+2\pi^0$  with a  $K_S^0$  and no second  $K$ . The  $K_S^0\pi^+2\pi^0$  mode is in fact the only unmeasured single- $K_S^0$  mode (throughout, we shall assume that fractions for modes with a  $K$  or  $K\bar{K}$  and more than three pions are negligible), and we shall take its fraction to be the same as for the  $K_S^02\pi^+\pi^-$  mode,  $(0.29 \pm 0.11)\%$ . Any reasonable deviation from this value would be too small to matter much in the following. Adding the several small single- $K_S^0$  branching fractions, including those from semileptonic modes, we get  $f(\text{single } K_S^0) = (1.67 \pm 0.26)\%$ .

Using this, we have:

$$\begin{aligned} f(K_S^0 K_L^0) &= f(K_S^0) - f(K^+ K_S^0) - f(K^- K_S^0) - 2f(2K_S^0) \\ &\quad - f(\text{single } K_S^0) \\ &= (19.0 \pm 1.1) - (5.8 \pm 0.5) - (1.9 \pm 0.4) \\ &\quad - 2 \times (1.70 \pm 0.32) - (1.67 \pm 0.26) \\ &= (6.2 \pm 1.4)\% . \end{aligned}$$

Here and below we treat the errors as uncorrelated, although often they are not. However, our main aim is to get numbers for Fig. 1; errors will be secondary.

There is a check on our result: The  $\phi$  inclusive branching fraction is  $(15.7 \pm 1.0)\%$ , of which 34%, or  $(5.34 \pm 0.34)\%$  of  $D_s^+$  decays, produces a  $K_S^0 K_L^0$ . Our  $f(K_S^0 K_L^0) = (6.2 \pm 1.4)\%$  has to be at least this large—and it is.

We now make a table. The first column gives the various particle pairings; here we use  $f(K^+ \bar{K}^0) = 2f(K^+ K_S^0)$ , and likewise for  $f(K^- K^0)$ . The second column gives the inclusive branching fractions; the third column gives the fractions for  $K^+ K^-$  and  $K_S^0 K_L^0$  from  $\phi \ell^+ \nu$  decay; the last column subtracts these off to get the purely hadronic  $K\bar{K}$  inclusive fractions.

$K^+ K^-$	15.8 (0.7)%	2.44 (0.14)%	13.4 (0.7)%
$K^+ \bar{K}^0$	11.6 (1.0)		11.6 (1.0)
$K^- K^0$	3.8 (0.8)		3.8 (0.8)
$K_S^0 K_S^0 + K_L^0 K_L^0$	3.4 (0.64)		3.4 (0.64)
$K_S^0 K_L^0$	6.2 (1.4)	1.69 (0.10)	4.5 (1.4) .

The values in the last column are shown in Fig. 1. Their sum is  $(36.7 \pm 2.1)\%$ .

We can add more information to the figure by summing up measured branching fractions for exclusive modes within each bin:

$K^+ K^-$  modes—The sum of measured  $K^+ K^- \pi^+$ ,  $K^+ K^- \pi^+ \pi^0$ , and  $K^+ K^- 2\pi^+ \pi^-$  branching fractions is  $(12.0 \pm 0.6)\%$ . That leaves  $(1.4 \pm 0.9)\%$  for the  $K^+ K^- \pi^+ 2\pi^0$  mode, which is the only other  $K^+ K^-$  mode with three or fewer pions. In Fig. 1, this unmeasured part of the  $K^+ K^-$  bin is shaded.

$K^+ \bar{K}^0$  modes—Twice the sum of measured  $K^+ K_S^0$  and  $K^+ K_S^0 \pi^+ \pi^-$  branching fractions is  $(4.9 \pm 0.3)\%$ . This leaves  $(6.7 \pm 1.0)\%$  for the unmeasured  $K^+ \bar{K}^0$  modes (there are four such modes with three or fewer pions). This is shaded in the figure.

$K^- K^0$  modes—Twice the  $K^- K_S^0 2\pi^+$  fraction is  $(3.28 \pm 0.24)\%$ , which leaves about  $(0.5 \pm 0.8)\%$  for  $K^- K^0 2\pi^+ \pi^0$ , the only other  $K^- K^0$  mode with three or fewer pions.

$K^0 \bar{K}^0$  modes—The only measurement of  $K^0 \bar{K}^0$  decays is of the  $2K_S^0 2\pi^+ \pi^-$  fraction,  $(0.084 \pm 0.035)\%$ ; so nearly everything is shaded here. However, most of the  $K_S^0 K_L^0$  fraction is accounted for by  $\phi$  decays (see below).

**Inclusive hadronic  $\eta$ ,  $\omega$ ,  $\eta'$ , and  $\phi$  fractions:** These are easier. We start with the inclusive branching fractions, and then, to avoid double counting, subtract: (1) fractions for modes

with leptons; (2)  $\eta$  mesons that are included in the inclusive  $\eta'$  fraction; and (3)  $K^+ K^-$  and  $K_S^0 K_L^0$  from  $\phi$  decays:

$$\begin{aligned} f(\eta \text{ hadronic}) &= f(\eta \text{ inclusive}) - 0.65 f(\eta' \text{ inclusive}) \\ &\quad - f(\eta \ell^+ \nu) = (17.0 \pm 3.1)\% \end{aligned}$$

$$\begin{aligned} f(\omega \text{ hadronic}) &= f(\omega \text{ inclusive}) - 0.03 f(\eta' \text{ inclusive}) \\ &= (5.7 \pm 1.4)\% \end{aligned}$$

$$\begin{aligned} f(\eta' \text{ hadronic}) &= f(\eta' \text{ inclusive}) - f(\eta' \ell^+ \nu) \\ &= (9.7 \pm 1.9)\% \end{aligned}$$

$$\begin{aligned} f(\phi \text{ hadronic, } \not\rightarrow K\bar{K}) &= 0.17 [f(\phi \text{ inclusive}) \\ &\quad - f(\phi \ell^+ \nu)] = (1.8 \pm 0.2)\% . \end{aligned}$$

The factors 0.65, 0.03, and 0.17 are the  $\eta' \rightarrow \eta$ ,  $\eta' \rightarrow \omega$ , and  $\phi \not\rightarrow K\bar{K}$  branching fractions. Figure 1 shows the results; the sum is  $(34.2 \pm 3.9)\%$ , which is about equal to the hadronic  $K\bar{K}$  total.

Note that the bin marked  $\phi$  near the top of Fig. 1 includes neither the  $\phi \ell^+ \nu$  decays nor the 83% of other  $\phi$  decays that produce a  $K\bar{K}$  pair. Compared to the size of that  $\phi$  bin, there is twice as much  $\phi$  in the  $K_S^0 K_L^0$  bin, and nearly three times as much in the  $K^+ K^-$  bin. These contributions are indicated in those bins.

Again, we can show how much of each bin is accounted for by measured exclusive branching fractions:

$\eta$  modes—The sum of  $\eta \pi^+$ ,  $\eta \rho^+$ , and  $\eta K^+$  branching fractions is  $(10.6 \pm 0.8)\%$ , which leaves a good part of the inclusive hadronic  $\eta$  fraction,  $(17.0 \pm 3.1)\%$ , to be accounted for. This is shaded in the figure.

$\omega$  modes—The sum of  $\omega \pi^+$ ,  $\omega \pi^+ \pi^0$ , and  $\omega 2\pi^+ \pi^-$  fractions is  $(4.6 \pm 0.9)\%$ , which is nearly as large as the inclusive hadronic  $\omega$  fraction,  $(5.7 \pm 1.4)\%$ .

$\eta'$  modes—The sum of  $\eta' \pi^+$ ,  $\eta' \rho^+$ , and  $\eta' K^+$  fractions is  $(16.5 \pm 2.2)\%$ , which is much larger than the inclusive hadronic  $\eta'$  fraction,  $(9.7 \pm 1.9)\%$ . If an exclusive measurement is at fault, it almost has to be the  $\eta' \rho^+$  fraction, which is  $(12.5 \pm 2.2)\%$ . It has been suggested that some of this signal might instead be misidentified kinematic reflections of other modes [2].

**Cabibbo-suppressed modes:** Remaining is  $(9.1 \pm 4.5)\%$  for hadronic Cabibbo-suppressed modes having no  $\eta$ ,  $\omega$ ,  $\eta'$ , or  $\phi$ . The contributions are:

$K^0 + pions$ —Above, we found that  $f(\text{single } K_S^0) = (1.67 \pm 0.26)\%$ ; subtracting leptonic contributions leaves  $(1.20 \pm 0.24)\%$ . The hadronic single- $K^0$  fraction is twice this,  $(2.40 \pm 0.48)\%$ .

$K^+ + pions$ —The  $K^+ \pi^0$  and  $K^+ \pi^+ \pi^-$  fractions sum to  $(0.77 \pm 0.05)\%$ . Much of the  $K^+ n\pi$  modes, where  $n \geq 3$ , is already in the  $\eta$ ,  $\omega$ , and  $\eta'$  bins, and the rest is not measured. The total  $K^+$  fraction wanted here is probably in the 1-to-2% range.

$Multi-pions$ —The  $2\pi^+ \pi^-$ ,  $\pi^+ 2\pi^0$ , and  $3\pi^+ 2\pi^-$  fractions total  $(2.6 \pm 0.2)\%$ . Modes not measured might double this.

## Meson Particle Listings

 $D_s^\pm$ 

The sum of the three contributions is certainly not inconsistent with the Cabibbo-suppressed total of  $(9.1 \pm 4.5)\%$ . The sum of actually measured fractions is  $(4.2 \pm 0.2)\%$ .

**A model:** With CLEO about to publish inclusive branching fractions [1], Gronau and Rosner predicted those fractions using a “statistical isospin” model [2]. Consider, say, the  $D_s^+ \rightarrow K\bar{K}\pi$  charge modes: the  $K^+K^-\pi^+$  branching fraction is measured, the  $K^+\bar{K}^0\pi^0$  and  $K^0\bar{K}^0\pi^+$  fractions are not. The statistical isospin model assumes that all the independent isospin amplitudes for  $D_s^+ \rightarrow K\bar{K}\pi$  decay are equal in magnitude and incoherent in phase—in which case, the ratio of the three fractions here is 3:3:2. (Actually, use was also made of the fact that  $D_s^+ \rightarrow K\bar{K}\pi$  decay is dominated by  $\phi\pi^+$ ,  $K^+\bar{K}^{*0}$ , and  $K^{*+}\bar{K}^0$  submodes; but the estimated charge-mode ratios were not far from 3:3:2.) A different, quark-antiquark pair-production model was used to estimate systematic uncertainties.

In this way, unmeasured exclusive fractions were calculated from measured exclusive fractions (the latter were taken from the 2008 Review, and so did not benefit from recent results). In the hadronic sector, the measured total of 59.4% of  $D_s^+$  decays led to an estimated total of 24.2% for unmeasured modes. Weighted counts of  $\pi^+$ ,  $K_S^0$ , etc., were then made to get the inclusive fractions.

Of interest here is that the sum of all the exclusive fractions—a way-stop in getting the inclusive values—was a nearly correct 103%. In the absence of complete measurements, the model is a way to, in effect, average over ignorance. It probably works better summed over a number of charge-mode sets than in detail. It is known to sometimes give incorrect results when there are sufficient measurements to test it.

## Leptonic and semileptonic modes

## LEPTONIC DECAYS OF CHARGED PSEUDO-SCALAR MESONS

Revised September 2013 by J. Rosner (Univ. Chicago) and S. Stone (Syracuse Univ.)

We review the physics of purely leptonic decays of  $\pi^\pm$ ,  $K^\pm$ ,  $D^\pm$ ,  $D_s^\pm$ , and  $B^\pm$  pseudoscalar mesons. The measured decay rates are related to the product of the relevant weak-interaction-based CKM matrix element of the constituent quarks and a strong interaction parameter related to the overlap of the quark and antiquark wave-functions in the meson, called the decay constant  $f_P$ . The interplay between theory and experiment is different for each particle. Theoretical predictions of  $f_B$  that are needed in the  $B$  sector can be tested by measuring  $f_{D^+}$  and  $f_{D_s^+}$  in the charm sector. The lighter  $\pi^\pm$  and  $K^\pm$  mesons provide stringent comparisons between experiment and theory due to the accuracy of both the measurements and the theoretical predictions [1].

**Introduction:** Charged mesons formed from a quark and an antiquark can decay to a charged lepton pair when these objects annihilate via a virtual  $W$  boson. Fig. 1 illustrates this process for the purely leptonic decay of a  $D^+$  meson.

**Figure 1:** The annihilation process for pure  $D^+$  leptonic decays in the Standard Model.

Similar quark-antiquark annihilations via a virtual  $W^+$  to the  $\ell^+\nu$  final states occur for the  $\pi^+$ ,  $K^+$ ,  $D_s^+$ , and  $B^+$  mesons. (Charge-conjugate particles and decays are implied.) Let  $P$  be any of these pseudoscalar mesons. To lowest order, the decay width is

$$\Gamma(P \rightarrow \ell\nu) = \frac{G_F^2}{8\pi} f_P^2 m_\ell^2 M_P \left(1 - \frac{m_\ell^2}{M_P^2}\right)^2 |V_{q_1 q_2}|^2. \quad (1)$$

Here  $M_P$  is the  $P$  mass,  $m_\ell$  is the  $\ell$  mass,  $V_{q_1 q_2}$  is the Cabibbo-Kobayashi-Maskawa (CKM) matrix element between the constituent quarks  $q_1 \bar{q}_2$  in  $P$ , and  $G_F$  is the Fermi coupling constant. The parameter  $f_P$  is the decay constant, proportional to the matrix element of the axial current between the one- $P$ -meson state and the vacuum, and is related to the wave-function overlap of the quark and antiquark.

The decay  $P \rightarrow \ell\nu$  starts with a spin-0 meson, and ends up with a left-handed neutrino or right-handed antineutrino. By angular momentum conservation, the  $\ell^\pm$  must then also be left-handed or right-handed, respectively. In the  $m_\ell = 0$  limit, the decay is forbidden, and can only occur as a result

of the finite  $\ell$  mass. This helicity suppression is the origin of the  $m_\ell^2$  dependence of the decay width. Radiative corrections are needed when the final charged particle is an electron or muon [2].

Measurements of purely leptonic decay branching fractions and lifetimes allow an experimental determination of the product  $|V_{q_1 q_2}| f_P$ . If the CKM element is well known from other measurements, then  $f_P$  can be well measured. If, on the other hand, the CKM element is not well measured, having theoretical input on  $f_P$  can allow a determination of the CKM element. The importance of measuring  $\Gamma(P \rightarrow \ell\nu)$  depends on the particle being considered. For example, the measurement of  $\Gamma(B^- \rightarrow \tau^- \bar{\nu})$  provides an indirect determination of  $|V_{ub}|$  provided that  $f_B$  is provided by theory. In addition,  $f_B$  is crucial for using measurements of  $B^0$ - $\bar{B}^0$  mixing to extract information on the fundamental CKM parameters. Knowledge of  $f_{B_s}$  is also needed, but it cannot be directly measured as the  $B_s$  is neutral, so the violation of the SU(3) relation  $f_{B_s} = f_B$  must be estimated theoretically. This difficulty does not occur for  $D$  mesons as both the  $D^+$  and  $D_s^+$  are charged, allowing the direct measurement of SU(3) breaking and a direct comparison with theory.

For  $B^-$  and  $D_s^+$  decays, the existence of a charged Higgs boson (or any other charged object beyond the Standard Model) would modify the decay rates; however, this would not necessarily be true for the  $D^+$  [3,4]. More generally, the ratio of  $\tau\nu$  to  $\mu\nu$  decays can serve as one probe of lepton universality [3,5].

As  $|V_{ud}|$  has been quite accurately measured in super-allowed  $\beta$  decays [6], with a value of 0.97425(22) [7], measurements of  $\Gamma(\pi^+ \rightarrow \mu^+\nu)$  yield a value for  $f_\pi$ . Similarly,  $|V_{us}|$  has been well measured in semileptonic kaon decays, so a value for  $f_K$  from  $\Gamma(K^- \rightarrow \mu^-\bar{\nu})$  can be compared to theoretical calculations. Lattice gauge theory calculations, however, have been claimed to be very accurate in determining  $f_K$ , and these have been used to predict  $|V_{us}|$  [8].

**Charmed mesons:** Our review of current measurements starts with the charm system. Measurements have been made for  $D^+ \rightarrow \mu^+\nu$ , and  $D_s^+ \rightarrow \mu^+\nu$  and  $\tau^+\nu$ . Only an upper limit has been determined for  $D^+ \rightarrow \tau^+\nu$ . Both CLEO-c and BES have made measurements of  $D^+$  decay using  $e^+e^-$  collisions at the  $\psi(3770)$  resonant energy where  $D^-D^+$  pairs are copiously produced. They fully reconstruct one of the  $D$ 's, say the  $D^-$ . Counting the number of these events provides the normalization for the branching fraction measurement. They then find a candidate  $\mu^+$ , and then form the missing-mass squared,  $MM^2 = (E_{\text{CM}} - E_{D^-})^2 - (\vec{p}_{\text{CM}} - \vec{p}_{D^-} - \vec{p}_{\mu^+})^2$ , taking into account their knowledge of the center-of-mass energy,  $E_{\text{CM}}$ , and momentum,  $p_{\text{CM}}$ , that equals zero in  $e^+e^-$  collisions. A peak at zero  $MM^2$  infers the existence of a missing neutrino and hence the  $\mu^+\nu$  decay of the  $D^+$ . CLEO-c does not explicitly identify the muon, so their data consist of a combination of  $\mu^+\nu$  and  $\tau^+\nu$ ,  $\tau^+ \rightarrow \pi^+\nu$  events. This permits them to do two fits; in

## Meson Particle Listings

 $D_s^\pm$ 

one they fit for the individual components, and in the other they fix the ratio of  $\tau^+\nu/\mu^+\nu$  events to be that given by the SM expectation. Thus, the latter measurement should be used for SM comparisons and the other for new physics searches. Our average uses the fixed ratio value. The measurements are shown in Table 1.

**Table 1:** Experimental results for  $\mathcal{B}(D^+ \rightarrow \mu^+\nu)$ ,  $\mathcal{B}(D^+ \rightarrow \tau^+\nu)$ , and  $f_{D^+}$ . Numbers for  $f_{D^+}$  have been extracted using updated values for masses and  $|V_{cd}|$  (see text). Radiative corrections are included. Systematic uncertainties arising from the  $D^+$  lifetime and mass are included.

Experiment	Mode	$\mathcal{B}$	$f_{D^+}$ (MeV)
CLEO-c [9]	$\mu^+\nu$	$(3.93 \pm 0.35 \pm 0.09) \times 10^{-4}$	$209.1 \pm 9.3 \pm 2.5$
CLEO-c [9]	$\mu^+\nu + \tau^+\nu$	$(3.82 \pm 0.32 \pm 0.09) \times 10^{-4}$	$206.2 \pm 8.6 \pm 2.6$
BES [10]	$\mu^+\nu$	$(3.74 \pm 0.21 \pm 0.06) \times 10^{-4}$	$204.0 \pm 5.7 \pm 2.0$
Average	$\mu^+\nu$	$(3.76 \pm 0.18) \times 10^{-4}$	$204.6 \pm 5.0$
CLEO-c [13]	$\tau^+\nu$	$< 1.2 \times 10^{-3}$	

To extract the value of  $f_{D^+}$  we use the well-measured  $D^+$  lifetime of 1.040(7) ps. The value of  $|V_{cd}|$  is taken to equal to the value of  $|V_{us}|$  of 0.2252(9) [7] minus higher-order correction terms [11], which results in  $|V_{cd}| = 0.2251(9)$ . The  $\mu^+\nu$  results include a 1% correction (lowering) of the rate due to the presence of the radiative  $\mu^+\nu\gamma$  final-state based on the estimate by Dobrescu and Kronfeld [12].

Before we compare this result with theoretical predictions, we discuss the  $D_s^+$ . Measurements of  $f_{D_s^+}$  have been made by several groups and are listed in Table 2 [13–17]. We exclude older values obtained by normalizing to  $D_s^+$  decay modes that are not well defined. Many measurements, for example, used the  $\phi\pi^+$  mode. This decay is a subset of the  $D_s^+ \rightarrow K^+K^-\pi^+$  channel which has interferences from other modes populating the  $K^+K^-$  mass region near the  $\phi$ , the most prominent of which is the  $f_0(980)$ . Thus the extraction of effective  $\phi\pi^+$  rate is sensitive to the mass resolution of the experiment and the cuts used to define the  $\phi$  mass region [18,19].

To find decays in the  $\mu^+\nu$  signal channels, CLEO, BaBar and Belle rely on fully reconstructing all the final-state particles except for neutrinos and using a missing-mass technique to infer the existence of the neutrino. CLEO uses  $e^+e^- \rightarrow D_s D_s^*$  collisions at 4170 MeV, while Babar and Belle use  $e^+e^- \rightarrow DKn\pi D_s^*$  collisions at energies near the  $\Upsilon(4S)$ . CLEO does a similar analysis as was done for the  $D^+$  above. Babar and Belle do a similar  $MM^2$  calculation by using the reconstructed hadrons, the photon from the  $D_s^{*+}$  decay and a detected  $\mu^+$ . To get the normalization they do a  $MM^2$  fit without the  $\mu^+$  and use the signal at the  $D_s^+$  mass squared to determine the total  $D_s^+$  yield.

When selecting the  $\tau^+ \rightarrow \pi^+\bar{\nu}$  and  $\tau^+ \rightarrow \rho^+\bar{\nu}$  decay modes, CLEO uses both calculation of the missing-mass and the fact that there should be no extra energy in the event beyond that deposited by the measured tagged  $D_s^-$  and the  $\tau^+$  decay products. The  $\tau^+ \rightarrow e^+\nu\bar{\nu}$  mode, however, uses only extra energy. Babar and Belle also use no extra energy to discriminate signal from background in their  $\tau^+\nu$  measurements.

We extract the decay constant from the measured branching ratios using the  $D_s^+$  mass of 1.96849(32) GeV, the  $\tau^+$  mass of 1.77682(16) GeV, and a lifetime of 0.500(7) ps. We use the first-order correction  $|V_{cs}| = |V_{ud}| - |V_{cb}|^2/2$  [11]; taking  $|V_{ud}| = 0.97425(22)$  [6], and  $|V_{cb}| = 0.04$  from an average of exclusive and inclusive semileptonic  $B$  decay results as discussed in Ref. [20], and find  $|V_{cs}| = 0.97345(22)$ . CLEO has included the radiative correction of 1% in the  $\mu^+\nu$  rate listed in the Table [12] (the  $\tau^+\nu$  rates need not be corrected). Other theoretical calculations show that the  $\mu^+\nu\gamma$  rate is a factor of 40–100 below the  $\mu^+\nu$  rate for charm [21]. As this is a small effect we do not attempt to correct the other measurements.

**Table 2:** Experimental results for  $\mathcal{B}(D_s^+ \rightarrow \mu^+\nu)$ ,  $\mathcal{B}(D_s^+ \rightarrow \tau^+\nu)$ , and  $f_{D_s^+}$ . Numbers for  $f_{D_s^+}$  have been extracted using updated values for masses and  $|V_{cs}|$  (see text). Radiative corrections and systematic uncertainties for errors on the  $D_s^+$  lifetime and mass have been included. Common systematic errors in each experiment have been taken into account.

Experiment	Mode	$\mathcal{B}(\%)$	$f_{D_s^+}$ (MeV)
CLEO-c [13]	$\mu^+\nu$	$0.565 \pm 0.045 \pm 0.017$	$257.6 \pm 10.3 \pm 4.3$
BaBar [14]	$\mu^+\nu$	$0.602 \pm 0.038 \pm 0.034$	$265.9 \pm 8.4 \pm 7.7$
Belle [15]	$\mu^+\nu$	$0.531 \pm 0.028 \pm 0.020$	$249 \pm 6.6 \pm 5.0$
Average	$\mu^+\nu$	$0.556 \pm 0.024$	$255.6 \pm 5.9$
CLEO-c [13]	$\tau^+\nu$ ( $\pi^+\bar{\nu}$ )	$6.42 \pm 0.81 \pm 0.18$	$278.0 \pm 17.5 \pm 4.4$
CLEO-c [16]	$\tau^+\nu$ ( $\rho^+\bar{\nu}$ )	$5.52 \pm 0.57 \pm 0.21$	$257.8 \pm 13.3 \pm 5.2$
CLEO-c [17]	$\tau^+\nu$ ( $e^+\nu\bar{\nu}$ )	$5.30 \pm 0.47 \pm 0.22$	$252.6 \pm 11.2 \pm 5.6$
BaBar [14]	$\tau^+\nu$ ( $e^+/\mu^+\nu\bar{\nu}$ )	$5.00 \pm 0.35 \pm 0.49$	$245.4 \pm 8.6 \pm 12.2$
Belle [15]	$\tau^+\nu$ ( $\pi^+\bar{\nu}$ )	$6.04 \pm 0.43^{+0.46}_{-0.40}$	$269.6 \pm 9.6^{+10.4}_{-9.1}$
Belle [15]	$\tau^+\nu$ ( $e^+\nu\bar{\nu}$ )	$5.37 \pm 0.33^{+0.35}_{-0.31}$	$254.2 \pm 7.8^{+8.5}_{-7.6}$
Belle [15]	$\tau^+\nu$ ( $\mu^+\nu\bar{\nu}$ )	$5.86 \pm 0.37^{+0.34}_{-0.59}$	$265.5 \pm 8.4^{+7.9}_{-13.5}$
Average	$\tau^+\nu$	$5.56 \pm 0.22$	$258.3 \pm 5.5$

The average decay constant cannot simply be obtained by averaging the values in Table 2 since there are correlated errors between the  $\mu^+\nu$  and  $\tau^+\nu$  values. Table 3 gives the average values of  $f_{D_s}$  where the experiments have included the correlations.

Our experimental average is

$$f_{D_s^+} = (257.5 \pm 4.6) \text{ MeV.}$$

**Table 3:** Experimental results for  $f_{D_s^+}$  taking into account the common systematic errors in the  $\mu^+\nu$  and  $\tau^+\nu$  measurements.

Experiment	$f_{D_s^+}$ (MeV)
CLEO-c	$259.0 \pm 6.2 \pm 3.0$
BaBar	$258.4 \pm 6.4 \pm 7.5$
Belle	$257.8 \pm 4.2 \pm 4.8$
Average of $\mu^+\nu + \tau^+\nu$	$257.5 \pm 4.6$

Furthermore, the ratio of branching fractions is found to be

$$R \equiv \frac{\mathcal{B}(D_s^+ \rightarrow \tau^+\nu)}{\mathcal{B}(D_s^+ \rightarrow \mu^+\nu)} = 10.0 \pm 0.6,$$

where a value of 9.76 is predicted in the Standard Model. Assuming lepton universality then we can derive improved values for the leptonic decay branching fractions of

$$\mathcal{B}(D_s^+ \rightarrow \mu^+\nu) = (5.64 \pm 0.20) \times 10^{-3}, \quad \text{and}$$

$$\mathcal{B}(D_s^+ \rightarrow \tau^+\nu) = (5.51 \pm 0.20) \times 10^{-2}.$$

The experimentally determined ratio of decay constants is  $f_{D_s^+}/f_{D^+} = 1.258 \pm 0.038$ . Table 4 compares the experimental  $f_{D_s^+}$  with theoretical calculations [22–27,30,31]. Most theories give values lower than the  $f_{D_s^+}$  measurement. The discrepancies with the models with the smallest quoted uncertainties, both unquenched lattice calculations, are 2.0 standard deviations with HPQCD [22], and 1.9 standard deviations with the preliminary FNAL+MILC prediction [23].

Upper limits on  $f_{D^+}$  and  $f_{D_s}$  of 230 and 270 MeV, respectively, have been determined using two-point correlation functions by Khodjamirian [32]. The  $D^+$  result is safely below this limit, while the average  $D_s^+$  result is also, but older results [1] not used in our average are often above the limit.

Akeroyd and Chen [33] pointed out that leptonic decay widths are modified in two-Higgs-doublet models (2HDM). Specifically, for the  $D^+$  and  $D_s^+$ , Eq. (1) is modified by a factor  $r_q$  multiplying the right-hand side [34]:

$$r_q = \left[ 1 + \left( \frac{1}{m_c + m_q} \right) \left( \frac{M_{D_q}}{M_{H^+}} \right)^2 \left( m_c - \frac{m_q \tan^2 \beta}{1 + \epsilon_0 \tan^2 \beta} \right) \right]^2,$$

where  $m_{H^+}$  is the charged Higgs mass,  $M_{D_q}$  is the mass of the  $D$  meson (containing the light quark  $q$ ),  $m_c$  is the charm quark mass,  $m_q$  is the light-quark mass, and  $\tan \beta$  is the ratio of the vacuum expectation values of the two Higgs doublets. In models where the fermion mass arises from coupling to more than one vacuum expectation value  $\epsilon_0$  can be non-zero, perhaps as large as 0.01. For the  $D^+$ ,  $m_d \ll m_c$ , and the change due to the  $H^+$  is very small. For the  $D_s^+$ , however, the effect can be substantial.

In order to investigate the possible presence of new physics we need to specify a SM value of  $f_{D_s^+}$ . We can only use a theory prediction. Our most aggressive choice is that of the unquenched lattice calculation [22], because it claims the smallest error. Since the charged Higgs would lower the rate compared to the SM, in principle, experiment gives a lower limit on the charged Higgs mass. However, the value for the

**Table 4:** Theoretical predictions of  $f_{D_s^+}$ ,  $f_{D^+}$ , and  $f_{D_s^+}/f_{D^+}$ . Quenched lattice calculations are omitted, while PQL indicates a partially-quenched lattice calculation. (Only selected results having errors are included.)

Model	$f_{D_s^+}$ (MeV)	$f_{D^+}$ (MeV)	$f_{D_s^+}/f_{D^+}$
Experiment (our averages)	$257.5 \pm 4.6$	$204.6 \pm 5.0$	$1.258 \pm 0.038$

## Meson Particle Listings

 $D_s^\pm$ 

predicted decay constant using this model is 2.0 standard deviations *below* the measurement. If this small discrepancy is to be taken seriously, either (a) the model of Ref. [22] is not representative; (b) no value of  $m_{H^\pm}$  in the two-Higgs doublet model will satisfy the constraint at 99% confidence level; or (c) there is new physics, different from the 2HDM, that interferes constructively with the SM amplitude such as in the R-parity-violating model of Akeroyd and Recksiegel [35].

To sum up, the standard model calculations are now consistent with the data and new physics effects are small. Limits can be placed on new particles depending on the specific model.

**The  $B^-$  meson:** The Belle and BaBar collaborations have found evidence for  $B^- \rightarrow \tau^- \bar{\nu}$  decay in  $e^+e^- \rightarrow B^- B^+$  collisions at the  $\Upsilon(4S)$  energy. The analysis relies on reconstructing a hadronic or semi-leptonic  $B$  decay tag, finding a  $\tau$  candidate in the remaining track and photon candidates, and examining the extra energy in the event which should be close to zero for a real  $\tau^-$  decay to  $e^- \nu \bar{\nu}$  or  $\mu^- \nu \bar{\nu}$  opposite a  $B^+$  tag. While the BaBar results have remained unchanged, Belle did a re-analysis of their data using the hadronic  $B$  decay sample. The branching fraction changed from  $1.79^{+0.56+0.46}_{-0.49-0.51} \times 10^{-4}$  [36] to  $0.72^{+0.27}_{-0.25} \pm 0.11 \times 10^{-4}$  [37]. This change demonstrates the difficulty of the analysis. It is unfortunate that other results have not been updated. The results are listed in Table 5.

**Table 5:** Experimental results for  $\mathcal{B}(B^- \rightarrow \tau^- \bar{\nu})$ .

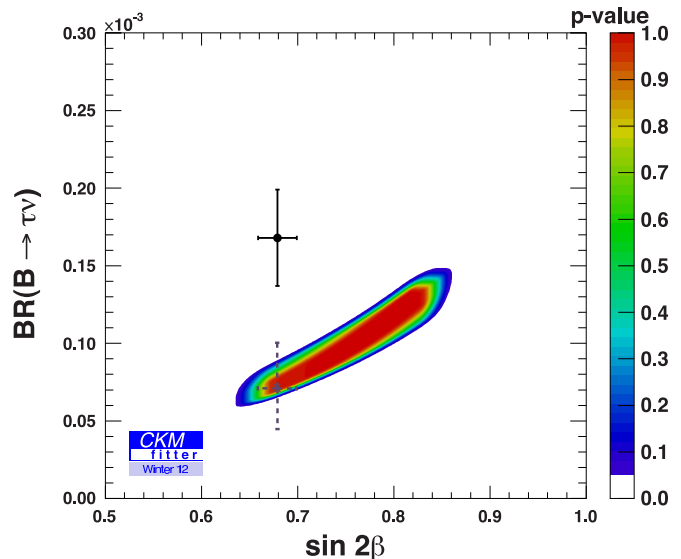

Experiment	Tag	$\mathcal{B}$ (units of $10^{-4}$ )
Belle [37]	Hadronic	$0.72^{+0.27}_{-0.25} \pm 0.11$
Belle [38]	Semileptonic	$1.54^{+0.38+0.29}_{-0.37-0.31}$
Belle [37]	Average	$0.96 \pm 0.26$
BaBar [39]	Hadronic	$1.83^{+0.53}_{-0.49} \pm 0.24$
BaBar [40]	Semileptonic	$1.7 \pm 0.8 \pm 0.2$
BaBar [39]	Average	$1.79 \pm 0.48$
	Our average	$1.14 \pm 0.23$

There are large backgrounds under the signals in all cases. The systematic errors are also quite large. Thus, the significances are not that large. Belle quotes  $3.0\sigma$  and  $3.6\sigma$  for their hadronic and semileptonic tags, while BaBar quotes  $3.3\sigma$  and  $2.3\sigma$  for these tags. More accuracy would be useful to investigate the effects of new physics.

We extract a SM value using Eq. (1). Here theory provides a value of  $f_B = (190.6 \pm 4.7)$  MeV [41]. We also need a value for  $|V_{ub}|$ . Here significant differences arise between using inclusive charmless semileptonic decays and the exclusive decay  $B \rightarrow \pi \ell^+ \nu$  [42]. The inclusive decays give rise to a value of  $|V_{ub}| = (4.41 \pm 0.22) \times 10^{-3}$  while the exclusive measurements yield  $|V_{ub}| = (3.23 \pm 0.31) \times 10^{-3}$ , where the errors are dominantly theoretical [43]. Their average, enlarging the error in the standard manner because the results differ, is  $|V_{ub}| = (4.01 \pm$

$0.56) \times 10^{-3}$ . Using these values and the PDG values for the  $B^+$  mass and lifetime, we arrive at the SM prediction for the  $\tau^- \bar{\nu}$  branching fraction of  $(1.03 \pm 0.29) \times 10^{-4}$ . This value is now consistent with the average.

It is instructive to examine the correlation between the CKM angle  $\beta$  and  $\mathcal{B}(B^- \rightarrow \tau^- \bar{\nu})$ . The CKM fitter group provides a fit to a large number of measurements involving heavy quark transitions [44]. The black point in Fig. 2 shows the directly measured values from 2012, while the predictions from their fit without the direct measurements are also shown. There is about a factor of two discrepancy between the old measured average value of  $\mathcal{B}(B^- \rightarrow \tau^- \bar{\nu})$  and the fit prediction. The (purple) dashed point shows the new Belle measurement only, and is consistent with the prediction, as is the new average.

**Figure 2:** Measured versus predicted values of  $\mathcal{B}(B^- \rightarrow \tau^- \bar{\nu})$  versus  $\sin 2\beta$  from the CKM fitter group. The solid (black) point with error bars shows the old (2012) measured average value, the dashed (purple) point the new Belle measurement, while the predictions are in colors, with the color being related to the confidence level. (Adopted from the CKM Fitter group.)

**Charged pions and kaons:** We now discuss the determination of charged pion and kaon decay constants. The sum of branching fractions for  $\pi^- \rightarrow \mu^- \bar{\nu}$  and  $\pi^- \rightarrow \mu^- \bar{\nu} \gamma$  is 99.98770(4)%. The two modes are difficult to separate experimentally, so we use this sum, with Eq. (1) modified to include photon emission and radiative corrections [45]. The branching fraction together with the lifetime 26.033(5) ns gives

$$f_{\pi^-} = (130.41 \pm 0.03 \pm 0.20) \text{ MeV} .$$

The first error is due to the error on  $|V_{ud}|$ , 0.97425(22) [6]; the second is due to the higher-order corrections, and is much larger.

Similarly, the sum of branching fractions for  $K^- \rightarrow \mu^- \bar{\nu}$  and  $K^- \rightarrow \mu^- \bar{\nu} \gamma$  is 63.55(11)%, and the lifetime is 12.3840(193) ns [46]. Measurements of semileptonic kaon decays provide a value for the product  $f_+(0)|V_{us}|$ , where  $f_+(0)$  is the form factor at zero four-momentum transfer between the initial state kaon and the final state pion. We use a value for  $f_+(0)|V_{us}|$  of 0.2163(5) [46]. The  $f_+(0)$  must be determined theoretically. The two most recent determinations from lattice QCD are 0.9667(23)(33) [47] and 0.9599(34)( $^{+31}_{-43}$ ) [48], whose average is  $f_+(0) = 0.9638(30)$ . This is more precise than the classic Leutwyler-Roos calculation  $f_+(0) = 0.961 \pm 0.008$  [49]. The result is  $|V_{us}| = 0.2244(9)$ , which is consistent with the hyperon decay value of 0.2250(27) [50].

Experimental branching ratios provide the ratio [52]

$$\frac{|V_{us}|f_{K^+}}{|V_{ud}|f_{\pi^-}} = 0.27598(35)(25) ,$$

where the first error is due to branching fractions and the second is due to electromagnetic corrections. With  $|V_{ud}| = 0.97425(22)$ ,  $f_{\pi^-}$  as given above, and  $|V_{us}| = 0.2244(9)$ , we then find

$$f_{K^-} = (156.2 \pm 0.2 \pm 0.6 \pm 0.3) \text{ MeV} .$$

The first uncertainty is due to the error on  $\Gamma$ ; the second is due to the CKM factor  $|V_{us}|$ , and the third is due to the higher-order corrections. The largest source of error in these corrections depends on the QCD part, which is based on one calculation in the large  $N_c$  framework. A large part of the additional uncertainty vanishes in the ratio of the  $K^-$  and  $\pi^-$  decay constants, which is

$$f_{K^-}/f_{\pi^-} = 1.198 \pm 0.002 \pm 0.005 \pm 0.001 .$$

The first uncertainty is due to the measured decay rates; the second is due to the uncertainties on the CKM factors; the third is due to the errors in the radiative correction ratio. These measurements can be used in conjunction with calculations of  $f_K/f_\pi$  in order to find a value for  $|V_{us}|/|V_{ud}|$  [51]. Recent lattice predictions of  $f_K/f_\pi$  are shown in Table 6.

**Table 6:** Lattice calculations of  $f_K/f_\pi$  and extracted values of  $|V_{us}|/|V_{ud}|$ .

Group	$f_K/f_\pi$	$ V_{us} / V_{ud} $
HPQCD [52]	$1.1916 \pm 0.0021$	0.23160(54)
Laiho and Van de Water [53]	$1.202 \pm 0.011 \pm 0.013$	–
BMW [54]	$1.192 \pm 0.007 \pm 0.006$	0.2315(19)
MILC [55]	$1.1947 \pm 0.0026 \pm 0.0037$	0.2309(10)
RBC/UKQCD [56]	$1.204 \pm 0.007 \pm 0.025$	–

These calculations are in agreement with our experimental average. Together with the precisely measured  $|V_{ud}|$ , these results can be used to find an independent measure of  $|V_{us}|$  [8,46].

$5.94 \pm 0.66 \pm 0.31$	88	4 PEDLAR	07A	CLEO See ALEXANDER 09
$6.8 \pm 1.1 \pm 1.8$	553	5 HEISTER	02i	ALEP Z decays

<sup>1</sup> ZUPANC 13 uses both  $\mu^+\nu$  and  $\tau^+\nu$  events to get  $f_{D_s} = (255.5 \pm 4.2 \pm 5.1)$  MeV.

<sup>2</sup> DEL-AMO-SANCHEZ 10J uses  $\mu^+\nu_\mu$  and  $\tau^+\nu_\tau$  events together to get  $f_{D_s} = (258.6 \pm 6.4 \pm 7.5)$  MeV.

<sup>3</sup> WIDHALM 08 gets  $f_{D_s} = (275 \pm 16 \pm 12)$  MeV from the branching fraction.

<sup>4</sup> PEDLAR 07A also fits  $\mu^+$  and  $\tau^+$  events together and gets an effective  $\mu^+\nu_\mu$  branching fraction of  $(6.38 \pm 0.59 \pm 0.33) \times 10^{-3}$ .

<sup>5</sup> This HEISTER 02i result is not actually an independent measurement of the absolute  $\mu^+\nu_\mu$  branching fraction, but is in fact based on our  $\phi\pi^+$  branching fraction of  $3.6 \pm 0.9\%$ , so it cannot be included in our overall fit. HEISTER 02i combines its  $D_s^+ \rightarrow \tau^+\nu_\tau$  and  $\mu^+\nu_\mu$  branching fractions to get  $f_{D_s} = (285 \pm 19 \pm 40)$  MeV.

$\Gamma(\mu^+ \nu_\mu)/\Gamma(\phi\pi^+)$   $\Gamma_{20}/\Gamma_{34}$ 

See the note on "Decay Constants of Charged Pseudoscalar Mesons" above.

VALUE	EVTS	DOCUMENT ID	TECN	COMMENT
••• We do not use the following data for averages, fits, limits, etc. •••				
$0.143 \pm 0.018 \pm 0.006$	489 ± 55	<sup>1</sup> AUBERT	07v BABR	$e^+e^- \approx \Upsilon(4S)$
$0.23 \pm 0.06 \pm 0.04$	18	<sup>2</sup> ALEXANDROV	00 BEAT	$\pi^-$ nucleus, 350 GeV
$0.173 \pm 0.023 \pm 0.035$	182	<sup>3</sup> CHADHA	98 CLE2	$e^+e^- \approx \Upsilon(4S)$
$0.245 \pm 0.052 \pm 0.074$	39	<sup>4</sup> ACOSTA	94 CLE2	See CHADHA 98

<sup>1</sup>AUBERT 07v gets  $f_{D_s^+} = (283 \pm 17 \pm 16)$  MeV, using  $\Gamma(D_S^+ \rightarrow \phi\pi^+)/\Gamma(\text{total}) = (4.71 \pm 0.46)\%$ .

<sup>2</sup>ALEXANDROV 00 uses  $f_D^2/f_{D_s}^2 = 0.82 \pm 0.09$  from a lattice-gauge-theory calculation to get the relative numbers of  $D^+ \rightarrow \mu^+\nu_\mu$  and  $D_S^+ \rightarrow \mu^+\nu_\mu$  events. The present result leads to  $f_{D_s} = (323 \pm 44 \pm 36)$  MeV.

<sup>3</sup>CHADHA 98 obtains  $f_{D_s} = (280 \pm 19 \pm 28 \pm 34)$  MeV from this measurement, using  $\Gamma(D_S^+ \rightarrow \phi\pi^+)/\Gamma(\text{total}) = 0.036 \pm 0.009$ .

<sup>4</sup>ACOSTA 94 obtains  $f_{D_s} = (344 \pm 37 \pm 52 \pm 42)$  MeV from this measurement, using  $\Gamma(D_S^+ \rightarrow \phi\pi^+)/\Gamma(\text{total}) = 0.037 \pm 0.009$ .

 $\Gamma(\tau^+ \nu_\tau)/\Gamma_{\text{total}}$   $\Gamma_{21}/\Gamma$ 

See the note on "Decay Constants of Charged Pseudoscalar Mesons" above.

$7.0 \pm 2.1 \pm 2.0$	22	<sup>6</sup> ABBIENDI	01L OPAL	$D_S^{*+} \rightarrow \gamma D_S^+$ from $Z^0$ 's
$7.4 \pm 2.8 \pm 2.4$	16	<sup>7</sup> ACCIARRI	97f L3	$D_S^{*+} \rightarrow \gamma D_S^+$ from $Z^0$ 's

<sup>1</sup>ZUPANC 13 uses both  $\mu^+\nu$  and  $\tau^+\nu$  events to get  $f_{D_s} = (255.5 \pm 4.2 \pm 5.1)$  MeV.

<sup>2</sup>DEL-AMO-SANCHEZ 10j uses  $\mu^+\nu_\mu$  and  $\tau^+\nu_\tau$  events together to get  $f_{D_s} = (258.6 \pm 6.4 \pm 7.5)$  MeV.

<sup>3</sup>ALEXANDER 09, NAIK 09a, and ONYISI 09 use different  $\tau$  decay modes and are independent. The three papers combined give  $f_{D_s} = (259.7 \pm 7.8 \pm 3.4)$  MeV.

<sup>4</sup>ECKLUND 08 and PEDLAR 07a are independent: ECKLUND 08 uses  $\tau^+ \rightarrow e^+ \nu_e \bar{\nu}_\tau$  events, PEDLAR 07a uses  $\tau^+ \rightarrow \pi^+ \bar{\nu}_\tau$  events.

<sup>5</sup>HEISTER 02i combines its  $D_S^+ \rightarrow \tau^+ \nu_\tau$  and  $\mu^+ \nu_\mu$  branching fractions to get  $f_{D_s} = (285 \pm 19 \pm 40)$  MeV.

<sup>6</sup>This ABBIENDI 01L value gives a decay constant  $f_{D_s}$  of  $(286 \pm 44 \pm 41)$  MeV.

<sup>7</sup>The normal ACCIARRI 97f error here combines in quadrature systematic (0.016) and normalization (0.018) errors. The branching fraction gives  $f_{D_s} = (309 \pm 58 \pm 33 \pm 38)$  MeV.

$5.50 \pm 0.23 \pm 0.16$		<sup>1</sup> ALEXANDER	08 CLEO See ONYISI 13

<sup>1</sup>ALEXANDER 08 uses single- and double-tagged events in an overall fit. The correlation matrix for the branching fractions is used in the fit.

$\Gamma(\phi\pi^+)/\Gamma_{\text{total}}$		$\Gamma_{34}/\Gamma$	
The results here are model-independent. For earlier, model-dependent results, see our PDG 06 edition. We decouple the $D_S^+ \rightarrow \phi\pi^+$ branching fraction obtained from mass projections (and used to get some of the other branching fractions) from the $D_S^+ \rightarrow \phi\pi^+, \phi \rightarrow K^+K^-$ branching fraction obtained from the Dalitz-plot analysis of $D_S^+ \rightarrow K^+K^-\pi^+$ . That is, the ratio of these two branching fractions is not exactly the $\phi \rightarrow K^+K^-$ branching fraction 0.491.

$4.81 \pm 0.52 \pm 0.38$	212 ± 19	<sup>2</sup> AUBERT	05V BABR $e^+e^- \approx \Upsilon(4S)$
$3.59 \pm 0.77 \pm 0.48$		<sup>3</sup> ARTUSO	96 CLE2 $e^+e^-$ at $\Upsilon(4S)$
••• We do not use the following data for averages, fits, limits, etc. •••			
$3.9^{+5.1}_{-1.9} \pm 1.8_{-1.1}$		4 BAI	95c BES $e^+e^-$ 4.03 GeV

<sup>1</sup>This AUBERT 06N measurement uses  $\bar{B}^0 \rightarrow D_S^{(*)-} D^{(*)+}$  and  $B^- \rightarrow D_S^{(*)-} D^{(*)0}$  decays, including some from other papers. However, the result is independent of AUBERT 05V.

<sup>2</sup>AUBERT 05V uses the ratio of  $B^0 \rightarrow D^{*-} D_S^{*+}$  events seen in two different ways, in both of which the  $D^{*-} \rightarrow \bar{D}^0 \pi^-$  decay is fully reconstructed: (1) The  $D_S^{*+} \rightarrow D_S^+ \gamma, D_S^+ \rightarrow \phi\pi^+$  decay is fully reconstructed. (2) The number of events in the  $D_S^+$  peak in the missing mass spectrum against the  $D^{*-} \gamma$  is measured.

<sup>3</sup>ARTUSO 96 uses partially reconstructed  $\bar{B}^0 \rightarrow D^{*+} D_S^{*-}$  decays to get a model-independent value for  $\Gamma(D_S^- \rightarrow \phi\pi^-)/\Gamma(D^0 \rightarrow K^-\pi^+)$  of  $0.92 \pm 0.20 \pm 0.11$ .

<sup>4</sup>BAI 95c uses  $e^+e^- \rightarrow D_S^+ D_S^-$  events in which one or both of the  $D_S^\pm$  are observed to obtain the first model-independent measurement of the  $D_S^+ \rightarrow \phi\pi^+$  branching fraction, without assumptions about  $\sigma(D_S^\pm)$ . However, with only two “doubly-tagged” events, the statistical error is very large.

$\Gamma(\phi\pi^+, \phi \rightarrow K^+K^-)/\Gamma(K^+K^-\pi^+)$		$\Gamma_{35}/\Gamma_{33}$	
This is the “fit fraction” from the Dalitz-plot analysis. We decouple the $D_S^+ \rightarrow \phi\pi^+$ branching fraction obtained from mass projections (and used to get some of the other branching fractions) from the $D_S^+ \rightarrow \phi\pi^+, \phi \rightarrow K^+K^-$ branching fraction obtained from the Dalitz-plot analysis of $D_S^+ \rightarrow K^+K^-\pi^+$ . That is, the ratio of these two branching fractions is not exactly the $\phi \rightarrow K^+K^-$ branching fraction 0.491.

$\Gamma(\pi^+(\pi^+\pi^-)S\text{-wave})/\Gamma(2\pi^+\pi^-)$		$\Gamma_{60}/\Gamma_{58}$	
This is the "fit fraction" from the Dalitz-plot analysis. See also KLEMP 08, which uses 568 $D_S^+ \rightarrow 3\pi$ decays (over 280 background events) from FNAL E791 to study various parametrizations of the decay amplitudes. The emphasis there is more on S-wave $\pi\pi$ decay products — 20 different solutions are given — than on $D_S^+$ fit fractions.

### $D_s^+ - D_s^-$ T-VIOLATING DECAY-RATE ASYMMETRIES

$A_{Tviol}(K_S^0 K^\pm \pi^+ \pi^-)$  in  $D_s^\pm \rightarrow K_S^0 K^\pm \pi^+ \pi^-$

$C_T \equiv \bar{p}_{K^+} \cdot (\bar{p}_{\pi^+} \times \bar{p}_{\pi^-})$  is a parity-odd correlation of the  $K^+$ ,  $\pi^+$ , and  $\pi^-$  momenta for the  $D_s^+$ .  $\bar{C}_T \equiv \bar{p}_{K^-} \cdot (\bar{p}_{\pi^-} \times \bar{p}_{\pi^+})$  is the corresponding quantity for the  $D_s^-$ . Then

$A_T \equiv [\Gamma(C_T > 0) - \Gamma(C_T < 0)] / [\Gamma(C_T > 0) + \Gamma(C_T < 0)]$ , and

$\bar{A}_T \equiv [\Gamma(-\bar{C}_T > 0) - \Gamma(-\bar{C}_T < 0)] / [\Gamma(-\bar{C}_T > 0) + \Gamma(-\bar{C}_T < 0)]$ , and

See key on page 547

Meson Particle Listings

$$D_s^\pm, D_s^{*\pm}$$

$A_{Tviol} \equiv \frac{1}{2}(A_T - \bar{A}_T)$ .  $C_T$  and  $\bar{C}_T$  are commonly referred to as  $T$ -odd moments, because they are odd under  $T$  reversal. However, the  $T$ -conjugate process  $K_S^0 K^\pm \pi^\pm \pi^\mp \rightarrow D_s^\pm$  is not accessible, while the  $P$ -conjugate process is.

 $D_s^{*+}$  DECAY MODES

$D_s^{*-}$  modes are charge conjugates of the modes below.

Mode	Fraction ( $\Gamma_i/\Gamma$ )
$\Gamma_1$ $D_s^+\gamma$	(94.2±0.7) %
$\Gamma_2$ $D_s^+\pi^0$	( 5.8±0.7) %

## CONSTRAINED FIT INFORMATION

An overall fit to a branching ratio uses 2 measurements and one constraint to determine 2 parameters. The overall fit has a  $\chi^2 = 0.0$  for 1 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

$$x_2 \begin{vmatrix} -100 \\ x_1 \end{vmatrix}$$

## CONSTRAINED FIT INFORMATION

An overall fit to 7 branching ratios uses 8 measurements and one constraint to determine 5 parameters. The overall fit has a  $\chi^2 = 3.4$  for 4 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

## *B* Meson Production and Decay, *b*-flavored hadrons

### BOTTOM MESONS

$$(B = \pm 1)$$

$$B^+ = u\bar{b}, B^0 = d\bar{b}, \bar{B}^0 = \bar{d}b, B^- = \bar{u}b, \text{ similarly for } B^{*s}$$

### *B*-particle organization

Many measurements of *B* decays involve admixtures of *B* hadrons. Previously we arbitrarily included such admixtures in the  $B^\pm$  section, but because of their importance we have created two new sections: “ $B^\pm/B^0$  Admixture” for  $T(4S)$  results and “ $B^\pm/B^0/B_S^0/b$ -baryon Admixture” for results at higher energies. Most inclusive decay branching fractions and  $\chi_b$  at high energy are found in the Admixture sections.  $B^0/\bar{B}^0$  mixing data are found in the  $B^0$  section, while  $B_S^0/\bar{B}_S^0$  mixing data and  $B-\bar{B}$  mixing data for a  $B^0/B_S^0$  admixture are found in the  $B_S^0$  section. *CP*-violation data are found in the  $B^\pm, B^0$ , and  $B^\pm/B^0$  Admixture sections. *b*-baryons are found near the end of the Baryon section. Recently, we also created a new section: “ $V_{cb}$  and  $V_{ub}$  CKM Matrix Elements.”

The organization of the *B* sections is now as follows, where bullets indicate particle sections and brackets indicate reviews.

[Production and Decay of *b*-flavored Hadrons]

[A Short Note on HFAG Activities]

- $B^\pm$ 
  - mass, mean life
  - branching fractions
  - polarization in  $B^\pm$  decay
  - CP* violation
- $B^0$ 
  - mass, mean life
  - branching fractions
  - [Polarization in *B* decay]
  - polarization in  $B^0$  decay
  - [ $B-\bar{B}$  Mixing]
  - $B^0/\bar{B}^0$  mixing
  - CP* violation
- $B^\pm/B^0$  Admixture
  - branching fractions, *CP* violation
  - CP* violation
- $B^\pm/B^0/B_S^0/b$ -baryon Admixture
  - mean life
  - production fractions
  - branching fractions
  - $\chi_b$  at high energy
  - production fractions in hadronic *Z* decay
- $V_{cb}$  and  $V_{ub}$  CKM Matrix Elements
  - [Determination of  $V_{cb}$  and  $V_{ub}$ ]
- $B^*$ 
  - mass
- $B_1(5721)^0$ 
  - mass
- $B_J^*(5732)$ 
  - mass, width
- $B_2(5747)^0$ 
  - mass
- $B_S^0$ 
  - mass, mean life
  - branching fractions
  - polarization in  $B_S^0$  decay
  - $B_S^0/\bar{B}_S^0$  mixing
- $B_S^*$ 
  - mass
- $B_{s,J}^*(5850)$ 
  - mass, width
- $B_C^\pm$ 
  - mass, mean life
  - branching fractions

At the end of Baryon Listings:

- $\Lambda_b$ 
  - mass, mean life
  - branching fractions
- $\Sigma_b, \Sigma_b^*$ 
  - mass
- $\Xi_b^0, \Xi_b^-$ 
  - mean life
- $\Omega_b^-$ 
  - mass, mean life
  - branching fractions
- *b*-baryon Admixture
  - mean life
  - branching fractions

### PRODUCTION AND DECAY OF *b*-FLAVORED HADRONS

Updated March 2014 by M. Kreps (U. of Warwick, Coventry, UK) and Y. Kwon (Yonsei U., Seoul, Korea).

The *b* quark belongs to the third generation of quarks and is the weak-doublet partner of the *t* quark. The existence of the third-generation quark doublet was proposed in 1973 by Kobayashi and Maskawa [1] in their model of the quark mixing matrix (“CKM” matrix), and confirmed four years later by the first observation of a  $b\bar{b}$  meson [2]. In the KM model, *CP* violation is explained within the Standard Model (SM) by an irreducible phase of the  $3 \times 3$  unitary matrix. The regular pattern of the three lepton and quark families is one of the most intriguing puzzles in particle physics. The existence of families gives rise to many of the free parameters in the SM, including the fermion masses, and the elements of the CKM matrix.

Since the *b* quark is the lighter element of the third-generation quark doublet, the decays of *b*-flavored hadrons occur via generation-changing processes through this matrix. Because of this, and the fact that the CKM matrix is close to a  $3 \times 3$  unit matrix, many interesting features such as loop and box diagrams, flavor oscillations, as well as large *CP* asymmetries, can be observed in the weak decays of *b*-flavored hadrons.

The CKM matrix is parameterized by three real parameters and one complex phase. This complex phase can become a source of *CP* violation in *B* meson decays. A crucial milestone was the first observation of *CP* violation in the *B* meson system in 2001, by the BaBar [3] and Belle [4] collaborations. They measured a large value for the parameter  $\sin 2\beta$  ( $= \sin 2\phi_1$ ) [5], almost four decades after the discovery of a small *CP* asymmetry in neutral kaons. A more detailed discussion of the CKM matrix and *CP* violation can be found elsewhere in this *Review* [6,7].

Recent developments in the physics of *b*-hadrons include the significant improvement in experimental determination of the CKM angle  $\gamma$ , the increased information on  $B_s, B_c$  and  $\Lambda_b$  decays, the precise determination of  $\Lambda_b$  lifetime, the wealth of information in the  $B^0 \rightarrow K^{*0}(892)\ell^+\ell^-$  decays and after many years of search, the observation of  $B_s \rightarrow \mu^+\mu^-$  decays along with ever increasing precision on the CKM matrix parameters.

The structure of this mini-review is organized as follows. After a brief description of theory and terminology, we discuss *b*-quark production and current results on spectroscopy and lifetimes of *b*-flavored hadrons. We then discuss some basic properties of *B*-meson decays, followed by summaries of hadronic, rare, and electroweak penguin decays of *B*-mesons. There are separate mini-reviews for  $B\bar{B}$  mixing [8] and the extraction of the CKM matrix elements  $V_{cb}$  and  $V_{ub}$  from *B*-meson decays [9] in this *Review*.

**Theory and terminology:** The ground states of *b*-flavored hadrons decay via weak interactions. In most hadrons, the *b*-quark is accompanied by light-partner quarks (*d*, *u*, or *s*), and the decay modes are well described by the decay of the *b* quark (spectator model) [10]. The dominant decay mode of a *b* quark is  $b \rightarrow cW^{*-}$  (referred to as a “tree” or “spectator” decay), where the virtual *W* materializes either into a pair of leptons  $\ell\bar{\nu}$  (“semileptonic decay”), or into a pair of quarks which then hadronizes. The decays in which the spectator quark combines with one of the quarks from  $W^*$  to form one of the final state hadrons are suppressed by a factor  $\sim (1/3)^2$ , because the colors of the two quarks from different sources must match (“color-suppression”).

Many aspects of *B* decays can be understood through the Heavy Quark Effective Theory (HQET) [11]. This has been particularly successful for semileptonic decays. For further discussion of HQET, see for instance Ref. 12. For hadronic decays, one typically uses effective Hamiltonian calculations that rely on a perturbative expansion with Wilson coefficients. In addition, some form of the factorization hypothesis is commonly used, where, in analogy with semileptonic decays, two-body hadronic decays of *B* mesons are expressed as the product of two independent hadronic currents, one describing the formation of a charm meson (in case of the dominant  $b \rightarrow cW^{*-}$  decays), and the other the hadronization of the remaining  $\bar{u}d$  (or  $\bar{c}s$ ) system from the virtual  $W^-$ . Qualitatively, for a *B* decay with a large energy release, the  $\bar{u}d$  pair (produced as a color singlet) travels fast enough to leave the interaction region without influencing the charm meson. This is known to work well for the dominant spectator decays [13]. There are several common implementations of these ideas for hadronic *B* decays, the most common of which are QCD factorization (QCDF) [14], perturbative QCD (pQCD) [15], and soft collinear effective theory (SCET) [16].

The transition  $b \rightarrow u$  is suppressed by  $|V_{ub}/V_{cb}|^2 \sim (0.1)^2$  relative to  $b \rightarrow c$  transitions. The transition  $b \rightarrow s$  is a flavor-changing neutral-current (FCNC) process, and although not allowed in the SM as a tree-process, can occur via more complex loop diagrams (denoted “penguin” decays). The rates for such processes are comparable or larger than CKM-suppressed  $b \rightarrow u$  processes. Penguin processes involving  $b \rightarrow d$  transitions are also possible, and have been observed [17,18]. Other decay processes discussed in this *Review* include *W*-exchange (a *W* is exchanged between initial-state quarks), penguin annihilation (the gluon from a penguin loop attaches to the spectator quark,

similar to an exchange diagram), and pure-annihilation (the initial quarks annihilate to a virtual *W*, which then decays).

**Production and spectroscopy:** The bound states of a  $\bar{b}$  antiquark and a *u*, *d*, *s*, or *c* quark are referred to as the  $B_u$  ( $B^+$ ),  $B_d$  ( $B^0$ ),  $B_s$ , and  $B_c$  mesons, respectively. The  $B_c$  is the heaviest of the ground-state *b*-flavored mesons, and the most difficult to produce: it was observed for the first time in the semileptonic mode by CDF in 1998 [19], but its mass was accurately determined only in 2006, from the fully reconstructed mode  $B_c^+ \rightarrow J/\psi\pi^+$  [20]. One of the best determination up to date uses  $B_c^+ \rightarrow J\psi D_s^+$  decay and yields  $M(B_c^+) = 6276.28 \pm 1.44 \pm 0.36$  MeV/ $c^2$  [21]. As this decay has very low energy release, it allows to decrease systematic uncertainty and thus offers prospects for future increase in precision.

The first excited meson is called the  $B^*$  meson, while  $B^{**}$  is the generic name for the four orbitally excited ( $L = 1$ ) *B*-meson states that correspond to the *P*-wave mesons in the charm system,  $D^{**}$ . Excited states of the  $B_s$  meson are similarly named  $B_s^*$  and  $B_s^{**}$ . Of the possible bound  $\bar{b}b$  states, the  $\Upsilon$  series (S-wave) and the  $\chi_b$  (P-wave) are well studied. The pseudoscalar ground state  $\eta_b$  also has been observed by BaBar [22] (and confirmed by CLEO [23]), indirectly through the decay  $\Upsilon(3S) \rightarrow \gamma\eta_b$ . See Ref. 45 for classification and naming of these and other states.

Experimental studies of *b* decays have been performed in  $e^+e^-$  collisions at the  $\Upsilon(4S)$  (ARGUS, CLEO, Belle, BaBar) and  $\Upsilon(5S)$  (CLEO, Belle) resonances, as well as at higher energies, at the *Z* resonance (SLC, LEP), in  $p\bar{p}$  (Tevatron) and  $pp$  collisions (LHC). The  $e^+e^- \rightarrow b\bar{b}$  production cross-section at the *Z*,  $\Upsilon(4S)$ , and  $\Upsilon(5S)$  resonances are about 6.6 *nb*, 1.1 *nb*, and 0.3 *nb* respectively. High-energy hadron collisions produce *b*-flavored hadrons of all species with much larger cross-sections:  $\sigma(p\bar{p} \rightarrow bX, |\eta| < 1) \sim 30$   $\mu\text{b}$  at the Tevatron ( $\sqrt{s} = 1.96$  TeV), and even higher at the energies of the LHC  $pp$  collider (at  $\sqrt{s} = 7$  TeV, visible *b*-hadron cross section at the LHCb is  $\sim 100$   $\mu\text{b}$ ).

BaBar and Belle have accumulated respectively 560  $\text{fb}^{-1}$  and 1020  $\text{fb}^{-1}$  of data, of which 433  $\text{fb}^{-1}$  and 710  $\text{fb}^{-1}$  respectively are at the  $\Upsilon(4S)$  resonance; CDF and D0 have accumulated by the end of their running about 10  $\text{fb}^{-1}$  each. At the LHC, CMS and ATLAS have collected 5  $\text{fb}^{-1}$  (20  $\text{fb}^{-1}$ ) of data at  $\sqrt{s} = 7$  (8) TeV respectively and LHCb has collected about 1  $\text{fb}^{-1}$  and 2  $\text{fb}^{-1}$  at the two energies. These numbers indicate that the majority of *b*-quarks have been produced in hadron collisions, but the large backgrounds cause the hadron collider experiments to have lower selection efficiency. While traditionally only the few decay modes for which triggering and reconstruction are easiest have been studied in hadron collisions, with current experiments at hadron colliders much more is possible. This is due to triggers based on the tracking first introduced in CDF and further improved by LHCb. LHCb experiment has also reasonable capability for detection of neutral

## *b*-flavored hadrons

pions and photons. While both  $e^+e^-$  and hadron colliders have their own strengths and weaknesses, in the domain of decays which involve neutrinos,  $e^+e^-$  experiments are in significant advantage.

In hadron collisions, most production happens as  $b\bar{b}$  pairs, either via  $s$ -channel production or gluon-splitting, with a smaller fraction of single  $b$ -quarks produced by flavor excitation. The total  $b$ -production cross section is an interesting test of our understanding of QCD processes. For many years, experimental measurements have been several times higher than predictions. With improved measurements [24], more accurate input parameters, and more advanced calculations [25], the discrepancy between theory and data diminished and there is now good agreement between measurements and predictions.

Each quark of a  $b\bar{b}$  pair produced in hadron collisions hadronizes separately and incoherently from the other, but it is still possible, although difficult, to obtain a statistical indication of the charge of a produced  $b/\bar{b}$  quark (“flavor tag” or “charge tag”) from the accompanying particles produced in the hadronization process, or from the decay products of the other quark. The momentum spectrum of produced  $b$ -quarks typically peaks near the  $b$ -quark mass, and extends to much higher momenta, dropping by about a decade for every ten GeV. This implies typical decay lengths of the order of a millimeter; the resolution for the decay vertex must be more precise than this to resolve the fast oscillations of  $B_s$  mesons.

In  $e^+e^-$  colliders, since the  $B$  mesons are very slow in the  $\Upsilon(4S)$  rest frame, asymmetric beam energies are used to boost the decay products to improve the precision of time-dependent measurements that are crucial for the study of  $CP$  violation. At KEKB, the boost is  $\beta\gamma = 0.43$ , and the typical  $B$ -meson decay length is dilated from  $\approx 20 \mu\text{m}$  to  $\approx 200 \mu\text{m}$ . PEP-II used a slightly larger boost,  $\beta\gamma = 0.55$ . The two  $B$  mesons produced in  $\Upsilon(4S)$  decay are in a coherent quantum state, which makes it easier than in hadron collisions to infer the charge state of one  $B$  meson from observation of the other; however, the coherence also requires determination of the decay time of both mesons, rather than just one, in order to perform time-dependent  $CP$ -violation measurements. For  $B_s$ , which can be produced at  $\Upsilon(5S)$  the situation is less favourable, as boost is not high enough to provide sufficient time resolution to resolve the fast  $B_s$  oscillations.

For the measurement of branching fractions, the initial composition of the data sample must be known. The  $\Upsilon(4S)$  resonance decays predominantly to  $B^0\bar{B}^0$  and  $B^+B^-$ ; the current experimental upper limit for non- $B\bar{B}$  decays of the  $\Upsilon(4S)$  is less than 4% at the 95% confidence level (CL) [26]. The only known modes of this category are decays to lower  $\Upsilon$  states and a pion pair, observed with branching fractions of order  $10^{-4}$  [27]. The ratio  $f_+/f_0$  of the fractions of charged to neutral  $B$  productions from  $\Upsilon(4S)$  decays has been measured by CLEO, BaBar, and Belle in various ways. They typically use pairs of isospin-related decays of  $B^+$  and  $B^0$ , such that it can be assumed that  $\Gamma(B^+ \rightarrow x^+) = \Gamma(B^0 \rightarrow x^0)$ . In this

way, the ratio of the number of events observed in these modes is proportional to  $(f_+\tau_+)/ (f_0\tau_0)$  [28–31]. BaBar has also performed an independent measurement of  $f_0$  with a different method that does not require isospin symmetry or the value of the lifetime ratio, based on the number of events with one or two reconstructed  $B^0 \rightarrow D^{*-}\ell^+\nu$  decays [32]. The combined result, from the current average of  $\tau_+/\tau_0$ , is  $f_+/f_0 = 1.058 \pm 0.024$  [33]. Though the current  $2.4\sigma$  discrepancy with equal production of  $B^+B^-$  and  $B^0\bar{B}^0$  pairs is somewhat larger than previous averages, we still assume  $f_+/f_0 = 1$  in this mini-review except where explicitly stated otherwise. This assumption is also supported by the near equality of the  $B^+$  and  $B^0$  masses: our fit of CLEO, ARGUS, CDF, and LHCb measurements yields  $m(B^0) = 5279.58 \pm 0.17 \text{ MeV}/c^2$ ,  $m(B^+) = 5279.26 \pm 0.17 \text{ MeV}/c^2$ , and  $m(B^0) - m(B^+) = 0.32 \pm 0.06 \text{ MeV}/c^2$ .

CLEO and Belle have also collected some data at the  $\Upsilon(5S)$  resonance [34,35]. Belle has accumulated more than  $100 \text{ fb}^{-1}$  at this resonance. This resonance does not provide the simple final states like the  $\Upsilon(4S)$ : there are seven possible final states with a pair of non-strange  $B$  mesons and three with a pair of strange  $B$  mesons ( $B_s^*\bar{B}_s^*$ ,  $B_s^*\bar{B}_s$ , and  $B_s\bar{B}_s$ ). The fraction of events with a pair of  $B_s$  mesons over the total number of events with a pair of  $b$ -flavored hadrons has been measured to be  $f_s[\Upsilon(5S)] = 0.201^{+0.030}_{-0.031}$ , of which 90% is  $B_s^*\bar{B}_s^*$  events. A few branching fractions of the  $B_s$  have been measured in this way; if the precision of  $f_s$  were improved, they would become the most accurate. Belle has observed a few new  $B_s$  modes that are difficult to reconstruct in hadron colliders and the most precise mass measurement of the  $B_s^*$  meson has been obtained [35,36]. However, the small boost of  $B_s$  mesons produced in this way prevents resolution of their fast oscillations for time-dependent measurements; these are only accessible in hadron collisions or at the  $Z$  peak.

In high-energy collisions, the produced  $b$  or  $\bar{b}$  quarks can hadronize with different probabilities into the full spectrum of  $b$ -hadrons, either in their ground or excited states. Table 1 shows the measured fractions  $f_d$ ,  $f_u$ ,  $f_s$ , and  $f_{\text{baryon}}$  of  $B^0$ ,  $B^+$ ,  $B_s^0$ , and  $b$  baryons, respectively, in an unbiased sample of weakly decaying  $b$  hadrons produced at the  $Z$  resonance or in  $p\bar{p}$  collisions [33]. The results were obtained from a fit where the sum of the fractions were constrained to equal 1.0, neglecting production of  $B_c$  mesons. The observed yields of  $B_c$  mesons at the Tevatron [19] yields  $f_c = 0.2\%$ , in agreement with expectations [37], and well below the current experimental uncertainties in the other fractions.

For rather long time, the average of fractions in  $p\bar{p}$  collisions and in  $Z$  decay was used as it was assumed that the hadronization is identical in the two environments. It was clear that this assumption does not have to hold in principle, because of the different momentum distributions of the  $b$ -quark in these processes; the sample used in the  $p\bar{p}$  measurements has momenta close to the  $b$  mass, rather than  $m_Z/2$ . But in the absence of any significant evidence there was also no

strong reason against the average. Some discrepancies were observed, but as picture was also obscured by  $1.8\sigma$  discrepancy in the average time-integrated mixing probability parameter  $\bar{\chi} = f_d\chi_d + f_s\chi_s$  between LEP and Tevatron [8], they were not directly attributed to breakdown of the assumption that hadronization is identical. The first indication that fraction for *b*-baryons depends on the momentum and thus environment came from CDF [38], but available precision did not allow for firm conclusion. The final evidence for non-universality of hadronization fractions came from LHCb, where strong dependence on the transverse momentum was observed for the  $\Lambda_b$  fraction [39].

**Table 1:** Fragmentation fractions of *b* quarks into weakly-decaying *b*-hadron species in  $Z \rightarrow b\bar{b}$  decay, in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV.

<i>b</i> hadron	Fraction at Z [%]	Fraction at $p\bar{p}$ [%]
$B^+, B^0$	$40.4 \pm 0.9$	$33.9 \pm 3.9$
$B_s$	$10.3 \pm 0.9$	$11.1 \pm 1.4$
<i>b</i> baryons	$8.9 \pm 1.5$	$21.2 \pm 6.9$

Excited *B*-meson states have been observed by CLEO, LEP, CUSB, D0, and CDF. The current world average of the  $B^{*-}B$  mass difference is  $45.78 \pm 0.35$  MeV/ $c^2$ . Evidence for  $B^{**}$  ( $L=1$ ) production has been initially obtained at LEP [40], as a broad resonance in the mass of an inclusively reconstructed bottom hadron candidate combined with a charged pion from the primary vertex. Detailed results from exclusive modes have been obtained at the Tevatron, allowing separation of the narrow states  $B_1$  and  $B_2^*$  and also a measurement of the  $B_2^*$  width [41].

Also the narrow  $B_s^{**}$  states, first sighted by OPAL as a single broad enhancement in the  $B^+K$  mass spectrum [42], have now been clearly observed and separately measured at the hadron colliders [43,44]. The measured masses are  $M(B_{s1}) = 5828.7 \pm 0.4$  MeV/ $c^2$  and  $M(B_{s2}^*) = 5839.96 \pm 0.2$  MeV/ $c^2$ .

Baryon states containing a *b* quark are labeled according to the same scheme used for non-*b* baryons, with the addition of a *b* subscript [45]. For many years, the only well-established *b* baryon was the  $\Lambda_b^0$  (quark composition  $udb$ ), with only indirect evidence for  $\Xi_b$  ( $dsb$ ) production from LEP [46]. This situation has changed dramatically in the past few years due to the large samples being accumulated at the Tevatron and LHCb. Clear signals of four strongly-decaying baryon states,  $\Sigma_b^+, \Sigma_b^{*+}$  ( $uub$ ),  $\Sigma_b^-, \Sigma_b^{*-}$  ( $ddb$ ) have been obtained by CDF in  $\Lambda_b^0\pi^\pm$  final states [47]. The strange bottom baryon  $\Xi_b^\pm$  was observed in the exclusive mode  $\Xi_b^\pm \rightarrow J/\psi\Xi^\pm$  by D0 [48], and CDF [49]. More recently CDF has also observed the  $\Xi_b$  in the  $\Xi_c\pi$  final state [50]. The relative production of  $\Xi_b$  and  $\Lambda_b$  baryons has been found to be consistent with the  $B_s$  to  $B_d$  production ratio [48]. Observation of the doubly-strange bottom baryon  $\Omega_b^-$  has been published by both D0 [51] and CDF [52]. However the masses measured by the two experiments show a large discrepancy. The

resolution is provided by LHCb which measures the  $\Omega_b^-$  mass consistent with CDF [53]. The CMS experiment added to the list also neutral spin-3/2  $\Xi_b^*$  [54]. The masses of all these new baryons have been measured to a precision of a few MeV/ $c^2$ , and found to be in agreement with predictions from HQET.

**Lifetimes:** Precise lifetimes are key in extracting the weak parameters that are important for understanding the role of the CKM matrix in *CP* violation, such as the determination of  $V_{cb}$  and  $B_s\bar{B}_s$  mixing parameters. In the naive spectator model, the heavy quark can decay only via the external spectator mechanism, and thus, the lifetimes of all mesons and baryons containing *b* quarks would be equal. Non-spectator effects, such as the interference between contributing amplitudes, modify this simple picture and give rise to a lifetime hierarchy for *b*-flavored hadrons similar to the one in the charm sector. However, since the lifetime differences are expected to scale as  $1/m_Q^2$ , where  $m_Q$  is the mass of the heavy quark, the variations in the *b* system are expected to be only 10% or less [55]. We expect:

$$\tau(B^+) \geq \tau(B^0) \approx \tau(B_s) > \tau(\Lambda_b^0) \gg \tau(B_c^+) . \quad (1)$$

For the  $B_c^\pm$ , both quarks decay weakly, so the lifetime is much shorter.

Measurements of the lifetimes of the different *b*-flavored hadrons thus provide a means to determine the importance of non-spectator mechanisms in the *b* sector. Over the past decade, the precision of silicon vertex detectors and the increasing availability of fully-reconstructed samples has resulted in much-reduced statistical and systematic uncertainties ( $\sim 1\%$ ). The averaging of precision results from different experiments is a complex task that requires careful treatment of correlated systematic uncertainties; the world averages given in Table 2 have been determined by the Heavy Flavor Averaging Group (HFAG) [33].

**Table 2:** Summary of inclusive and exclusive world-average *b*-hadron lifetime measurements. For the two  $B_s$  averages, see text below.

Particle	Lifetime [ps]
$B^+$	$1.638 \pm 0.004$
$B^0$	$1.519 \pm 0.005$
$B_s$ (flavor-specific)	$1.465 \pm 0.031$
$B_s$ ( $1/\Gamma_s$ )	$1.512 \pm 0.007$
$B_c^+$	$0.500 \pm 0.013$
$\Lambda_b^0$	$1.451 \pm 0.013$
$\Xi_b^-$	$1.56^{+0.27}_{-0.25}$
$\Omega_b^-$	$1.13^{+0.53}_{-0.40}$
$\Xi_b$ mixture	$1.49^{+0.19}_{-0.18}$
<i>b</i> -baryon mixture	$1.449 \pm 0.015$
<i>b</i> -hadron mixture	$1.568 \pm 0.009$

# Meson Particle Listings

## *b*-flavored hadrons

The short  $B_c^+$  lifetime is in good agreement with predictions [56]. With large samples of  $B_c^+$  mesons at the LHCb precision on the lifetimes should significantly improve. First measurement using semileptonic decays gives  $\tau_{B_c^+} = 0.509 \pm 0.008 \pm 0.012$  [57], which is already more precise than combination of all previous experiment. For precision comparisons with theory, lifetime ratios are more sensitive. Experimentally we find:

$$\frac{\tau_{B^+}}{\tau_{B^0}} = 1.076 \pm 0.004, \quad \frac{\tau_{B_s}}{\tau_{B^0}} = 0.995 \pm 0.006,$$

$$\frac{\tau_{\Lambda_b}}{\tau_{B^0}} = 0.955 \pm 0.009,$$

while theory makes the following predictions [55,58]

$$\frac{\tau_{B^+}}{\tau_{B^0}} = 1.06 \pm 0.02, \quad \frac{\tau_{B_s}}{\tau_{B^0}} = 1.00 \pm 0.01, \quad \frac{\tau_{\Lambda_b}}{\tau_{B^0}} = 0.88 \pm 0.05.$$

The ratio of  $B^+$  to  $B^0$  lifetimes has a precision of better than 1%, and is significantly different from 1.0, in agreement with predictions [55]. The ratio of  $B_s$  to  $B^0$  lifetimes is expected to be very close to 1.0. While early measurements were in mild tension with theory, the high precision measurements using fully reconstructed decays and clear definition of lifetime (see below) are in good agreement with theory [59,60,61]. The  $\Lambda_b$  lifetime has a history of discrepancies. Predictions were higher than data before the introduction of higher-order effects lowered them. The first indication that early measurements of the  $\Lambda_b$  are on low side came from the CDF data [62,63]. The recent measurements from LHC experiments [64,65,66,67] significantly improve precision and favour higher lifetime, much closer to the lifetime of  $B^0$  meson. The most precise measurement of the  $\Lambda_b$  lifetime performed by LHCb uses  $\Lambda_b \rightarrow J/\psi p K^-$  decays and finds  $\tau_{\Lambda_b} = 1.482 \pm 0.018 \pm 0.012$  ps [66]. With new results, the discrepancy between theory and experiment on the  $\Lambda_b$  lifetime can be considered resolved.

Neutral  $B$  mesons are two-component systems similar to neutral kaons, with a light (L) and a heavy (H) mass eigenstate, and independent decay widths  $\Gamma_L$  and  $\Gamma_H$ . The SM predicts a non-zero width difference  $\Delta\Gamma = \Gamma_L - \Gamma_H > 0$  for both  $B_s$  and  $B_d$ . For  $B_d$ ,  $\Delta\Gamma_d/\Gamma_d$  is expected to be  $\sim 0.2\%$ . Analysis of BaBar and DELPHI data on  $CP$ -specific modes of the  $B^0$  yield a combined result:  $\Delta\Gamma_d/\Gamma_d = 0.015 \pm 0.018$  [33]. Very recently LHCb determined value of  $\Delta\Gamma_d/\Gamma_d = -0.044 \pm 0.025 \pm 0.011$  [67], which is based on the comparison of lifetimes in the  $B^0 \rightarrow J/\psi K^{*0}(892)$  and  $B^0 \rightarrow J/\psi K_S$  decays. Average including latest LHCb measurement yields  $\Delta\Gamma_d/\Gamma_d = 0.001 \pm 0.010$ . The issue is much more interesting for the  $B_s$ , since the SM expectation for  $\Delta\Gamma_s/\Gamma_s$  is of order 10%. This potentially non-negligible difference requires care when defining the  $B_s$  lifetime. As indicated in Table 2, two different lifetimes are defined for the  $B_s$  meson: one is defined as  $1/\Gamma_s$ , where  $\Gamma_s$  is the average width of the two mass eigenstates  $(\Gamma_L + \Gamma_H)/2$ ; the other is obtained from “flavor-specific” (*e.g.*, semileptonic) decays and depends both on  $\Gamma_s$  and  $\Delta\Gamma_s$ . Experimentally, the quantity  $\Delta\Gamma_s$  can be accessed by measuring lifetimes in decays into  $CP$  eigenstates,

which in the SM are expected to be close approximations to the mass eigenstates. This has been done with the  $J/\psi\phi$  mode, where the two  $CP$  eigenstates are distinguished by angular distributions, and in  $B_s \rightarrow K^+K^-$  or  $B_s \rightarrow J/\psi f_0(980)$  which are  $CP$ -eigenstates. The current experimental information is dominated by measurements on the  $J/\psi\phi$  mode performed by CDF, D0, ATLAS and LHCb experiments. By appropriately combining all published measurements of  $J/\psi\phi$  lifetimes, flavor-specific lifetimes and effective lifetimes in  $CP$  eigenstates, the HFAG group obtains a world-average  $\Delta\Gamma_s/\Gamma_s = 0.138 \pm 0.012$  [33]; the latest theoretical predictions yield  $\Delta\Gamma_s/\Gamma_s = 0.133 \pm 0.032$  [68], in agreement with measurements within the uncertainties. The constraint from measurements of lifetimes in  $CP$  eigenstates is based on the notion of effective lifetime introduced in Ref. [69]. In this class, measurements in decays  $B_s \rightarrow J/\psi f_0(980)$  [70],  $B_s \rightarrow K^+K^-$  [71] decays are used currently. From the theoretical point of view, the best quantity to use is  $\Delta\Gamma_s/\Delta M_s$ , which is much less affected by hadronic uncertainties [68]. Exploiting the accurate measurement of  $\Delta M_s$  available [72], this can be turned into a SM prediction with an uncertainty of only 20%:  $\Delta\Gamma_s/\Gamma_s = 0.137 \pm 0.027$ . This is likely to be of importance in future comparisons, as the experimental precision improves with the growth of LHC samples. Historically, branching fraction of the decay  $B_s \rightarrow D_s^{(*)+} D_s^{(*)-}$  was used to set an bound on  $\Delta\Gamma_s/\Gamma_s$ , but the method is highly model-dependent and with increased precision of direct determinations it stops to be useful.

The width difference  $\Delta\Gamma_s$  is connected to the  $B_s$  mixing phase  $\phi_s$  by  $\Delta\Gamma_s = \Gamma_{12} \cos \phi_s$ , where  $\Gamma_{12}$  is the off-diagonal element of the decay matrix [6,8,68]. The early measurements by CDF [73] and D0 [74] have produced CL contours in the  $(\phi_s, \Delta\Gamma)$  plane, and both observed a mild deviation, in the same direction, from the expectation of the SM of the phase  $\phi_s$  near  $\Delta\Gamma = 0$ . The possibility of a large value of  $\phi_s$  has attracted significant interest, as it would be very clean evidence for the existence of new sources of  $CP$  violation beyond the SM. However the latest measurements from CDF [59], D0 [75], ATLAS [60] and LHCb [61], which provide significant improvements over initial measurements, show good agreement with the SM. While most experiments use up to now only  $B_s \rightarrow J/\psi\phi$  decay, LHCb also exploits  $B_s \rightarrow J/\psi\pi^+\pi^-$  decays, which are experimentally determined to be pure  $CP$ -odd and therefore in  $B_s \rightarrow J/\psi\pi^+\pi^-$  decays no angular analysis is needed. It should be noted that in pure  $B_s \rightarrow J/\psi\phi$  decay, there is a two-fold ambiguity in the sign of  $\Delta\Gamma_s$  and  $\phi_s$ . This can be resolved using the interference between the decays to  $J/\psi\phi$  and  $J/\psi K^+K^-$ , where  $K^+K^-$  is in relative S-wave state. This has been used by LHCb experiment to determine the sign of  $\Delta\Gamma_s$  to be positive [76] in accordance with SM. The world average value of the  $CP$  violating phase is  $\phi_s = 0.04_{-0.13}^{+0.10}$  [33] without any tension with the SM.

***B meson decay properties:*** Semileptonic  $B$  decays  $B \rightarrow X_c \ell \nu$  and  $B \rightarrow X_u \ell \nu$  provide an excellent way to measure the

magnitude of the CKM elements  $|V_{cb}|$  and  $|V_{ub}|$  respectively, because the strong interaction effects are much simplified due to the two leptons in the final state. Both exclusive and inclusive decays can be used with dominant uncertainties being complementary. For exclusive decay analysis, knowledge of the form factors for the exclusive hadronic system  $X_{c(u)}$  is required. For inclusive analysis, it is usually necessary to restrict the available phase-space of the decay products to suppress backgrounds; subsequently uncertainties are introduced in the extrapolation to the full phase-space. Moreover, restriction to a small corner of the phase-space may result in breakdown of the operator-product expansion scheme, thus making theoretical calculations unreliable. A more detailed discussion of  $B$  semileptonic decays and the extraction of  $|V_{cb}|$  and  $|V_{ub}|$  is given elsewhere in this *Review* [9].

On the other hand, hadronic decays of  $B$  are complicated because of strong interaction effects caused by the surrounding cloud of light quarks and gluons. While this complicates the extraction of CKM matrix elements, it also provides a great opportunity to study perturbative and non-perturbative QCD, hadronization, and Final State Interaction (FSI) effects. Pure-penguin decays were first established by the observation of  $B \rightarrow K^* \gamma$  [77]. Some observed decay modes such as  $B^0 \rightarrow D_s^- K^+$ , may be interpreted as evidence of a  $W$ -exchange process [78]. The evidence for the decay  $B^+ \rightarrow \tau^+ \nu$  from Belle [79] and BaBar [80] is the first sign of a pure annihilation decay. There is growing evidence that penguin annihilation processes may be important in decays with two vector mesons in the final state [81].

**Hadronic decays:** Most of the hadronic  $B$  decays involve  $b \rightarrow c$  transition at the quark level, resulting in a charmed hadron or charmonium in the final state. Other types of hadronic decays are very rare and will be discussed separately in the next section. The experimental results on hadronic  $B$  decays have steadily improved over the past few years, and the measurements have reached sufficient precision to challenge our understanding of the dynamics of these decays. With the good neutral particle detection and hadron identification capabilities of  $B$ -factory detectors, a substantial fraction of hadronic  $B$  decay events can be fully reconstructed. Because of the kinematic constraint of  $\Upsilon(4S)$ , the energy sum of the final-state particles of a  $B$  meson decay is always equal to one half of the total energy in the center of mass frame. As a result, the two variables,  $\Delta E$  (energy difference) and  $M_B$  ( $B$  candidate mass with a beam-energy constraint) are very effective for suppressing combinatorial background both from  $\Upsilon(4S)$  and  $e^+e^- \rightarrow q\bar{q}$  continuum events. In particular, the energy-constraint in  $M_B$  improves the signal resolution by almost an order of magnitude.

The kinematically clean environment of  $B$  meson decays provides an excellent opportunity to search for new states. For instance, quark-level  $b \rightarrow c\bar{c}s$  decays have been used to search for new charmonium and charm-strange mesons and study their properties in detail. In 2003, BaBar discovered a new narrow

charm-strange state  $D_{sJ}^*(2317)$  [82], and CLEO observed a similar state  $D_{sJ}(2460)$  [83]. The properties of these new states were studied in the  $B$  meson decays,  $B \rightarrow DD_{sJ}^*(2317)$  and  $B \rightarrow DD_{sJ}(2460)$  by Belle [84]. Further studies of  $D_{sJ}^{(*)}$  meson production in  $B$  decays have been made by Belle [85] and BaBar [86]. Now these charm-strange meson states are identified as  $D_{s0}^*(2317)$  and  $D_{s1}(2460)$ , respectively.

More recently, Belle observed a new  $D_{sJ}$  meson produced in  $B^+ \rightarrow \bar{D}^0 D_{sJ} \rightarrow \bar{D}^0 D^0 K^+$  [87]. Combined with a subsequent measurement by BaBar [88], the mass and width of this state are determined to be  $2709_{-6}^{+9}$  MeV/ $c^2$  and  $125 \pm 30$  MeV, respectively. An analysis of the helicity angle distribution determines its spin-parity to be  $1^-$ .

A variety of exotic particles have been discovered in  $B$  decays. Belle found the  $X(3872)$  state [89], which is confirmed by CDF [90] and BaBar [91]. Analyzing their full  $\Upsilon(4S)$  data sample, Belle finds a new upper limit on the width of  $X(3872)$  to be  $\Gamma_{X(3872)} < 1.2$  MeV [92], improving on the existing limit by nearly a factor of 2. Radiative decays of  $X(3872)$  can play a crucial role in understanding the nature of the particle. For example, in the molecular model the decay of  $X(3872)$  to  $\psi' \gamma$  is expected to be highly suppressed in comparison to the decay to  $J/\psi \gamma$  [93]. BaBar has seen the evidence for the decay to  $J/\psi \gamma$  [94]. The ratio  $R \equiv \mathcal{B}(X(3872) \rightarrow \psi' \gamma) / \mathcal{B}(X(3872) \rightarrow J/\psi \gamma)$  is measured to be  $3.4 \pm 1.4$  by BaBar [95], while Belle obtains  $R < 2.1$  at 90% CL [96].

Belle has observed a near-threshold enhancement in the  $J/\psi \omega$  invariant mass for  $B \rightarrow J/\psi \omega K$  decays [97]. BaBar has studied  $B \rightarrow J/\psi \pi^+ \pi^- K$ , finding an excess of  $J/\psi \pi^+ \pi^-$  events with a mass just above 4.2 GeV/ $c^2$ ; this is consistent with the  $Y(4260)$  that was observed by BaBar in ISR (Initial State Radiation) events [98]. A Belle study of  $B \rightarrow \psi' K \pi^\pm$  [99] finds a state called  $X(4430)^\pm$  that decays to  $\psi' \pi^\pm$ . Since it is charged, it could not be a charmonium state. This state was searched for by BaBar with similar sensitivity but was not found [100]. In a Dalitz plot analysis of  $\bar{B}^0 \rightarrow \chi_{c1} K^- \pi^+$ , Belle has observed two resonance-like structures in the  $\chi_{c1} \pi^+$  mass distribution [101], labelled as  $X(4050)^\pm$  and  $X(4250)^\pm$  in this *Review*, while no evidence is found by BaBar in a search with similar sensitivity [102].

The hadronic decays  $\bar{B}^0 \rightarrow D^{(*)0} h^0$ , where  $h^0$  stands for light neutral mesons such as  $\pi^0, \eta^{(\prime)}, \rho^0, \omega$ , proceed through color-suppressed diagrams, hence they provide useful tests on the factorization models. Both Belle and BaBar have made comprehensive measurements of such color-suppressed hadronic decays of  $\bar{B}^0$  [103].

Information on  $B_s$  and  $\Lambda_b$  decays is limited, though improving with recent studies of large samples at the Tevatron and LHC experiments. Recent additions are decays of  $B_s \rightarrow J/\psi f_0(980)$  [70,104],  $B_s \rightarrow J/\psi f_2'(1525)$  [105], and  $\Lambda_b \rightarrow \Lambda_c \pi^+ \pi^- \pi^-$  [106]. For the later, not only the total rate is measured, but also structure involving decays through excited  $\Lambda_c$  and  $\Sigma_c$  baryons.

## *b*-flavored hadrons

There have been hundreds of publications on hadronic  $B$  decays to open-charm and charmonium final states mostly from the  $B$ -factory experiments. These results are nicely summarized in a recent report by HFAG [33].

**Rare  $B$  decays:** All  $B$ -meson decays that do not occur through the  $b \rightarrow c$  transition are usually called rare  $B$  decays. These include both semileptonic and hadronic  $b \rightarrow u$  decays that are suppressed at leading order by the small CKM matrix element  $V_{ub}$ , as well as higher-order  $b \rightarrow s(d)$  processes such as electroweak and gluonic penguin decays.

Charmless  $B$  meson decays into two-body hadronic final states such as  $B \rightarrow \pi\pi$  and  $K\pi$  are experimentally clean, and provide good opportunities to probe new physics and search for indirect and direct  $CP$  violations. Since the final state particles in these decays tend to have larger momenta than average  $B$  decay products, the event environment is cleaner than for  $b \rightarrow c$  decays. Branching fractions are typically around  $10^{-5}$ . Over the past decade, many such modes have been observed by BaBar, Belle, and CLEO. More recently, comparable samples of the modes with all charged final particles have been reconstructed in  $p\bar{p}$  collisions by CDF and  $pp$  collisions by LHCb by triggering on the impact parameter of the charged tracks. This has also allowed observation of charmless decays of the  $B_s$ , in final states such as  $\phi\phi$  [107],  $K^+K^-$  [108], and  $K^-\pi^+$  [109], and of charmless decays of the  $\Lambda_b^0$  baryon [109]. Charmless  $B_s$  modes are related to corresponding  $B^0$  modes by U-spin symmetry, and are determined by similar amplitudes. Combining the observables from  $B_s$  and  $B^0$  modes is a further way of eliminating hadronic uncertainties and extracting relevant CKM information [110].

Because of relatively high-momenta for final state particles, the dominant source of background in  $e^+e^-$  collisions is  $q\bar{q}$  continuum events; sophisticated background suppression techniques exploiting event shape variables are essential for these analyses. In hadron collisions, the dominant background comes from QCD or partially reconstructed heavy flavors, and is similarly suppressed by a combination of kinematic and isolation requirements. The results are in general consistent among the experiments.

BaBar [111] and Belle [112] have observed the decays  $B^+ \rightarrow \bar{K}^0 K^+$  and  $B^0 \rightarrow K^0 \bar{K}^0$ . The world-average branching fractions are  $\mathcal{B}(B^0 \rightarrow K^0 \bar{K}^0) = (0.96^{+0.20}_{-0.18}) \times 10^{-6}$  and  $\mathcal{B}(B^+ \rightarrow \bar{K}^0 K^+) = (1.36 \pm 0.27) \times 10^{-6}$ . These are the first observations of hadronic  $b \rightarrow d$  transitions, with significance  $> 5\sigma$  for all four measurements.  $CP$  asymmetries have even been measured for these modes, though with large errors.

Most rare decay modes including  $B^0 \rightarrow K^+\pi^-$  have contributions from both  $b \rightarrow u$  tree and  $b \rightarrow sg$  penguin processes. If the size of the two contributions are comparable, the interference between them may result in direct  $CP$  violation, seen experimentally as a charge asymmetry in the decay rate measurement. BaBar [113], Belle [114], and CDF [108] have measured the direct  $CP$  violating asymmetry in  $B^0 \rightarrow K^+\pi^-$

decays. The BaBar and Belle measurements constitute observation of direct  $CP$  violation with a significance of more than  $5\sigma$ . The world average for this quantity is now rather precise,  $-0.098 \pm 0.013$ . There are sum rules [115] that relate the decay rates and decay-rate asymmetries between the four  $K\pi$  charge states. The experimental measurements of the other three modes are not yet precise enough to test these sum rules.

There is now evidence for direct  $CP$  violation in three other decays:  $B^+ \rightarrow \rho^0 K^+$  [116],  $B^+ \rightarrow \eta K^+$  [117], and  $B^0 \rightarrow \eta K^{*0}$  [118]. The significance is typically  $3\text{--}4\sigma$ , though the significance for the  $B^+ \rightarrow \eta K^+$  decay is now nearly  $5\sigma$  with the recent Belle measurement [117]. In at least the first two cases, a large direct  $CP$  violation might be expected since the penguin amplitude is suppressed so the tree and penguin amplitudes may have comparable magnitudes.

The decay  $B^0 \rightarrow \pi^+\pi^-$  can be used to extract the CKM angle  $\alpha$ . This is complicated by the presence of significant contributions from penguin diagrams. An isospin analysis [119] can be used to untangle the penguin complications. The decay  $B^0 \rightarrow \pi^0\pi^0$ , which is now measured by both BaBar and Belle, is crucial in this analysis. Unfortunately the amount of penguin pollution in the  $B \rightarrow \pi\pi$  system is rather large. In the past few years, measurements in the  $B^0 \rightarrow \rho\rho$  system have produced more precise values of  $\alpha$ , since penguin amplitudes are generally smaller for decays with vector mesons. An important ingredient in the analysis is the  $B^0 \rightarrow \rho^0\rho^0$  branching fraction. The average of measurements from BaBar and Belle [120] yields a branching fraction of  $(0.73 \pm 0.28) \times 10^{-6}$ . This is only 3% of the  $\rho^+\rho^-$  branching fraction, much smaller than the corresponding ratio in the  $\pi\pi$  system.

The decay  $B \rightarrow a_1\pi$  has been seen by BaBar. An analysis of the time evolution of this decay [121] together with measurements of other related decays has been used to measure the CKM angle  $\alpha$  [122] in agreement with the more precise measurements from the  $\rho\rho$  system.

Since  $B \rightarrow \rho\rho$  has two vector mesons in the final state, the  $CP$  eigenvalue of the final state depends on the longitudinal polarization fraction  $f_L$  for the decay. Therefore, a measurement of  $f_L$  is needed to extract the CKM angle  $\alpha$ . Both BaBar and Belle have measured  $f_L$  for the decays  $\rho^+\rho^-$  and  $\rho^+\rho^0$  and in both cases the measurements show  $f_L > 0.9$ , making a complete angular analysis unnecessary.

By analyzing the angular distributions of the  $B$  decays to two vector mesons, we can learn a lot about both weak- and strong-interaction dynamics in  $B$  decays. Decays that are penguin-dominated surprisingly have values of  $f_L$  near 0.5. The list of such decays has now grown to include  $B \rightarrow \phi K^*$ ,  $B \rightarrow \rho K^*$ , and  $B \rightarrow \omega K^*$ . The reasons for this "polarization puzzle" are not fully understood. A detailed description of the angular analysis of  $B$  decays to two vector mesons can be found in a separate mini-review [123] in this *Review*.

There has been substantial progress in measurements of many other rare- $B$  decays. The decay  $B \rightarrow \eta' K$  stood out as the largest rare- $B$  decay for many years. The reasons for

the large rate are now largely understood [14,124]. However, there are now measurements of several 3-body or quasi-3-body modes with similarly large branching fractions. States seen so far include  $K\pi\pi$  (three charge states) [125],  $KKK$  (four charge states) [126], and  $K^*\pi\pi$  (two charged states) [127]. Many of these analyses now include Dalitz plot treatments with many intermediate resonances. There has also been an observation of the decay  $B^+ \rightarrow K^+K^-\pi^+$  by BaBar [128], noteworthy because an even number of kaons is typically indicative of suppressed  $b \rightarrow d$  transitions as discussed above.

Belle [79] and BaBar [80] have found evidence for  $B^+ \rightarrow \tau^+\nu$ ; the average branching fraction, with a significance of nearly  $5\sigma$  is  $(165 \pm 34) \times 10^{-6}$ . This is somewhat larger than, though consistent with, the value expected in the SM. This is the first observation of a pure annihilation decay. A substantial region of parameter space of charged Higgs mass vs.  $\tan\beta$  is excluded by the measurements of this mode.

**Electroweak penguin decays:** More than 20 years have passed since the CLEO experiment first observed an exclusive radiative  $b \rightarrow s\gamma$  transition,  $B \rightarrow K^*(892)\gamma$  [77], thus providing the first evidence for the one-loop FCNC electromagnetic penguin decay. Using much larger data samples, both Belle and BaBar have updated this analysis [129] with an average branching fraction  $\mathcal{B}(B^0 \rightarrow K^{*0}\gamma) = (43.3 \pm 1.5) \times 10^{-6}$ , and have added several new decay modes such as  $B \rightarrow K_1\gamma$ ,  $K_2^*(1430)\gamma$ , *etc.* [130]. With a sample of  $24 \text{ fb}^{-1}$  at  $\Upsilon(5S)$ , Belle observed the radiative penguin decay of  $B_s \rightarrow \phi\gamma$  [131]. The decay  $B_s \rightarrow \phi\gamma$  was also seen at LHCb with higher statistics [132]. The two measurements give average branching fraction of  $(36 \pm 4) \times 10^{-6}$ .

Compared to  $b \rightarrow s\gamma$ , the  $b \rightarrow d\gamma$  transitions such as  $B \rightarrow \rho\gamma$ , are suppressed by the small CKM element  $V_{td}$ . Both Belle and BaBar have observed these decays [17,18]. The world average  $\mathcal{B}(B \rightarrow (\rho,\omega)\gamma) = (1.30 \pm 0.23) \times 10^{-6}$ . This can be used to calculate  $|V_{td}/V_{ts}|$  [133]; the measured values are  $0.233_{-0.032}^{+0.033}$  from BaBar [18] and  $0.195_{-0.024}^{+0.025}$  from Belle [17].

The observed radiative penguin branching fractions can constrain a large class of SM extensions [134]. However, due to the uncertainties in the hadronization, only the inclusive  $b \rightarrow s\gamma$  rate can be reliably compared with theoretical calculations. This rate can be measured from the endpoint of the inclusive photon spectrum in  $B$  decay. By combining the measurements of  $B \rightarrow X_s\gamma$  from CLEO, BaBar, and Belle experiments [135,136,137], HFAG obtains the new average:  $\mathcal{B}(B \rightarrow X_s\gamma) = (3.43 \pm 0.21 \pm 0.07) \times 10^{-4}$  [33] for  $E_\gamma \geq 1.6 \text{ GeV}$ , which averages over  $B^+$  and  $B^0$ . Consistent but less precise results have been reported by ALEPH for inclusive  $b$ -hadrons produced at the  $Z$ , which includes also small fraction of  $B_s$  and  $\Lambda_b$  hadrons. The measured branching fraction can be compared to theoretical calculations. Recent calculations of  $\mathcal{B}(b \rightarrow s\gamma)$  at NNLO level predict the values of  $(3.15 \pm 0.23) \times 10^{-4}$  [138] and  $(2.98 \pm 0.26) \times 10^{-4}$  [139], where the latter is calculated requiring  $E_\gamma \geq 1.6 \text{ GeV}$ .

The  $CP$  asymmetry in  $b \rightarrow s\gamma$  is extensively studied theoretically both in the SM and beyond [140]. According to the

SM, the  $CP$  asymmetry in  $b \rightarrow s\gamma$  is smaller than 1%, but some non-SM models allow significantly larger  $CP$  asymmetry ( $\sim 10\%$ ) without altering the inclusive branching fraction. The current world average is  $A_{CP} = -0.008 \pm 0.029$ , again dominated by BaBar and Belle [141,136]. In addition to the  $CP$  asymmetry, BaBar also measured the isospin asymmetry  $\Delta_{0-} = -0.01 \pm 0.06$  in  $b \rightarrow s\gamma$  measured using sum of exclusive decays [142]. Alternative measurement using full reconstruction of the companion  $B$  in the hadronic decay modes yields consistent, but less precise result [143].

In addition, all three experiments have measured the inclusive photon energy spectrum for  $b \rightarrow s\gamma$ , and by analyzing the shape of the spectrum they obtain the first and second moments for photon energies. Belle has measured these moments covering the widest range in the photon energy ( $1.7 < E_\gamma < 2.8 \text{ GeV}$ ) [137]. The measurement by BaBar has slightly smaller range with lower limit at  $1.8 \text{ GeV}$  [144]. These results can be used to extract non-perturbative HQET parameters that are needed for precise determination of the CKM matrix element  $V_{ub}$ .

Additional information on FCNC processes can be obtained from  $b \rightarrow s\ell^+\ell^-$  decays, which are mediated by electroweak penguin and  $W$ -box diagrams. Measurements at Belle and BaBar suffered from low statistics and therefore they typically provide average between charged and neutral  $B$  mesons as well as between  $e^+e^-$  and  $\mu^+\mu^-$  final states [145,146]. The total branching fraction measured at B-factories for  $B \rightarrow K\ell^+\ell^-$  is  $(0.45 \pm 0.04) \times 10^{-6}$  and for  $B \rightarrow K^*(892)\ell^+\ell^-$  is  $(1.05 \pm 0.10) \times 10^{-6}$ . Measurements at B-factories were complemented by CDF [147], which used only muons in the final state. While precision at CDF was similar to B-factories, it had access also to  $B_s \rightarrow \phi\mu^+\mu^-$  and  $\Lambda_b \rightarrow \Lambda\mu^+\mu^-$  decays, which were observed for the first time [147,148] and confirmed by LHCb [149,150].  $B$ -factory experiments also measured the branching fractions for inclusive  $B \rightarrow X_s\ell^+\ell^-$  decays [151], with an average of  $(3.66_{-0.77}^{+0.76}) \times 10^{-6}$  [152]. In  $b \rightarrow s\ell^+\ell^-$  decays, the angular analysis provides several interesting observables, which can be studied as function of dilepton invariant mass squared,  $q^2$ . While first measurements were done by Belle, Babar and CDF, real advance of these measurements came with LHC experiments, where samples available are significantly larger than before. The best known of angular observables is forward-backward asymmetry, which was measurement in  $B \rightarrow K^*(892)\ell^+\ell^-$  by several experiments having access to the decay [145,153,154,155] with most precise measurement coming from LHCb [156]. Measurements of the  $CP$  asymmetries [146,157,158], the isospin asymmetry [145,146,159] and several other angular observables [156,160] are possible in this class of decays. While most of the measurements agree with the SM, isospin asymmetry in  $B \rightarrow K\mu^+\mu^-$  and one of the other angular observables measured by the LHCb exhibit small tension with the SM expectation. While the angular analysis was up to recently mainly concentrating on the decay  $B \rightarrow K^*(892)\ell^+\ell^-$ , with samples available at LHC, also first angular analysis of the

## *b*-flavored hadrons

$B_s \rightarrow \phi \mu^+ \mu^-$  decay was performed [149] with its results being consistent with the SM.

Finally the decays  $B_{(s)}^0 \rightarrow e^+ e^-$  and  $\mu^+ \mu^-$  are interesting since they only proceed at second order in weak interactions in the SM, but may have large contributions from supersymmetric loops, proportional to  $(\tan \beta)^6$ . First limits were published 30 years ago and since then experiments at Tevatron, *B*-factories and LHC gradually improved those and effectively excluded whole models of new physics and significantly constrained allowed parameter space of others. For the decays to  $\mu^+ \mu^-$ , Tevatron experiments pushed the limits down to roughly factor of 5-10 above the SM expectation [161,162]. The long journey in the search for these decays culminated in 2012, when first evidence for  $B_s \rightarrow \mu^+ \mu^-$  decay was seen [163]. Currently LHCb [164] and CMS [165] observe this decay with significance between 4 and 5 standard deviations. The measured branching fraction is  $(2.9_{-1.0}^{+1.1}) \times 10^{-9}$  at LHCb and  $(3.0_{-0.9}^{+1.0}) \times 10^{-9}$  at CMS, both in agreement with the SM expectation. The best limit for  $B^0 \rightarrow \mu^+ \mu^-$  is obtained by LHCb with value  $< 7.4 \times 10^{-10}$  at 95% confidence level. The limits for the  $e^+ e^-$  modes are:  $< 2.8 \times 10^{-7}$  and  $< 8.3 \times 10^{-8}$ , respectively, for  $B_s$  and  $B^0$  [166]. The searches were also performed for lepton flavour violating decays to two leptons with best limits in  $e^\pm \mu^\mp$  channel, where limits are  $< 3.7 \times 10^{-9}$  for  $B^0$  and  $< 1.4 \times 10^{-8}$  at 95% confidence level [167].

**Summary and Outlook:** The study of *B* mesons continues to be one of the most productive fields in particle physics. With the two asymmetric *B*-factory experiments Belle and BaBar, we now have a combined data sample of well over  $1 \text{ ab}^{-1}$ . *CP* violation has been firmly established in many decays of *B* mesons. Evidence for direct *CP* violation has been observed. Many rare decays resulting from hadronic  $b \rightarrow u$  transitions and  $b \rightarrow s(d)$  penguin decays have been observed, and the emerging pattern is still full of surprises. Despite the remarkable successes of the *B*-factory experiments, many fundamental questions in the flavor sector remain unanswered.

At Fermilab, CDF and D0 each has accumulated about  $10 \text{ fb}^{-1}$ , which is the equivalent of about  $10^{12}$  *b*-hadrons produced. In spite of the low trigger efficiency of hadronic experiments, a selection of modes have been reconstructed in large quantities, giving a start to a program of studies on  $B_s$  and *b*-flavored baryons, in which a first major step has been the determination of the  $B_s$  oscillation frequency.

As Tevatron and *B*-factories stop their taking data, the new experiments at the LHC have become very active. The LHC accelerator performed very well in 2011 and 2012. The general purpose experiments ATLAS and CMS collected about  $25 \text{ fb}^{-1}$  while LHCb collected about  $3 \text{ fb}^{-1}$ . LHCb, which is almost fully dedicated to the studies of *b*- and *c*-hadrons, has a data sample that is for many decays larger than the sum of all previous experiments. Of particular note is the first evidence of the decay  $B_s \rightarrow \mu^+ \mu^-$  by LHCb and CMS experiments in 2013.

In addition, the preparation of the next generation high-luminosity *B*-factory at KEK is ongoing with first physics

data taking expected in 2016. The aim to increase sample to  $\sim 50 \text{ ab}^{-1}$  will make it possible to explore the indirect evidence of new physics beyond the SM in the heavy-flavor particles (*b*, *c*, and  $\tau$ ), in a way that is complementary to the LHC. In the same time, LHCb Collaboration is working on the upgrade of its detector, which should be installed in 2018 and 2019. Aim of the upgrade is to increase flexibility of trigger, which will allow to significantly increase instantaneous luminosity and possibly integrate about  $50 \text{ fb}^{-1}$  of data.

These experiments promise a rich spectrum of rare and precise measurements that have the potential to fundamentally affect our understanding of the SM and *CP*-violating phenomena.

## $b$ -flavored hadrons, $B^\pm$

### A NOTE ON HFAG ACTIVITIES

The Heavy Flavor Averaging Group (HFAG) has been formed, continuing the activities of the LEP Heavy Flavor Steering group, to provide the averages for measurements dedicated to the  $b$ -flavor related quantities. The HFAG consists of representatives and contacts from the experimental groups: BaBar, Belle, CDF, CLEO, DØ, LEP, SLD, and LHCb.

In the averaging the input parameters used in the various analyses are adjusted (rescaled) to common values, and all known correlations are taken into account. The HFAG has seven sub-groups providing averages for  $b$ -hadron lifetimes and  $B$ -oscillation parameters,  $CP$ -violation measurements, semileptonic parameters, rare branching fractions,  $b$ -hadron decays to charm, charm mixing and decays, and  $\tau$  decays. The averages provided by the HFAG are listed as "OUR EVALUATION" with a corresponding note.

The most up-to-date and complete listing of averages and more detailed information on the averaging procedures are available at:

<http://www.slac.stanford.edu/xorg/hfag>.

**$B^\pm$**

$$I(J^P) = \frac{1}{2}(0^-)$$

Quantum numbers not measured. Values shown are quark-model predictions.

See also the  $B^\pm/B^0$  ADMIXTURE and  $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE sections.

### $B^\pm$ MASS

The fit uses  $m_{B^+}$ , ( $m_{B^0} - m_{B^+}$ ), and  $m_{B^0}$  to determine  $m_{B^+}$ ,  $m_{B^0}$ , and the mass difference.

- Uses  $B^+ \rightarrow J/\psi K^+$  fully reconstructed decays.
- Uses exclusively reconstructed final states containing a  $J/\psi \rightarrow \mu^+ \mu^-$  decays.
- CSORNA 00 uses fully reconstructed 526  $B^+ \rightarrow J/\psi(\ell^+) K^+$  events and invariant masses without beam constraint.
- ALBRECHT 90J assumes 10580 for  $\Upsilon(4S)$  mass. Supersedes ALBRECHT 87C and ALBRECHT 87D.
- Found using fully reconstructed decays with  $J/\psi(1S)$ . ALBRECHT 87D assume  $m_{\Upsilon(4S)} = 10577$  MeV.

### $B^\pm$ MEAN LIFE

See  $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE section for data on  $B$ -hadron mean life averaged over species of bottom particles.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors.

- Measured mean life using fully reconstructed decays ( $J/\psi K^{(*)}$ ).
- Measured using  $B^- \rightarrow D^0 \pi^-$  with  $D^0 \rightarrow K^- \pi^+$  events that were selected using a silicon vertex trigger.
- Measurement performed using a combined fit of  $CP$ -violation, mixing and lifetimes.
- Measurement performed using an inclusive reconstruction and  $B$  flavor identification technique.
- Measured mean life using fully reconstructed decays.
- Events are selected in which one  $B$  meson is fully reconstructed while the second  $B$  meson is reconstructed inclusively.
- Data analyzed using  $D/D^* \ell X$  event vertices.
- Data analyzed using charge of secondary vertex.
- ABREU 95Q assumes  $B(B^0 \rightarrow D^{*-} \ell^+ \nu_\ell) = 3.2 \pm 1.7\%$ .
- Data analyzed using vertex-charge technique to tag  $B$  charge.
- Combined result of  $D/D^* \ell X$  analysis and fully reconstructed  $B$  analysis.
- Combined ABREU 95Q and ADAM 95 result.

### $\tau_{B^+}/\tau_{B^-}$

VALUE	DOCUMENT ID	TECN	COMMENT
<b>1.002 ± 0.004 ± 0.002</b>	<sup>1</sup> AAIJ	14E	LHCb $pp$ at 7 TeV

- Measured using  $B^\pm \rightarrow J/\psi K^\pm$  decays.

### $B^\pm$ DECAY MODES

$B^\pm$  modes are charge conjugates of the modes below. Modes which do not identify the charge state of the  $B$  are listed in the  $B^\pm/B^0$  ADMIXTURE section.

The branching fractions listed below assume 50%  $B^0 \bar{B}^0$  and 50%  $B^+ B^-$  production at the  $\Upsilon(4S)$ . We have attempted to bring older measurements up to date by rescaling their assumed  $\Upsilon(4S)$  production ratio to 50:50 and their assumed  $D, D_s, D^*$ , and  $\psi$  branching ratios to current values whenever this would affect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

For inclusive branching fractions, e.g.,  $B \rightarrow D^\pm$  anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

Mode	Fraction ( $\Gamma_i/\Gamma$ )	Scale factor/ Confidence level

- [a] An  $\ell$  indicates an  $e$  or a  $\mu$  mode, not a sum over these modes.
- [b] An  $CP(\pm 1)$  indicates the  $CP=+1$  and  $CP=-1$  eigenstates of the  $D^0$ - $\bar{D}^0$  system.
- [c]  $D$  denotes  $D^0$  or  $\bar{D}^0$ .
- [d]  $D_{CP}^0$  decays into  $D^0 \pi^0$  with the  $D^0$  reconstructed in  $CP$ -even eigenstates  $K^+ K^-$  and  $\pi^+ \pi^-$ .
- [e]  $\bar{D}^{**}$  represents an excited state with mass  $2.2 < M < 2.8$  GeV/ $c^2$ .
- [f]  $X(3872)^+$  is a hypothetical charged partner of the  $X(3872)$ .
- [g]  $\Theta(1710)^{++}$  is a possible narrow pentaquark state and  $G(2220)$  is a possible glueball resonance.
- [h]  $(\bar{\Lambda}_c^- \rho)_s$  denotes a low-mass enhancement near 3.35 GeV/ $c^2$ .

**CONSTRAINED FIT INFORMATION**

An overall fit to 3 branching ratios uses 6 measurements and one constraint to determine 3 parameters. The overall fit has a  $\chi^2 = 3.7$  for 4 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

$x_{322}$	10
	$x_{262}$

**CONSTRAINED FIT INFORMATION**

An overall fit to 18 branching ratios uses 53 measurements and one constraint to determine 12 parameters. The overall fit has a  $\chi^2 = 48.9$  for 42 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

10.1 ± 1.8 ± 1.5	ATHANAS 94	CLE2	Sup. by ARTUSO 97

- <sup>1</sup> URQUIJO 07 report a measurement of  $(10.34 \pm 0.23 \pm 0.25)\%$  for the partial branching fraction of  $B^+ \rightarrow e^+ \nu_e X_C$  decay with electron energy above 0.6 GeV. We converted the result to  $B^+ \rightarrow e^+ \nu_e X$  branching fraction.
- <sup>2</sup> The measurements are obtained for charged and neutral  $B$  mesons partial rates of semileptonic decay to electrons with momentum above 0.6 GeV/ $c$  in the  $B$  rest frame. The best precision on the ratio is achieved for a momentum threshold of 1.0 GeV:  $B(B^+ \rightarrow e^+ \nu_e X) / B(B^0 \rightarrow e^+ \nu_e X) = 1.074 \pm 0.041 \pm 0.026$ .
- <sup>3</sup> ARTUSO 97 uses partial reconstruction of  $B \rightarrow D^* \ell \nu_\ell$  and inclusive semileptonic branching ratio from BARISH 96B ( $0.1049 \pm 0.0017 \pm 0.0043$ ).
- <sup>4</sup> The measurements are obtained for charged and neutral  $B$  mesons partial rates of semileptonic decay to electrons with momentum above 0.6 GeV/ $c$  in the  $B$  rest frame, and their ratio of  $B(B^+ \rightarrow e^+ \nu_e X) / B(B^0 \rightarrow e^+ \nu_e X) = 1.08 \pm 0.05 \pm 0.02$ .

$\Gamma(e^+ \nu_e X_C) / \Gamma_{\text{total}}$

“OUR EVALUATION” is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements.  $\ell = e$  or  $\mu$ , not sum over  $e$  and  $\mu$  modes.

0.070 ± 0.018 ± 0.014		<sup>9</sup> ANTREASYAN	90B	CBAL $e^+ e^- \rightarrow \Upsilon(4S)$

<sup>1</sup> Measured using the dependence of  $B^- \rightarrow D^{*0} e^- \bar{\nu}_e$  decay differential rate and the form factor description by CAPRINI 98.  
<sup>2</sup> Simultaneous measurements of both  $B^0 \rightarrow D^*(2010)^- \ell \nu$  and  $B^+ \rightarrow \bar{D}^*(2007)^0 \ell \nu$ .  
<sup>3</sup> ALBRECHT 92c reports 0.058 ± 0.014 ± 0.013. We rescale using the method described in STONE 94 but with the updated PDG 94  $B(D^0 \rightarrow K^- \pi^+)$ . Assumes equal production of  $B^0 \bar{B}^0$  and  $B^+ B^-$  at the  $\Upsilon(4S)$ .  
<sup>4</sup> Uses a fully reconstructed  $B$  meson as a tag on the recoil side.  
<sup>5</sup> The results are based on the same analysis and data sample reported in ADAM 03.  
<sup>6</sup> BARISH 95 use  $B(D^0 \rightarrow K^- \pi^+) = (3.91 \pm 0.08 \pm 0.17)\%$  and  $B(D^{*0} \rightarrow D^0 \pi^0) = (63.6 \pm 2.3 \pm 3.3)\%$ .  
<sup>7</sup> Combining  $\bar{D}^{*0} \ell^+ \nu_\ell$  and  $\bar{D}^{*0} \ell^+ \nu_\ell$  SANGHERA 93 test  $V-A$  structure and fit the decay angular distributions to obtain  $A_{FB} = 3/4 * (\Gamma^- - \Gamma^+) / \Gamma = 0.14 \pm 0.06 \pm 0.03$ . Assuming a value of  $V_{cb}$ , they measure  $V_1$ ,  $A_1$ , and  $A_2$ , the three form factors for the  $D^* \ell \nu_\ell$  decay, where results are slightly dependent on model assumptions.  
<sup>8</sup> Assumes equal production of  $B^0 \bar{B}^0$  and  $B^+ B^-$  at the  $\Upsilon(4S)$ . Uncorrected for  $D$  and  $D^*$  branching ratio assumptions.  
<sup>9</sup> ANTREASYAN 90b is average over  $B$  and  $\bar{D}^*(2010)$  charge states.

1.14 ± 0.16 ± 0.08		<sup>2</sup> AUBERT 09Q	BABR	Repl. by LEES 13A
<2.1	90	<sup>7</sup> BEAN 93B	CLE2	$e^+ e^- \rightarrow \Upsilon(4S)$

<sup>1</sup> LEES 13A reports  $(1.21 \pm 0.14 \pm 0.08) \times 10^{-4}$  from a measurement of  $[\Gamma(B^+ \rightarrow \omega \ell^+ \nu_\ell)/\Gamma_{\text{total}}] \times [B(\omega(782) \rightarrow \pi^+ \pi^- \pi^0)]$  assuming  $B(\omega(782) \rightarrow \pi^+ \pi^- \pi^0) = (89.2 \pm 0.7) \times 10^{-2}$ .

<sup>2</sup> Uses  $B(\Upsilon(4S) \rightarrow B^+ B^-) = (51.6 \pm 0.6)\%$  and  $B(\Upsilon(4S) \rightarrow B^0 \overline{B}^0) = (48.4 \pm 0.6)\%$ .

<sup>3</sup> Uses semileptonic tagging. Assumes  $B(\omega \rightarrow \pi^+ \pi^- \pi^0) = (89.2 \pm 0.7)\%$  and that the production ratio of  $B^+ B^-$  to  $B^0 \overline{B}^0$  from  $\Upsilon(4S)$  is  $1.056 \pm 0.028$ . The partial branching fractions in three bins of  $q^2$  are also reported.

<sup>4</sup> The signal events are tagged by a second  $B$  meson reconstructed in the fully hadronic decays.

<sup>5</sup> Uses loose neutrino reconstruction technique.

<sup>6</sup> Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .

<sup>7</sup> BEAN 93B limit set using ISGW Model. Using isospin and the quark model to combine  $\Gamma(\rho^0 \ell^+ \nu_\ell)$  and  $\Gamma(\rho^- \ell^+ \nu_\ell)$  with this result, they obtain a limit  $<(1.6-2.7) \times 10^{-4}$  at 90% CL for  $B^+ \rightarrow \omega \ell^+ \nu_\ell$ . The range corresponds to the ISGW, WSB, and KS models. An upper limit on  $|V_{ub}/V_{cb}| < 0.8-0.13$  at 90% CL is derived as well.

“OUR EVALUATION” is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at <http://www.slac.stanford.edu/xorg/hfag/>. The averaging/rescaling procedure takes into account correlations between the measurements and asymmetric lifetime errors.

< 18 90 <sup>10</sup> BUSKULIC 95 ALEP  $e^+ e^- \rightarrow Z$

<sup>1</sup> The authors combine their result with that from HARA 10 obtaining  $B(B^- \rightarrow \tau^- \bar{\nu}_\tau) = (0.96 \pm 0.26) \times 10^{-4}$  and deriving  $f_B |V_{ub}| = (7.4 \pm 0.8 \pm 0.5) \times 10^{-4}$  GeV.

<sup>2</sup> Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .

<sup>3</sup> Requires a fully reconstructed hadronic  $B$ -decay in the recoil. Reports that this result combined with AUBERT 10E value gives  $B(B^- \rightarrow \tau^- \bar{\nu}_\tau) = (1.79 \pm 0.48) \times 10^{-4}$ .

<sup>4</sup> Requires one reconstructed semileptonic  $B$  decay  $B^- \rightarrow D^{(*)0} \ell^- \bar{\nu}_\ell X$  in the recoil.

<sup>5</sup> Requires one reconstructed semileptonic  $B$  decay  $B^- \rightarrow D^{(*)0} \ell^- \bar{\nu}_\ell X$  in the recoil.

<sup>6</sup> The analysis is based on a sample of events with one fully reconstructed tag  $B$  in a hadronic decay mode  $B^- \rightarrow D^{(*)0} X^-$ .

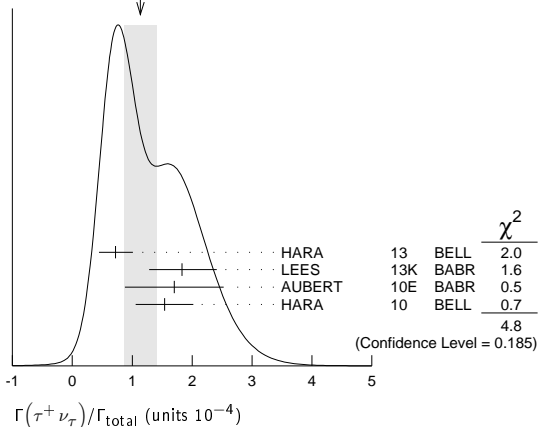

<sup>7</sup> The energy-flow and  $b$ -tagging algorithms were used.

<sup>8</sup> ACCIARRI 97F uses missing-energy technique and  $f(b \rightarrow B^-) = (38.2 \pm 2.5)\%$ .

<sup>9</sup> ALBRECHT 95D uses full reconstruction of one  $B$  decay as tag.

<sup>10</sup> BUSKULIC 95 uses same missing-energy technique as in  $\bar{D} \rightarrow \tau^+ \nu_\tau X$ , but analysis is restricted to endpoint region of missing-energy distribution.

1.9 ± 1.0 ± 0.6	7	9 ALBRECHT 88K	ARG	$e^+e^- \rightarrow \Upsilon(4S)$

- Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$ .
- ABULENCIA 06J reports  $[\Gamma(B^+ \rightarrow \bar{D}^0 \pi^+)/\Gamma_{total}] / [B(D^0 \rightarrow D^- \pi^+)] = 1.97 \pm 0.10 \pm 0.21$  which we multiply by our best value  $B(D^0 \rightarrow D^- \pi^+) = (2.68 \pm 0.13) \times 10^{-3}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.
- Uses a missing-mass method. Does not depend on  $D$  branching fractions or  $B^+ / B^0$  production rates.
- AHMED 02B reports an additional uncertainty on the branching ratios to account for 4.5% uncertainty on relative production of  $B^0$  and  $B^+$ , which is not included here.
- Assumes equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$  and uses the MarkIII branching fractions for the  $D$ .
- BEBEK 87 value has been updated in BERKELMAN 91 to use same assumptions as noted for BORTOLETTO 92.
- AUBERT, B 04P reports  $[\Gamma(B^+ \rightarrow \bar{D}^0 \pi^+)/\Gamma_{total}] \times [B(D^0 \rightarrow K^- \pi^+)] = (1.846 \pm 0.032 \pm 0.097) \times 10^{-4}$  which we divide by our best value  $B(D^0 \rightarrow K^- \pi^+) = (3.88 \pm 0.05) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.
- ALAM 94 assume equal production of  $B^+$  and  $B^0$  at the  $\Upsilon(4S)$  and use the CLEOII absolute  $B(D^0 \rightarrow K^- \pi^+)$  and the PDG 1992  $B(D^0 \rightarrow K^- \pi^+ \pi^0) / B(D^0 \rightarrow K^- \pi^+)$  and  $B(D^0 \rightarrow K^- 2\pi^+ \pi^-) / B(D^0 \rightarrow K^- \pi^+)$ .
- ALBRECHT 88K assumes  $B^0 \bar{B}^0 : B^+ B^-$  ratio is 45:55. Superseded by ALBRECHT 90J.
