<sup>1</sup> ABDALLAH 05 obtain an enriched samples of  $b\bar{b}$  events using lifetime information. The quark (or antiquark) charge is determined with a neural network using the secondary vertex charge, the jet charge and particle identification.

<sup>2</sup> ABDALLAH 04F tag b- and c-quarks using semileptonic decays combined with charge flow information from the hemisphere opposite to the lepton. Enriched samples of  $c\bar{c}$  and  $b\bar{b}$  events are obtained using lifetime information.

<sup>3</sup> ABBIENDI 03P tag heavy flavors using events with one or two identified leptons. This allows the simultaneous fitting of the  $b$  and  $c$  quark forward-backward asymmetries as well as the average  $B^0$ - $\bar{B}^0$  mixing.

<sup>4</sup> ABBIENDI 02i tag  $Z^0 \rightarrow b\bar{b}$  decays using a combination of secondary vertex and lepton tags. The sign of the  $b$ -quark charge is determined using an inclusive tag based on jet, vertex, and kaon charges.

<sup>5</sup> HEISTER 02H measure simultaneously  $b$  and  $c$  quark forward-backward asymmetries using their semileptonic decays to tag the quark charge. The flavor separation is obtained with a discriminating multivariate analysis.

<sup>6</sup> HEISTER 01D tag  $Z \rightarrow b\bar{b}$  events using the impact parameters of charged tracks complemented with information from displaced vertices, event shape variables, and lepton identification. The  $b$ -quark direction and charge is determined using the hemisphere charge method along with information from fast kaon tagging and charge estimators of primary and secondary vertices. The change in the quoted value due to variation of  $A_{FB}^c$  and  $R_b$  is given as  $+0.103 (A_{FB}^c - 0.0651) - 0.440 (R_b - 0.21585)$ .

<sup>7</sup> ABREU 99Y tag  $Z \rightarrow b\bar{b}$  and  $Z \rightarrow c\bar{c}$  events by an exclusive reconstruction of several  $D$  meson decay modes ( $D^{*+}$ ,  $D^0$ , and  $D^+$  with their charge-conjugate states).

<sup>8</sup> ACCIARRI 99D tag  $Z \rightarrow b\bar{b}$  events using high  $p$  and  $p_T$  leptons. The analysis determines simultaneously a mixing parameter  $\chi_b = 0.1192 \pm 0.0068 \pm 0.0051$  which is used to correct the observed asymmetry.

<sup>9</sup> ACCIARRI 98u tag  $Z \rightarrow b\bar{b}$  events using lifetime and measure the jet charge using the hemisphere charge.

<sup>10</sup> ALEXANDER 97C identify the  $b$  and  $c$  events using a  $D/D^*$  tag.

### CHARGE ASYMMETRY IN $e^+e^- \rightarrow q\bar{q}$

Summed over five lighter flavors.

Experimental and Standard Model values are somewhat event-selection dependent. Standard Model expectations contain some assumptions on  $B^0$ - $\bar{B}^0$  mixing and on other electroweak parameters.

### ANOMALOUS $Z\gamma$ , $Z\gamma\gamma$ , AND $ZZV$ COUPLINGS

Revised September 2013 by M.W. Gr̄unewald (U. College Dublin and U. Ghent) and A. Gurtu (Formerly Tata Inst.).

In on-shell  $Z\gamma$  production, deviations from the Standard Model for the  $Z\gamma\gamma^*$  and  $Z\gamma Z^*$  couplings may be described in terms of eight parameters,  $h_i^V$  ( $i = 1, 4; V = \gamma, Z$ ) [1]. The parameters  $h_i^\gamma$  describe the  $Z\gamma\gamma^*$  couplings and the parameters  $h_i^Z$  the  $Z\gamma Z^*$  couplings. In this formalism  $h_1^V$  and  $h_2^V$  lead to  $CP$ -violating and  $h_3^V$  and  $h_4^V$  to  $CP$ -conserving effects. All these anomalous contributions to the cross section increase rapidly with center-of-mass energy. In order to ensure unitarity, these parameters are usually described by a form-factor representation,  $h_i^V(s) = h_{i0}^V / (1 + s/\Lambda^2)^n$ , where  $\Lambda$  is the energy scale for the manifestation of a new phenomenon and  $n$  is a sufficiently large power. By convention one uses  $n = 3$  for  $h_{1,3}^V$  and  $n = 4$  for  $h_{2,4}^V$ . Usually limits on  $h_i^V$ 's are put assuming some value of  $\Lambda$ , sometimes  $\infty$ .

In on-shell  $ZZ$  production, deviations from the Standard Model for the  $ZZ\gamma^*$  and  $ZZZ^*$  couplings may be described by

means of four anomalous couplings  $f_i^V$  ( $i = 4, 5; V = \gamma, Z$ ) [2]. As above, the parameters  $f_i^\gamma$  describe the  $ZZ\gamma^*$  couplings and the parameters  $f_i^Z$  the  $ZZZ^*$  couplings. The anomalous couplings  $f_5^V$  lead to violation of  $C$  and  $P$  symmetries while  $f_4^V$  introduces  $CP$  violation. Also here, formfactors depending on a scale  $\Lambda$  are used.

All these couplings  $h_i^V$  and  $f_i^V$  are zero at tree level in the Standard Model; they are measured in  $e^+e^-$ ,  $p\bar{p}$  and  $pp$  collisions at LEP, Tevatron and LHC.

<sup>1</sup> AAD 13AN study  $Z\gamma$  production in  $pp$  collisions. In events with no additional jet, 1417 (2031)  $Z$  decays to electron (muon) pairs are selected, with an expected background of  $156 \pm 54$  (244  $\pm$  64) events, as well as 662  $Z$  decays to neutrino pairs with an expected background of 302  $\pm$  42 events. Analysing the photon  $p_T$  spectrum above 100 GeV yields the 95% C.L. limits:  $-0.013 < h_2^Z < 0.014$ ,  $-8.7 \times 10^{-5} < h_4^Z < 8.7 \times 10^{-5}$ ,  $-0.015 < h_3^\gamma < 0.016$ ,  $-9.4 \times 10^{-5} < h_4^\gamma < 9.2 \times 10^{-5}$ . Supersedes AAD 12BX.

<sup>2</sup> CHATRCHYAN 13Bi determine the  $Z\gamma \rightarrow \nu\bar{\nu}\gamma$  cross section by selecting events with a photon of  $E_T > 145$  GeV and a  $B_T > 130$  GeV. 73 candidate events are observed with an expected SM background of  $30.2 \pm 6.5$ . The  $E_T$  spectrum of the photon is used to set 95% C.L. limits as follows:  $|h_2^Z| < 2.7 \times 10^{-3}$ ,  $|h_4^Z| < 1.3 \times 10^{-5}$ ,  $|h_3^\gamma| < 2.9 \times 10^{-3}$ ,  $|h_4^\gamma| < 1.5 \times 10^{-5}$ .

<sup>3</sup> ABAZOV 12s study  $Z\gamma$  production in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV using 6.2 fb<sup>-1</sup> of data where the  $Z$  decays to electron (muon) pairs and the photon has at least 10 GeV of transverse momentum. In data, 304 (308) di-electron (di-muon) events are observed with an expected background of 255  $\pm$  16 (285  $\pm$  24) events. Based on the photon  $p_T$  spectrum, and including also earlier data and the  $Z \rightarrow \nu\bar{\nu}$  decay mode (from ABAZOV 09L), the following 95% C.L. limits are reported:  $|h_{03}^Z| < 0.026$ ,  $|h_{04}^Z| < 0.0013$ ,  $|h_{03}^\gamma| < 0.027$ ,  $|h_{04}^\gamma| < 0.0014$  for a form factor scale of  $\Lambda = 1.5$  TeV.

<sup>4</sup> AALTONEN 11s study  $Z\gamma$  events in  $p\bar{p}$  interactions at  $\sqrt{s} = 1.96$  TeV with integrated luminosity 5.1 fb<sup>-1</sup> for  $Z \rightarrow e^+e^-/\mu^+\mu^-$  and 4.9 fb<sup>-1</sup> for  $Z \rightarrow \nu\bar{\nu}$ . For the charged lepton case, the two leptons must be of the same flavor with the transverse momentum/energy of one  $> 20$  GeV and the other  $> 10$  GeV. The isolated photon must have  $E_T > 50$  GeV. They observe 91 events with  $87.2 \pm 7.8$  events expected from standard model processes. For the  $\nu\bar{\nu}$  case they require solitary photons with  $E_T > 25$  GeV and missing  $E_T > 25$  GeV and observe 85 events with standard model expectation of 85.9  $\pm$  5.6 events. Taking the form factor  $\Lambda = 1.5$  TeV they derive 95% C.L. limits as  $|h_3^Z| < 0.022$  and  $|h_4^Z| < 0.0009$ .

<sup>5</sup> CHATRCHYAN 11M study  $Z\gamma$  production in  $pp$  collisions at  $\sqrt{s} = 7$  TeV using 36 pb<sup>-1</sup>  $pp$  data, where the  $Z$  decays to  $e^+e^-$  or  $\mu^+\mu^-$ . The total cross sections are measured for photon transverse energy  $E_T^\gamma > 10$  GeV and spatial separation from charged leptons in the plane of pseudo rapidity and azimuthal angle  $\Delta R(\ell, \gamma) > 0.7$  with the dilepton invariant mass requirement of  $M_{\ell\ell} > 50$  GeV. The number of  $e^+e^- \gamma$  and  $\mu^+\mu^- \gamma$  candidates is 81 and 90 with estimated backgrounds of 20.5  $\pm$  2.5 and 27.3  $\pm$  3.2 events respectively. The 95% CL limits for  $Z\gamma\gamma$  couplings are  $-0.05 < h_3^Z < 0.06$

- and  $-0.0005 < h_4^Z < 0.0005$ , and for  $Z\gamma\gamma$  couplings are  $-0.07 < h_3^\gamma < 0.07$  and  $-0.0005 < h_4^\gamma < 0.0006$ .
- <sup>6</sup> ABAZOV 09L study  $Z\gamma, Z \rightarrow \nu\bar{\nu}$  production in  $p\bar{p}$  collisions at 1.96 TeV C.M. energy. They select 51 events with a photon of transverse energy  $E_T$  larger than 90 GeV, with an expected background of 17 events. Based on the photon  $E_T$  spectrum and including also Z decays to charged leptons (from ABAZOV 07M), the following 95% CL limits are reported:  $|h_{30}^\gamma| < 0.033$ ,  $|h_{40}^\gamma| < 0.0017$ ,  $|h_{30}^Z| < 0.033$ ,  $|h_{40}^Z| < 0.0017$ .
- <sup>7</sup> ABAZOV 07M use 968  $p\bar{p} \rightarrow e^+e^-/\mu^+\mu^-\gamma X$  candidates, at 1.96 TeV center of mass energy, to tag  $p\bar{p} \rightarrow Z\gamma$  events by requiring  $E_T(\gamma) > 7$  GeV, lepton-gamma separation  $\Delta R_{\ell\gamma} > 0.7$ , and dilepton invariant mass  $> 30$  GeV. The cross section is in agreement with the SM prediction. Using these  $Z\gamma$  events they obtain 95% C.L. limits on each  $h_i^\gamma$ , keeping all others fixed at their SM values. They report:  $-0.083 < h_{30}^Z < 0.082$ ,  $-0.0053 < h_{40}^Z < 0.0054$ ,  $-0.085 < h_{30}^\gamma < 0.084$ ,  $-0.0053 < h_{40}^\gamma < 0.0054$ , for the form factor scale  $\Lambda = 1.2$  TeV.
- <sup>8</sup> Using data collected at  $\sqrt{s} = 183-208$  GeV, ABDALLAH 07c select 1,877  $e^+e^- \rightarrow Z\gamma$  events with  $Z \rightarrow q\bar{q}$  or  $\nu\bar{\nu}$ , 171  $e^+e^- \rightarrow Z\gamma$  events with  $Z \rightarrow q\bar{q}$  or lepton pair (except an explicit  $\tau$  pair), and 74  $e^+e^- \rightarrow Z\gamma^*$  events with a  $q\bar{q}\mu^+\mu^-$  or  $q\bar{q}e^+e^-$  signature, to derive 95% CL limits on  $h_i^\gamma$ . Each limit is derived with other parameters set to zero. They report:  $-0.23 < h_1^\gamma < 0.23$ ,  $-0.30 < h_2^\gamma < 0.16$ ,  $-0.14 < h_3^\gamma < 0.14$ ,  $-0.049 < h_3^\gamma < 0.044$ .
- <sup>9</sup> ACHARD 04H select 3515  $e^+e^- \rightarrow Z\gamma$  events with  $Z \rightarrow q\bar{q}$  or  $\nu\bar{\nu}$  at  $\sqrt{s} = 189-209$  GeV to derive 95% CL limits on  $h_i^\gamma$ . For deriving each limit the other parameters are fixed at zero. They report:  $-0.153 < h_1^\gamma < 0.141$ ,  $-0.087 < h_2^\gamma < 0.079$ ,  $-0.220 < h_3^\gamma < 0.112$ ,  $-0.068 < h_4^\gamma < 0.148$ ,  $-0.057 < h_1^\gamma < 0.057$ ,  $-0.050 < h_2^\gamma < 0.023$ ,  $-0.059 < h_3^\gamma < 0.004$ ,  $-0.004 < h_4^\gamma < 0.042$ .
- <sup>10</sup> ABBIENDI, G 00c study  $e^+e^- \rightarrow Z\gamma$  events (with  $Z \rightarrow q\bar{q}$  and  $Z \rightarrow \nu\bar{\nu}$ ) at 189 GeV to obtain the central values (and 95% CL limits) of these couplings:  $h_1^\gamma = 0.000 \pm 0.100$  ( $-0.190, 0.190$ ),  $h_2^\gamma = 0.000 \pm 0.068$  ( $-0.128, 0.128$ ),  $h_3^\gamma = -0.074 \pm_{-0.103}^{+0.102}$  ( $-0.269, 0.119$ ),  $h_4^\gamma = 0.046 \pm 0.068$  ( $-0.084, 0.175$ ),  $h_1^\gamma = 0.000 \pm 0.061$  ( $-0.115, 0.115$ ),  $h_2^\gamma = 0.000 \pm 0.041$  ( $-0.077, 0.077$ ),  $h_3^\gamma = -0.080 \pm_{-0.041}^{+0.039}$  ( $-0.164, -0.006$ ),  $h_4^\gamma = 0.064 \pm_{-0.030}^{+0.033}$  ( $-0.007, +0.134$ ). The results are derived assuming that only one coupling at a time is different from zero.
- <sup>11</sup> ABBOTT 98M study  $p\bar{p} \rightarrow Z\gamma + X$ , with  $Z \rightarrow e^+e^-, \mu^+\mu^-, \nu\bar{\nu}$  at 1.8 TeV, to obtain 95% CL limits at  $\Lambda = 750$  GeV:  $|h_{30}^Z| < 0.36$ ,  $|h_{40}^Z| < 0.05$  (keeping  $h_1^\gamma = 0$ ), and  $|h_{30}^\gamma| < 0.37$ ,  $|h_{40}^\gamma| < 0.05$  (keeping  $h_1^\gamma = 0$ ). Limits on the  $CP$ -violating couplings are  $|h_{20}^\gamma| < 0.36$ ,  $|h_{20}^Z| < 0.05$  (keeping  $h_1^\gamma = 0$ ), and  $|h_{10}^\gamma| < 0.37$ ,  $|h_{20}^Z| < 0.05$  (keeping  $h_1^\gamma = 0$ ).
- <sup>12</sup> ABREU 98k determine a 95% CL upper limit on  $\sigma(e^+e^- \rightarrow \gamma + \text{invisible particles}) < 2.5$  pb using 161 and 172 GeV data. This is used to set 95% CL limits on  $|h_{30}^\gamma| < 0.8$  and  $|h_{30}^Z| < 1.3$ , derived at a scale  $\Lambda = 1$  TeV and with  $n=3$  in the form factor representation.

 $f_V^\gamma$ 

Combining the LEP-2 results taking into account the correlations, the following 95% CL limits are derived [SCHAEEL 13A]:

$$\begin{aligned} -0.28 < f_4^Z < +0.32, & \quad -0.34 < f_5^Z < +0.35, \\ -0.17 < f_4^\gamma < +0.19, & \quad -0.35 < f_5^\gamma < +0.32. \end{aligned}$$

- <sup>1</sup> AAD 13z study ZZ production in  $pp$  collisions at  $\sqrt{s} = 7$  TeV. In the  $ZZ \rightarrow \ell^+\ell^-\ell'^+\ell'^-$  final state they observe a total of 66 events with an expected background of  $0.9 \pm 1.3$ . In the  $ZZ \rightarrow \ell^+\ell^-\nu\nu$  final state they observe a total of 87 events with an expected background of  $46.9 \pm 5.2$ . The limits on anomalous TGCs are determined using the observed and expected numbers of these ZZ events binned in  $p_T^Z$ . The 95% C.L. are as follows: for form factor scale  $\Lambda = \infty$ ,  $-0.015 < f_4^\gamma < 0.015$ ,  $-0.013 < f_4^Z < 0.013$ ,  $-0.016 < f_5^\gamma < 0.015$ ,  $-0.013 < f_5^Z < 0.013$ ; for form factor scale  $\Lambda = 3$  TeV,  $-0.022 < f_4^\gamma < 0.023$ ,  $-0.019 < f_4^Z < 0.019$ ,  $-0.023 < f_5^\gamma < 0.023$ ,  $-0.020 < f_5^Z < 0.019$ .
- <sup>2</sup> CHATRCHYAN 13B study ZZ production in  $pp$  collisions and select 54 ZZ candidates in the Z decay channel with electrons or muons with an expected background of  $1.4 \pm 0.5$  events. The resulting 95% C.L. ranges are:  $-0.013 < f_4^\gamma < 0.015$ ,  $-0.011 < f_4^Z < 0.012$ ,  $-0.014 < f_5^\gamma < 0.014$ ,  $-0.012 < f_5^Z < 0.012$ .
- <sup>3</sup> Using data collected in the center of mass energy range 192-209 GeV, SCHAEEL 09 select 318  $e^+e^- \rightarrow ZZ$  events with 319.4 expected from the standard model. Using this data they derive the following 95% CL limits:  $-0.321 < f_4^\gamma < 0.318$ ,  $-0.534 < f_4^Z < 0.534$ ,  $-0.724 < f_5^\gamma < 0.733$ ,  $-1.194 < f_5^Z < 1.190$ .

- <sup>4</sup> ABAZOV 08k search for ZZ and  $Z\gamma^*$  events with  $1 \text{ fb}^{-1} p\bar{p}$  data at  $\sqrt{s} = 1.96$  TeV in  $(e\ell)(e\ell)$ ,  $(\mu\mu)(\mu\mu)$ ,  $(e\ell)(\mu\mu)$  final states requiring the lepton pair masses to be  $> 30$  GeV. They observe 1 event, which is consistent with an expected signal of  $1.71 \pm 0.15$  events and a background of  $0.13 \pm 0.03$  events. From this they derive the following limits, for a form factor ( $\Lambda$ ) value of 1.2 TeV:  $-0.28 < f_{40}^Z < 0.28$ ,  $-0.31 < f_{50}^Z < 0.29$ ,  $-0.26 < f_{40}^\gamma < 0.26$ ,  $-0.30 < f_{50}^\gamma < 0.28$ .
- <sup>5</sup> Using data collected at  $\sqrt{s} = 183-208$  GeV, ABDALLAH 07c select 171  $e^+e^- \rightarrow ZZ$  events with  $Z \rightarrow q\bar{q}$  or lepton pair (except an explicit  $\tau$  pair), and 74  $e^+e^- \rightarrow Z\gamma^*$  events with a  $q\bar{q}\mu^+\mu^-$  or  $q\bar{q}e^+e^-$  signature, to derive 95% CL limits on  $f_V^\gamma$ . Each limit is derived with other parameters set to zero. They report:  $-0.40 < f_4^Z < 0.42$ ,  $-0.38 < f_5^Z < 0.62$ ,  $-0.23 < f_4^\gamma < 0.25$ ,  $-0.52 < f_5^\gamma < 0.48$ .
- <sup>6</sup> ABBIENDI 04c study ZZ production in  $e^+e^-$  collisions in the C.M. energy range 190-209 GeV. They select 340 events with an expected background of 180 events. Including the ABBIENDI 00N data at 183 and 189 GeV (118 events with an expected background of 65 events) they report the following 95% CL limits:  $-0.45 < f_4^Z < 0.58$ ,  $-0.94 < f_5^Z < 0.25$ ,  $-0.32 < f_4^\gamma < 0.33$ , and  $-0.71 < f_5^\gamma < 0.59$ .
- <sup>7</sup> ACHARD 03D study Z-boson pair production in  $e^+e^-$  collisions in the C.M. energy range 200-209 GeV. They select 549 events with an expected background of 432 events. Including the ACCIARRI 99G and ACCIARRI 99o data (183 and 189 GeV respectively, 286 events with an expected background of 241 events) and the 192-202 GeV ACCIARRI 01i results (656 events, expected background of 512 events), they report the following 95% CL limits:  $-0.48 \leq f_4^Z \leq 0.46$ ,  $-0.36 \leq f_5^Z \leq 1.03$ ,  $-0.28 \leq f_4^\gamma \leq 0.28$ , and  $-0.40 \leq f_5^\gamma \leq 0.47$ .

### ANOMALOUS W/Z QUARTIC COUPLINGS

Revised September 2013 by M.W. Grunewald (U. College Dublin and U. Ghent) and A. Gurtu (Formerly Tata Inst.).

The Standard Model quartic couplings,  $WWWW$ ,  $WWZZ$ ,  $WWZ\gamma$ ,  $WW\gamma\gamma$ , and  $ZZ\gamma\gamma$ , lead to negligible effects at LEP energies, while they are important at a TeV Linear Collider. Outside the Standard Model framework, possible quartic couplings,  $a_0, a_c, a_n$ , are expressed in terms of the following dimension-6 operators [1,2];

$$\begin{aligned} L_6^0 &= -\frac{e^2}{16\Lambda^2} a_0 F^{\mu\nu} F_{\mu\nu} \vec{W}^\alpha \cdot \vec{W}_\alpha \\ L_6^c &= -\frac{e^2}{16\Lambda^2} a_c F^{\mu\alpha} F_{\mu\beta} \vec{W}^\beta \cdot \vec{W}_\alpha \\ L_6^n &= -i\frac{e^2}{16\Lambda^2} a_n \epsilon_{ijk} W_{\mu\alpha}^{(i)} W_\nu^{(j)} W^{(k)\alpha} F^{\mu\nu} \\ \tilde{L}_6^0 &= -\frac{e^2}{16\Lambda^2} \tilde{a}_0 F^{\mu\nu} \tilde{F}_{\mu\nu} \vec{W}^\alpha \cdot \vec{W}_\alpha \\ \tilde{L}_6^n &= -i\frac{e^2}{16\Lambda^2} \tilde{a}_n \epsilon_{ijk} W_{\mu\alpha}^{(i)} W_\nu^{(j)} W^{(k)\alpha} \tilde{F}^{\mu\nu} \end{aligned}$$

where  $F, W$  are photon and  $W$  fields,  $L_6^0$  and  $L_6^c$  conserve  $C, P$  separately ( $\tilde{L}_6^0$  conserves only  $C$ ) and generate anomalous  $W^+W^-\gamma\gamma$  and  $ZZ\gamma\gamma$  couplings,  $L_6^n$  violates  $CP$  ( $\tilde{L}_6^n$  violates both  $C$  and  $P$ ) and generates an anomalous  $W^+W^-Z\gamma$  coupling, and  $\Lambda$  is an energy scale for new physics. For the  $ZZ\gamma\gamma$  coupling the  $CP$ -violating term represented by  $L_6^n$  does not contribute. These couplings are assumed to be real and to vanish at tree level in the Standard Model.

Within the same framework as above, a more recent description of the quartic couplings [3] treats the anomalous parts of the  $WW\gamma\gamma$  and  $ZZ\gamma\gamma$  couplings separately, leading to two sets parameterized as  $a_0^V/\Lambda^2$  and  $a_c^V/\Lambda^2$ , where  $V = W$  or  $Z$ .

At LEP the processes studied in search of these quartic couplings are  $e^+e^- \rightarrow WW\gamma$ ,  $e^+e^- \rightarrow \gamma\gamma\nu\bar{\nu}$ , and  $e^+e^- \rightarrow Z\gamma\gamma$  and limits are set on the quantities  $a_0^W/\Lambda^2, a_c^W/\Lambda^2, a_n/\Lambda^2$ . The characteristics of the first process depend on all the three couplings whereas those of the latter two depend only on the two  $CP$ -conserving couplings. The sensitive measured variables are the cross sections for these processes as well as the energy and angular distributions of the photon and recoil mass to the photon pair. At hadron colliders, tri-boson production  $VV\gamma$  as

well as di-boson scattering  $\gamma\gamma \rightarrow VV$  is analysed to set limits on anomalous QGCs.

## $a_0/\Lambda^2, a_c/\Lambda^2$

Combining published and unpublished preliminary LEP results the following 95% CL intervals for the QGCs associated with the  $ZZ\gamma\gamma$  vertex are derived (CERN-PH-EP/2005-051 or hep-ex/0511027):

$$-0.008 < a_0^Z/\Lambda^2 < +0.021$$

$$-0.029 < a_c^Z/\Lambda^2 < +0.039$$

VALUE DOCUMENT ID TECN

••• We do not use the following data for averages, fits, limits, etc. •••

1 ABBIENDI 04L OPAL  
2 HEISTER 04A ALEP  
3 ACHARD 02G L3

- <sup>1</sup> ABBIENDI 04L select 20  $e^+e^- \rightarrow \nu\bar{\nu}\gamma\gamma$  acoplanar events in the energy range 180–209 GeV and 176  $e^+e^- \rightarrow q\bar{q}\gamma\gamma$  events in the energy range 130–209 GeV. These samples are used to constrain possible anomalous  $W^+W^-\gamma\gamma$  and  $ZZ\gamma\gamma$  quartic couplings. Further combining with the  $W^+W^-\gamma$  sample of ABBIENDI 04B the following one-parameter 95% CL limits are obtained:  $-0.007 < a_0^Z/\Lambda^2 < 0.023 \text{ GeV}^{-2}$ ,  $-0.029 < a_c^Z/\Lambda^2 < 0.029 \text{ GeV}^{-2}$ ,  $-0.020 < a_0^W/\Lambda^2 < 0.020 \text{ GeV}^{-2}$ ,  $-0.052 < a_c^W/\Lambda^2 < 0.037 \text{ GeV}^{-2}$ .
- <sup>2</sup> In the CM energy range 183 to 209 GeV HEISTER 04A select 30  $e^+e^- \rightarrow \nu\bar{\nu}\gamma\gamma$  events with two acoplanar, high energy and high transverse momentum photons. The photon-photon acoplanarity is required to be  $> 5^\circ$ ,  $E_{T\gamma}/\sqrt{s} > 0.025$  (the more energetic photon having energy  $> 0.2\sqrt{s}$ ),  $p_{T\gamma}/E_{\text{beam}} > 0.05$  and  $|\cos\theta_\gamma| < 0.94$ . A likelihood fit to the photon energy and recoil mass yields the following one-parameter 95% CL limits:  $-0.012 < a_0^Z/\Lambda^2 < 0.019 \text{ GeV}^{-2}$ ,  $-0.041 < a_c^Z/\Lambda^2 < 0.044 \text{ GeV}^{-2}$ ,  $-0.060 < a_0^W/\Lambda^2 < 0.055 \text{ GeV}^{-2}$ ,  $-0.099 < a_c^W/\Lambda^2 < 0.093 \text{ GeV}^{-2}$ .
- <sup>3</sup> ACHARD 02G study  $e^+e^- \rightarrow Z\gamma\gamma \rightarrow q\bar{q}\gamma\gamma$  events using data at center-of-mass energies from 200 to 209 GeV. The photons are required to be isolated, each with energy  $> 5 \text{ GeV}$  and  $|\cos\theta| < 0.97$ , and the di-jet invariant mass to be compatible with that of the Z boson (74–111 GeV). Cuts on Z velocity ( $\beta < 0.73$ ) and on the energy of the most energetic photon reduce the backgrounds due to non-resonant production of the  $q\bar{q}\gamma\gamma$  state and due to ISR respectively, yielding a total of 40 candidate events of which 8.6 are expected to be due to background. The energy spectra of the least energetic photon are fitted for all ten center-of-mass energy values from 130 GeV to 209 GeV (as obtained adding to the present analysis 130–202 GeV data of ACCIARRI 01E, for a total of 137 events with an expected background of 34.1 events) to obtain the fitted values  $a_0/\Lambda^2 = 0.00 \pm 0.02 \text{ GeV}^{-2}$  and  $a_c/\Lambda^2 = 0.03 \pm 0.01 \text{ GeV}^{-2}$ , where the other parameter is kept fixed to its Standard Model value (0). A simultaneous fit to both parameters yields the 95% CL limits  $-0.02 \text{ GeV}^{-2} < a_0/\Lambda^2 < 0.03 \text{ GeV}^{-2}$  and  $-0.07 \text{ GeV}^{-2} < a_c/\Lambda^2 < 0.05 \text{ GeV}^{-2}$ .

126.8±0.2±0.7	<sup>2</sup> AAD	13AK ATLS	$pp, 7$ and $8$ TeV, $\gamma\gamma$
124.3+0.6+0.5 -0.5-0.3	<sup>2</sup> AAD	13AK ATLS	$pp, 7, 8$ TeV, $ZZ^* \rightarrow 4\ell$
126.2±0.6±0.2	<sup>3</sup> CHATRCHYAN13j	CMS	$pp, 7, 8$ TeV, $ZZ^* \rightarrow 4\ell$
126.0±0.4±0.4	<sup>1,4</sup> AAD	12AI ATLS	$pp, 7$ and $8$ TeV
125.3±0.4±0.5	<sup>1,5</sup> CHATRCHYAN12N	CMS	$pp, 7$ and $8$ TeV

<sup>1</sup> Combined value from  $\gamma\gamma$  and  $ZZ^* \rightarrow 4\ell$  final states.

<sup>2</sup> AAD 13AK use 4.7 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm}=7$  TeV and 20.7 fb<sup>-1</sup> at  $E_{cm}=8$  TeV.

<sup>3</sup> CHATRCHYAN 13j use 5.1 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV and 12.2 fb<sup>-1</sup> at  $E_{cm} = 8$  TeV.

<sup>4</sup> AAD 12AI obtain results based on 4.6–4.8 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV and 5.8–5.9 fb<sup>-1</sup> at  $E_{cm} = 8$  TeV. An excess of events over background with a local significance of 5.9  $\sigma$  is observed at  $m_{H^0} = 126$  GeV. See also AAD 12DA.

<sup>5</sup> CHATRCHYAN 12N obtain results based on 4.9–5.1 fb<sup>-1</sup> of  $pp$  collisions at  $E_{cm} = 7$  TeV and 5.1–5.3 fb<sup>-1</sup> at  $E_{cm} = 8$  TeV. An excess of events over background with a local significance of 5.0  $\sigma$  is observed at about  $m_{H^0} = 125$  GeV. See also CHATRCHYAN 12BY and CHATRCHYAN 13Y.

 $H^0$  SPIN AND CP PROPERTIES

The observation of the signal in the  $\gamma\gamma$  final state rules out the possibility that the discovered particle has spin 1, as a consequence of the Landau-Yang theorem. This argument relies on the assumptions that the decaying particle is an on-shell resonance and that the decay products are indeed two photons rather than two pairs of boosted photons, which each could in principle be misidentified as a single photon.

Concerning distinguishing the spin 0 hypothesis from a spin 2 hypothesis, some care has to be taken in modelling the latter in order to ensure that the discriminating power is actually based on the spin properties rather than on unphysical behavior that may affect the model of the spin 2 state.

Under the assumption that the observed signal consists of a single state rather than an overlap of more than one resonance, it is sufficient to discriminate between distinct hypotheses in the spin analyses. On the other hand, the determination of the CP properties is in general much more difficult since in principle the observed state could consist of any admixture of CP-even and CP-odd components. As a first step, the compatibility of the data with distinct hypotheses of pure CP-even and pure CP-odd states with different spin assignments has been investigated. In CHATRCHYAN 13J angular distributions of the lepton pairs have been studied in the  $ZZ^*$  channel where both Z bosons decay to e or  $\mu$  pairs. Under the assumption that the observed particle has spin 0, the data are found to be consistent with the pure CP-even hypothesis, while the pure CP-odd hypothesis is disfavored. In AAD 13AJ the spin 0, CP-even hypothesis has been compared with specific alternative hypotheses of spin 0, CP-odd, spin 1, CP-even and CP-odd, and spin 2, CP-even models using the Higgs boson decays  $H \rightarrow \gamma\gamma, H \rightarrow ZZ^* \rightarrow 4\ell$  and  $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$  and combinations thereof. The data are compatible with the spin 0, CP-even hypothesis, while all other tested hypotheses are excluded at confidence levels above 97.8%.

 $H^0$  DECAY WIDTH

The total decay width for a light Higgs boson with a mass in the observed range is not expected to be directly observable at the LHC. For the case of the Standard Model the prediction for the total width is about 4 MeV, which is three orders of magnitude smaller than the experimental mass resolution. There is no indication from the results observed so far that the natural width is broadened by new physics effects to such an extent that it could be directly observable. Furthermore, as all LHC Higgs channels rely on the identification of Higgs decay products, the total Higgs width cannot be measured indirectly without additional assumptions. The different dependence of on-peak and off-peak contributions on the total width in Higgs decays to  $ZZ^*$  and interference effects between signal and background in Higgs decays to  $\gamma\gamma$  can provide additional information in this context. Without an experimental determination of the total width or further theoretical assumptions, only ratios of couplings can be determined at the LHC rather than absolute values of couplings.

 $H^0$  DECAY MODES

Mode
$\Gamma_1$ $WW^*$
$\Gamma_2$ $ZZ^*$
$\Gamma_3$ $\gamma\gamma$
$\Gamma_4$ $b\bar{b}$
$\Gamma_5$ $\tau^+\tau^-$
$\Gamma_6$ $Z\gamma$

 $H^0$  SIGNAL STRENGTHS IN DIFFERENT CHANNELS

The  $H^0$  signal strength in a particular final state  $xx$  is given by the cross section times branching ratio in this channel normalized to the Standard Model (SM) value,  $\sigma \cdot B(H^0 \rightarrow xx) / (\sigma \cdot B(H^0 \rightarrow xx))_{SM}$ , for the specified mass value of  $H^0$ .

 $H^0$ 

$$J = 0$$

In the following  $H^0$  refers to the signal that has been discovered in the Higgs searches. Whereas the observed signal is labeled as a spin 0 particle and is called a Higgs Boson, the detailed properties of  $H^0$  and its role in the context of electroweak symmetry breaking need to be further clarified. These issues are addressed by the measurements listed below.

Concerning mass limits and cross section limits that have been obtained in the searches for neutral and charged Higgs bosons, see the sections "Searches for Neutral Higgs Bosons" and "Searches for Charged Higgs Bosons ( $H^\pm$  and  $H^{\pm\pm}$ )", respectively.

 $H^0$  MASS

A combination of the results from ATLAS and CMS, where a recent unpublished result from CMS is used, yields an average value of  $125.6 \pm 0.3$  GeV, see the review on "Status of Higgs Boson Physics."

## MASS LIMITS FOR NEUTRAL HIGGS BOSONS IN SUPERSYMMETRIC MODELS

The minimal supersymmetric model has two complex doublets of Higgs bosons. The resulting physical states are two scalars [ $H^0_1$  and  $H^0_2$ ], where we define  $m_{H^0_1} < m_{H^0_2}$ , a pseudoscalar ( $A^0$ ), and a charged Higgs pair

( $H^\pm$ ).  $H^0_1$  and  $H^0_2$  are also called  $h$  and  $H$  in the literature. There are two free parameters in the Higgs sector which can be chosen to be  $m_{A^0}$  and  $\tan\beta = v_2/v_1$ , the ratio of vacuum expectation values of the two Higgs doublets. Tree-level Higgs masses are constrained by the model to be  $m_{H^0_1} \leq m_Z$ ,  $m_{H^0_2} \geq m_Z$ ,  $m_{A^0} \geq m_{H^0_1}$ , and  $m_{H^\pm} \geq m_W$ . However, as described in the review on “Status of Higgs Boson Physics” in this Volume these relations are violated by radiative corrections.

Unless otherwise noted, the experiments in  $e^+e^-$  collisions search for the processes  $e^+e^- \rightarrow H^0_1 Z^0$  in the channels used for the Standard Model Higgs searches and  $e^+e^- \rightarrow H^0_2 A^0$  in the final states  $b\bar{b}b\bar{b}$  and  $b\bar{b}\tau^+\tau^-$ . In  $p\bar{p}$  and  $pp$  collisions the experiments search for a variety of processes, as explicitly specified for each entry. Limits on the  $A^0$  mass arise from these direct searches, as well as from the relations valid in the minimal supersymmetric model between  $m_{A^0}$  and  $m_{H^0_1}$ . As discussed in the review on “Status of Higgs Boson Physics” in this Volume, these relations depend, via potentially large radiative corrections, on the mass of the  $t$  quark and on the supersymmetric parameters, in particular those of the stop sector. These indirect limits are weaker for larger  $t$  and  $\bar{t}$  masses. To include the radiative corrections to the Higgs masses, unless otherwise stated, the listed papers use theoretical predictions incorporating two-loop corrections, and the results are given for the  $m_h^{\text{max}}$  benchmark scenario, which gives rise to the most conservative upper bound on the mass of  $H^0_1$  for given values of  $m_{A^0}$  and  $\tan\beta$ , see CARENA 99b, CARENA 03, and CARENA 13.

Limits in the low-mass region of  $H^0_1$ , as well as other by now obsolete limits from different techniques, have been removed from this compilation, and can be found in earlier editions of this Review. Unless otherwise stated, the following results assume no invisible  $H^0_1$  or  $A^0$  decays.

The observed signal at about 126 GeV, see section “ $H^0$ ”, can be interpreted as one of the neutral Higgs bosons of supersymmetric models.

<sup>1</sup> ABDALLAH 08b give limits in eight  $CP$ -conserving benchmark scenarios and some  $CP$ -violating scenarios. See paper for excluded regions for each scenario. Supersedes ABDALLAH 04.  
<sup>2</sup> SCHAEEL 06b make a combined analysis of the LEP data. The quoted limit is for the  $m_h^{\max}$  scenario with  $m_t = 174.3$  GeV. In the  $CP$ -violating CPX scenario no lower bound on  $m_{H_1^0}$  can be set at 95% CL. See paper for excluded regions in various scenarios. See Figs. 2-6 and Tabs. 14-21 for limits on  $\sigma(ZH^0) \cdot B(H^0 \rightarrow b\bar{b}, \tau^+\tau^-)$  and  $\sigma(H_1^0 H_2^0) \cdot B(H_1^0 H_2^0 \rightarrow b\bar{b}, \tau^+\tau^-)$ .

<sup>3</sup> Search for  $e^+e^- \rightarrow H_1^0 A^0$  in the final states  $b\bar{b}b\bar{b}$  and  $b\bar{b}\tau^+\tau^-$ , and  $e^+e^- \rightarrow H_1^0 Z$ . Universal scalar mass of 1 TeV,  $SU(2)$  gaugino mass of 200 GeV, and  $\mu = -200$  GeV are assumed, and two-loop radiative corrections incorporated. The limits hold for  $m_t = 175$  GeV, and for the  $m_h^{\max}$  scenario.

<sup>4</sup> ABBIENDI 04M exclude  $0.7 < \tan\beta < 1.9$ , assuming  $m_t = 174.3$  GeV. Limits for other MSSM benchmark scenarios, as well as for  $CP$  violating cases, are also given.

<sup>5</sup> ACHARD 02H also search for the final state  $H_1^0 Z \rightarrow 2A^0 q\bar{q}, A^0 \rightarrow q\bar{q}$ . In addition, the MSSM parameter set in the "large- $\mu$ " and "no-mixing" scenarios are examined.

<sup>6</sup> AAD 13o search for production of a Higgs boson in the decay  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$  and  $\mu^+\mu^-$  with  $4.7$ - $4.8$  fb $^{-1}$  of  $pp$  collisions at  $E_{cm} = 7$  TeV. See their Fig. 6 for the excluded region in the MSSM parameter space and their Fig. 7 for the limits on cross section times branching ratio. For  $m_{A^0} = 110$ - $170$  GeV,  $\tan\beta \gtrsim 10$  is excluded, and for  $\tan\beta = 50$ ,  $m_{A^0}$  below 470 GeV is excluded at 95% CL in the  $m_h^{\max}$  scenario.

<sup>7</sup> AAIJ 13T search for production of a Higgs boson in the forward region in the decay  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$  in  $1.0$  fb $^{-1}$  of  $pp$  collisions at  $E_{cm} = 7$  TeV. See their Fig. 2 for the limits on cross section times branching ratio and the excluded region in the MSSM parameter space.

<sup>8</sup> CHATRCHYAN 13AG search for production of a Higgs boson in association with a  $b$  quark in the decay  $H_{1,2}^0/A^0 \rightarrow b\bar{b}$  in  $2.7$ - $4.8$  fb $^{-1}$  of  $pp$  collisions at  $E_{cm} = 7$  TeV. See their Fig. 6 for the excluded region in the MSSM parameter space and Fig. 5 for the limits on cross section times branching ratio. For  $m_{A^0} = 90$ - $350$  GeV, upper bounds on  $\tan\beta$  of  $18$ - $42$  at 95% CL are obtained in the  $m_h^{\max}$  scenario with  $\mu = +200$  GeV.

<sup>9</sup> AALTONEN 12AQ combine AALTONEN 12X and ABAZOV 11K. See their Table I and Fig. 1 for the limit on cross section times branching ratio and Fig. 2 for the excluded region in the MSSM parameter space.

<sup>10</sup> AALTONEN 12X search for associated production of a Higgs boson and a  $b$  quark in the decay  $H_{1,2}^0/A^0 \rightarrow b\bar{b}$ , with  $2.6$  fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. See their Table III and Fig. 15 for the limit on cross section times branching ratio and Figs. 17, 18 for the excluded region in the MSSM parameter space.

<sup>11</sup> ABAZOV 12 search for production of a Higgs boson followed by the decay  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$  in  $5.4$  fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. See their Fig. 2 for the limit on cross section times branching ratio and Fig. 3 for the excluded region in the MSSM parameter space. Superseded by ABAZOV 12G.

<sup>12</sup> ABAZOV 12c search for production of a Higgs boson in the decay  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$  with  $7.3$  fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV and combine with ABAZOV 11W and ABAZOV 11K. See their Figs. 4, 5, and 6 for the excluded region in the MSSM parameter space. For  $m_{A^0} = 90$ - $180$  GeV,  $\tan\beta \gtrsim 30$  is excluded at 95% CL in the  $m_h^{\max}$  scenario.

<sup>13</sup> CHATRCHYAN 12k search for production of a Higgs boson in the decay  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$  with  $4.6$  fb $^{-1}$  of  $pp$  collisions at  $E_{cm} = 7$  TeV. See their Fig. 3 and Table 4 for the excluded region in the MSSM parameter space. For  $m_{A^0} = 160$  GeV, the region  $\tan\beta > 7.1$  is excluded at 95% CL in the  $m_h^{\max}$  scenario.

<sup>14</sup> AAD 11R search for production of a Higgs boson followed by the decay  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$  in  $36$  pb $^{-1}$  of  $pp$  collisions at  $E_{cm} = 7$  TeV. See their Fig. 3 for the limit on cross section times branching ratio and for the excluded region in the MSSM parameter space. Superseded by AAD 13o.

<sup>15</sup> ABAZOV 11k search for associated production of a Higgs boson and a  $b$  quark, followed by the decay  $H_{1,2}^0/A^0 \rightarrow b\bar{b}$ , in  $5.2$  fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. See their Fig. 5/ Table 2 for the limit on cross section times branching ratio and Fig. 6 for the excluded region in the MSSM parameter space for  $\mu = -200$  GeV.

<sup>16</sup> ABAZOV 11w search for associated production of a Higgs boson and a  $b$  quark, followed by the decay  $H_{1,2}^0/A^0 \rightarrow \tau\tau$ , in  $7.3$  fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. See their

Fig. 2 for the limit on cross section times branching ratio and for the excluded region in the MSSM parameter space.

<sup>17</sup> CHATRCHYAN 11H search for production of a Higgs boson followed by the decay  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$  in  $36$  pb $^{-1}$  of  $pp$  collisions at  $E_{cm} = 7$  TeV. See their Fig. 2 for the limit on cross section times branching ratio and Fig. 3 for the excluded region in the MSSM parameter space. Superseded by CHATRCHYAN 12k.

<sup>18</sup> AALTONEN 09AR search for Higgs bosons decaying to  $\tau^+\tau^-$  in two doublet models in  $1.8$  fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. See their Fig. 2 for the limit on  $\sigma \cdot B(H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-)$  for different Higgs masses, and see their Fig. 3 for the excluded region in the MSSM parameter space.

<sup>19</sup> ABAZOV 08w search for Higgs boson production in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV with the decay  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$ . See their Fig. 3 for the limit on  $\sigma \cdot B(H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-)$  for different Higgs masses, and see their Fig. 4 for the excluded region in the MSSM parameter space. Superseded by ABAZOV 12.

<sup>20</sup> ABBIENDI 03G search for  $e^+e^- \rightarrow H_1^0 Z$  followed by  $H_1^0 \rightarrow A^0 A^0, A^0 \rightarrow c\bar{c}, g\bar{g},$  or  $\tau^+\tau^-$ . In the no-mixing scenario, the region  $m_{H_1^0} = 45$ - $85$  GeV and  $m_{A^0} = 2$ - $9.5$  GeV is excluded at 95% CL.

<sup>21</sup> HEISTER 02 excludes the range  $0.7 < \tan\beta < 2.3$ . A wider range is excluded with different stop mixing assumptions. Updates BARATE 01c.

See their Fig. 6 for the excluded region in the MSSM parameter space and Fig. 5 for the limits on cross section times branching ratio. For  $m_{A^0} = 90\text{--}350\text{ GeV}$ , upper bounds on  $\tan\beta$  of  $18\text{--}42$  at 95% CL are obtained in the  $m_h^{\text{max}}$  scenario with  $\mu = +200\text{ GeV}$ .
- <sup>10</sup> AALTONEN 12AQ combine AALTONEN 12X and ABAZOV 11K. See their Table I and Fig. 1 for the limit on cross section times branching ratio and Fig. 2 for the excluded region in the MSSM parameter space.
- <sup>11</sup> AALTONEN 12X search for associated production of a Higgs boson and a  $b$  quark in the decay  $H_{1,2}^0/A^0 \rightarrow b\bar{b}$ , with  $2.6\text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96\text{ TeV}$ . See their Table III and Fig. 15 for the limit on cross section times branching ratio and Figs. 17, 18 for the excluded region in the MSSM parameter space.
- <sup>12</sup> ABAZOV 12 search for production of a Higgs boson followed by the decay  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$  in  $5.4\text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96\text{ TeV}$ . See their Fig. 2 for the limit on cross section times branching ratio and Fig. 3 for the excluded region in the MSSM parameter space. Superseded by ABAZOV 12G.
- <sup>13</sup> ABAZOV 12G search for production of a Higgs boson in the decay  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$  with  $7.3\text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96\text{ TeV}$  and combine with ABAZOV 11W and ABAZOV 11K. See their Figs. 4, 5, and 6 for the excluded region in the MSSM parameter space. For  $m_{A^0} = 90\text{--}180\text{ GeV}$ ,  $\tan\beta \gtrsim 30$  is excluded at 95% CL in the  $m_h^{\text{max}}$  scenario.
- <sup>14</sup> CHATRCHYAN 12K search for production of a Higgs boson in the decay  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$  with  $4.6\text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7\text{ TeV}$ . See their Fig. 3 and Table 4 for the excluded region in the MSSM parameter space. For  $m_{A^0} = 160\text{ GeV}$ , the region  $\tan\beta > 7.1$  is excluded at 95% CL in the  $m_h^{\text{max}}$  scenario.
- <sup>15</sup> AAD 11R search for production of a Higgs boson followed by the decay  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$  in  $36\text{ pb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7\text{ TeV}$ . See their Fig. 3 for the limit on cross section times branching ratio and for the excluded region in the MSSM parameter space. Superseded by AAD 130.
- <sup>16</sup> ABAZOV 11K search for associated production of a Higgs boson and a  $b$  quark, followed by the decay  $H_{1,2}^0/A^0 \rightarrow b\bar{b}$ , in  $5.2\text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96\text{ TeV}$ . See their Fig. 5/Table 2 for the limit on cross section times branching ratio and Fig. 6 for the excluded region in the MSSM parameter space for  $\mu = -200\text{ GeV}$ .
- <sup>17</sup> ABAZOV 11W search for associated production of a Higgs boson and a  $b$  quark, followed by the decay  $H_{1,2}^0/A^0 \rightarrow \tau\tau$ , in  $7.3\text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96\text{ TeV}$ . See their Fig. 2 for the limit on cross section times branching ratio and for the excluded region in the MSSM parameter space.
- <sup>18</sup> CHATRCHYAN 11H search for production of a Higgs boson followed by the decay  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$  in  $36\text{ pb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7\text{ TeV}$ . See their Fig. 2 for the limit on cross section times branching ratio and Fig. 3 for the excluded region in the MSSM parameter space. Superseded by CHATRCHYAN 12K.
- <sup>19</sup> AALTONEN 09AR search for Higgs bosons decaying to  $\tau^+\tau^-$  in two doublet models in  $1.8\text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96\text{ TeV}$ . See their Fig. 2 for the limit on  $\sigma \cdot B(H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-)$  for different Higgs masses, and see their Fig. 3 for the excluded region in the MSSM parameter space.
- <sup>20</sup> ACOSTA 05Q search for  $H_{1,2}^0/A^0$  production in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.8\text{ TeV}$  with  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$ . At  $m_{A^0} = 100\text{ GeV}$ , the obtained cross section upper limit is above theoretical expectation.
- <sup>21</sup> ABBIENDI 03G search for  $e^+e^- \rightarrow H_1^0 Z$  followed by  $H_1^0 \rightarrow A^0 A^0$ ,  $A^0 \rightarrow c\bar{c}$ ,  $g g$ , or  $\tau^+\tau^-$ . In the no-mixing scenario, the region  $m_{H_1^0} = 45\text{--}85\text{ GeV}$  and  $m_{A^0} = 2\text{--}9.5\text{ GeV}$  is excluded at 95% CL.
- <sup>22</sup> AKEROYD 02 examine the possibility of a light  $A^0$  with  $\tan\beta < 1$ . Electroweak measurements are found to be inconsistent with such a scenario.

### MASS LIMITS FOR NEUTRAL HIGGS BOSONS IN EXTENDED HIGGS MODELS

This Section covers models which do not fit into either the Standard Model or its simplest minimal Supersymmetric extension (MSSM), leading to anomalous production rates, or nonstandard final states and branching ratios. In particular, this Section covers limits which may apply to generic two-Higgs-doublet models (2HDM), or to special regions of the MSSM parameter space where decays to invisible particles or to photon pairs are dominant (see the review on "Status of Higgs Boson Physics"). Concerning the mass limits for  $H^0$  and  $A^0$  listed below, see the footnotes or the comment lines for details on the nature of the models to which the limits apply.

The observed signal at about  $126\text{ GeV}$ , see section "H<sup>0</sup>", can be interpreted as one of the neutral Higgs bosons of an extended Higgs sector.

### Mass Limits in General two-Higgs-doublet Models

- <sup>1</sup> AALTONEN 09AR search for Higgs bosons decaying to  $\tau^+\tau^-$  in two doublet models in  $1.8\text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96\text{ TeV}$ . See their Fig. 2 for the limit on  $\sigma \cdot B(H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-)$  for different Higgs masses, and see their Fig. 3 for the excluded region in the MSSM parameter space.
- <sup>2</sup> ABBIENDI 05A search for  $e^+e^- \rightarrow H_1^0 A^0$  in general Type-II two-doublet models, with decays  $H_1^0, A^0 \rightarrow q\bar{q}, g g, \tau^+\tau^-,$  and  $H_1^0 \rightarrow A^0 A^0$ .
- <sup>3</sup> ABDALLAH 05D search for  $e^+e^- \rightarrow H^0 Z$  and  $H^0 A^0$  with  $H^0, A^0$  decaying to two jets of any flavor including  $g g$ . The limit is for SM  $H^0 Z$  production cross section with  $B(H^0 \rightarrow jj) = 1$ .
- <sup>4</sup> ABDALLAH 04O search for  $Z \rightarrow b\bar{b}H^0, b\bar{b}A^0, \tau^+\tau^-H^0$  and  $\tau^+\tau^-A^0$  in the final states  $4b, b\bar{b}\tau^+\tau^-,$  and  $4\tau$ . See paper for limits on Yukawa couplings.
- <sup>5</sup> ABDALLAH 04O search for  $e^+e^- \rightarrow H^0 Z$  and  $H^0 A^0$ , with  $H^0, A^0$  decaying to  $b\bar{b}, \tau^+\tau^-,$  or  $H^0 \rightarrow A^0 A^0$  at  $E_{\text{cm}} = 189\text{--}208\text{ GeV}$ . See paper for limits on couplings.
- <sup>6</sup> ABBIENDI 02D search for  $Z \rightarrow b\bar{b}H^0$  and  $b\bar{b}A^0$  with  $H_{1,2}^0/A^0 \rightarrow \tau^+\tau^-$ , in the range  $4 < m_H < 12\text{ GeV}$ . See their Fig. 8 for limits on the Yukawa coupling.
- <sup>7</sup> ABBIENDI 01E search for neutral Higgs bosons in general Type-II two-doublet models, at  $E_{\text{cm}} \leq 189\text{ GeV}$ . In addition to usual final states, the decays  $H_1^0, A^0 \rightarrow q\bar{q}, g g$  are searched for. See their Figs. 15,16 for excluded regions.
- <sup>8</sup> ABBIENDI 99E search for  $e^+e^- \rightarrow H^0 A^0$  and  $H^0 Z$  at  $E_{\text{cm}} = 183\text{ GeV}$ . The limit is with  $m_H = m_A$  in general two Higgs-doublet models. See their Fig. 18 for the exclusion limit in the  $m_H\text{--}m_A$  plane. Updates the results of ACKERSTAFF 98s.
- <sup>9</sup> See Fig. 4 of ABREU 95H for the excluded region in the  $m_{H^0} - m_{A^0}$  plane for general two-doublet models. For  $\tan\beta > 1$ , the region  $m_{H^0} + m_{A^0} \lesssim 87\text{ GeV}$ ,  $m_{H^0} < 47\text{ GeV}$  is excluded at 95% CL.
- <sup>10</sup> PICH 92 analyse  $H^0$  with  $m_{H^0} < 2m_\mu$  in general two-doublet models. Excluded regions in the space of mass-mixing angles from LEP, beam dump, and  $\pi^\pm, \eta$  rare decays are shown in Figs. 3.4. The considered mass region is not totally excluded.

### Mass Limits for H<sup>0</sup> with Vanishing Yukawa Couplings

These limits assume that  $H^0$  couples to gauge bosons with the same strength as the Standard Model Higgs boson, but has no coupling to quarks and leptons (this is often referred to as "fermiophobic").

## Neutral Higgs Bosons, Searches for

- <sup>3</sup> LEES 13R search for the process  $\Upsilon(2S) \rightarrow \Upsilon(1S)\pi^+\pi^- \rightarrow A^0\gamma\pi^+\pi^-$  with  $A^0$  decaying to  $\tau^+\tau^-$  and give limits on  $B(\Upsilon(1S) \rightarrow A^0\gamma) \cdot B(A^0 \rightarrow \tau^+\tau^-)$  in the range  $0.9\text{--}13 \times 10^{-5}$  (90% CL) for  $3.6 \leq m_{A^0} \leq 9.2$  GeV. See their Fig. 4 for limits on the  $b - A^0$  Yukawa coupling derived by combining this result with AUBERT 09P.
- <sup>4</sup> CHATRCHYAN 12v search for  $A^0$  production in the decay  $A^0 \rightarrow \mu^+\mu^-$  with  $1.3 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7$  TeV. A limit on  $\sigma(A^0) \cdot B(A^0 \rightarrow \mu^+\mu^-)$  in the range (1.5–7.5) pb is given for  $m_{A^0} = (5.5\text{--}8.7)$  and (11.5–14) GeV at 95% CL.
- <sup>5</sup> AALTONEN 11P search in  $2.7 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV for the decay chain  $t \rightarrow bH^+, H^+ \rightarrow W^+A^0, A^0 \rightarrow \tau^+\tau^-$  with  $m_{A^0}$  between 4 and 9 GeV. See their Fig. 4 for limits on  $B(t \rightarrow bH^+)$  for  $90 < m_{H^+} < 160$  GeV.
- <sup>6</sup> ABOUZAIID 11A search for the decay chain  $K_L \rightarrow \pi^0\pi^0A^0, A^0 \rightarrow \mu^+\mu^-$  and give a limit  $B(K_L \rightarrow \pi^0\pi^0A^0) \cdot B(A^0 \rightarrow \mu^+\mu^-) < 1.0 \times 10^{-10}$  at 90% CL for  $m_{A^0} = 214.3$  MeV.
- <sup>7</sup> The search was motivated by PARK 05.
- <sup>8</sup> DEL-AMO-SANCHEZ 11J search for the process  $\Upsilon(2S) \rightarrow \Upsilon(1S)\pi^+\pi^- \rightarrow A^0\gamma\pi^+\pi^-$  with  $A^0$  decaying to invisible final states. They give limits on  $B(\Upsilon(1S) \rightarrow A^0\gamma) \cdot B(A^0 \rightarrow \text{invisible})$  in the range (1.9–4.5)  $\times 10^{-6}$  (90% CL) for  $0 \leq m_{A^0} \leq 8.0$  GeV, and (2.7–37)  $\times 10^{-6}$  for  $8.0 \leq m_{A^0} \leq 9.2$  GeV.
- <sup>9</sup> LEES 11H search for the process  $\Upsilon(2S, 3S) \rightarrow A^0\gamma$  with  $A^0$  decaying hadronically and give limits on  $B(\Upsilon(2S, 3S) \rightarrow A^0\gamma) \cdot B(A^0 \rightarrow \text{hadrons})$  in the range  $1 \times 10^{-6}\text{--}8 \times 10^{-5}$  (90% CL) for  $0.3 < m_{A^0} < 7$  GeV. The decay rates for  $\Upsilon(2S)$  and  $\Upsilon(3S)$  are assumed to be equal up to the phase space factor.
- <sup>10</sup> ANDREAS 10 analyze constraints from rare decays and other processes on a light  $A^0$  with  $m_{A^0} < 2m_{\mu}$  and give limits on its coupling to fermions at the level of  $10^{-4}$  times the Standard Model value.
- <sup>11</sup> HYUN 10 search for the decay chain  $B^0 \rightarrow K^{*0}A^0, A^0 \rightarrow \mu^+\mu^-$  and give a limit on  $B(B^0 \rightarrow K^{*0}A^0) \cdot B(A^0 \rightarrow \mu^+\mu^-)$  in the range (2.26–5.53)  $\times 10^{-8}$  at 90%CL for  $m_{A^0} = 212\text{--}300$  MeV. The limit for  $m_{A^0} = 214.3$  MeV is  $2.26 \times 10^{-8}$ .
- <sup>12</sup> HYUN 10 search for the decay chain  $B^0 \rightarrow \rho^0A^0, A^0 \rightarrow \mu^+\mu^-$  and give a limit on  $B(B^0 \rightarrow \rho^0A^0) \cdot B(A^0 \rightarrow \mu^+\mu^-)$  in the range (1.73–4.51)  $\times 10^{-8}$  at 90%CL for  $m_{A^0} = 212\text{--}300$  MeV. The limit for  $m_{A^0} = 214.3$  MeV is  $1.73 \times 10^{-8}$ .
- <sup>13</sup> AUBERT 09P search for the process  $\Upsilon(3S) \rightarrow A^0\gamma$  with  $A^0 \rightarrow \tau^+\tau^-$  for  $4.03 < m_{A^0} < 9.52$  and  $9.61 < m_{A^0} < 10.10$  GeV, and give limits on  $B(\Upsilon(3S) \rightarrow A^0\gamma) \cdot B(A^0 \rightarrow \tau^+\tau^-)$  in the range (1.5–16)  $\times 10^{-5}$  (90% CL).
- <sup>14</sup> AUBERT 09Z search for the process  $\Upsilon(2S) \rightarrow A^0\gamma$  with  $A^0 \rightarrow \mu^+\mu^-$  for  $0.212 < m_{A^0} < 9.3$  GeV and give limits on  $B(\Upsilon(2S) \rightarrow A^0\gamma) \cdot B(A^0 \rightarrow \mu^+\mu^-)$  in the range (0.3–8)  $\times 10^{-6}$  (90% CL).
- <sup>15</sup> AUBERT 09Z search for the process  $\Upsilon(3S) \rightarrow A^0\gamma$  with  $A^0 \rightarrow \mu^+\mu^-$  for  $0.212 < m_{A^0} < 9.3$  GeV and give limits on  $B(\Upsilon(3S) \rightarrow A^0\gamma) \cdot B(A^0 \rightarrow \mu^+\mu^-)$  in the range (0.3–5)  $\times 10^{-6}$  (90% CL).
- <sup>16</sup> TUNG 09 search for the decay chain  $K_L \rightarrow \pi^0\pi^0A^0, A^0 \rightarrow \gamma\gamma$  and give a limit on  $B(K_L \rightarrow \pi^0\pi^0A^0) \cdot B(A^0 \rightarrow \gamma\gamma)$  in the range (2.4–10.7)  $\times 10^{-7}$  at 90%CL for  $m_{A^0} = 194.3\text{--}219.3$  MeV. The limit for  $m_{A^0} = 214.3$  MeV is  $2.4 \times 10^{-7}$ .
- <sup>17</sup> LOVE 08 search for the process  $\Upsilon(1S) \rightarrow A^0\gamma$  with  $A^0 \rightarrow \mu^+\mu^-$  (for  $m_{A^0} < 2m_{\tau}$ ) and  $A^0 \rightarrow \tau^+\tau^-$ . Limits on  $B(\Upsilon(1S) \rightarrow A^0\gamma) \cdot B(A^0 \rightarrow \ell^+\ell^-)$  in the range  $10^{-6}\text{--}10^{-4}$  (90% CL) are given.
- <sup>18</sup> BESSON 07 give a limit  $B(\Upsilon(1S) \rightarrow \eta_b\gamma) \cdot B(\eta_b \rightarrow \tau^+\tau^-) < 0.27\%$  (95% CL), which constrains a possible  $A^0$  exchange contribution to the  $\eta_b$  decay.
- <sup>19</sup> PARK 05 found three candidate events for  $\Sigma^+ \rightarrow p\mu^+\mu^-$  in the HyperCP experiment. Due to a narrow spread in dimuon mass, they hypothesize the events as a possible signal of a new boson. It can be interpreted as a neutral particle with  $m_{A^0} = 214.3 \pm 0.5$  MeV and the branching fraction  $B(\Sigma^+ \rightarrow pA^0) \cdot B(A^0 \rightarrow \mu^+\mu^-) = (3.1^{+2.4}_{-1.9} \pm 1.5) \times 10^{-8}$ .
- <sup>20</sup> BALEST 95 two-body limit is for pseudoscalar  $A^0$ . The limit becomes  $< 10^{-4}$  for  $m_{A^0} < 7.7$  GeV.
- <sup>21</sup> ANTREASIAN 90c assume that  $A^0$  does not decay in the detector.

		21 KRAWCZYK 97	RVUE	$(g-2)_\mu$
		22 ALEXANDER 96H	OPAL	$Z \rightarrow H^0\gamma$

- <sup>1</sup> AALTONEN 13P search for production of a heavy Higgs boson  $H^0$  that decays into a charged Higgs boson  $H^\pm$  and a lighter Higgs boson  $H^0$  via the decay chain  $H^0 \rightarrow H^\pm W^\mp, H^\pm \rightarrow W^\pm H^0, H^0 \rightarrow b\bar{b}$  in the final state  $\ell\nu$  plus 4 jets in  $8.7 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. See their Fig. 4 for limits on cross section times branching ratio in the  $m_{H^\pm}\text{--}m_{H^0}$  plane for  $m_{H^0} = 126$  GeV.
- <sup>2</sup> CHATRCHYAN 13BJ search for  $H^0$  production in the decay chain  $H^0 \rightarrow A^0 A^0, A^0 \rightarrow \mu^+\mu^-$  in  $5.3 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7$  TeV. See their Fig. 2 for limits on cross section times branching ratio.
- <sup>3</sup> AALTONEN 11P search in  $2.7 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV for the decay chain  $t \rightarrow bH^+, H^+ \rightarrow W^+A^0, A^0 \rightarrow \tau^+\tau^-$  with  $m_{A^0}$  between 4 and 9 GeV. See their Fig. 4 for limits on  $B(t \rightarrow bH^+)$  for  $90 < m_{H^+} < 160$  GeV.
- <sup>4</sup> ABBIENDI 10 search for  $e^+e^- \rightarrow ZH^0$  with the decay chain  $H^0 \rightarrow \tilde{\chi}_1^0 \tilde{\chi}_2^0, \tilde{\chi}_2^0 \rightarrow \tilde{\chi}_1^0 + (\gamma \text{ or } Z^*)$ , when  $\tilde{\chi}_1^0$  and  $\tilde{\chi}_2^0$  are nearly degenerate. For a mass difference of 2 (4) GeV, a lower limit on  $m_{H^0}$  of 108.4 (107.0) GeV (95% CL) is obtained for SM  $ZH^0$  cross section and  $B(H^0 \rightarrow \tilde{\chi}_1^0 \tilde{\chi}_2^0) = 1$ .
- <sup>5</sup> SCHAEEL 10 search for the process  $e^+e^- \rightarrow H^0 Z$  followed by the decay chain  $H^0 \rightarrow A^0 A^0 \rightarrow \tau^+\tau^-\tau^+\tau^-$  with  $Z \rightarrow \ell^+\ell^-, \nu\bar{\nu}$  at  $E_{\text{cm}} = 183\text{--}209$  GeV. For a  $H^0 Z$  coupling equal to the SM value,  $B(H^0 \rightarrow A^0 A^0) = B(A^0 \rightarrow \tau^+\tau^-) = 1$ , and  $m_{A^0} = 4\text{--}10$  GeV,  $m_{H^0}$  up to 107 GeV is excluded at 95% CL.
- <sup>6</sup> ABAZOV 09v search for  $H^0$  production followed by the decay chain  $H^0 \rightarrow A^0 A^0 \rightarrow \mu^+\mu^-\mu^+\mu^-$  or  $\mu^+\mu^-\tau^+\tau^-$  in  $4.2 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. See their Fig. 3 for limits on  $\sigma(H^0) \cdot B(H^0 \rightarrow A^0 A^0)$  for  $m_{A^0} = 3.6\text{--}19$  GeV.
- <sup>7</sup> ABBIENDI 05A search for  $e^+e^- \rightarrow H^0 A^0$  in general Type-II two-doublet models, with decays  $H^0_1 \rightarrow q\bar{q}, gg, \tau^+\tau^-$ , and  $H^0_2 \rightarrow A^0 A^0$ .
- <sup>8</sup> ABBIENDI 04k search for  $e^+e^- \rightarrow H^0 Z$  with  $H^0$  decaying to two jets of any flavor including  $gg$ . The limit is for SM production cross section with  $B(H^0 \rightarrow jj) = 1$ .
- <sup>9</sup> ABDALLAH 04 consider the full combined LEP and LEP2 datasets to set limits on the Higgs coupling to  $W$  or  $Z$  bosons, assuming SM decays of the Higgs. Results in Fig. 26.
- <sup>10</sup> ACHARD 04B search for  $e^+e^- \rightarrow H^0 Z$  with  $H^0$  decaying to  $b\bar{b}, c\bar{c}$ , or  $gg$ . The limit is for SM production cross section with  $B(H^0 \rightarrow jj) = 1$ .
- <sup>11</sup> ACHARD 04F search for  $H^0$  with anomalous coupling to gauge boson pairs in the processes  $e^+e^- \rightarrow H^0\gamma, e^+e^- H^0, H^0 Z$  with decays  $H^0 \rightarrow f\bar{f}, \gamma\gamma, Z\gamma$ , and  $W^* W$  at  $E_{\text{cm}} = 189\text{--}209$  GeV. See paper for limits.
- <sup>12</sup> ABBIENDI 03F search for  $H^0 \rightarrow$  anything in  $e^+e^- \rightarrow H^0 Z$ , using the recoil mass spectrum of  $Z \rightarrow e^+e^-$  or  $\mu^+\mu^-$ . In addition, it searched for  $Z \rightarrow \nu\bar{\nu}$  and  $H^0 \rightarrow e^+e^-$  or photons. Scenarios with large width or continuum  $H^0$  mass distribution are considered. See their Figs. 11–14 for the results.
- <sup>13</sup> ABBIENDI 03G search for  $e^+e^- \rightarrow H^0_1 Z$  followed by  $H^0_1 \rightarrow A^0 A^0, A^0 \rightarrow c\bar{c}, gg$ , or  $\tau^+\tau^-$  in the region  $m_{H^0_1} = 45\text{--}86$  GeV and  $m_{A^0} = 2\text{--}11$  GeV. See their Fig. 7 for the limits.
- <sup>14</sup> Search for associated production of a  $\gamma\gamma$  resonance with a  $Z$  boson, followed by  $Z \rightarrow q\bar{q}, \ell^+\ell^-,$  or  $\nu\bar{\nu}$ , at  $E_{\text{cm}} \leq 209$  GeV. The limit is for a  $H^0$  with SM production cross section and  $B(H^0 \rightarrow f\bar{f})=0$  for all fermions  $f$ .
- <sup>15</sup> For  $B(H^0 \rightarrow \gamma\gamma)=1, m_{H^0} > 113.1$  GeV is obtained.
- <sup>16</sup> HEISTER 02M search for  $e^+e^- \rightarrow H^0 Z$ , assuming that  $H^0$  decays to  $q\bar{q}, gg$ , or  $\tau^+\tau^-$  only. The limit assumes SM production cross section.
- <sup>17</sup> ABBIENDI 01E search for neutral Higgs bosons in general Type-II two-doublet models, at  $E_{\text{cm}} \leq 189$  GeV. In addition to usual final states, the decays  $H^0_1, A^0 \rightarrow q\bar{q}, gg$  are searched for. See their Figs. 15,16 for excluded regions.
- <sup>18</sup> ACCIARRI 00R search for  $e^+e^- \rightarrow H^0\gamma$  with  $H^0 \rightarrow b\bar{b}, Z\gamma$ , or  $\gamma\gamma$ . See their Fig. 3 for limits on  $\sigma\text{--}B$ . Explicit limits within an effective interaction framework are also given, for which the Standard Model Higgs search results are used in addition.
- <sup>19</sup> ACCIARRI 00R search for the two-photon type processes  $e^+e^- \rightarrow e^+e^- H^0$  with  $H^0 \rightarrow b\bar{b}$  or  $\gamma\gamma$ . See their Fig. 4 for limits on  $\Gamma(H^0 \rightarrow \gamma\gamma) \cdot B(H^0 \rightarrow \gamma\gamma \text{ or } b\bar{b})$  for  $m_{H^0} = 70\text{--}170$  GeV.
- <sup>20</sup> GONZALEZ-GARCIA 98B use  $D\bar{0}$  limit for  $\gamma\gamma$  events with missing  $E_T$  in  $p\bar{p}$  collisions (ABBOTT 98) to constrain possible  $ZH$  or  $WH$  production followed by unconventional  $H \rightarrow \gamma\gamma$  decay which is induced by higher-dimensional operators. See their Figs. 1 and 2 for limits on the anomalous couplings.
- <sup>21</sup> KRAWCZYK 97 analyse the muon anomalous magnetic moment in a two-doublet Higgs model (with type II Yukawa couplings) assuming no  $H^0_1 Z$  coupling and obtain  $m_{H^0_1} \gtrsim 5$  GeV or  $m_{A^0} \gtrsim 5$  GeV for  $\tan\beta > 50$ . Other Higgs bosons are assumed to be much heavier.
- <sup>22</sup> ALEXANDER 96H give  $B(Z \rightarrow H^0\gamma) \cdot B(H^0 \rightarrow q\bar{q}) < 1\text{--}4 \times 10^{-5}$  (95%CL) and  $B(Z \rightarrow H^0\gamma) \cdot B(H^0 \rightarrow b\bar{b}) < 0.7\text{--}2 \times 10^{-5}$  (95%CL) in the range  $20 < m_{H^0} < 80$  GeV.

### SEARCHES FOR A HIGGS BOSON WITH STANDARD MODEL COUPLINGS

These listings are based on experimental searches for a scalar boson whose couplings to  $W, Z$  and fermions are precisely those of the Higgs boson predicted by the three-generation Standard Model with the minimal Higgs sector.

For a review and a bibliography, see the review on "Status of Higgs Boson Physics."

### Direct Mass Limits for $H^0$

The mass limits shown below apply to a Higgs boson  $H^0$  with Standard Model couplings whose mass is a priori unknown. These mass limits are compatible with and independent of the observed signal at about 126 GeV. In particular, the symbol  $H^0$  employed below does not in general refer to the observed signal at about 126 GeV.

See key on page 547

Gauge & Higgs Boson Particle Listings  
Neutral Higgs Bosons, Searches for

The cross section times branching ratio limits quoted in the footnotes below are typically given relative to those of a Standard Model Higgs boson of the relevant mass. These limits can be reinterpreted in terms of more general models (e.g. extended Higgs sectors) in which the Higgs couplings to  $W$ ,  $Z$  and fermions are re-scaled from their Standard Model values.

All data that have been superseded by newer results are marked as "not used" or have been removed from this compilation, and are documented in previous editions of this Review of Particle Physics.

1 AALTONEN 13L combine all CDF searches with  $9.45\text{--}10.0\text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96\text{ TeV}$ . A limit on cross section times branching ratio which corresponds to  $(0.45\text{--}4.8)$  times the expected Standard Model cross section is given for  $m_{H^0} = 90\text{--}200\text{ GeV}$  at 95% CL. An excess of events over background is observed with a local significance of  $2.0\sigma$  at  $m_{H^0} = 125\text{ GeV}$ . In the Standard Model with an additional generation of heavy quarks and leptons which receive their masses via the Higgs mechanism,  $m_{H^0}$  values between 124 and 203 GeV are excluded at 95% CL.

2 AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations. A limit on cross section times branching ratio which corresponds to  $(0.37\text{--}3.1)$  times the expected Standard Model cross section is given for  $m_{H^0} = 90\text{--}200\text{ GeV}$  at 95% CL. An excess of events over background is observed with a local significance of  $3.0\sigma$  at  $m_{H^0} = 125\text{ GeV}$ . In the Standard Model with an additional generation of heavy quarks and leptons which receive their masses via the Higgs mechanism,  $m_{H^0}$  values between 121 and 225 GeV are excluded at 95% CL.

3 ABAZOV 13L combine all D0 results with up to  $9.7\text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96\text{ TeV}$ . A limit on cross section times branching ratio which corresponds to  $(0.66\text{--}3.1)$  times the expected Standard Model cross section is given in the range  $m_{H^0} = 90\text{--}200\text{ GeV}$  at 95% CL. An excess of events over background is observed with a local significance of  $1.7\sigma$  at  $m_{H^0} = 125\text{ GeV}$ . In the Standard Model with an additional generation of heavy quarks and leptons which receive their masses via the Higgs mechanism,  $m_{H^0}$  values between 125 and 218 GeV are excluded at 95% CL.

4 CHATRCHYAN 13Q search for  $H^0$  production in the decays  $H \rightarrow W^+W^- \rightarrow \ell\nu\ell\nu, \ell\nu q\bar{q}$  and  $H \rightarrow ZZ \rightarrow 4\ell, \ell\ell\tau\tau, \ell\nu\nu\nu, \ell\ell q\bar{q}$  in up to  $5.1\text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7\text{ TeV}$  and up to  $5.3\text{ fb}^{-1}$  at  $E_{\text{cm}} = 8\text{ TeV}$  in the range  $m_{H^0} = 145\text{--}1000\text{ GeV}$ .

5 AAD 12AI search for  $H^0$  production in  $pp$  collisions for the final states  $H^0 \rightarrow ZZ^{(*)}, \gamma\gamma, WW^{(*)}, b\bar{b}, \tau\tau$  with  $4.6\text{--}4.8\text{ fb}^{-1}$  at  $E_{\text{cm}} = 7\text{ TeV}$ , and  $H^0 \rightarrow ZZ^{(*)} \rightarrow 4\ell, \gamma\gamma, WW^{(*)} \rightarrow e\nu\mu\nu$  with  $5.8\text{--}5.9\text{ fb}^{-1}$  at  $E_{\text{cm}} = 8\text{ TeV}$ . The 99% CL excluded range is  $113\text{--}114, 117\text{--}121, \text{ and } 132\text{--}527\text{ GeV}$ . An excess of events over background with a local significance of  $5.9\sigma$  is observed at  $m_{H^0} = 126\text{ GeV}$ .

6 CHATRCHYAN 12N search for  $H^0$  production in the decays  $H \rightarrow \gamma\gamma, ZZ^* \rightarrow 4\ell, WW^* \rightarrow \ell\nu\ell\nu, \tau\tau$ , and  $b\bar{b}$  in  $4.9\text{--}5.1\text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7\text{ TeV}$  and  $5.1\text{--}5.3\text{ fb}^{-1}$  at  $E_{\text{cm}} = 8\text{ TeV}$ . The expected exclusion region for no signal is  $110\text{--}145\text{ GeV}$  at 99.9% CL. See also CHATRCHYAN 13Y.

7 Search for  $e^+e^- \rightarrow H^0 Z$  at  $E_{\text{cm}} \leq 209\text{ GeV}$  in the final states  $H^0 \rightarrow b\bar{b}$  with  $Z \rightarrow \ell\bar{\ell}, \nu\bar{\nu}, q\bar{q}, \tau^+\tau^-$  and  $H^0 \rightarrow \tau^+\tau^-$  with  $Z \rightarrow q\bar{q}$ .

8 Combination of the results of all LEP experiments.

9 A  $3\sigma$  excess of candidate events compatible with  $m_{H^0}$  near  $114\text{ GeV}$  is observed in the combined channels  $q\bar{q}q\bar{q}, q\bar{q}\ell\bar{\ell}, q\bar{q}\tau^+\tau^-$ .

## Neutral Higgs Bosons, Searches for

- 10 AALTONEN 13B search for associated  $H^0 Z$  production in the final state  $H^0 \rightarrow b\bar{b}$ ,  $Z \rightarrow \nu\bar{\nu}$ , and  $H^0 W$  production in  $H^0 \rightarrow b\bar{b}$ ,  $W \rightarrow \ell\nu$  ( $\ell$  not identified) with an improved  $b$  identification algorithm in 9.45 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. A limit on cross section times branching ratio which corresponds to (0.72–11.8) times the expected Standard Model cross section is given for  $m_{H^0} = 90$ –150 GeV at 95% CL. The limit for  $m_{H^0} = 125$  GeV is 3.06, where 3.33 is expected for no signal.
- 11 AALTONEN 13C search for associated  $H^0 W$  and  $H^0 Z$  as well as vector-boson fusion  $H^0 q\bar{q}'$  production in the final state  $H^0 \rightarrow b\bar{b}$ ,  $W/Z \rightarrow q\bar{q}'$  with 9.45 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. A limit on cross section times branching ratio which is (7.0–64.6) times larger than the expected Standard Model cross section is given in the range  $m_{H^0} = 100$ –150 GeV at 95% CL. The limit for  $m_{H^0} = 125$  GeV is 9.0, where 11.0 is expected for no signal.
- 12 AALTONEN 13K search for  $H^0$  production (with a possible additional  $W$  or  $Z$ ) in the final state  $H^0 \rightarrow WW^{(*)} \rightarrow \ell\nu\ell\nu$  in 9.7 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. A limit on cross section times branching ratio which corresponds to (0.49–14.1) times the expected Standard Model cross section is given in the range  $m_{H^0} = 110$ –200 GeV at 95% CL. The limit at  $m_{H^0} = 125$  GeV is 3.26, where 3.25 is expected for no signal. In the Standard Model with an additional generation of heavy quarks and leptons which receive their masses via the Higgs mechanism,  $m_{H^0}$  values between 124 and 200 GeV are excluded at 95% CL.
- 13 ABAZOV 13E search for  $H^0$  production in four-lepton final states from  $H^0 \rightarrow ZZ^{(*)}$  and  $H^0 Z$  in 9.6–9.8 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. A limit on cross section times branching ratio which corresponds to (8.6–78.9) times the expected Standard Model cross section is given in the range  $m_{H^0} = 115$ –200 GeV at 95% CL. The limit for  $m_{H^0} = 125$  GeV is 42.3, where 42.8 is expected for no signal.
- 14 ABAZOV 13F search for  $H^0$  production in final states  $e\tau jj$  and  $\mu\tau jj$  in 9.7 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. The search is sensitive to  $H \rightarrow \tau\tau$  and  $H \rightarrow WW^{(*)}$ . A limit on cross section times branching ratio which corresponds to (9.4–17.9) times the expected Standard Model cross section is given in the range  $m_{H^0} = 105$ –150 GeV at 95% CL. The limit for  $m_{H^0} = 125$  GeV is 11.3, where 9.0 is expected for no signal.
- 15 ABAZOV 13G search for  $H^0$  production in final states  $H^0 \rightarrow WW^{(*)} \rightarrow \ell^+\nu\ell^-\nu$  in 9.7 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV and give a limit on cross section times branching ratio for  $m_{H^0} = 100$ –150 GeV at 95% CL. The limit for  $m_{H^0} = 125$  GeV is 4.1, where 3.4 is expected for no signal. In the Standard Model with an additional generation of heavy quarks and leptons which receive their masses via the Higgs mechanism,  $m_{H^0}$  values between 125 and 218 GeV are excluded at 95% CL.
- 16 ABAZOV 13H search for  $H^0$  production with the decay  $H^0 \rightarrow \gamma\gamma$  in 9.6 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. A limit on cross section times branching ratio which corresponds to (8.3–25.4) times the expected Standard Model cross section is given in the range  $m_{H^0} = 100$ –150 GeV at 95% CL. The limit for  $m_{H^0} = 125$  GeV is 12.8, where 8.7 is expected for no signal.
- 17 ABAZOV 13I search for  $H^0$  production in the final state with one lepton and two or more jets plus missing  $E_T$  with  $b$  identification in 9.7 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. The search is mainly sensitive to  $H^0 W \rightarrow b\bar{b}\ell\nu$ ,  $H^0 \rightarrow WW^{(*)} \rightarrow \ell\nu q\bar{q}$ , and  $H^0 V \rightarrow VWW^{(*)} \rightarrow \ell\nu q\bar{q}$  ( $V = W, Z$ ). A limit on cross section times branching ratio which corresponds to (1.3–11.4) times the expected Standard Model cross section is given in the range  $m_{H^0} = 90$ –200 GeV at 95% CL. The limit for  $m_{H^0} = 125$  GeV is 5.8, where 4.7 is expected for no signal. In the Standard Model with an additional generation of heavy quarks and leptons which receive their masses via the Higgs mechanism,  $m_{H^0}$  values between 150 and 188 GeV are excluded at 95% CL.
- 18 ABAZOV 13J search for  $H^0$  production in the final states  $e e\mu$ ,  $e\mu\mu$ ,  $\mu\tau\tau$ , and  $e^{\pm}\mu^{\pm}$  in 8.6–9.7 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. The search is sensitive to  $WH^0$ ,  $ZH^0$  and gluon fusion production with  $H^0 \rightarrow WW^{(*)}$ ,  $ZZ^{(*)}$ , decaying to leptonic final states, and to  $WH^0$ ,  $ZH^0$  production with  $H^0 \rightarrow \tau^+\tau^-$ . A limit on cross section times branching ratio which corresponds to (4.4–12.7) times the expected Standard Model cross section is given in the range  $m_{H^0} = 100$ –200 GeV at 95% CL. The limit for  $m_{H^0} = 125$  GeV is 8.4, where 6.3 is expected for no signal.
- 19 ABAZOV 13K search for associated  $H^0 Z$  production in the final states  $\ell\ell b\bar{b}$  with  $b$  identification in 9.7 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. A limit on cross section times branching ratio which corresponds to (1.8–5.3) times the expected Standard Model cross section is given for  $m_{H^0} = 90$ –150 GeV at 95% CL. The limit for  $m_{H^0} = 125$  GeV is 7.1, where 5.1 is expected for no signal.
- 20 CHATRCHYAN 13AL search for  $H^0 \rightarrow \tau^+\tau^-$ ,  $WW^{(*)}$ , and  $ZZ^{(*)}$  in 5.1 fb $^{-1}$  and 5.3 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7$  and 8 TeV. In the Standard Model with an additional generation of heavy quarks and leptons which receive their masses via the Higgs mechanism,  $m_{H^0}$  values between 110 and 600 GeV are excluded at 99% CL.
- 21 CHATRCHYAN 13BK search for  $H^0 \rightarrow Z\gamma \rightarrow \ell\ell\gamma$  in 5.0 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7$  TeV and 19.6 fb $^{-1}$  at  $E_{\text{cm}} = 8$  TeV. A limit on cross section times branching ratio which corresponds to (4–25) times the expected Standard Model cross section is given in the range  $m_{H^0} = 120$ –160 GeV at 95% CL. The limit for  $m_{H^0} = 125$  GeV is 9.5, where 10 is expected for no signal.
- 22 CHATRCHYAN 13X search for  $H^0 t\bar{t}$  production followed by  $H^0 \rightarrow b\bar{b}$ , one top decaying to  $\ell\nu$  and the other to either  $\ell\nu$  or  $q\bar{q}$  in 5.0 fb $^{-1}$  and 5.1 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7$  and 8 TeV. A limit on cross section times branching ratio which corresponds to (4.0–8.6) times the expected Standard Model cross section is given for  $m_{H^0} = 110$ –140 GeV at 95% CL. The limit for  $m_{H^0} = 125$  GeV is 5.8, where 5.2 is expected for no signal.
- 23 CHATRCHYAN 13Y search for  $H^0$  production in the decay  $H \rightarrow \gamma\gamma$  in 5.1 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7$  TeV and 5.3 fb $^{-1}$  at  $E_{\text{cm}} = 8$  TeV. The expected exclusion region for no signal is 110–144 GeV at 95% CL.
- 24 CHATRCHYAN 13Z search for  $H^0$  production in the decay  $H \rightarrow ZZ^* \rightarrow 4\ell$  in 5.0 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7$  TeV and 5.3 fb $^{-1}$  at  $E_{\text{cm}} = 8$  TeV. The expected exclusion region for no signal is 120–180 GeV at 95% CL.
- 25 CHATRCHYAN 13Y search for  $H^0$  production in the decay  $H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$  in 4.9 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7$  TeV and 5.3 fb $^{-1}$  at  $E_{\text{cm}} = 8$  TeV. The expected exclusion region for no signal is 122–160 GeV at 95% CL.
- 26 AAD 12 search for  $H^0$  production with  $H \rightarrow ZZ \rightarrow \ell^+\ell^-q\bar{q}$  in 1.04 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7$  TeV. A limit on cross section times branching ratio which is (1.7–13) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 200$ –600 GeV at 95% CL. The best limit is at  $m_{H^0} = 360$  GeV. Superseded by AAD 12CA.
- 27 AAD 12AJ search for  $H^0$  production in the decay  $H^0 \rightarrow WW^{(*)} \rightarrow \ell\nu\ell\nu$  with 4.7 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7$  TeV. A limit on cross section times branching ratio which corresponds to (0.2–10) times the expected Standard Model cross section is given for  $m_{H^0} = 110$ –600 GeV at 95% CL.
- 28 AAD 12BD search for  $H^0$  production in the decay modes  $H^0 \rightarrow \gamma\gamma$ ,  $WW^{(*)}$ ,  $ZZ^{(*)}$ ,  $\tau^+\tau^-$ , and  $b\bar{b}$  with 4.6 to 4.9 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7$  TeV. The 99% CL excluded range is 130.7–506 GeV. A limit on cross section times branching ratio which corresponds to (0.2–2) times the expected Standard Model cross section is given for  $m_{H^0} = 110$ –600 GeV at 95% CL. An excess of events over background with a local significance of 2.9  $\sigma$  is observed at about  $m_{H^0} = 126$  GeV. Superseded by AAD 12AI.
- 29 AAD 12BU search for  $H^0$  production in the decay  $H \rightarrow \tau^+\tau^-$  with 4.7 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7$  TeV. A limit on cross section times branching ratio which is (2.9–11.7) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 100$ –150 GeV at 95% CL.
- 30 AAD 12BZ search for  $H^0$  production in the decay  $H \rightarrow ZZ \rightarrow \ell^+\ell^-\nu\bar{\nu}$  with 4.7 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7$  TeV. A limit on cross section times branching ratio which corresponds to (0.2–4) times the expected Standard Model cross section is given for  $m_{H^0} = 200$ –600 GeV at 95% CL.
- 31 AAD 12CA search for  $H^0$  production in the decay  $H \rightarrow ZZ \rightarrow \ell^+\ell^-q\bar{q}$  with 4.7 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7$  TeV. A limit on cross section times branching ratio which corresponds to (0.7–9) times the expected Standard Model cross section is given for  $m_{H^0} = 200$ –600 GeV at 95% CL.
- 32 AAD 12CN search for associated  $H^0 W$  and  $H^0 Z$  production in the channels  $W \rightarrow \ell\nu$ ,  $Z \rightarrow \ell^+\ell^-$ ,  $\nu\bar{\nu}$ , and  $H^0 \rightarrow b\bar{b}$ , with 4.7 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7$  TeV. A limit on cross section times branching ratio which is (2.5–5.5) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 110$ –130 GeV at 95% CL.
- 33 AAD 12CO search for  $H^0$  production in the decay  $H \rightarrow WW \rightarrow \ell\nu q\bar{q}$  with 4.7 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7$  TeV. A limit on cross section times branching ratio which is (1.9–10) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 300$ –600 GeV at 95% CL.
- 34 AAD 12D search for  $H^0$  production with  $H \rightarrow ZZ^{(*)} \rightarrow 4\ell$  in 4.8 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7$  TeV in the mass range  $m_{H^0} = 110$ –600 GeV. An excess of events over background with a local significance of 2.1  $\sigma$  is observed at 125 GeV.
- 35 AAD 12E combine data from AAD 11V, AAD 11AB, AAD 12, AAD 12D, AAD 12F, AAD 12G. The 99% CL exclusion range is 133–230 and 260–437 GeV. An excess of events over background with a local significance of 3.5  $\sigma$  is observed at about  $m_{H^0} = 126$  GeV. Superseded by AAD 12AI.
- 36 AAD 12F search for  $H^0$  production with  $H \rightarrow WW^{(*)} \rightarrow \ell^+\nu\ell^-\bar{\nu}$  in 2.05 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7$  TeV in the mass range  $m_{H^0} = 110$ –300 GeV. Superseded by AAD 12AJ.
- 37 AAD 12G search for  $H^0$  production with  $H \rightarrow \gamma\gamma$  in 4.9 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7$  TeV in the mass range  $m_{H^0} = 110$ –150 GeV. An excess of events over background with a local significance of 2.8  $\sigma$  is observed at 126.5 GeV.
- 38 AALTONEN 12 search for  $H^0 \rightarrow \gamma\gamma$  in 7.0 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. A limit on cross section times branching ratio which is (8.5–29) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 100$ –150 GeV at 95% CL. Superseded by AALTONEN 12AA.
- 39 AALTONEN 12AA search for associated  $H^0 W$  production in the final state  $H^0 \rightarrow b\bar{b}$ ,  $W \rightarrow \ell\nu$  with 5.6 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. A limit on cross section times branching ratio which is (2.1–35.3) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 100$ –150 GeV at 95% CL. Superseded by AALTONEN 12AE.
- 40 AALTONEN 12AE search for associated  $H^0 W$  production in the final state  $H^0 \rightarrow b\bar{b}$ ,  $W \rightarrow \ell\nu$  with 7.5 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. A limit on cross section times branching ratio which is (1.1–34.4) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 100$ –150 GeV at 95% CL. The limit for  $m_{H^0} = 125$  GeV is 4.4, where 3.7 is expected. Superseded by AALTONEN 12R.
- 41 AALTONEN 12AK search for associated  $H^0 t\bar{t}$  production in the decay chain  $t\bar{t} \rightarrow WWbb \rightarrow \ell\nu q\bar{q}b\bar{b}$  with 9.45 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. A limit on cross section times branching ratio which is (10–40) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 100$ –150 GeV at 95% CL. The limit for  $m_{H^0} = 125$  GeV is 20.5, where 12.6 is expected.
- 42 AALTONEN 12AM search for  $H^0$  production in inclusive four-lepton final states coming from  $H^0 \rightarrow ZZ$ ,  $H^0 Z \rightarrow WW^{(*)}\ell\ell$ , or  $H^0 Z \rightarrow \tau\tau\ell\ell$ , with 9.7 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. A limit on cross section times branching ratio which is (7.2–42.4) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 120$ –300 GeV at 95% CL. The best limit is for  $m_{H^0} = 200$  GeV.
- 43 AALTONEN 12AN search for  $H^0$  production in the decay  $H^0 \rightarrow \gamma\gamma$  with 10 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. A limit on cross section times branching ratio which is (7.7–21.3) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 100$ –150 GeV at 95% CL. The limit for  $m_{H^0} = 125$  GeV is 17.0, where 9.9 is expected.
- 44 AALTONEN 12H search for associated  $H^0 Z$  production in the final state  $Z \rightarrow \ell^+\ell^-$ ,  $H^0 \rightarrow b\bar{b}$  with 7.9 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. A limit on cross section times branching ratio which is (2.8–22) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 100$ –150 GeV at 95% CL. The best limit is for  $m_{H^0} = 100$  GeV. Superseded by AALTONEN 12Q.
- 45 AALTONEN 12S search for  $H^0$  production in the decay  $H^0 \rightarrow \tau^+\tau^-$  (one leptonic, the other hadronic) with 6.0 fb $^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96$  TeV. A limit on cross section times branching ratio which is (14.6–70.2) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 100$ –150 GeV at 95% CL. The best limit is for  $m_{H^0} = 120$  GeV.
- 46 AALTONEN 12P combine AALTONEN 12Q, AALTONEN 12R, and AALTONEN 12S. An excess of events over background is observed in the region  $m_{H^0} = 100$ –150 GeV, with a local significance of 2.7  $\sigma$  for  $m_{H^0} = 125$  GeV. This corresponds to  $(\sigma(H^0 W) + \sigma(H^0 Z))B(H^0 \rightarrow b\bar{b}) = (291^{+118}_{-113})$  fb. Superseded by AALTONEN 13L.

## Neutral Higgs Bosons, Searches for

- 47 AALTONEN 12Q search for associated  $H^0 Z$  production in the final state  $H^0 \rightarrow b\bar{b}$ ,  $Z \rightarrow \ell^+ \ell^-$  with  $9.45 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . A limit on cross section times branching ratio which corresponds to (1.0–3.75) times the expected Standard Model cross section is given for  $m_{H^0} = 90\text{--}150 \text{ GeV}$  at 95% CL. The limit for  $m_{H^0} = 125 \text{ GeV}$  is 7.1, where 3.9 is expected. A broad excess of events for  $m_{H^0} > 110 \text{ GeV}$  is observed, with a local significance of  $2.4 \sigma$  at  $m_{H^0} = 135 \text{ GeV}$ .
- 48 AALTONEN 12R search for associated  $H^0 W$  production in the final state  $H^0 \rightarrow b\bar{b}$ ,  $W \rightarrow \ell\nu$  with  $9.45 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . A limit on cross section times branching ratio which is (1.4–21.7) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 90\text{--}150 \text{ GeV}$  at 95% CL. The limit for  $m_{H^0} = 125 \text{ GeV}$  is 4.9, where 2.8 is expected. Superseded by AALTONEN 13B.
- 49 AALTONEN 12S search for associated  $H^0 Z$  production in the final state  $H^0 \rightarrow b\bar{b}$ ,  $Z \rightarrow \nu\bar{\nu}$ , and  $H^0 W$  production in  $H^0 \rightarrow b\bar{b}$ ,  $W \rightarrow \ell\nu$  ( $\ell$  not identified) with  $9.45 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . A limit on cross section times branching ratio which is (1.7–27.2) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 90\text{--}150 \text{ GeV}$  at 95% CL. The limit for  $m_{H^0} = 125 \text{ GeV}$  is 6.7, where 3.6 is expected. Superseded by AALTONEN 13B.
- 50 AALTONEN 12T combine AALTONEN 12Q, AALTONEN 12R, AALTONEN 12S, ABZOV 12O, ABZOV 12P, and ABZOV 12K. An excess of events over background is observed which is most significant in the region  $m_{H^0} = 120\text{--}135 \text{ GeV}$ , with a local significance of up to  $3.3 \sigma$ . The local significance at  $m_{H^0} = 125 \text{ GeV}$  is  $2.8 \sigma$ , which corresponds to  $(\sigma(H^0 W) + \sigma(H^0 Z)) \text{ B}(H^0 \rightarrow b\bar{b}) = (0.23^{+0.09}_{-0.08}) \text{ pb}$ , compared to the Standard Model expectation at  $m_{H^0} = 125 \text{ GeV}$  of  $0.12 \pm 0.01 \text{ pb}$ .
- 51 AALTONEN 12Y search for associated  $H^0 W$  production in the final state  $H^0 \rightarrow b\bar{b}$ ,  $W \rightarrow \ell\nu$  with  $2.7 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . A limit on cross section times branching ratio which is (3.6–61.1) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 100\text{--}150 \text{ GeV}$  at 95% CL. Superseded by AALTONEN 12AA.
- 52 ABZOV 12J search for  $H^0$  and associated  $H^0 W$ ,  $H^0 Z$  production, in the final state including a  $\tau$  and  $e/\mu$  with  $7.3 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . A limit on cross section times branching ratio which is (6.8–29.9) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 105\text{--}200 \text{ GeV}$  at 95% CL. The limit for  $m_{H^0} = 125 \text{ GeV}$  is 15.7, where 12.8 is expected. Superseded by ABZOV 13F.
- 53 ABZOV 12K search for associated  $H^0 Z$  production in the final state  $H^0 \rightarrow b\bar{b}$ ,  $Z \rightarrow \nu\bar{\nu}$ , and  $H^0 W$  production with  $W \rightarrow \ell\nu$  ( $\ell$  not identified) with  $9.5 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . A limit on cross section times branching ratio which is (1.9–16.8) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 100\text{--}150 \text{ GeV}$  at 95% CL. The limit for  $m_{H^0} = 125 \text{ GeV}$  is 4.3, where 3.9 is expected.
- 54 ABZOV 12N combine ABZOV 12O, ABZOV 12P, and ABZOV 12K. A limit on cross section times branching ratio which corresponds to (0.94–14) times the expected Standard Model cross section is given for  $m_{H^0} = 100\text{--}150 \text{ GeV}$  at 95% CL. An excess of events over background is observed in the region  $m_{H^0} = 120\text{--}145 \text{ GeV}$  with a local significance of  $1.0\text{--}1.7 \sigma$ . Superseded by ABZOV 13L.
- 55 ABZOV 12O search for associated  $H^0 Z$  production in the final state  $H^0 \rightarrow b\bar{b}$ ,  $Z \rightarrow \ell^+ \ell^-$  with  $9.7 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . A limit on cross section times branching ratio which is (1.8–5.3) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 90\text{--}150 \text{ GeV}$  at 95% CL. The limit for  $m_{H^0} = 125 \text{ GeV}$  is 7.1, where 5.1 is expected. Superseded by ABZOV 13K.
- 56 ABZOV 12P search for associated  $H^0 W$  production in the final state  $H^0 \rightarrow b\bar{b}$ ,  $W \rightarrow \ell\nu$  with  $9.7 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . A limit on cross section times branching ratio which is (2.6–21.8) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 100\text{--}150 \text{ GeV}$  at 95% CL. The limit for  $m_{H^0} = 125 \text{ GeV}$  is 5.2, where 4.7 is expected. Superseded by ABZOV 13I.
- 57 ABZOV 12V search for associated  $H^0 W$  production in the final state  $H^0 \rightarrow b\bar{b}$ ,  $W \rightarrow \ell\nu$  with  $5.3 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . A limit on cross section times branching ratio which is (2.7–30.4) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 100\text{--}150 \text{ GeV}$  at 95% CL. The limit for  $m_{H^0} = 125 \text{ GeV}$  is 6.6, where 6.8 is expected. Superseded by ABZOV 12P.
- 58 ABZOV 12W search for  $H^0$  production in the decay  $H^0 \rightarrow WW^* \rightarrow \ell\nu\ell\nu$  with  $8.6 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . A limit on cross section times branching ratio which is (1.1–13.3) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 115\text{--}200 \text{ GeV}$  at 95% CL. The best limit is at  $m_{H^0} = 160 \text{ GeV}$ . The limit for  $m_{H^0} = 125 \text{ GeV}$  is 5.0, where 3.8 is expected. Superseded by ABZOV 13G.
- 59 CHATRCHYAN 12AY search for associated  $H^0 W$  and  $H^0 Z$  production in the channels  $W \rightarrow \ell\nu$ ,  $Z \rightarrow \ell^+ \ell^-$ , and  $H^0 \rightarrow \tau\tau$ ,  $WW^*$ , with  $5 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . A limit on cross section times branching ratio which is (3.1–9.1) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 110\text{--}200 \text{ GeV}$  at 95% CL.
- 60 CHATRCHYAN 12AY combine CHATRCHYAN 12F and CHATRCHYAN 12AO in addition and give a limit on cross section times branching ratio which is (2.1–3.7) times larger than the expected Standard Model cross section for  $m_{H^0} = 110\text{--}170 \text{ GeV}$  at 95% CL. The limit for  $m_{H^0} = 125 \text{ GeV}$  is 3.3.
- 61 CHATRCHYAN 12B combine CHATRCHYAN 12E, CHATRCHYAN 12F, CHATRCHYAN 12G, CHATRCHYAN 12H, CHATRCHYAN 12I, CHATRCHYAN 12C, CHATRCHYAN 12D, as well as a search in the decay mode  $H^0 \rightarrow \tau\tau$ . The 99% CL exclusion range is 129–525 GeV. An excess of events over background with a local significance of  $3.1 \sigma$  is observed at about  $m_{H^0} = 124 \text{ GeV}$ . Superseded by CHATRCHYAN 12N and CHATRCHYAN 13Q.
- 62 CHATRCHYAN 12C search for  $H^0$  production with  $H \rightarrow ZZ \rightarrow \ell^+ \ell^- \tau^+ \tau^-$  in  $4.7 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . A limit on cross section times branching ratio which is (4–12) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 190\text{--}600 \text{ GeV}$  at 95% CL. The best limit is at  $m_{H^0} = 200 \text{ GeV}$ .
- 63 CHATRCHYAN 12D search for  $H^0$  production with  $H \rightarrow ZZ^* \rightarrow \ell^+ \ell^- q\bar{q}$  in  $4.6 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . A limit on cross section times branching ratio which corresponds to (1–22) times the expected Standard Model cross section is given for  $m_{H^0} = 130\text{--}164 \text{ GeV}$ ,  $200\text{--}600 \text{ GeV}$  at 95% CL. The best limit is at  $m_{H^0} = 230 \text{ GeV}$ . In the Standard Model with an additional generation of heavy quarks and leptons which receive their masses via the Higgs mechanism,  $m_{H^0}$  values in the ranges  $m_{H^0} = 154\text{--}161 \text{ GeV}$  and  $200\text{--}470 \text{ GeV}$  are excluded at 95% CL.
- 64 CHATRCHYAN 12E search for  $H^0$  production with  $H \rightarrow WW^* \rightarrow \ell^+ \nu \ell^- \bar{\nu}$  in  $4.6 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  in the mass range  $m_{H^0} = 110\text{--}600 \text{ GeV}$ .
- 65 CHATRCHYAN 12F search for associated  $H^0 W$  and  $H^0 Z$  production followed by  $W \rightarrow \ell\nu$ ,  $Z \rightarrow \ell^+ \ell^-$ ,  $\nu\bar{\nu}$ , and  $H^0 \rightarrow b\bar{b}$ , in  $4.7 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . A limit on cross section times branching ratio which is (3.1–9.0) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 110\text{--}135 \text{ GeV}$  at 95% CL. The best limit is at  $m_{H^0} = 110 \text{ GeV}$ .
- 66 CHATRCHYAN 12G search for  $H^0$  production with  $H \rightarrow \gamma\gamma$  in  $4.8 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  in the mass range  $m_{H^0} = 110\text{--}150 \text{ GeV}$ . An excess of events over background with a local significance of  $3.1 \sigma$  is observed at  $124 \text{ GeV}$ .
- 67 CHATRCHYAN 12H search for  $H^0$  production with  $H \rightarrow ZZ^* \rightarrow 4\ell$  in  $4.7 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  in the mass range  $m_{H^0} = 110\text{--}600 \text{ GeV}$ . Excesses of events over background are observed around 119, 126 and 320 GeV. The region  $m_{H^0} = 114.4\text{--}134 \text{ GeV}$  remains consistent with the expectation for the production of a SM-like Higgs boson.
- 68 CHATRCHYAN 12I search for  $H^0$  production with  $H \rightarrow ZZ \rightarrow \ell^+ \ell^- \nu\bar{\nu}$  in  $4.6 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$  in the mass range  $m_{H^0} = 250\text{--}600 \text{ GeV}$ .
- 69 CHATRCHYAN 12K search for  $H^0$  production in the decay  $H \rightarrow \tau^+ \tau^-$  with  $4.6 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . A limit on cross section times branching ratio which is (3.2–7.0) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 110\text{--}145 \text{ GeV}$  at 95% CL.
- 70 AAD 11AB search for  $H^0$  production with  $H \rightarrow W^+ W^- \rightarrow \ell\nu q\bar{q}$  in  $1.04 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . A limit on cross section times branching ratio which is (2.7–20) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 240\text{--}600 \text{ GeV}$  at 95% CL. The best limit is at  $m_{H^0} = 400 \text{ GeV}$ . Superseded by AAD 12C.
- 71 AAD 11V search for  $H^0$  production with  $H \rightarrow ZZ \rightarrow \ell^+ \ell^- \nu\bar{\nu}$  in  $1.04 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . A limit on cross section times branching ratio which corresponds to (0.6–6) times the expected Standard Model cross section is given for  $m_{H^0} = 200\text{--}600 \text{ GeV}$  at 95% CL. Superseded by AAD 12Bz.
- 72 AAD 11W search for Higgs boson production in the decay channels  $\gamma\gamma$ ,  $ZZ^* \rightarrow 4\ell$ ,  $ZZ \rightarrow \ell\nu\nu$ ,  $ZZ \rightarrow \ell\ell q\bar{q}$ ,  $WW^* \rightarrow \ell\nu\nu$ ,  $WW^* \rightarrow \ell\nu q\bar{q}$  in  $35\text{--}40 \text{ pb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . A limit on cross section times branching ratio which is (2–40) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 110\text{--}600 \text{ GeV}$  at 95% CL. In the Standard Model with an additional generation of heavy quarks and leptons which receive their masses via the Higgs mechanism,  $m_{H^0}$  values between 140 and 185 GeV are excluded at 95% CL. The results for the Standard Model Higgs are superseded by AAD 12E.
- 73 AALTONEN 11AA search in  $4.0 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$  for associated  $H^0 W$  and  $H^0 Z$  production followed by  $W/Z \rightarrow q\bar{q}$ , and for  $p\bar{p} \rightarrow H^0 q\bar{q}X$  (vector boson fusion), both with  $H^0 \rightarrow b\bar{b}$ . A limit on cross section times branching ratio which is (9–100) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 100\text{--}150 \text{ GeV}$  at 95% CL. The best limit is at  $m_{H^0} = 115 \text{ GeV}$ . Superseded by AALTONEN 13C.
- 74 ABZOV 11AB search for associated  $H^0 W$  and  $H^0 Z$  production followed by  $H^0 \rightarrow WW^*$  in like-sign dilepton final states using  $5.3 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . A limit on cross section times branching ratio which is (6.4–18) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 115\text{--}200 \text{ GeV}$  at 95% CL. The best limit is for  $m_{H^0} = 135$  and  $165 \text{ GeV}$ . Superseded by ABZOV 13J.
- 75 ABZOV 11G search for  $H^0$  production in  $5.4 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$  in the decay mode  $H^0 \rightarrow WW^* \rightarrow \ell\nu q\bar{q}$  (and processes with similar final states). A limit on cross section times branching ratio which is (3.9–37) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 115\text{--}200 \text{ GeV}$  at 95% CL. The best limit is at  $m_{H^0} = 160 \text{ GeV}$ .
- 76 ABZOV 11J search for associated  $H^0 W$  production in  $5.3 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$  in the final state  $H^0 \rightarrow b\bar{b}$ ,  $W \rightarrow \ell\nu$ . A limit on cross section times branching ratio which is (2.7–30) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 100\text{--}150 \text{ GeV}$  at 95% CL. The limit at  $m_{H^0} = 115 \text{ GeV}$  is 4.5 times larger than the expected Standard Model cross section. Superseded by ABZOV 12P.
- 77 ABZOV 11V search for  $H^0 \rightarrow \gamma\gamma$  in  $8.2 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . A limit on cross section times branching ratio which is (10–25) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 100\text{--}150 \text{ GeV}$  at 95% CL. Superseded by ABZOV 13H.
- 78 CHATRCHYAN 11J search for  $H^0$  production with  $H \rightarrow W^+ W^- \rightarrow \ell\nu\nu$  in  $36 \text{ pb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . See their Fig. 6 for a limit on cross section times branching ratio for  $m_{H^0} = 120\text{--}600 \text{ GeV}$  at 95% CL. In the Standard Model with an additional generation of heavy quarks and leptons which receive their masses via the Higgs mechanism,  $m_{H^0}$  values between 144 and 207 GeV are excluded at 95% CL.
- 79 AALTONEN 10AD search for associated  $H^0 Z$  production in  $4.1 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$  in the decay mode  $H^0 \rightarrow b\bar{b}$ ,  $Z \rightarrow \ell^+ \ell^-$ . A limit  $\sigma \cdot \text{B}(H^0 \rightarrow b\bar{b}) < (4.5\text{--}43) \sigma \cdot \text{B}(\text{SM})$  (95% CL) is given for  $m_{H^0} = 100\text{--}150 \text{ GeV}$ . The limit for  $m_{H^0} = 115 \text{ GeV}$  is 5.9 times larger than the expected Standard Model cross section. Superseded by AALTONEN 12H.
- 80 AALTONEN 10F combine searches for  $H^0$  decaying to  $W^+ W^-$  in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$  with  $4.8 \text{ fb}^{-1}$  (CDF) and  $5.4 \text{ fb}^{-1}$  (DØ).
- 81 AALTONEN 10G search for  $H^0$  production in  $4.8 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$  in the decay mode  $H^0 \rightarrow WW^*$ . A limit on  $\sigma(H^0)$  which is (1.3–39) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 110\text{--}200 \text{ GeV}$  at 95% CL. The best limit is obtained for  $m_{H^0} = 165 \text{ GeV}$ . Superseded by AALTONEN 13K.
- 82 AALTONEN 10J search for associated  $H^0 W$  and  $H^0 Z$  production in  $2.1 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$  in the final state with (b) jets and missing  $p_T$ . A limit  $\sigma < (5.8\text{--}50) \sigma_{\text{SM}}$  (95% CL) is given for  $m_{H^0} = 110\text{--}150 \text{ GeV}$ . The limit for  $m_{H^0} = 115 \text{ GeV}$  is 6.9 times larger than the expected Standard Model cross section. Superseded by AALTONEN 12S.
- 83 AALTONEN 10M combine searches for  $H^0$  decaying to  $W^+ W^-$  in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$  with  $4.8 \text{ fb}^{-1}$  (CDF) and  $5.4 \text{ fb}^{-1}$  (DØ) and derive limits  $\sigma(p\bar{p} \rightarrow H^0) \cdot \text{B}(H^0 \rightarrow W^+ W^-) < (1.75\text{--}0.38) \text{ pb}$  for  $m_H = 120\text{--}165 \text{ GeV}$ , where  $H^0$  is produced

- in  $gg$  fusion. In the Standard Model with an additional generation of heavy quarks,  $m_{H^0}$  between 131 and 204 GeV is excluded at 95% CL.
- 84 ABAZOV 10b search for  $H^0$  production in 5.4 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV in the decay mode  $H^0 \rightarrow WW^{(*)}$ . A limit on  $\sigma(H^0)$  which is (1.6–21) times larger than the expected Standard Model cross section is given for  $m_{H^0} = 115$ –200 GeV at 95% CL. The best limit is obtained for  $m_{H^0} = 165$  GeV. Superseded by ABAZOV 12w.
- 85 ABAZOV 10c search for associated  $H^0 Z$  and  $H^0 W$  production in 5.2 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV in the final states  $H^0 \rightarrow b\bar{b}$ ,  $Z \rightarrow \nu\bar{\nu}$ , and  $W \rightarrow (\ell)\nu$ , where  $\ell$  is not identified. A limit  $\sigma \cdot B(H^0 \rightarrow b\bar{b}) < (3.4\text{--}38) \sigma \cdot B_{SM}$  (95% CL) is given for  $m_{H^0} = 100$ –150 GeV. The limit for  $m_{H^0} = 115$  GeV is 3.7 times larger than the expected Standard Model cross section. Superseded by ABAZOV 12k.
- 86 ABAZOV 10t search for associated  $H^0 Z$  production in 4.2 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV in the decay mode  $H^0 \rightarrow b\bar{b}$ ,  $Z \rightarrow \ell^+ \ell^-$ . A limit  $\sigma \cdot B(H^0 \rightarrow b\bar{b}) < (3.0\text{--}49) \sigma \cdot B_{SM}$  (95% CL) is given for  $m_{H^0} = 100$ –150 GeV. The limit for  $m_{H^0} = 115$  GeV is 5.9 times larger than the expected Standard Model cross section. Superseded by ABAZOV 12o.
- 87 AALTONEN 09a search for  $H^0$  production in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV in the decay mode  $H^0 \rightarrow WW^{(*)} \rightarrow \ell^+ \ell^- \nu\bar{\nu}$ . A limit on  $\sigma(H^0) \cdot B(H^0 \rightarrow WW^{(*)})$  between 0.7 and 2.5 pb (95% CL) is given for  $m_{H^0} = 110$ –200 GeV, which is 1.7–4.5 times larger than the expected Standard Model cross section. The best limit is obtained for  $m_{H^0} = 160$  GeV.
- 88 AALTONEN 09a1 search for associated  $H^0 W$  production in 2.7 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV in the decay mode  $H^0 \rightarrow b\bar{b}$ ,  $W \rightarrow \ell\nu$ . A limit on  $\sigma(H^0 W) \cdot B(H^0 \rightarrow b\bar{b})$  (95% CL) is given for  $m_{H^0} = 100$ –150 GeV, which is 3.3–75.5 times larger than the expected Standard Model cross section. The limit for  $m_{H^0} = 115$  GeV is 5.6 times larger than the expected Standard Model cross section. Superseded by AALTONEN 12AA.
- 89 ABAZOV 09u search for  $H^0 \rightarrow \tau^+ \tau^-$  with  $\tau \rightarrow$  hadrons in 1 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The production mechanisms include associated  $W/Z + H^0$  production, weak boson fusion, and gluon fusion. A limit (95% CL) is given for  $m_{H^0} = 105$ –145 GeV, which is 20–82 times larger than the expected Standard Model cross section. The limit for  $m_{H^0} = 115$  GeV is 29 times larger than the expected Standard Model cross section.
- 90 ABAZOV 08v search for associated  $H^0 W$  production in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV in the decay mode  $H^0 \rightarrow b\bar{b}$ ,  $W \rightarrow \ell\nu$ . A limit  $\sigma(H^0 W) \cdot B(H^0 \rightarrow b\bar{b}) < (1.9\text{--}1.6)$  pb (95% CL) is given for  $m_{H^0} = 105$ –145 GeV, which is 10–93 times larger than the expected Standard Model cross section. These results are combined with ABAZOV 06, ABAZOV 06a, ABAZOV 06b, and ABAZOV 07x to give cross section limits for  $m_{H^0} = 100$ –200 GeV which are 6–24 times larger than the Standard Model expectation. Superseded by ABAZOV 12n.
- 91 ABAZOV 06 search for Higgs boson production in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV with the decay chain  $H^0 \rightarrow WW^{*} \rightarrow \ell^{\pm} \nu \ell^{\mp} \bar{\nu}$ . A limit  $\sigma(H^0) \cdot B(H^0 \rightarrow WW^{*}) < (5.6\text{--}3.2)$  pb (95% CL) is given for  $m_{H^0} = 120$ –200 GeV, which far exceeds the expected Standard Model cross section.
- 92 ABAZOV 06o search for associated  $H^0 W$  production in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV with the decay  $H^0 \rightarrow WW^{*}$ , in the final states  $\ell^{\pm} \ell^{\mp} \nu \nu' X$  where  $\ell = e, \mu$ . A limit  $\sigma(H^0 W) \cdot B(H^0 \rightarrow WW^{*}) < (3.2\text{--}2.8)$  pb (95% CL) is given for  $m_{H^0} = 115$ –175 GeV, which far exceeds the expected Standard Model cross section.

### Indirect Mass Limits for $H^0$ from Electroweak Analysis

The mass limits shown below apply to a Higgs boson  $H^0$  with Standard Model couplings whose mass is a priori unknown.

For limits obtained before the direct measurement of the top quark mass, see the 1996 (Physical Review **D54** 1 (1996)) Edition of this Review. Other studies based on data available prior to 1996 can be found in the 1998 Edition (The European Physical Journal **C3** 1 (1998)) of this Review.

- 1 BAAK 12a make Standard Model fits to  $Z$  and neutral current parameters,  $m_t$ ,  $m_W$ , and  $\Gamma_W$  measurements available in 2012 (using also preliminary data). The quoted result is obtained from a fit that does not include the measured mass value of the signal observed at the LHC and also no limits from direct Higgs searches.
- 2 BAAK 12 make Standard Model fits to  $Z$  and neutral current parameters,  $m_t$ ,  $m_W$ , and  $\Gamma_W$  measurements available in 2010 (using also preliminary data). The quoted result is obtained from a fit that does not include the limit from the direct Higgs searches. The result including direct search data from LEP2, the Tevatron and the LHC is  $120^{+12}_{-5}$  GeV.
- 3 ERLER 10a makes Standard Model fits to  $Z$  and neutral current parameters,  $m_t$ ,  $m_W$  measurements available in 2009 (using also preliminary data). The quoted result is obtained from a fit that does not include the limits from the direct Higgs searches. With direct search data from LEP2 and Tevatron added to the fit, the 90% CL (99% CL) interval is 115–148 (114–197) GeV.
- 4 FLACHER 09 make Standard Model fits to  $Z$  and neutral current parameters,  $m_t$ ,  $m_W$ , and  $\Gamma_W$  measurements available in 2008 (using also preliminary data). The  $2\sigma$  ( $3\sigma$ ) interval is 39–155 (26–209) GeV. The quoted results are obtained from a fit that does not include the limit from the direct Higgs searches. Superseded by BAAK 12.
- 5 LEP-SLC 06 make Standard Model fits to  $Z$  parameters from LEP/SLC and  $m_t$ ,  $m_W$ , and  $\Gamma_W$  measurements available in 2005 with  $\Delta\alpha_{had}^{(5)}(m_Z) = 0.02758 \pm 0.00035$ . The 95% CL limit is 285 GeV.

in this compilation, and can be found in a previous Edition (The European Physical Journal **C15** 1 (2000)) of this Review.

In the following, and unless otherwise stated, results from the LEP experiments (ALEPH, DELPHI, L3, and OPAL) are assumed to derive from the study of the  $e^+e^- \rightarrow H^\pm H^\mp$  process. Limits from  $b \rightarrow s\gamma$  decays are usually stronger in generic 2HDM models than in Supersymmetric models.

<sup>1</sup> The limit refers to the Type II scenario. The limit for  $B(H^+ \rightarrow \tau\nu) = 1$  is 94 GeV (95% CL), and for  $B(H^+ \rightarrow c s) = 1$  the region below 80.5 as well as the region 83–88 GeV is excluded (95% CL). LEP 13 also search for the decay mode  $H^+ \rightarrow A^0 W^*$  with  $A^0 \rightarrow b\bar{b}$ , which is not negligible in Type I models. The limit in Type I models is 72.5 GeV (95% CL) if  $m_{A^0} > 12\text{ GeV}$ .

<sup>2</sup> ABBIENDI 12 also search for the decay mode  $H^+ \rightarrow A^0 W^*$  with  $A^0 \rightarrow b\bar{b}$ .

<sup>3</sup> AAD 13AC search for  $t\bar{t}$  production followed by  $t \rightarrow bH^+, H^+ \rightarrow c\bar{s}$  (flavor unidentified) in 4.7  $\text{fb}^{-1}$  of  $pp$  collisions at  $E_{cm} = 7\text{ TeV}$ . Upper limits on  $B(t \rightarrow bH^+)$  between 0.05 and 0.01 (95%CL) are given for  $m_{H^+} = 90\text{--}150\text{ GeV}$  and  $B(H^+ \rightarrow c\bar{s}) = 1$ .

<sup>4</sup> AAD 13V search for  $t\bar{t}$  production followed by  $t \rightarrow bH^+, H^+ \rightarrow \tau^+\nu$  through violation of lepton universality with 4.6  $\text{fb}^{-1}$  of  $pp$  collisions at  $E_{cm} = 7\text{ TeV}$ . Upper limits on  $B(t \rightarrow bH^+)$  between 0.032 and 0.044 (95% CL) are given for  $m_{H^+} = 90\text{--}140\text{ GeV}$  and  $B(H^+ \rightarrow \tau^+\nu) = 1$ . By combining with AAD 12BH, the limits improve to 0.008 to 0.034 for  $m_{H^+} = 90\text{--}160\text{ GeV}$ . See their Fig. 7 for the excluded region in the  $m_h^{\text{max}}$  scenario of the MSSM.

<sup>5</sup> AAD 12BH search for  $t\bar{t}$  production followed by  $t \rightarrow bH^+, H^+ \rightarrow \tau^+\nu$  with 4.6  $\text{fb}^{-1}$  of  $pp$  collisions at  $E_{cm} = 7\text{ TeV}$ . Upper limits on  $B(t \rightarrow bH^+)$  between 0.01 and 0.05 (95% CL) are given for  $m_{H^+} = 90\text{--}160\text{ GeV}$  and  $B(H^+ \rightarrow \tau^+\nu) = 1$ . See their Fig. 8 for the excluded region in the  $m_h^{\text{max}}$  scenario of the MSSM.

<sup>6</sup> CHATRCHYAN 12AA search for  $t\bar{t}$  production followed by  $t \rightarrow bH^+, H^+ \rightarrow \tau^+\nu$  with 2  $\text{fb}^{-1}$  of  $pp$  collisions at  $E_{cm} = 7\text{ TeV}$ . Upper limits on  $B(t \rightarrow bH^+)$  between 0.019 and 0.041 (95% CL) are given for  $m_{H^+} = 80\text{--}160\text{ GeV}$  and  $B(H^+ \rightarrow \tau^+\nu) = 1$ .

<sup>7</sup> AALTONEN 11P search in 2.7  $\text{fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{cm} = 1.96\text{ TeV}$  for the decay chain  $t \rightarrow bH^+, H^+ \rightarrow W^+A^0, A^0 \rightarrow \tau^+\tau^-$  with  $m_{A^0}$  between 4 and 9 GeV. See their Fig. 4 for limits on  $B(t \rightarrow bH^+)$  for  $90 < m_{H^+} < 160\text{ GeV}$ .

<sup>8</sup> DESCHAMPS 10 make Type II two Higgs doublet model fits to weak leptonic and semileptonic decays,  $b \rightarrow s\gamma, B, B_s$  mixings, and  $Z \rightarrow b\bar{b}$ . The limit holds irrespective of  $\tan\beta$ .

Charged Higgs Bosons ( $H^\pm$  &  $H^{\pm\pm}$ ), Searches for

## CONTENTS:

$H^\pm$  (Charged Higgs) Mass Limits

Mass limits for  $H^{\pm\pm}$  (doubly-charged Higgs boson)

- Limits for  $H^{\pm\pm}$  with  $T_3 = \pm 1$
- Limits for  $H^{\pm\pm}$  with  $T_3 = 0$

 $H^\pm$  (Charged Higgs) MASS LIMITS

Unless otherwise stated, the limits below assume  $B(H^+ \rightarrow \tau^+\nu) + B(H^+ \rightarrow c\bar{s}) = 1$ , and hold for all values of  $B(H^+ \rightarrow \tau^+\nu_\tau)$ , and assume  $H^+$  weak isospin of  $T_3 = +1/2$ . In the following,  $\tan\beta$  is the ratio of the two vacuum expectation values in two-doublet models (2HDM).

The limits are also applicable to point-like technipions. For a discussion of techniparticles, see the Review of Dynamical Electroweak Symmetry Breaking in this Review.

For limits obtained in hadronic collisions before the observation of the top quark, and based on the top mass values inconsistent with the current measurements, see the 1996 (Physical Review **D54** 1 (1996)) Edition of this Review.

Searches in  $e^+e^-$  collisions at and above the  $Z$  pole have conclusively ruled out the existence of a charged Higgs in the region  $m_{H^\pm} \lesssim 45\text{ GeV}$ , and are meanwhile superseded by the searches in higher energy  $e^+e^-$  collisions at LEP. Results that are by now obsolete are therefore not included

# Gauge & Higgs Boson Particle Listings

## Charged Higgs Bosons ( $H^\pm$ and $H^{\pm\pm}$ ), Searches for

- <sup>9</sup> AALTONEN 09AJ search for  $t \rightarrow bH^+$ ,  $H^+ \rightarrow c\bar{s}$  in  $t\bar{t}$  events in  $2.2 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . Upper limits on  $B(t \rightarrow bH^+)$  between 0.08 and 0.32 (95% CL) are given for  $m_{H^+} = 60\text{--}150 \text{ GeV}$  and  $B(H^+ \rightarrow c\bar{s}) = 1$ .
- <sup>10</sup> ABAZOV 09AC search for  $t \rightarrow bH^+$ ,  $H^+ \rightarrow \tau^+\nu$  in  $t\bar{t}$  events in  $0.9 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . Upper limits on  $B(t \rightarrow bH^+)$  between 0.19 and 0.25 (95% CL) are given for  $m_{H^+} = 80\text{--}155 \text{ GeV}$  and  $B(H^+ \rightarrow \tau^+\nu) = 1$ . See their Fig. 4 for an excluded region in a MSSM scenario.
- <sup>11</sup> ABAZOV 09AG measure  $t\bar{t}$  cross sections in final states with  $\ell$  + jets ( $\ell = e, \mu$ ),  $\ell\ell$ , and  $\tau\ell$  in  $1 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ , which constrains possible  $t \rightarrow bH^+$  branching fractions. Upper limits (95% CL) on  $B(t \rightarrow bH^+)$  between 0.15 and 0.40 (0.48 and 0.57) are given for  $B(H^+ \rightarrow \tau^+\nu) = 1$  ( $B(H^+ \rightarrow c\bar{s}) = 1$ ) for  $m_{H^+} = 80\text{--}155 \text{ GeV}$ .
- <sup>12</sup> ABAZOV 09AI search for  $t \rightarrow bH^+$  in  $t\bar{t}$  events in  $1 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . Final states with  $\ell$  + jets ( $\ell = e, \mu$ ),  $\ell\ell$ , and  $\tau\ell$  are examined. Upper limits on  $B(t \rightarrow bH^+)$  (95% CL) between 0.15 and 0.19 (0.19 and 0.22) are given for  $B(H^+ \rightarrow \tau^+\nu) = 1$  ( $B(H^+ \rightarrow c\bar{s}) = 1$ ) for  $m_{H^+} = 80\text{--}155 \text{ GeV}$ . For  $B(H^+ \rightarrow \tau^+\nu) = 1$  also a simultaneous extraction of  $B(t \rightarrow bH^+)$  and the  $t\bar{t}$  cross section is performed, yielding a limit on  $B(t \rightarrow bH^+)$  between 0.12 and 0.26 for  $m_{H^+} = 80\text{--}155 \text{ GeV}$ . See their Figs. 5–8 for excluded regions in several MSSM scenarios.
- <sup>13</sup> ABAZOV 09P search for  $H^+$  production by  $q\bar{q}$  annihilation followed by  $H^+ \rightarrow t\bar{b}$  decay in  $0.9 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . Cross section limits in several two-doublet models are given for  $m_{H^+} = 180\text{--}300 \text{ GeV}$ . A region with  $20 \lesssim \tan\beta \lesssim 70$  is excluded (95% CL) for  $180 \text{ GeV} \lesssim m_{H^+} \lesssim 184 \text{ GeV}$  in type-I models.
- <sup>14</sup> FLACHER 09 make Type II two Higgs doublet model fits to weak leptonic and semileptonic decays,  $b \rightarrow s\gamma$ , and  $Z \rightarrow b\bar{b}$ . The limit holds irrespective of  $\tan\beta$ .
- <sup>15</sup> ABULENCIA 06E search for associated  $H^0 W$  production in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . A fit is made for  $t\bar{t}$  production processes in dilepton, lepton + jets, and lepton +  $\tau$  final states, with the decays  $t \rightarrow W^+ b$  and  $t \rightarrow H^+ b$  followed by  $H^+ \rightarrow \tau^+\nu, c\bar{s}, t^*\bar{b},$  or  $W^+ H^0$ . Within the MSSM the search is sensitive to the region  $\tan\beta < 1$  or  $> 30$  in the mass range  $m_{H^+} = 80\text{--}160 \text{ GeV}$ . See Fig. 2 for the excluded region in a certain MSSM scenario.
- <sup>16</sup> ABDALLAH 04i search for  $e^+e^- \rightarrow H^+H^-$  with  $H^\pm$  decaying to  $\tau\nu, c\bar{s}$ , or  $W^* A^0$  in Type-I two-Higgs-doublet models.
- <sup>17</sup> ABBIENDI 03 give a limit  $m_{H^+} > 1.28\tan\beta \text{ GeV}$  (95%CL) in Type II two-doublet models.
- <sup>18</sup> ABAZOV 02B search for a charged Higgs boson in top decays with  $H^+ \rightarrow \tau^+\nu$  at  $E_{\text{cm}} = 1.8 \text{ TeV}$ . For  $m_{H^+} = 75 \text{ GeV}$ , the region  $\tan\beta > 32.0$  is excluded at 95%CL. The excluded mass region extends to over 140 GeV for  $\tan\beta$  values above 100.
- <sup>19</sup> BORZUMATI 02 point out that the decay modes such as  $b\bar{b}W, A^0 W$ , and supersymmetric ones can have substantial branching fractions in the mass range explored at LEP II and Tevatron.
- <sup>20</sup> ABBIENDI 01Q give a limit  $\tan\beta/m_{H^+} < 0.53 \text{ GeV}^{-1}$  (95%CL) in Type II two-doublet models.
- <sup>21</sup> BARATE 01E give a limit  $\tan\beta/m_{H^+} < 0.40 \text{ GeV}^{-1}$  (90% CL) in Type II two-doublet models. An independent measurement of  $B \rightarrow \tau\nu_\tau X$  gives  $\tan\beta/m_{H^+} < 0.49 \text{ GeV}^{-1}$  (90% CL).
- <sup>22</sup> GAMBINO 01 use the world average data in the summer of 2001  $B(b \rightarrow s\gamma) = (3.23 \pm 0.42) \times 10^{-4}$ . The limit applies for Type-II two-doublet models.
- <sup>23</sup> AFFOLDER 00i search for a charged Higgs boson in top decays with  $H^+ \rightarrow \tau^+\nu$  in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.8 \text{ TeV}$ . The excluded mass region extends to over 120 GeV for  $\tan\beta$  values above 100 and  $B(\tau\nu) = 1$ . If  $B(t \rightarrow bH^+) \gtrsim 0.6$ ,  $m_{H^+}$  up to 160 GeV is excluded. Updates ABE 97L.
- <sup>24</sup> ABBOTT 99e search for a charged Higgs boson in top decays in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.8 \text{ TeV}$ , by comparing the observed  $t\bar{t}$  cross section (extracted from the data assuming the dominant decay  $t \rightarrow bW^+$ ) with theoretical expectation. The search is sensitive to regions of the domains  $\tan\beta \lesssim 1, 50 < m_{H^+} (\text{GeV}) \lesssim 120$  and  $\tan\beta \gtrsim 40, 50 < m_{H^+} (\text{GeV}) \lesssim 160$ . See Fig. 3 for the details of the excluded region.
- <sup>25</sup> ACKERSTAFF 99D measure the Michel parameters  $\rho, \xi, \eta$ , and  $\xi\delta$  in leptonic  $\tau$  decays from  $Z \rightarrow \tau\tau$ . Assuming  $e\text{--}\mu$  universality, the limit  $m_{H^+} > 0.97 \tan\beta \text{ GeV}$  (95% CL) is obtained for two-doublet models in which only one doublet couples to leptons.
- <sup>26</sup> ACCIARRI 97F give a limit  $m_{H^+} > 2.6 \tan\beta \text{ GeV}$  (90% CL) from their limit on the exclusive  $B \rightarrow \tau\nu_\tau$  branching ratio.
- <sup>27</sup> AMMAR 97b measure the Michel parameter  $\rho$  from  $\tau \rightarrow e\nu\nu$  decays and assumes  $e/\mu$  universality to extract the Michel  $\eta$  parameter from  $\tau \rightarrow \mu\nu\nu$  decays. The measurement is translated to a lower limit on  $m_{H^+}$  in a two-doublet model  $m_{H^+} > 0.97 \tan\beta \text{ GeV}$  (90% CL).
- <sup>28</sup> COARASA 97 reanalyzed the constraint on the  $(m_{H^\pm}, \tan\beta)$  plane derived from the inclusive  $B \rightarrow \tau\nu_\tau X$  branching ratio in GROSSMAN 95b and BUSKULIC 95. They show that the constraint is quite sensitive to supersymmetric one-loop effects.
- <sup>29</sup> GUCHAIT 97 studies the constraints on  $m_{H^\pm}$  set by Tevatron data on  $\ell\tau$  final states in  $t\bar{t} \rightarrow (Wb)(Hb), W \rightarrow \ell\nu, H \rightarrow \tau\nu_\tau$ . See Fig. 2 for the excluded region.
- <sup>30</sup> MANGANO 97 reconsiders the limit in ACCIARRI 97F including the effect of the potentially large  $B_c \rightarrow \tau\nu_\tau$  background to  $B_u \rightarrow \tau\nu_\tau$  decays. Stronger limits are obtained.
- <sup>31</sup> STAHL 97 fit  $\tau$  lifetime, leptonic branching ratios, and the Michel parameters and derive limit  $m_{H^+} > 1.5 \tan\beta \text{ GeV}$  (90% CL) for a two-doublet model. See also STAHL 94.
- <sup>32</sup> ALAM 95 measure the inclusive  $b \rightarrow s\gamma$  branching ratio at  $\mathcal{T}(4S)$  and give  $B(b \rightarrow s\gamma) < 4.2 \times 10^{-4}$  (95% CL), which translates to the limit  $m_{H^+} > [244 + 63/(\tan\beta)^{1.3}] \text{ GeV}$  in the Type II two-doublet model. Light supersymmetric particles can invalidate this bound.
- <sup>33</sup> BUSKULIC 95 give a limit  $m_{H^+} > 1.9 \tan\beta \text{ GeV}$  (90% CL) for Type-II models from  $b \rightarrow \tau\nu_\tau X$  branching ratio, as proposed in GROSSMAN 94.

### MASS LIMITS for $H^{\pm\pm}$ (doubly-charged Higgs boson)

This section covers searches for a doubly-charged Higgs boson with couplings to lepton pairs. Its weak isospin  $T_3$  is thus restricted to two possibilities depending on lepton chiralities:  $T_3(H^{\pm\pm}) = \pm 1$ , with the coupling  $g_{\ell\ell}$  to  $\ell_L^-\ell_L^-$  and  $\ell_R^+\ell_R^+$  ("left-handed") and  $T_3(H^{\pm\pm}) = 0$ , with the coupling to  $\ell_R^-\ell_R^-$  and  $\ell_L^+\ell_L^+$  ("right-handed"). These Higgs bosons appear in some left-right symmetric models based on the gauge group  $SU(2)_L \times SU(2)_R \times U(1)$ . These two cases are listed separately in the following. Unless noted, one of the lepton flavor combinations is assumed to be dominant in the decay.

- <sup>1</sup> AAD 12CQ search for  $H^{++}H^{--}$  production with  $4.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . The limit assumes 100% branching ratio to the specified final state. See their Table 1 for limits assuming smaller branching ratios.
- <sup>2</sup> CHATRCHYAN 12AU search for  $H^{++}H^{--}$  production with  $4.9 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . The limit assumes 100% branching ratio to the specified final state. See their Table 6 for limits including associated  $H^{++}H^{--}$  production or assuming different scenarios.
- <sup>3</sup> ABDALLAH 03 search for  $H^{++}H^{--}$  pair production either followed by  $H^{++} \rightarrow \tau^+\tau^+$ , or decaying outside the detector.
- <sup>4</sup> ABBIENDI 02c searches for pair production of  $H^{++}H^{--}$ , with  $H^{\pm\pm} \rightarrow \ell^\pm\ell^\pm$  ( $\ell, \ell' = e, \mu, \tau$ ). The limit holds for  $\ell = \ell' = \tau$ , and becomes stronger for other combinations of leptonic final states. To ensure the decay within the detector, the limit only applies for  $g(H\ell\ell) \gtrsim 10^{-7}$ .
- <sup>5</sup> AAD 13Y search for  $H^{++}H^{--}$  production in a generic search of events with three charged leptons in  $4.6 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . The limit assumes 100% branching ratio to the specified final state.
- <sup>6</sup> AAD 12AY search for  $H^{++}H^{--}$  production with  $1.6 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{\text{cm}} = 7 \text{ TeV}$ . The limit assumes 100% branching ratio to the specified final state.
- <sup>7</sup> ABAZOV 12A search for  $H^{++}H^{--}$  production in  $7.0 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ .
- <sup>8</sup> AALTONEN 11AF search for  $H^{++}H^{--}$  production in  $6.1 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ .
- <sup>9</sup> AALTONEN 08AA search for  $H^{++}H^{--}$  production in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . The limit assumes 100% branching ratio to the specified final state.
- <sup>10</sup> ABAZOV 08v search for  $H^{++}H^{--}$  production in  $p\bar{p}$  collisions at  $E_{\text{cm}} = 1.96 \text{ TeV}$ . The limit is for  $B(H \rightarrow \mu\mu) = 1$ . The limit is updated in ABAZOV 12A.
- <sup>11</sup> AKTAS 06A search for single  $H^{\pm\pm}$  production in  $ep$  collisions at HERA. Assuming that  $H^{++}$  only couples to  $e^+\mu^+$  with  $g_{e\mu} = 0.3$  (electromagnetic strength), a limit  $m_{H^{++}} > 141 \text{ GeV}$  (95% CL) is derived. For the case where  $H^{++}$  couples to  $e\tau$  only the limit is 112 GeV.
- <sup>12</sup> ACOSTA 05L search for  $H^{++}H^{--}$  pair production in  $p\bar{p}$  collisions. The limit is valid for  $g_{\ell\ell} < 10^{-8}$  so that the Higgs decays outside the detector.
- <sup>13</sup> ABAZOV 04E search for  $H^{++}H^{--}$  pair production in  $H^{\pm\pm} \rightarrow \mu^\pm\mu^\pm$ . The limit is valid for  $g_{\mu\mu} \gtrsim 10^{-7}$ .
- <sup>14</sup> ABBIENDI 03Q searches for single  $H^{\pm\pm}$  via direct production in  $e^+e^- \rightarrow e^\mp e^\mp H^{\pm\pm}$ , and via t-channel exchange in  $e^+e^- \rightarrow e^+e^-$ . In the direct case, and assuming  $B(H^{\pm\pm} \rightarrow \ell^\pm\ell^\pm) = 1$ , a 95% CL limit on  $h_{ee} < 0.071$  is set for  $m_{H^{\pm\pm}} < 160 \text{ GeV}$  (see Fig. 6). In the second case, indirect limits on  $h_{ee}$  are set for  $m_{H^{\pm\pm}} < 2 \text{ TeV}$  (see Fig. 8).

## Charged Higgs Bosons ( $H^\pm$ and $H^{\pm\pm}$ ), Searches for, New Heavy Bosons

15 GORDEEV 97 search for muonium-antimuonium conversion and find  $G_{M\bar{M}}/G_F < 0.14$  (90% CL), where  $G_{M\bar{M}}$  is the lepton-flavor violating effective four-fermion coupling.

This limit may be converted to  $m_{H^{++}} > 210$  GeV if the Yukawa couplings of  $H^{++}$  to  $ee$  and  $\mu\mu$  are as large as the weak gauge coupling. For similar limits on muonium-antimuonium conversion, see the muon Particle Listings.

16 ASAKA 95 point out that  $H^{++}$  decays dominantly to four fermions in a large region of parameter space where the limit of ACTON 92M from the search of dilepton modes does not apply.

17 ACTON 92M limit assumes  $H^{\pm\pm} \rightarrow \ell^\pm \ell^\pm$  or  $H^{\pm\pm}$  does not decay in the detector. Thus the region  $g_{\ell\ell} \approx 10^{-7}$  is not excluded.

18 ACTON 92M from  $\Delta\Gamma_Z < 40$  MeV.

19 SWARTZ 90 assume  $H^{\pm\pm} \rightarrow \ell^\pm \ell^\pm$  (any flavor). The limits are valid for the Higgs-lepton coupling  $g(H\ell\ell) \gtrsim 7.4 \times 10^{-7}/[m_H/\text{GeV}]^{1/2}$ . The limits improve somewhat for  $ee$  and  $\mu\mu$  decay modes.

1 AAD 12CQ search for  $H^{++}H^{--}$  production with  $4.7 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit assumes 100% branching ratio to the specified final state. See their Table 1 for limits assuming smaller branching ratios.

2 ABDALLAH 03 search for  $H^{++}H^{--}$  pair production either followed by  $H^{++} \rightarrow \tau^+ \tau^+$ , or decaying outside the detector.

3 ACHARD 03F search for  $e^+e^- \rightarrow H^{++}H^{--}$  with  $H^{\pm\pm} \rightarrow \ell^\pm \ell^\pm$ . The limit holds for  $\ell = \ell' = \tau$ , and slightly different limits apply for other flavor combinations. The limit is valid for  $g_{\ell\ell'} \gtrsim 10^{-7}$ .

4 ABBIENDI 02C searches for pair production of  $H^{++}H^{--}$ , with  $H^{\pm\pm} \rightarrow \ell^\pm \ell^\pm$  ( $\ell, \ell' = e, \mu, \tau$ ), the limit holds for  $\ell = \ell' = \tau$ , and becomes stronger for other combinations of leptonic final states. To ensure the decay within the detector, the limit only applies for  $g(H\ell\ell) \gtrsim 10^{-7}$ .

5 AAD 12AY search for  $H^{++}H^{--}$  production with  $1.6 \text{ fb}^{-1}$  of  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit assumes 100% branching ratio to the specified final state.

6 ABAZOV 12A search for  $H^{++}H^{--}$  production in  $7.0 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV.

7 AALTONEN 11AF search for  $H^{++}H^{--}$  production in  $6.1 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV.

8 ABAZOV 08V search for  $H^{++}H^{--}$  production in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The limit is for  $B(H \rightarrow \mu\mu) = 1$ . The limit is updated in ABAZOV 12A.

9 AKTAS 06A search for single  $H^{\pm\pm}$  production in  $ep$  collisions at HERA. Assuming that  $H^{++}$  only couples to  $e^+ \mu^+$  with  $g_{e\mu} = 0.3$  (electromagnetic strength), a limit  $m_{H^{++}} > 141$  GeV (95% CL) is derived. For the case where  $H^{++}$  couples to  $e\tau$  only the limit is 112 GeV.

10 ACOSTA 05L search for  $H^{++}H^{--}$  pair production in  $p\bar{p}$  collisions. The limit is valid for  $g_{\ell\ell'} < 10^{-8}$  so that the Higgs decays outside the detector.

11 ABAZOV 04E search for  $H^{++}H^{--}$  pair production in  $H^{\pm\pm} \rightarrow \mu^\pm \mu^\pm$ . The limit is valid for  $g_{\mu\mu} \gtrsim 10^{-7}$ .

12 ABBIENDI 03Q searches for single  $H^{\pm\pm}$  via direct production in  $e^+e^- \rightarrow e^\mp e^\mp H^{\pm\pm}$ , and via  $t$ -channel exchange in  $e^+e^- \rightarrow e^+e^-$ . In the direct case, and assuming  $B(H^{\pm\pm} \rightarrow \ell^\pm \ell^\pm) = 1$ , a 95% CL limit on  $h_{ee} < 0.071$  is set for  $m_{H^{\pm\pm}} < 160$  GeV (see Fig. 6). In the second case, indirect limits on  $h_{ee}$  are set for  $m_{H^{\pm\pm}} < 2$  TeV (see Fig. 8).

13 GORDEEV 97 search for muonium-antimuonium conversion and find  $G_{M\bar{M}}/G_F < 0.14$  (90% CL), where  $G_{M\bar{M}}$  is the lepton-flavor violating effective four-fermion coupling.

This limit may be converted to  $m_{H^{++}} > 210$  GeV if the Yukawa couplings of  $H^{++}$  to  $ee$  and  $\mu\mu$  are as large as the weak gauge coupling. For similar limits on muonium-antimuonium conversion, see the muon Particle Listings.

14 ACTON 92M limit assumes  $H^{\pm\pm} \rightarrow \ell^\pm \ell^\pm$  or  $H^{\pm\pm}$  does not decay in the detector. Thus the region  $g_{\ell\ell} \approx 10^{-7}$  is not excluded.

15 ACTON 92M from  $\Delta\Gamma_Z < 40$  MeV.

16 SWARTZ 90 assume  $H^{\pm\pm} \rightarrow \ell^\pm \ell^\pm$  (any flavor). The limits are valid for the Higgs-lepton coupling  $g(H\ell\ell) \gtrsim 7.4 \times 10^{-7}/[m_H/\text{GeV}]^{1/2}$ . The limits improve somewhat for  $ee$  and  $\mu\mu$  decay modes.

## New Heavy Bosons

### W'-BOSON SEARCHES

Revised November 2013 by G. Brooijmans (Columbia University), M.-C. Chen (UC Irvine) and B.A. Dobrescu (Fermilab).

The  $W'$  boson is a massive hypothetical particle of charge  $\pm 1$  and spin 1, predicted in various extensions of the Standard Model (SM).

**W' couplings to quarks and leptons.** The Lagrangian terms describing couplings of a  $W'^+$  boson to fermions are given by

$$\frac{W'^+}{\sqrt{2}} \left[ \bar{u}_i \left( C_{qij}^R P_R + C_{qij}^L P_L \right) \gamma^\mu d_j + \bar{\nu}_i \left( C_{lij}^R P_R + C_{lij}^L P_L \right) \gamma^\mu e_j \right]. \quad (1)$$

Here  $u, d, \nu$  and  $e$  are the SM fermions in the mass eigenstate basis,  $i, j = 1, 2, 3$  label the fermion generation, and  $P_{R,L} = (1 \pm \gamma_5)/2$ . The coefficients  $C_{qij}^L, C_{qij}^R, C_{lij}^L, C_{lij}^R$  are complex dimensionless parameters. If  $C_{lij}^R \neq 0$ , then the  $i$ th generation includes a right-handed neutrino. Using this notation, the SM  $W$  couplings are  $C_q^L = g V_{CKM}$ ,  $C_l^L = g$  and  $C_q^R = C_l^R = 0$ .

Unitarity considerations imply that the  $W'$  boson is associated with a spontaneously-broken gauge symmetry. This is true even when it is a composite particle (*e.g.*,  $\rho^\pm$ -like bound states [1]) if its mass is much smaller than the compositeness scale, or a Kaluza-Klein mode in theories where the  $W$  boson propagates in extra dimensions [2]. The simplest extension of the electroweak gauge group that includes a  $W'$  boson is  $SU(2)_1 \times SU(2)_2 \times U(1)$ , but larger groups are encountered in some theories. A generic property of these gauge theories is that they also include a  $Z'$  boson [3]; whether the  $W'$  boson can be discovered first depends on theoretical and experimental details.

The renormalizable photon- $W'$  coupling is fixed by electromagnetic gauge invariance. By contrast, the  $W'WZ$  and  $W'W'Z$  couplings as well as the  $W'$  boson couplings to  $Z'$  or Higgs bosons are model-dependent.

A tree-level mass mixing may be induced between the electrically-charged gauge bosons. Upon diagonalization of their mass matrix, the  $W - Z$  mass ratio and the couplings of the observed  $W$  boson are shifted from the SM values. Their measurements imply that the  $W - W'$  mixing angle must be smaller than about  $10^{-2}$ . Similarly, a  $Z - Z'$  mixing is induced in generic theories, leading to even tighter constraints. There are, however, theories in which these mixings are negligible (*e.g.* due to a new parity [4]), even when the  $W'$  and  $Z'$  masses are below the electroweak scale.

A popular model [5] is based on the “left-right symmetric” gauge group,  $SU(2)_L \times SU(2)_R \times U(1)_{B-L}$ , with the SM fermions that couple to the  $W$  boson transforming as doublets under  $SU(2)_L$ , and the other ones transforming as doublets under  $SU(2)_R$ . In this model the  $W'$  boson couples primarily to right-handed fermions, and its coupling to left-handed fermions arises solely due to  $W - W'$  mixing. As a result,  $C_q^L$  is proportional to the CKM matrix, and its elements are much smaller than the diagonal elements of  $C_q^R$ .

There are many other models based on the  $SU(2)_1 \times SU(2)_2 \times U(1)$  gauge symmetry. In the “alternate left-right” model [6], all the couplings shown in Eq. (1) vanish, but there are some new fermions such that the  $W'$  boson couples to pairs involving a SM fermion and a new fermion. In the “unified SM” [7], the left-handed quarks are doublets under one  $SU(2)$ , and the left-handed leptons are doublets under a different  $SU(2)$ , leading to a mostly leptophobic  $W'$  boson:  $C_{lij}^L \ll C_{qij}^L$  and  $C_{qij}^R = C_{lij}^R = 0$ . Fermions of different generations may also transform as doublets under different  $SU(2)$  gauge groups [8]. In particular, the couplings to third generation quarks may be enhanced [9].

It is also possible that the  $W'$  couplings to SM fermions are highly suppressed. For example, if the quarks and leptons are singlets under one  $SU(2)$  [10], then the couplings are proportional to a mixing angle that could be very small. Similar suppressions may arise if some vectorlike fermions mix with the SM ones [11].

Gauge groups that embed the electroweak symmetry, such as  $SU(3)_W \times U(1)$  or  $SU(4)_W \times U(1)$ , also include one or more  $W'$  bosons [12].

**Collider searches.** At LEP-II,  $W'$  bosons could have been produced in pairs via their photon and  $Z$  couplings. The production cross section depends only on the  $W'$  mass, and is large enough to rule out  $M_{W'} \leq \sqrt{s}/2 \approx 105$  GeV for most patterns of decay modes.

At hadron colliders,  $W'$  bosons can be detected through resonant pair production of fermions or electroweak bosons. Assuming that the  $W'$  width is much smaller than its mass, the contribution of the  $s$ -channel  $W'$  boson exchange to the total rate for  $pp \rightarrow f \bar{f}' X$ , where  $f$  and  $f'$  are fermions whose electric charges differ by  $\pm 1$ , and  $X$  is any final state, may be approximated by the branching fraction  $B(W' \rightarrow f \bar{f}')$  times the production cross section

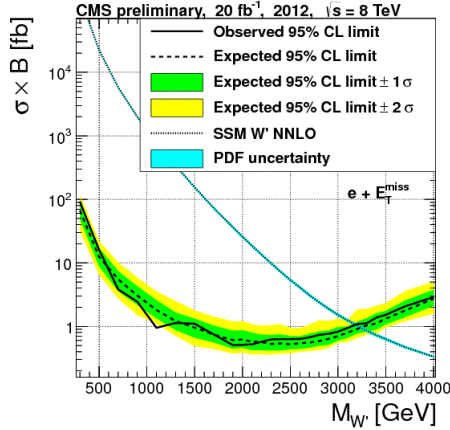

$$\sigma(pp \rightarrow W' X) \simeq \frac{\pi}{48 s} \sum_{i,j} \left[ (C_{qij}^L)^2 + (C_{qij}^R)^2 \right] w_{ij}(M_{W'}^2/s, M_{W'}). \quad (2)$$

The functions  $w_{ij}$  include the information about proton structure, and are given to leading order in  $\alpha_s$  by

$$w_{ij}(z, \mu) = \int_z^1 \frac{dx}{x} \left[ u_i(x, \mu) \bar{d}_j\left(\frac{z}{x}, \mu\right) + \bar{u}_i(x, \mu) d_j\left(\frac{z}{x}, \mu\right) \right], \quad (3)$$

where  $u_i(x, \mu)$  and  $d_i(x, \mu)$  are the parton distributions inside the proton, at the factorization scale  $\mu$  and parton momentum fraction  $x$ , for the up- and down-type quark of the  $i$ th generation, respectively. QCD corrections to  $W'$  production are sizable (they also include quark-gluon initial states), but preserve the above factorization of couplings at next-to-leading order [13].

The most commonly studied  $W'$  signal consists of a high-energy electron or muon and large missing transverse energy, with the transverse mass distribution forming a Jacobian peak with its endpoint at  $M_{W'}$  (see Fig. 2 of Ref. 14) Given that the branching fractions for  $W' \rightarrow e\nu$  and  $W' \rightarrow \mu\nu$  could be

**Figure 1:** 95% CL limit on  $\sigma(pp \rightarrow W'X) \times B(W' \rightarrow e\nu)$  from CMS [16]. The theoretical prediction (dotted line) is for  $C_q^R = gV_{\text{CKM}}$ ,  $C_l^R = g$ ,  $C_q^L = C_l^L = 0$ .

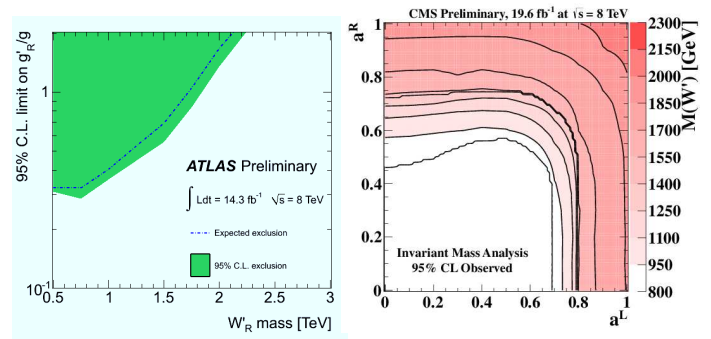

very different, these channels should be analyzed separately. Searches in these channels often assume that the left-handed couplings vanish (no interference between  $W$  and  $W'$ ), and that the right-handed neutrino of the first generation is light compared to  $M_{W'}$  and escapes the detector. However, if a  $W'$  boson were discovered and the final state fermions have left-handed helicity, then the effects of  $W - W'$  interference could be observed [15], providing useful information about the  $W'$  couplings.

In the  $e\nu$  channel, the CMS Collab. has set limits [16] for  $M_{W'}$  in the 0.3 – 4 TeV range, based on  $20 \text{ fb}^{-1}$  of LHC data at  $\sqrt{s} = 8 \text{ TeV}$ , as shown in Fig. 1. For  $M_{W'}$  in the 500 – 600 GeV range, the limits on  $W'$  couplings set by CDF [17] are also stringent (for a comparison, see Fig. 4 of Ref. 14). The limits are much weaker for  $M_{W'}$  in the 200 – 300 GeV range because these were obtained using only  $0.2 \text{ fb}^{-1}$  of Tevatron data [18], while the 105 – 200 GeV range has been even less explored (see the UA1 and UA2 references in Ref. 19).

In the  $\mu\nu$  channel, the most stringent limits in the 0.3 – 4 TeV range are set by CMS [16] using the  $\sqrt{s} = 8 \text{ TeV}$  data. When combined with the  $e\nu$  channel, the limit varies between 71 and 1.7 fb. The ATLAS  $\mu\nu$  limit [14] uses the 7 TeV data set. For  $M_{W'}$  in the 200 – 300 GeV range there are only weak limits on the  $W'$  couplings from Run I [20] of the Tevatron. There are no direct limits on  $W' \rightarrow \mu\nu$  for  $M_{W'}$  in the 105 – 200 GeV range. Note that masses of the order of the electroweak scale are interesting from a theory point of view, while lepton universality does not necessarily apply to a  $W'$  boson.

Dedicated searches for the  $W' \rightarrow \tau\nu$  decay have not yet been performed, but limits can be derived from some searches in the  $\ell + \cancel{E}_T$  channel as well as from charged-Higgs searches such as  $pp \rightarrow t\bar{b}\tau\nu X$ .

The  $W'$  decay into a lepton and a right-handed neutrino,  $\nu_R$ , may also be followed by the  $\nu_R$  decay through a virtual  $W'$  boson into a lepton and two quark jets. The CMS [21] and

**Figure 2:** 95% CL upper limits on  $W'$  couplings using the  $t\bar{b}$  and  $\bar{t}b$  final states, assuming that the diagonal couplings are generation independent. Left panel: ATLAS [23] limit on  $C_{q11}^R/g$ . Right panel: CMS [24] limit on  $M_{W'}$  as contours in the  $C_{q11}^R/g - C_{q11}^L/g$  plane.

ATLAS [22] searches in the  $eejj$ ,  $\mu\mu jj$  and  $\tau\tau jj$  channels have set limits on various quantities for  $M_{W'}$  in the 0.6 – 3 TeV range.

The  $\bar{t}b$  channel is particularly important because a  $W'$  boson that  $\bar{t}b$  couples only to right-handed fermions cannot decay to leptons when the right-handed neutrinos are heavier than  $M_{W'}$  (additional motivations are provided by a  $W'$  boson with enhanced couplings to the third generation [9], and by a leptophobic  $W'$  boson). The usual signal consists of a leptonically decaying  $W$  boson and two  $b$ -jets. Upper limits on the  $W'$  couplings to right- and left-handed quarks normalized to the SM  $W$  couplings, have been set by ATLAS [23] and CMS [24] as shown in Fig. 2. The best limits on the couplings to right-handed quarks for  $M_{W'}$  in the 300–500 GeV range have been set by CDF with  $1.9 \text{ fb}^{-1}$  [25], while on couplings to left-handed quarks for  $M_{W'}$  in the 600–800 GeV range have been set by  $D\phi$  with  $2.3 \text{ fb}^{-1}$  [26]. For  $M_{W'} \gg m_t$ , one could also use hadronic  $W$  boson decays to search for  $W' \rightarrow \bar{t}b$  with a boosted top quark. Finally, if  $W'$  couplings to left-handed quarks are large, then interference effects modify the SM  $s$ -channel single-top production [27].

Searches for dijet resonances may be used to set limits on  $W' \rightarrow q\bar{q}'$ . The best limits on  $W'$  couplings to quarks have been set by UA2 [28] in the 140 – 250 GeV mass range, by CDF [29] in the 250 – 900 GeV range, and by CMS [30] in the  $\sim 1 - 3$  TeV range.

In some theories [4], the  $W'$  couplings to SM fermions are suppressed by discrete symmetries.  $W'$  production then occurs in pairs, through a photon or  $Z$  boson. The decay modes are model-dependent and often involve other new particles. The ensuing collider signals arise from cascade decays and typically include missing transverse energy.

Searches for  $WZ$  resonances at the LHC have focused on the process  $pp \rightarrow W' \rightarrow WZ$  with the production mainly from  $u\bar{d} \rightarrow W'$  assuming SM-like couplings to quarks. CMS [32] and ATLAS [33] have set upper limits on the  $W'WZ$  coupling for  $M_{W'}$  in the 170 – 2000 GeV range. Similar searches have also been performed at the Tevatron [34].

## New Heavy Bosons

A fermiophobic  $W'$  boson that couples to  $WZ$  may be produced at hadron colliders in association with a  $Z$  boson, or via  $WZ$  fusion. This would give rise to  $(WZ)Z$  and  $(WZ)jj$  final states, where the parentheses represent a resonance [31].

**Low-energy constraints.** The properties of  $W'$  bosons are also constrained by measurements of processes at energies much below  $M_{W'}$ . The bounds on  $W - W'$  mixing [19] are mostly due to the change in  $W$  properties compared to the SM. Limits on deviations in the  $ZWW$  couplings provide a leading constraint for fermiophobic  $W'$  bosons [11].

Constraints arising from low-energy effects of  $W'$  exchange are strongly model-dependent. If the  $W'$  couplings to quarks are not suppressed, then box diagrams involving a  $W$  and a  $W'$  boson contribute to neutral meson-mixing. In the case of  $W'$  couplings to right-handed quarks as in the left-right symmetric model, the limit from  $K_L - K_S$  mixing is severe:  $M_{W'} > 2.5$  TeV [35]. However, if no correlation between  $C_{qij}^R$  and  $C_{lij}^R$  is assumed, then the limit on  $M_{W'}$  may be significantly relaxed [36].

$W'$  exchange also contributes at tree level to various low-energy processes. In particular, it would impact the measurement of the Fermi constant  $G_F$  in muon decay, which in turn would change the predictions of many other electroweak processes. A recent test of parity violation in polarized muon decay [37] has set limits of about 600 GeV on  $M_{W'}$ , assuming  $W'$  couplings to right-handed leptons as in left-right symmetric models. There are also  $W'$  contributions to the neutron electric dipole moment,  $\beta$  decays, and other processes [19].

If right-handed neutrinos have Majorana masses, then there are tree-level contributions to neutrinoless double-beta decay, and a limit on  $M_{W'}$  versus the  $\nu_R$  mass may be derived [38]. For  $\nu_R$  masses below a few GeV, the  $W'$  boson contributes to leptonic and semileptonic  $B$  meson decays, so that limits may be placed on various combinations of  $W'$  parameters [36]. For  $\nu_R$  masses below  $\sim 30$  MeV, most stringent constraints on  $M_{W'}$  are due to the limits on  $\nu_R$  emission from supernovae.

### MASS LIMITS for $W'$ (Heavy Charged Vector Boson Other Than $W$ ) in Hadron Collider Experiments

Couplings of  $W'$  to quarks and leptons are taken to be identical with those of  $W$ . The following limits are obtained from  $p\bar{p}$  or  $pp \rightarrow W'X$  with  $W'$  decaying to the mode indicated in the comments. New decay channels (*e.g.*,  $W' \rightarrow WZ$ ) are assumed to be suppressed. The most recent preliminary results can be found in the “ $W'$ -boson searches” review above.

- 1 AAD 12AV search for  $W'$  decaying into the  $WZ$  final state with  $W \rightarrow \ell\nu, Z \rightarrow 2j$ . The quoted limit assumes  $\tilde{g}_{W'WZ}/\tilde{g}_{WWZ} = (M_W/M_{W'})^2$ .
- 2 CHATRCHYAN 13AJ limit is for  $W'$  with SM-like coupling which interferes with the SM  $W$  boson.
- 3 CHATRCHYAN 13AS limit is for  $W'$  with SM-like coupling which interferes with the SM  $W$  boson. For  $W'$  with right-handed coupling, the bound becomes  $>1850$  GeV ( $>1910$  GeV) if  $W'$  decays to both leptons and quarks (only to quarks). If both left- and right-handed couplings are present, the limit becomes  $>1640$  GeV.
- 4 The AAD 12AV quoted limit is for a SM-like right-handed  $W'$ .  $W' \rightarrow \ell\nu$  decay is assumed to be forbidden.
- 5 The quoted limit assumes  $\tilde{g}_{W'WZ}/\tilde{g}_{WWZ} = (M_W/M_{W'})^2$ .
- 6 CHATRCHYAN 12AB limit is for  $W'$  with SM-like coupling which interferes with the SM  $W$  boson constructively. For  $W'$  with right-handed coupling, the bound becomes  $>2.5$  TeV.
- 7 CHATRCHYAN 13AJ search for resonances decaying to  $WZ$  pair, using the hadronic decay modes of  $W$  and  $Z$ . See their Fig. 7 for the limit on the cross section.
- 8 CHATRCHYAN 13AS search for new resonance decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 8$  TeV.
- 9 CHATRCHYAN 13U search for  $W'$  decaying to the  $WZ$  final state, with  $W$  decaying into jets. The quoted limit assumes  $\tilde{g}_{W'WZ}/\tilde{g}_{WWZ} = (M_W/M_{W'})^2$ .
- 10 AAD 12CK search for  $pp \rightarrow tW', W' \rightarrow \bar{\tau}q$  events in  $pp$  collisions. See their Fig. 5 for the limit on  $\sigma \cdot B$ .
- 11 AAD 12M search for right-handed  $W_R$  in  $pp$  collisions at  $\sqrt{s} = 7$  TeV.  $W_R$  is assumed to decay into  $\ell$  and hypothetical heavy neutrino  $N$ , with  $N$  decaying into  $\ell jj$ . See their Fig. 4 for the limit in the  $m_N - m_{W'}$  plane.
- 12 AALTONEN 12N search for  $p\bar{p} \rightarrow tW', W' \rightarrow \bar{\tau}d$  events in  $p\bar{p}$  collisions. See their Fig. 3 for the limit on  $\sigma \cdot B$ .
- 13 CHATRCHYAN 12AR search for  $pp \rightarrow tW', W' \rightarrow \bar{\tau}d$  events in  $pp$  collisions. See their Fig. 2 for the limit on  $\sigma \cdot B$ .
- 14 CHATRCHYAN 12BG search for right-handed  $W_R$  in  $pp$  collisions at  $\sqrt{s} = 7$  TeV.  $W_R$  is assumed to decay into  $\ell$  and hypothetical heavy neutrino  $N$ , with  $N$  decaying into  $\ell jj$ . See their Fig. 3 for the limit in the  $m_N - m_{W'}$  plane.
- 15 The quoted limit is obtained assuming  $W'WZ$  coupling strength is the same as the ordinary  $WWZ$  coupling strength in the Standard Model.
- 16 ABAZOV 11L limit is for  $W'$  with SM-like coupling which interferes with the SM  $W$  boson. For  $W'$  with right-handed coupling, the bound becomes  $>885$  GeV ( $>890$  GeV) if  $W'$  decays to both leptons and quarks (only to quarks). If both left- and right-handed couplings present, the limit becomes  $>916$  GeV.
- 17 The quoted limit assumes  $\tilde{g}_{W'WZ}/\tilde{g}_{WWZ} = (M_W/M_{W'})^2$ . See their Fig. 4 for limits in mass-coupling plane.
- 18 The quoted limit assumes  $\tilde{g}_{W'WZ}/\tilde{g}_{WWZ} = (M_W/M_{W'})^2$ . See their Fig. 3 for limits in mass-coupling plane.
- 19 The AALTONEN 09AA quoted limit is for a right-handed  $W'$  with SM-like coupling allowing  $W' \rightarrow \ell\nu$  decays.

- 20 AALTONEN 09AC search for new particle decaying to dijets.
- 21 The ABAZOV 08P quoted limit is for  $W'$  with SM-like coupling which interferes with the SM  $W$  boson. For  $W'$  with right-handed coupling, the bound becomes  $>739$  GeV ( $>768$  GeV) if  $W'$  decays to both leptons and quarks (only to quarks).
- 22 The ABAZOV 06N quoted limit is for  $W'$  with SM-like coupling which interferes with the SM  $W$  boson. For  $W'$  with right-handed coupling,  $M_{W'}$  between 200 and 630 (670) GeV is excluded for  $M_{\nu_R} \ll M_{W'} (M_{\nu_R} > M_{W'})$ .
- 23 The ACOSTA 03B quoted limit is for  $M_{W'} \gg M_{\nu_R}$ . For  $M_{W'} < M_{\nu_R}$ ,  $M_{W'}$  between 225 and 566 GeV is excluded.
- 24 The quoted limit is obtained assuming  $W'WZ$  coupling strength is the same as the ordinary  $WWZ$  coupling strength in the Standard Model. See their Fig. 2 for the limits on the production cross sections as a function of the  $W'$  width.
- 25 AFFOLDER 01I combine a new bound on  $W' \rightarrow e\nu$  of 754 GeV with the bound of ABE 00 on  $W' \rightarrow \mu\nu$  to obtain quoted bound.
- 26 ABE 00 assume that the neutrino from  $W'$  decay is stable and has a mass significantly less than  $m_{W'}$ .
- 27 ABE 97G search for new particle decaying to dijets.
- 28 For bounds on  $W_R$  with nonzero right-handed mass, see Fig. 5 from ABACHI 96C.
- 29 ABACHI 95E assume that the decay  $W' \rightarrow WZ$  is suppressed and that the neutrino from  $W'$  decay is stable and has a mass significantly less  $m_{W'}$ .
- 30 ABE 95M assume that the decay  $W' \rightarrow WZ$  is suppressed and the (right-handed) neutrino is light, noninteracting, and stable. If  $m_{\nu} = 60$  GeV, for example, the effect on the mass limit is negligible.
- 31 RIZZO 93 analyses CDF limit on possible two-jet resonances. The limit is sensitive to the inclusion of the assumed  $K$  factor.

 **$W_R$  (Right-Handed  $W$  Boson) MASS LIMITS**

Assuming a light right-handed neutrino, except for BEALL 82, LANGACKER 89B, and COLANGELO 91.  $\tilde{g}_R = \tilde{g}_L$  assumed. [Limits in the section MASS LIMITS for  $W'$  below are also valid for  $W_R$  if  $m_{\nu_R} \ll m_{W_R}$ .] Some limits assume manifest left-right symmetry, i.e., the equality of left- and right Cabibbo-Kobayashi-Maskawa matrices. For a comprehensive review, see LANGACKER 89B. Limits on the  $W_L - W_R$  mixing angle  $\zeta$  are found in the next section. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

### $Z'$ -BOSON SEARCHES

Revised November 2013 by G. Brooijmans (Columbia University), M.-C. Chen (UC Irvine), and B.A. Dobrescu (Fermilab).

The  $Z'$  boson is a massive, electrically-neutral and color-singlet hypothetical particle of spin 1. This particle is predicted in many extensions of the Standard Model (SM), and has been the object of extensive phenomenological studies [1].

**$Z'$  boson couplings to quarks and leptons.** The couplings of a  $Z'$  boson to the first-generation fermions are given by

$$Z'_\mu (g_u^L \bar{u}_L \gamma^\mu u_L + g_d^L \bar{d}_L \gamma^\mu d_L + g_u^R \bar{u}_R \gamma^\mu u_R + g_d^R \bar{d}_R \gamma^\mu d_R + g_\nu^L \bar{\nu}_L \gamma^\mu \nu_L + g_e^L \bar{e}_L \gamma^\mu e_L + g_e^R \bar{e}_R \gamma^\mu e_R) , \quad (1)$$

where  $u, d, \nu$  and  $e$  are the quark and lepton fields in the mass eigenstate basis, and the coefficients  $g_u^L, g_d^L, g_u^R, g_d^R, g_\nu^L, g_e^L, g_e^R$  are real dimensionless parameters. If the  $Z'$  couplings to quarks and leptons are generation-independent, then these seven parameters describe the couplings of the  $Z'$  boson to all SM fermions. More generally, however, the  $Z'$  couplings to fermions are generation-dependent, in which case Eq. (1) may be written with generation indices  $i, j = 1, 2, 3$  labeling the quark and lepton fields, and with the seven coefficients promoted to  $3 \times 3$  Hermitian matrices (e.g.,  $g_{eij}^L \bar{e}_L^i \gamma^\mu e_L^j$ , where  $e_L^2$  is the left-handed muon, etc.).

These parameters describing the  $Z'$  boson interactions with quarks and leptons are subject to some theoretical constraints. Quantum field theories that include a heavy spin-1 particle are well behaved at high energies only if that particle is a gauge boson associated with a spontaneously broken gauge symmetry. Quantum effects preserve the gauge symmetry only if the couplings of the gauge boson to fermions satisfy anomaly cancellation conditions. Furthermore, the fermion charges under the new gauge symmetry are constrained by the requirement that the quarks and leptons get masses from gauge-invariant interactions with Higgs fields.

The relation between the couplings displayed in Eq. (1) and the gauge charges  $z_{fi}^L$  and  $z_{fi}^R$  of the fermions  $f = u, d, \nu, e$  involves the unitary  $3 \times 3$  matrices  $V_f^L$  and  $V_f^R$  that transform the gauge eigenstate fermions  $f_L^i$  and  $f_R^i$ , respectively, into the mass eigenstates. In addition, the  $Z'$  couplings are modified if the new gauge boson in the gauge eigenstate basis ( $\tilde{Z}'_\mu$ ) has a kinetic mixing  $(-\chi/2)B^{\mu\nu}\tilde{Z}'_{\mu\nu}$  with the hypercharge gauge boson  $B^\mu$  (due to a dimension-4 or 6 operator, depending on whether the new gauge symmetry is Abelian or not), or a mass mixing  $\delta M^2 \tilde{Z}'^\mu \tilde{Z}'_\mu$  with the linear combination ( $\tilde{Z}_\mu$ ) of neutral bosons that couples as the SM  $Z$  boson [2]. Since both the kinetic and mass mixings shift the mass and couplings of the  $Z$  boson, electroweak measurements impose upper limits on  $\chi$  and  $\delta M^2/(M_Z^2 - M_{Z'}^2)$  of the order of  $10^{-3}$  [3]. Keeping only

**Table 1:** Examples of generation-independent  $U(1)'$  charges for quarks and leptons. The parameter  $x$  is an arbitrary rational number. Anomaly cancellation requires certain new fermions [4].

fermion	$U(1)_{B-xL}$	$U(1)_{10+x\bar{5}}$	$U(1)_{d-xu}$	$U(1)_{q+xu}$
$(u_L, d_L)$	1/3	1/3	0	1/3
$u_R$	1/3	-1/3	$-x/3$	$x/3$
$d_R$	1/3	$-x/3$	1/3	$(2-x)/3$
$(\nu_L, e_L)$	$-x$	$x/3$	$(-1+x)/3$	-1
$e_R$	$-x$	-1/3	$x/3$	$-(2+x)/3$

linear terms in these two small quantities, the couplings of the mass-eigenstate  $Z'$  boson are given by

$$g_{f_{ij}}^L = g_z V_{f_{ii}'}^L z_{f_{i'j}'}^L (V_f^L)_{ij}^\dagger + \frac{e}{c_W} \left( \frac{s_W \chi M_{Z'}^2 + \delta M^2}{2s_W (M_{Z'}^2 - M_Z^2)} \sigma_f^3 - \epsilon Q_f \right),$$

$$g_{f_{ij}}^R = g_z V_{f_{ii}'}^R z_{f_{i'j}'}^R (V_f^R)_{ij}^\dagger - \frac{e}{c_W} \epsilon Q_f, \quad (2)$$

where  $g_z$  is the new gauge coupling,  $Q_f$  is the electric charge of  $f$ ,  $e$  is the electromagnetic gauge coupling,  $s_W$  and  $c_W$  are the sine and cosine of the weak mixing angle,  $\sigma_f^3 = +1$  for  $f = u, \nu$  and  $\sigma_f^3 = -1$  for  $f = d, e$ , and

$$\epsilon = \frac{\chi (M_{Z'}^2 - c_W^2 M_Z^2) + s_W \delta M^2}{M_{Z'}^2 - M_Z^2}. \quad (3)$$

While an interaction of a  $Z'$  boson with a pair of  $W$  bosons is also allowed, its coupling is typically smaller than the  $\tilde{Z}^\mu \tilde{Z}'_\mu$  mixing.

**$U(1)$  gauge groups.** A simple origin of a  $Z'$  boson is a new  $U(1)'$  gauge symmetry. In that case, the matricial equalities  $z_u^L = z_d^L$  and  $z_\nu^L = z_e^L$  are required by the SM  $SU(2)_W$  gauge symmetry. Given that the  $U(1)'$  interaction is not asymptotically free, the theory may be well-behaved at high energies (for example, by embedding  $U(1)'$  in a non-Abelian gauge group) only if the  $Z'$  couplings are commensurate numbers, *i.e.* any ratio of couplings is a rational number. Satisfying the anomaly cancellation conditions (which include an equation cubic in charges) with rational numbers is highly nontrivial, and in general new fermions charged under  $U(1)'$  are necessary.

Consider first the case where the couplings are generation-independent (the  $V_f$  matrices then disappear from Eq. (2)), so that there are five commensurate couplings:  $g_q^L$ ,  $g_u^R$ ,  $g_d^R$ ,  $g_l^L$ ,  $g_e^R$ . Four sets of charges are displayed in Table 1, each of them spanned by one free parameter,  $x$  [4]. The first set, labelled  $B - xL$ , has charges proportional to the baryon number minus  $x$  times the lepton number. These charges allow all SM Yukawa couplings to a Higgs doublet which is neutral under  $U(1)_{B-xL}$ , so that there is no tree-level  $\tilde{Z} - \tilde{Z}'$  mixing. For  $x = 1$  one recovers the  $U(1)_{B-L}$  group, which is non-anomalous in the presence of one “right-handed neutrino” (a chiral fermion that is a singlet under the SM gauge group) per generation. For

$x \neq 1$ , it is necessary to include some fermions that are vector-like (*i.e.* their mass terms are gauge invariant) with respect to the electroweak gauge group and chiral with respect to  $U(1)_{B-xL}$ . In the particular cases  $x = 0$  or  $x \gg 1$  the  $Z'$  is leptophobic or quark-phobic, respectively.

The second set,  $U(1)_{10+x\bar{5}}$ , has charges that commute with the representations of the  $SU(5)$  grand unified group. Here  $x$  is related to the mixing angle between the two  $U(1)$  bosons encountered in the  $E_6 \rightarrow SU(5) \times U(1) \times U(1)$  symmetry breaking patterns of grand unified theories [1,5]. This set leads to  $\tilde{Z} - \tilde{Z}'$  mass mixing at tree level, such that for a  $Z'$  mass close to the electroweak scale, the measurements at the  $Z$ -pole require some fine tuning between the charges and VEVs of the two Higgs doublets. Vector-like fermions charged under the electroweak gauge group and also carrying color are required (except for  $x = -3$ ) to make this set anomaly free. The particular cases  $x = -3, 1, -1/2$  are usually labelled  $U(1)_\chi$ ,  $U(1)_\psi$ , and  $U(1)_\eta$ , respectively. Under the third set,  $U(1)_{d-xu}$ , the weak-doublet quarks are neutral, and the ratio of  $u_R$  and  $d_R$  charges is  $-x$ . For  $x = 1$  this is the “right-handed” group  $U(1)_R$ . For  $x = 0$ , the charges are those of the  $E_6$ -inspired  $U(1)_I$  group, which requires new quarks and leptons. Other generation-independent sets of  $U(1)'$  charges are given in [6].

In the absence of new fermions charged under the SM group, the most general generation-independent charge assignment is  $U(1)_{q+xu}$ , which is a linear combination of hypercharge and  $B - L$ . Many other anomaly-free solutions exist if generation-dependent charges are allowed. An example is  $B - xL_e - yL_\mu + (y - 3)L_\tau$ , with  $x, y$  free parameters. This allows all fermion masses to be generated by Yukawa couplings to a single Higgs doublet, without inducing tree-level flavor-changing neutral current (FCNC) processes. There are also lepton-flavor dependent charges that allow neutrino masses to arise only from operators of high dimensionality [7].

If the  $SU(2)_W$ -doublet quarks have generation-dependent  $U(1)'$  charges, then the mass eigenstate quarks have flavor off-diagonal couplings to the  $Z'$  boson (see Eq. (1), and note that  $V_u^L (V_d^L)^\dagger$  is the CKM matrix). These are severely constrained by measurements of FCNC processes, which in this case are mediated at tree-level by  $Z'$  boson exchange [8]. The constraints are relaxed if the first and second generation charges are the same, although they are increasingly tightened by the measurements of  $B$  meson properties [9]. If only the  $SU(2)_W$ -singlet quarks have generation-dependent  $U(1)'$  charges, there is more freedom in adjusting the flavor off-diagonal couplings because the  $V_{u,d}^R$  matrices are not observable in the SM.

The anomaly cancellation conditions for  $U(1)'$  could be relaxed only if there is an axion with certain dimension-5 couplings to the gauge bosons. However, such a scenario violates unitarity unless the quantum field theory description breaks down at a scale near  $M_{Z'}$  [10].

**Other models.**  $Z'$  bosons may also arise from larger gauge groups. These may be orthogonal to the electroweak group, as in

## Gauge & Higgs Boson Particle Listings

### New Heavy Bosons

$SU(2)_W \times U(1)_Y \times SU(2)'$ , or may embed the electroweak group, as in  $SU(3)_W \times U(1)$  [11]. If the larger group is spontaneously broken down to  $SU(2)_W \times U(1)_Y \times U(1)'$  at a scale  $v_* \gg M_{Z'}/g_z$ , then the above discussion applies up to corrections of order  $M_{Z'}^2/(g_z v_*)^2$ . For  $v_* \sim M_{Z'}/g_z$ , additional gauge bosons have masses comparable to  $M_{Z'}$ , including at least a  $W'$  boson [11]. If the larger gauge group breaks together with the electroweak symmetry directly to the electromagnetic  $U(1)_{\text{em}}$ , then the left-handed fermion charges are no longer correlated ( $z_u^L \neq z_d^L$ ,  $z_\nu^L \neq z_e^L$ ) and a  $Z'W^+W^-$  coupling is induced.

If the electroweak gauge bosons propagate in extra dimensions, then their Kaluza-Klein (KK) excitations include a series of  $Z'$  boson pairs. Each of these pairs can be associated with a different  $SU(2) \times U(1)$  gauge group in four dimensions. The properties of the KK particles depend strongly on the extra-dimensional theory [12]. For example, in universal extra dimensions there is a parity that forces all couplings of Eq. (1) to vanish in the case of the lightest KK bosons, while allowing couplings to pairs of fermions involving a SM and a heavy vector-like fermion. There are also 4-dimensional gauge theories (e.g. little Higgs with  $T$  parity) with  $Z'$  bosons exhibiting similar properties. By contrast, in a warped extra dimension, the couplings of Eq. (1) may be sizable even when SM fields propagate along the extra dimension.

$Z'$  bosons may also be composite particles. For example, in confining gauge theories [13], the  $\rho$ -like bound state is a spin-1 boson that may be interpreted as arising from a spontaneously broken gauge symmetry [14].

**Resonances versus cascade decays.** In the presence of the couplings shown in Eq. (1), the  $Z'$  boson may be produced in the  $s$ -channel at colliders, and would decay to pairs of fermions. The decay width into a pair of electrons is given by

$$\Gamma(Z' \rightarrow e^+e^-) \simeq \left[ (g_e^L)^2 + (g_e^R)^2 \right] \frac{M_{Z'}}{24\pi}, \quad (4)$$

where small corrections from electroweak loops are not included. The decay width into  $q\bar{q}$  is similar, except for an additional color factor of 3, QCD radiative corrections, and fermion mass corrections. Thus, one may compute the  $Z'$  branching fractions in terms of the couplings of Eq. (1). However, other decay channels, such as  $WW$  or a pair of new particles, could have large widths and need to be added to the total decay width.

As mentioned above, there are theories in which the  $Z'$  couplings are controlled by a discrete symmetry which does not allow decay into a pair of SM particles. Typically, such theories involve several new particles, which may be produced only in pairs and undergo cascade decays through  $Z'$  bosons, leading to signals involving some missing (transverse) energy. Given that the cascade decays depend on the properties of new particles other than the  $Z'$  boson, this case is not discussed further here.

**LEP-II limits.** The  $Z'$  contribution to the cross sections for  $e^+e^- \rightarrow f\bar{f}$  proceeds through an  $s$ -channel  $Z'$  exchange (when  $f = e$ , there are also  $t$ - and  $u$ -channel exchanges). For

$M_{Z'} < \sqrt{s}$ , the  $Z'$  appears as an  $f\bar{f}$  resonance in the radiative return process where photon emission tunes the effective center-of-mass energy to  $M_{Z'}$ . The agreement between the LEP-II measurements and the SM predictions implies that either the  $Z'$  couplings are smaller than or of order  $10^{-2}$ , or else  $M_{Z'}$  is above 209 GeV, the maximum energy of LEP-II. In the latter case, the  $Z'$  effects may be approximated up to corrections of order  $s/M_{Z'}^2$  by the contact interactions

$$\frac{g_z^2}{M_{Z'}^2 - s} [\bar{e}\gamma_\mu (z_e^L P_L + z_e^R P_R) e] [\bar{f}\gamma^\mu (z_f^L P_L + z_f^R P_R) f], \quad (5)$$

where  $P_{L,R}$  are chirality projection operators, and the relation between  $Z'$  couplings and charges (see Eq. (2) in the limit where the mass and kinetic mixings are neglected) is used, assuming generation-independent charges. The four LEP collaborations have set limits on the coefficients of such operators for all possible chiral structures and for various combinations of fermions [15]. Thus, one may derive bounds on  $(M_{Z'}/g_z)|z_e^L z_f^L|^{-1/2}$  and the analogous combinations of  $LR$ ,  $RL$  and  $RR$  charges, which are typically on the order of a few TeV. LEP-II limits were derived [4] on the four sets of charges shown in Table 1.

Somewhat stronger bounds can be set on  $M_{Z'}/g_z$  for specific sets of  $Z'$  couplings if the effects of several operators from Eq. (5) are combined. Dedicated analyses by the LEP collaborations have set limits on  $Z'$  bosons for particular values of the gauge coupling (see section 3.5.2 of [15]).

**Searches at hadron colliders.**  $Z'$  bosons with couplings to quarks (see Eq. (1)) may be produced at hadron colliders in the  $s$ -channel, and would show up as resonances in the invariant mass distribution of the decay products. The cross section for producing a  $Z'$  boson at the LHC which then decays to some  $f\bar{f}$  final state takes the form

$$\sigma(pp \rightarrow Z'X \rightarrow f\bar{f}X) \simeq \frac{\pi}{48s} \sum_q c_q^f w_q(s, M_{Z'}^2) \quad (6)$$

for flavor-diagonal couplings to quarks. Here we have neglected the interference with the SM contribution to  $f\bar{f}$  production, which is a good approximation for a narrow  $Z'$  resonance (deviations from the narrow width approximation are discussed in [16]). The coefficients

$$c_q^f = \left[ (g_q^L)^2 + (g_q^R)^2 \right] B(Z' \rightarrow f\bar{f}) \quad (7)$$

contain all the dependence on the  $Z'$  couplings, while the functions  $w_q$  include all the information about parton distributions and QCD corrections [4,6]. This factorization holds exactly to NLO, and the deviations from it induced at NNLO are very small. Note that the  $w_u$  and  $w_d$  functions are substantially larger than the  $w_q$  functions for the other quarks. Eq. (6) also applies to the Tevatron, except for changing the  $pp$  initial state to  $p\bar{p}$ , which implies that the  $w_q(s, M_{Z'}^2)$  functions are replaced by some other functions  $\bar{w}_q((1.96 \text{ TeV})^2, M_{Z'}^2)$ .

# Gauge & Higgs Boson Particle Listings

## New Heavy Bosons

Although the LHC data are most constraining for many  $Z'$  models, one should be careful in assessing the relative reach of various experiments given the freedom in  $Z'$  couplings. For example, a  $Z'$  coupled to  $B - yL_\mu + (y - 3)L_\tau$  has implications for the muon  $g - 2$ , neutrino oscillations or  $\tau$  decays, and would be hard to see in processes involving first-generation fermions. Moreover, the combination of LHC searches and low-energy measurements could allow a precise determination of the  $Z'$  parameters [41].

### MASS LIMITS for $Z'$ (Heavy Neutral Vector Boson Other Than $Z$ )

#### Limits for $Z'_{SM}$

$Z'_{SM}$  is assumed to have couplings with quarks and leptons which are identical to those of  $Z$ , and decays only to known fermions. The most recent preliminary results can be found in the “ $Z'$ -boson searches” review above.

- 11 ABAZOV 11A, AALTONEN 09T, AALTONEN 07H, and ABULENCIA 06L search for resonances decaying to  $e^+e^-$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV.
- 12 CHATRCHYAN 11 search for resonances decaying to  $e^+e^-$  or  $\mu^+\mu^-$  in  $pp$  collisions at  $\sqrt{s} = 7$  TeV.
- 13 The quoted limit assumes  $g_{WWZ}/g_{WWZ} = (M_{W'}/M_{Z'})^2$ . See their Fig. 4 for limits in mass-coupling plane.
- 14 AALTONEN 09AC search for new particle decaying to dijets.
- 15 AALTONEN 09V search for resonances decaying to  $\mu^+\mu^-$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV.
- 16 ERLER 09 give 95% CL limit on the  $Z$ - $Z'$  mixing  $-0.0026 < \theta < 0.0006$ .
- 17 ABDALLAH 06c use data  $\sqrt{s} = 130$ -207 GeV.
- 18 ABULENCIA 05A search for resonances decaying to electron or muon pairs in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV.
- 19 ACOSTA 05r search for resonances decaying to tau lepton pairs in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV.
- 20 ABBIENDI 04G give 95% CL limit on  $Z$ - $Z'$  mixing  $-0.00422 < \theta < 0.00091$ .  $\sqrt{s} = 91$  to 207 GeV.
- 21 ABAZOV 01B search for resonances in  $p\bar{p} \rightarrow e^+e^-$  at  $\sqrt{s}=1.8$  TeV. They find  $\sigma \cdot B(Z' \rightarrow ee) < 0.06$  pb for  $M_{Z'} > 500$  GeV.
- 22 ABREU 00s uses LEP data at  $\sqrt{s}=90$  to 189 GeV.
- 23 BARATE 00i search for deviations in cross section and asymmetries in  $e^+e^- \rightarrow$  fermions at  $\sqrt{s}=90$  to 183 GeV. Assume  $\theta=0$ . Bounds in the mass-mixing plane are shown in their Figure 18.
- 24 ERLER 99 give 90%CL limit on the  $Z$ - $Z'$  mixing  $-0.0041 < \theta < 0.0003$ .  $\rho_0=1$  is assumed.
- 25 ABE 97s find  $\sigma(Z') \times B(e^+e^-, \mu^+\mu^-) < 40$  fb for  $m_{Z'} > 600$  GeV at  $\sqrt{s}=1.8$  TeV.
- 26 VILAIN 94B assume  $m_t = 150$  GeV.
- 27 ALITTI 93 search for resonances in the two-jet invariant mass. The limit assumes  $B(Z' \rightarrow q\bar{q})=0.7$ . See their Fig. 5 for limits in the  $m_{Z'}-B(q\bar{q})$  plane.
- 28 RIZZO 93 analyses CDF limit on possible two-jet resonances.
- 29 ABE 90F use data for  $R, R_{\ell\ell}$ , and  $A_{\ell\ell}$ . They fix  $m_{W'} = 80.49 \pm 0.43 \pm 0.24$  GeV and  $m_{Z'} = 91.13 \pm 0.03$  GeV.

Limits for  $Z_{LR}$ 

$Z_{LR}$  is the extra neutral boson in left-right symmetric models.  $g_L = g_R$  is assumed unless noted. Values in parentheses assume stronger constraint on the Higgs sector, usually motivated by specific left-right symmetric models (see the Note on the  $W'$ ). Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino. Direct search bounds assume decays to Standard Model fermions only, unless noted.

- 1 DEL-AGUILA 10 give 95% CL limit on the  $Z$ - $Z'$  mixing  $-0.0012 < \theta < 0.0004$ .
- 2 ABE 97s find  $\sigma(Z') \times B(e^+e^-, \mu^+\mu^-) < 40$  fb for  $m_{Z'} > 600$  GeV at  $\sqrt{s}=1.8$  TeV.
- 3 ERLER 09 give 95% CL limit on the  $Z$ - $Z'$  mixing  $-0.0013 < \theta < 0.0006$ .
- 4 ABDALLAH 06c give 95% CL limit  $|\theta| < 0.0028$ . See their Fig. 14 for limit contours in the mass-mixing plane.
- 5 ABBIENDI 04G give 95% CL limit on  $Z$ - $Z'$  mixing  $-0.00098 < \theta < 0.00190$ . See their Fig. 20 for the limit contour in the mass-mixing plane.  $\sqrt{s} = 91$  to 207 GeV.
- 6 CHEUNG 01B limit is derived from bounds on contact interactions in a global electroweak analysis.
- 7 ABREU 00s give 95% CL limit on  $Z$ - $Z'$  mixing  $|\theta| < 0.0018$ . See their Fig. 6 for the limit contour in the mass-mixing plane.  $\sqrt{s}=90$  to 189 GeV.
- 8 BARATE 00i search for deviations in cross section and asymmetries in  $e^+e^- \rightarrow$  fermions at  $\sqrt{s}=90$  to 183 GeV. Assume  $\theta=0$ . Bounds in the mass-mixing plane are shown in their Figure 18.
- 9 CHAY 00 also find  $-0.0003 < \theta < 0.0019$ . For  $g_R$  free,  $m_{Z'} > 430$  GeV.
- 10 ERLER 00 discuss the possibility that a discrepancy between the observed and predicted values of  $Q_W(\text{Cs})$  is due to the exchange of  $Z'$ . The data are better described in a certain class of the  $Z'$  models including  $Z_{LR}$  and  $Z_\chi$ .
- 11 CASALBUONI 99 discuss the discrepancy between the observed and predicted values of  $Q_W(\text{Cs})$ . It is shown that the data are better described in a class of models including the  $Z_{LR}$  model.
- 12 CZAKON 99 perform a simultaneous fit to charged and neutral sectors. Assumes manifest left-right symmetric model. Finds  $|\theta| < 0.0042$ .
- 13 ERLER 99 give 90% CL limit on the  $Z$ - $Z'$  mixing  $-0.0009 < \theta < 0.0017$ .
- 14 ERLER 99 assumes 2 Higgs doublets, transforming as 10 of  $SO(10)$ , embedded in  $E_6$ .
- 15 BARENBOIM 98 also gives 68% CL limits on the  $Z$ - $Z'$  mixing  $-0.0005 < \theta < 0.0033$ . Assumes Higgs sector of minimal left-right model.
- 16 CONRAD 98 limit is from measurements at CCFR, assuming no  $Z$ - $Z'$  mixing.
- 17 VILAIN 94B assume  $m_t = 150$  GeV and  $\theta=0$ . See Fig. 2 for limit contours in the mass-mixing plane.
- 18 RIZZO 93 analyses CDF limit on possible two-jet resonances.
- 19 GRIFOLS 90 limit holds for  $m_{\nu_R} \lesssim 1$  MeV. A specific Higgs sector is assumed. See also GRIFOLS 90D, RIZZO 91.
- 20 BARBIERI 89B limit holds for  $m_{\nu_R} \leq 10$  MeV. Bounds depend on assumed supernova core temperature.

Limits for  $Z_\chi$ 

$Z_\chi$  is the extra neutral boson in  $SO(10) \rightarrow SU(5) \times U(1)_\chi$ .  $g_\chi = e/\cos\theta_W$  is assumed unless otherwise stated. We list limits with the assumption  $\rho=1$  but with no further constraints on the Higgs sector. Values in parentheses assume stronger constraint on the Higgs sector motivated by superstring models. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

## New Heavy Bosons

- 1 AAD 12cc search for resonances decaying to  $e^+e^-$ ,  $\mu^+\mu^-$  in  $pp$  collisions at  $\sqrt{s} = 7$  TeV.
- 2 ERLER 09 give 95% CL limit on the  $Z$ - $Z'$  mixing  $-0.0016 < \theta < 0.0006$ .
- 3 AAD 11AD search for resonances decaying to  $e^+e^-$ ,  $\mu^+\mu^-$  in  $pp$  collisions at  $\sqrt{s} = 7$  TeV.
- 4 AAD 11J search for resonances decaying to  $e^+e^-$  or  $\mu^+\mu^-$  in  $pp$  collisions at  $\sqrt{s} = 7$  TeV.
- 5 AALTONEN 11i search for resonances decaying to  $\mu^+\mu^-$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV.
- 6 ABZOV 11A, AALTONEN 09T, AALTONEN 07H, and ABULENCIA 06L search for resonances decaying to  $e^+e^-$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV.
- 7 DEL-AGUILA 10 give 95% CL limit on the  $Z$ - $Z'$  mixing  $-0.0011 < \theta < 0.0007$ .
- 8 AALTONEN 09v search for resonances decaying to  $\mu^+\mu^-$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV.
- 9 ABDALLAH 06c give 95% CL limit  $|\theta| < 0.0031$ . See their Fig. 14 for limit contours in the mass-mixing plane.
- 10 ABULENCIA 05A search for resonances decaying to electron or muon pairs in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV.
- 11 ABBIENDI 04c give 95% CL limit on  $Z$ - $Z'$  mixing  $-0.00099 < \theta < 0.00194$ . See their Fig. 20 for the limit contour in the mass-mixing plane.  $\sqrt{s} = 91$  to 207 GeV.
- 12 BARGER 03b limit is from the nucleosynthesis bound on the effective number of light neutrinos  $\delta N_\nu < 1$ . The quark-hadron transition temperature  $T_C = 150$  MeV is assumed. The limit with  $T_C = 400$  MeV is  $> 4300$  GeV.
- 13 CHEUNG 01B limit is derived from bounds on contact interactions in a global electroweak analysis.
- 14 ABREU 00s give 95% CL limit on  $Z$ - $Z'$  mixing  $|\theta| < 0.0017$ . See their Fig. 6 for the limit contour in the mass-mixing plane.  $\sqrt{s} = 90$  to 189 GeV.
- 15 BARATE 00i search for deviations in cross section and asymmetries in  $e^+e^- \rightarrow$  fermions at  $\sqrt{s} = 90$  to 183 GeV. Assume  $\theta = 0$ . Bounds in the mass-mixing plane are shown in their Figure 18.
- 16 CHO 00 use various electroweak data to constrain  $Z'$  models assuming  $m_H = 100$  GeV. See Fig. 3 for limits in the mass-mixing plane.
- 17 ERLER 00 discuss the possibility that a discrepancy between the observed and predicted values of  $Q_{WY}(Cs)$  is due to the exchange of  $Z'$ . The data are better described in a certain class of the  $Z'$  models including  $Z'_{LR}$  and  $Z'_X$ .
- 18 ROSNER 00 discusses the possibility that a discrepancy between the observed and predicted values of  $Q_{WY}(Cs)$  is due to the exchange of  $Z'$ . The data are better described in a certain class of the  $Z'$  models including  $Z'_X$ .
- 19 ERLER 99 give 90% CL limit on the  $Z$ - $Z'$  mixing  $-0.0020 < \theta < 0.0015$ .
- 20 ERLER 99 assumes 2 Higgs doublets, transforming as 10 of  $SO(10)$ , embedded in  $E_6$ .
- 21 CONRAD 98 limit is from measurements at CCFR, assuming no  $Z$ - $Z'$  mixing.
- 22 ABE 97s find  $\sigma(Z') \times B(e^+e^-, \mu^+\mu^-) < 40$  fb for  $m_{Z'} > 600$  GeV at  $\sqrt{s} = 1.8$  TeV.
- 23  $Z$ - $Z'$  mixing is assumed to be zero.  $\sqrt{s} = 57.77$  GeV.
- 24 VILAIN 94B assume  $m_t = 150$  GeV and  $\theta = 0$ . See Fig. 2 for limit contours in the mass-mixing plane.
- 25 FARAGGI 91 limit assumes the nucleosynthesis bound on the effective number of neutrinos  $\Delta N_\nu < 0.5$  and is valid for  $m_{\nu_R} < 1$  MeV.
- 26 ABE 90f use data for  $R$ ,  $R_{\ell\ell}$ , and  $A_{\ell\ell}$ . ABE 90f fix  $m_W = 80.49 \pm 0.43 \pm 0.24$  GeV and  $m_Z = 91.13 \pm 0.03$  GeV.
- 27 Assumes the nucleosynthesis bound on the effective number of light neutrinos ( $\delta N_\nu < 1$ ) and that  $\nu_R$  is light ( $\lesssim 1$  MeV).
- 28 GRIFOLS 90 limit holds for  $m_{\nu_R} \lesssim 1$  MeV. See also GRIFOLS 90D, RIZZO 91.

### Limits for $Z_\psi$

$Z_\psi$  is the extra neutral boson in  $E_6 \rightarrow SO(10) \times U(1)_\psi$ .  $g_\psi = e/\cos\theta_W$  is assumed unless otherwise stated. We list limits with the assumption  $\rho = 1$  but with no further constraints on the Higgs sector. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

- 9 ABZOV 11A, AALTONEN 09T, AALTONEN 07H, and ABULENCIA 06L search for resonances decaying to  $e^+e^-$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV.
- 10 CHATRCHYAN 11 search for resonances decaying to  $e^+e^-$  or  $\mu^+\mu^-$  in  $pp$  collisions at  $\sqrt{s} = 7$  TeV.
- 11 AALTONEN 09v search for resonances decaying to  $\mu^+\mu^-$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV.
- 12 ERLER 09 give 95% CL limit on the  $Z$ - $Z'$  mixing  $-0.0018 < \theta < 0.0009$ .
- 13 ABDALLAH 06c give 95% CL limit  $|\theta| < 0.0027$ . See their Fig. 14 for limit contours in the mass-mixing plane.
- 14 ABULENCIA 05A search for resonances decaying to electron or muon pairs in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV.
- 15 ABBIENDI 04c give 95% CL limit on  $Z$ - $Z'$  mixing  $-0.00129 < \theta < 0.00258$ . See their Fig. 20 for the limit contour in the mass-mixing plane.  $\sqrt{s} = 91$  to 207 GeV.
- 16 BARGER 03b limit is from the nucleosynthesis bound on the effective number of light neutrino  $\delta N_\nu < 1$ . The quark-hadron transition temperature  $T_C = 150$  MeV is assumed. The limit with  $T_C = 400$  MeV is  $> 1100$  GeV.
- 17 ABREU 00s give 95% CL limit on  $Z$ - $Z'$  mixing  $|\theta| < 0.0018$ . See their Fig. 6 for the limit contour in the mass-mixing plane.  $\sqrt{s} = 90$  to 189 GeV.
- 18 BARATE 00i search for deviations in cross section and asymmetries in  $e^+e^- \rightarrow$  fermions at  $\sqrt{s} = 90$  to 183 GeV. Assume  $\theta = 0$ . Bounds in the mass-mixing plane are shown in their Figure 18.
- 19 CHO 00 use various electroweak data to constrain  $Z'$  models assuming  $m_H = 100$  GeV. See Fig. 3 for limits in the mass-mixing plane.
- 20 ERLER 99 give 90% CL limit on the  $Z$ - $Z'$  mixing  $-0.0013 < \theta < 0.0024$ .
- 21 CONRAD 98 limit is from measurements at CCFR, assuming no  $Z$ - $Z'$  mixing.
- 22 ABE 97s find  $\sigma(Z') \times B(e^+e^-, \mu^+\mu^-) < 40$  fb for  $m_{Z'} > 600$  GeV at  $\sqrt{s} = 1.8$  TeV.
- 23 VILAIN 94B assume  $m_t = 150$  GeV and  $\theta = 0$ . See Fig. 2 for limit contours in the mass-mixing plane.
- 24 ABE 90f use data for  $R$ ,  $R_{\ell\ell}$ , and  $A_{\ell\ell}$ . ABE 90f fix  $m_W = 80.49 \pm 0.43 \pm 0.24$  GeV and  $m_Z = 91.13 \pm 0.03$  GeV.
- 25 Assumes the nucleosynthesis bound on the effective number of light neutrinos ( $\delta N_\nu < 1$ ) and that  $\nu_R$  is light ( $\lesssim 1$  MeV).
- 26 GRIFOLS 90D limit holds for  $m_{\nu_R} \lesssim 1$  MeV. See also RIZZO 91.

### Limits for $Z_\eta$

$Z_\eta$  is the extra neutral boson in  $E_6$  models, corresponding to  $Q_\eta = \sqrt{3/8} Q_X - \sqrt{5/8} Q_\psi$ .  $g_\eta = e/\cos\theta_W$  is assumed unless otherwise stated. We list limits with the assumption  $\rho = 1$  but with no further constraints on the Higgs sector. Values in parentheses assume stronger constraint on the Higgs sector motivated by superstring models. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

## Indirect Constraints on Kaluza-Klein Gauge Bosons

Bounds on a Kaluza-Klein excitation of the  $Z$  boson or photon in  $d=1$  extra dimension. These bounds can also be interpreted as a lower bound on  $1/R$ , the size of the extra dimension. Unless otherwise stated, bounds assume all fermions live on a single brane and all gauge fields occupy the  $4+d$ -dimensional bulk. See also the section on "Extra Dimensions" in the "Searches" Listings in this Review.

> 3.4	95	9 STRUMIA	99 RVUE	Electroweak

- 1 MUECK 02 limit is  $2\sigma$  and is from global electroweak fit ignoring correlations among observables. Higgs is assumed to be confined on the brane and its mass is fixed. For scenarios of bulk Higgs, of brane-SU(2)<sub>L</sub>, bulk-U(1)<sub>Y</sub>, and of bulk-SU(2)<sub>L</sub>, brane-U(1)<sub>Y</sub>, the corresponding limits are  $> 4.6$  TeV,  $> 4.3$  TeV and  $> 3.0$  TeV, respectively.
- 2 Bound is derived from limits on  $e\nu qq'$  contact interaction, using data from HERA and the Tevatron.
- 3 Bound holds only if first two generations of quarks lives on separate branes. If quark mixing is not complex, then bound lowers to 400 TeV from  $\Delta m_K$ .
- 4 See Figs. 1 and 2 of DELGADO 00 for several model variations. Special boundary conditions can be found which permit KK states down to 950 GeV and that agree with the measurement of  $Q_{WW}(Cs)$ . Quoted bound assumes all Higgs bosons confined to brane; placing one Higgs doublet in the bulk lowers bound to 2.3 TeV.
- 5 Bound is derived from global electroweak analysis assuming the Higgs field is trapped on the matter brane. If the Higgs propagates in the bulk, the bound increases to 3.8 TeV.
- 6 Bound is derived from global electroweak analysis but considering only presence of the KK  $W$  bosons.
- 7 Global electroweak analysis used to obtain bound independent of position of Higgs on brane or in bulk.
- 8 Bounds from effect of KK states on  $G_F, \alpha, M_W$ , and  $M_Z$ . Hard cutoff at string scale determined using gauge coupling unification. Limits for  $d=2,3,4$  rise to 3.5, 5.7, and 7.8 TeV.
- 9 Bound obtained for Higgs confined to the matter brane with  $m_H=500$  GeV. For Higgs in the bulk, the bound increases to 3.5 TeV.

$V_0^\dagger$	1	0	3	1	2/3	$\bar{q}_L \gamma^\mu \ell_L$ or $\bar{d}_R \gamma^\mu e_R$
$\tilde{V}_0^\dagger$	1	0	3	1	5/3	$\bar{u}_R \gamma^\mu e_R$
$V_1^\dagger$	1	0	3	3	2/3	$\bar{q}_L \gamma^\mu \ell_L$

Leptoquarks are hypothetical particles carrying both baryon number (B) and lepton number (L). The possible quantum numbers of leptoquark states can be restricted by assuming that their direct interactions with the ordinary SM fermions are dimensionless and invariant under the standard model (SM) gauge group. Table 1 shows the list of all possible quantum numbers with this assumption [1]. The columns of  $SU(3)_C$ ,  $SU(2)_W$ , and  $U(1)_Y$  in Table 1 indicate the QCD representation, the weak isospin representation, and the weak hypercharge, respectively. The spin of a leptoquark state is taken to be 1 (vector leptoquark) or 0 (scalar leptoquark).

If we do not require leptoquark states to couple directly with SM fermions, different assignments of quantum numbers become possible [2,3].

Leptoquark states are expected to exist in various extensions of SM. The Pati-Salam model [4] is an example predicting the existence of a leptoquark state. Vector leptoquark states also exist in grand unification theories based on  $SU(5)$  [5],  $SO(10)$  [6], which includes Pati-Salam color  $SU(4)$ , and larger gauge groups. Scalar quarks in supersymmetric models with R-parity violation may also have leptoquark-type Yukawa couplings. The bounds on the leptoquark states can therefore be applied to constrain R-parity-violating supersymmetric models [7]. Scalar leptoquarks are expected to exist at TeV scale in extended technicolor models [8,9], where leptoquark states appear as the bound states of techni-fermions. Compositeness of quarks and leptons also provides examples of models which may have light leptoquark states [10].

Bounds on leptoquark states are obtained both directly and indirectly. Direct limits are from their production cross sections at colliders, while indirect limits are calculated from the bounds on the leptoquark-induced four-fermion interactions, which are obtained from low-energy experiments, or from collider experiments below threshold.

If a leptoquark couples to fermions belonging to more than a single generation in the mass eigenbasis of the SM fermions, it can induce four-fermion interactions causing flavor-changing neutral currents and lepton-family-number violations. The quantum number assignment of Table 1 allows several leptoquark states to couple to both left- and right-handed quarks simultaneously. Such leptoquark states are called non-chiral and may cause four-fermion interactions affecting the  $(\pi \rightarrow e\nu)/(\pi \rightarrow \mu\nu)$  ratio [11]. Non-chiral scalar leptoquarks also contribute to the muon anomalous magnetic moment [12,13]. Since indirect limits provide more stringent constraints on these types of leptoquarks, it is often assumed that a leptoquark state couples only to a single generation in a chiral interaction, for which indirect limits become much weaker. Additionally, this assumption gives strong constraints on concrete models of leptoquarks.

Leptoquark states which couple only to left- or right-handed quarks are called chiral leptoquarks. Leptoquark states which couple only to the first (second, third) generation are referred as the first- (second-, third-) generation leptoquarks. Refs. [14,15] give extensive lists of the bounds on the leptoquark-induced four-fermion interactions. For the isoscalar, scalar and vector leptoquarks  $S_0$  and  $V_0$ , for example, which couple with the first- (second-) generation left-handed quark, and the first-generation left-handed lepton, the bounds of Ref. 14 read  $\lambda^2 < 0.03 \times (M_{LQ}/300 \text{ GeV})^2$  for  $S_0$ , and  $\lambda^2 < 0.02 \times (M_{LQ}/300 \text{ GeV})^2$  for  $V_0$  ( $\lambda^2 < 5 \times (M_{LQ}/300 \text{ GeV})^2$  for  $S_0$ , and  $\lambda^2 < 3 \times (M_{LQ}/300 \text{ GeV})^2$  for  $V_0$ ) with  $\lambda$  being the leptoquark coupling strength. The  $e^+e^-$  experiments are sensitive to the indirect effects coming from  $t$ - and  $u$ -channel exchanges of leptoquarks in the  $e^+e^- \rightarrow q\bar{q}$  process. The HERA experiments give bounds on the leptoquark-induced four-fermion interaction. For detailed bounds obtained in this way, see the Boson Particle Listings for ‘‘Indirect Limits for Leptoquarks’’ and its references.

Collider experiments provide direct limits on the leptoquark states through limits on the pair- and single-production cross sections. The leading-order cross sections of the parton processes

$$\begin{aligned}
 q + \bar{q} &\rightarrow LQ + \overline{LQ} \\
 g + g &\rightarrow LQ + \overline{LQ} \\
 e + q &\rightarrow LQ
 \end{aligned} \tag{1}$$

may be written as [16]

$$\begin{aligned}
 \hat{\sigma}_{\text{LO}} [q\bar{q} \rightarrow LQ + \overline{LQ}] &= \frac{2\alpha_s^2 \pi}{27\hat{s}} \beta^3, \\
 \hat{\sigma}_{\text{LO}} [gg \rightarrow LQ + \overline{LQ}] &= \frac{\alpha_s^2 \pi}{96\hat{s}} \\
 &\times \left[ \beta(41 - 31\beta^2) + (18\beta^2 - \beta^4 - 17) \log \frac{1+\beta}{1-\beta} \right], \\
 \hat{\sigma}_{\text{LO}} [eq \rightarrow LQ] &= \frac{\pi\lambda^2}{4} \delta(\hat{s} - M_{LQ}^2)
 \end{aligned} \tag{2}$$

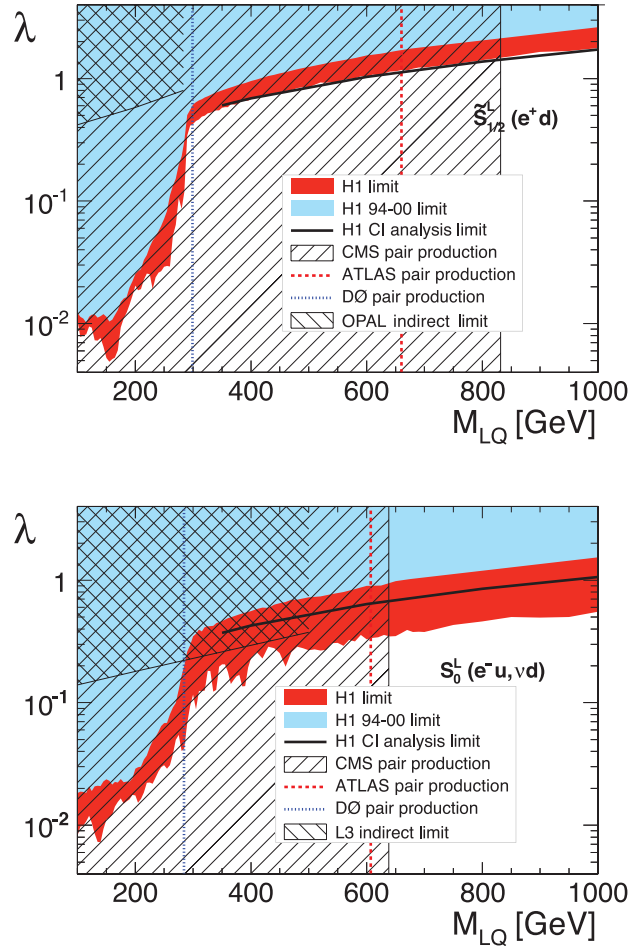

for a scalar leptoquark. Here  $\sqrt{s}$  is the invariant energy of the parton subprocess, and  $\beta \equiv \sqrt{1 - 4M_{LQ}^2/s}$ . Leptoquarks are also produced singly at hadron colliders through  $g + q \rightarrow LQ + \ell$  [17], which allows extending to higher masses the collider reach in the leptoquark search [18], depending on the leptoquark Yukawa coupling.

The LHC, Tevatron and LEP experiments have searched for pair production of the leptoquark states, which arises from the leptoquark gauge interaction. The searches are carried on in signatures including high  $P_T$  leptons,  $E_T$  jets and large missing transverse energy, due to the typical decay of the leptoquark. The gauge couplings of a scalar leptoquark are determined uniquely according to its quantum numbers in Table 1. Since all of the leptoquark states belong to color-triplet representation, the scalar leptoquark pair-production cross section at the Tevatron and LHC is essentially independent from the leptoquark Yukawa coupling and can be determined solely as a function of the leptoquark mass. This is in contrast to the indirect or single-production limits, which give constraints in the leptoquark mass-coupling plane. For the first- and second-generation scalar leptoquark states with decaying branching fraction  $\beta = B(eq) = 1$  and  $\beta = B(\mu q) = 1$ , the CDF and  $D\bar{O}$  experiments obtain the lower bounds on the leptoquark mass  $> 236$  GeV (first generation, CDF) [19],  $> 299$  GeV (first generation,  $D\bar{O}$ ) [20],  $> 226$  GeV (second generation, CDF) [21], and  $> 316$  GeV (second generation,  $D\bar{O}$ ) [22] at 95% CL. Third generation leptoquark mass bounds come from the  $D\bar{O}$  experiment [23] which sets a limit at 247 GeV for a charge  $-1/3$  third generation scalar leptoquark, at 95% C.L.

Recent results from the LHC proton-proton collider, running at a center of mass energy of 7 TeV, extend previous Tevatron mass limits for scalar leptoquarks to  $> 830$  GeV (first generation, CMS,  $\beta = 1$ ) and  $> 640$  GeV (first generation, CMS,  $\beta = 0.5$ ) [24];  $> 660$  GeV (first generation, ATLAS,  $\beta = 1$ ) and  $> 607$  GeV (first generation, ATLAS,  $\beta = 0.5$ ) [25];  $> 1070$  GeV (second generation, CMS,  $\beta = 1$ ) [26] and  $> 785$  GeV (second generation, CMS,  $\beta = 0.5$ ) [26]; and  $> 685$  GeV (second generation, ATLAS,  $\beta = 1$ ) and  $> 594$  GeV (second generation, ATLAS,  $\beta = 0.5$ ) [27]. All limits are at 95% C.L.

Finally new measurements performed by the CMS experiment extend the mass limit to 450 GeV ( $\beta = 0.5$ ) [28] and 525 GeV ( $\beta = 1$ ) [29] for third generation scalar leptoquarks, at 95% C.L. The ATLAS collaboration published a similar limit on third generation scalar leptoquark for the case of  $\beta = 1$  of 525 GeV [30].

The magnetic-dipole-type and the electric-quadrupole-type interactions of a vector leptoquark are not determined even if we fix its gauge quantum numbers as listed in the Table [31]. The production of vector leptoquarks depends in general on additional assumptions that the leptoquark couplings and their pair-production cross sections are enhanced relative to the scalar leptoquark contributions. At the Tevatron for instance, since the acceptance for vector and scalar leptoquark detection is similar, limits on the vector leptoquark mass will be

**Figure 1:** Limits on two typical first-generation scalar leptoquark states in the mass-coupling plane. The upper figure is for a weak-isodoublet, weak-hypercharge  $7/6$ ,  $3B + L = 0$  leptoquark state, while the lower figure for a weak-isosinglet, weak-hypercharge  $-1/3$ ,  $3B + L = 2$  state. Figure adopted from Ref. 36.

more stringent (see for example [37,20]). The leptoquark pair-production cross sections in  $e^+e^-$  collisions depend on the leptoquark  $SU(2)_W \times U(1)_Y$  quantum numbers and Yukawa coupling with electron [32]. The OPAL experiment sets mass bounds on various leptoquark states from the pair-production cross sections [33]. For a second-generation weak-isosinglet weak-hypercharge  $-4/3$  scalar-leptoquark state, for example, the OPAL pair-production bound is  $M_{LQ} > 100$  GeV/ $c^2$  at 95% C.L. The LEP experiments also searched for the single production of the leptoquark states from the process  $e\gamma \rightarrow LQ + q$ .

The most stringent searches for the leptoquark single production are performed by the HERA experiments. Since the leptoquark single-production cross section depends on its Yukawa coupling, the leptoquark mass limits from HERA are usually displayed in the mass-coupling plane. For leptoquark Yukawa coupling  $\lambda = 0.1$ , the ZEUS bounds on the first-generation

## New Heavy Bosons

leptoquarks range from 248 to 290 GeV, depending on the leptoquark species [34]. Recently the H1 Collab. released a comprehensive summary of searches for first generation leptoquarks using the full data sample collected in  $ep$  collisions at HERA ( $446 \text{ pb}^{-1}$ ). No evidence of production of leptoquarks is observed in final states with a large transverse momentum electron or large missing transverse momentum. For a coupling strength  $\lambda = 0.3$ , first generation leptoquarks with masses up to 800 GeV are excluded at 95% C.L. [36].

Fig. 1 summarizes ATLAS, CMS, DØ, LEP, and H1 limits on two typical first-generation scalar-leptoquark states in the mass-coupling plane [36].

The search for LQ will be continued with more LHC data. Early feasibility studies by the LHC experiments ATLAS [38] and CMS [39] indicate that clear signals can be established for masses up to about  $M(\text{LQ})$  1.3 to 1.4 TeV for first- and second-generation scalar LQ, with a likely final reach 1.5 TeV, for collisions at 14 TeV in the center of mass.

- AAD 13AE search for scalar leptoquarks using  $\tau\tau b\bar{b}$  events in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above assumes  $B(\tau b) = 1$ .
- CHATRCHYAN 13M search for scalar and vector leptoquarks decaying to  $\tau b$  in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above is for scalar leptoquarks with  $B(\tau b) = 1$ .
- AAD 12H search for scalar leptoquarks using  $e\bar{e}jj$  and  $e\nu jj$  events in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above assumes  $B(eq) = 1$ . For  $B(eq) = 0.5$ , the limit becomes 607 GeV.
- CHATRCHYAN 12AG search for scalar leptoquarks using  $e\bar{e}jj$  and  $e\nu jj$  events in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above assumes  $B(eq) = 1$ . For  $B(eq) = 0.5$ , the limit becomes 640 GeV.
- CHATRCHYAN 12AG search for scalar leptoquarks using  $\mu\nu jj$  and  $\mu\nu jj$  events in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above assumes  $B(\mu q) = 1$ . For  $B(\mu q) = 0.5$ , the limit becomes 650 GeV.
- AAD 11D search for scalar leptoquarks using  $\mu jj$  and  $\mu\nu jj$  events in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above assumes  $B(\mu q) = 1$ . For  $B(\mu q) = 0.5$ , the limit becomes 362 GeV.
- AAD 12O search for scalar leptoquarks using  $\mu jj$  and  $\mu\nu jj$  events in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above assumes  $B(\mu q) = 1$ . For  $B(\mu q) = 0.5$ , the limit becomes 594 GeV.
- CHATRCHYAN 12BO search for scalar leptoquarks decaying to  $\nu b$  in  $pp$  collisions at  $\sqrt{s} = 7$  TeV. The limit above assumes  $B(\nu b) = 1$ .
- AAD 11D search for scalar leptoquarks using  $e\bar{e}jj$  and  $e\nu jj$  events in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above assumes  $B(eq) = 1$ . For  $B(eq) = 0.5$ , the limit becomes 319 GeV.
- ABAZOV 11V search for scalar leptoquarks using  $e\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The limit above assumes  $B(eq) = 0.5$ .
- CHATRCHYAN 11N search for scalar leptoquarks using  $e\nu jj$  events in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above assumes  $B(eq) = 0.5$ .
- KHACHATRYAN 11D search for scalar leptoquarks using  $e\bar{e}jj$  events in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above assumes  $B(eq) = 1$ .
- KHACHATRYAN 11E search for scalar leptoquarks using  $\mu jj$  events in  $pp$  collisions at  $E_{cm} = 7$  TeV. The limit above assumes  $B(\mu q) = 1$ .
- ABAZOV 10L search for pair productions of scalar leptoquark state decaying to  $\nu b$  in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The limit above assumes  $B(\nu b) = 1$ .
- ABAZOV 09 search for scalar leptoquarks using  $\mu jj$  and  $\mu\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The limit above assumes  $B(\mu q) = 1$ . For  $B(\mu q) = 0.5$ , the limit becomes 270 GeV.
- ABAZOV 09AF search for scalar leptoquarks using  $e\bar{e}jj$  and  $e\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The limit above assumes  $B(eq) = 1$ . For  $B(eq) = 0.5$  the bound becomes 284 GeV.
- AALTONEN 08P search for vector leptoquarks using  $\tau^+\tau^-b\bar{b}$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. Assuming Yang-Mills (minimal) couplings, the mass limit is  $>317$  GeV (251 GeV) at 95% CL for  $B(\tau b) = 1$ .
- Search for pair production of scalar leptoquark state decaying to  $\tau b$  in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The limit above assumes  $B(\tau b) = 1$ .
- Search for scalar leptoquarks using  $\nu\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The limit above assumes  $B(\nu q) = 1$ .
- ABAZOV 07J search for pair productions of scalar leptoquark state decaying to  $\nu b$  in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The limit above assumes  $B(\nu b) = 1$ .
- ABAZOV 06A search for scalar leptoquarks using  $\mu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV and 1.96 TeV. The limit above assumes  $B(\mu q) = 1$ . For  $B(\mu q) = 0.5$ , the limit becomes 204 GeV.
- ABAZOV 06I search for scalar leptoquarks using  $\nu\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV and at 1.96 TeV. The limit above assumes  $B(\nu q) = 1$ .
- ABULENCIA 06T search for scalar leptoquarks using  $\mu jj$ ,  $\mu\nu jj$ , and  $\nu\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The quoted limit assumes  $B(\mu q) = 1$ . For  $B(\mu q) = 0.5$  or 0.1, the bound becomes 208 GeV or 143 GeV, respectively. See their Fig. 4 for the exclusion limit as a function of  $B(\mu q)$ .
- ABAZOV 05H search for scalar leptoquarks using  $e\bar{e}jj$  and  $e\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV and 1.96 TeV. The limit above assumes  $B(eq) = 1$ . For  $B(eq) = 0.5$  the bound becomes 234 GeV.
- ACOSTA 05P search for scalar leptoquarks using  $e\bar{e}jj$ ,  $e\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.96$  TeV. The limit above assumes  $B(eq) = 1$ . For  $B(eq) = 0.5$  and 0.1, the bound becomes 205 GeV and 145 GeV, respectively.
- ABBIENDI 03R search for scalar/vector leptoquarks in  $e^+e^-$  collisions at  $\sqrt{s} = 189-209$  GeV. The quoted limits are for charge  $-4/3$  isospin 0 scalar-leptoquark with  $B(\ell q) = 1$ . See their table 12 for other cases.

- ABAZOV 02 search for scalar leptoquarks using  $\nu\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV. The bound holds for all leptoquark generations. Vector leptoquarks are likewise constrained to lie above 200 GeV.
- ABAZOV 01D search for scalar leptoquarks using  $e\nu jj$ ,  $e\bar{e}jj$ , and  $\nu\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV. The limit above assumes  $B(eq) = 1$ . For  $B(eq) = 0.5$  and 0, the bound becomes 204 and 79 GeV, respectively. Bounds for vector leptoquarks are also given. Supersedes ABBOTT 98E.
- ABBIENDI 00M search for scalar/vector leptoquarks in  $e^+e^-$  collisions at  $\sqrt{s} = 183$  GeV. The quoted limits are for charge  $-4/3$  isospin 0 scalar-leptoquarks with  $B(\ell q) = 1$ . See their Table 8 and Figs. 6-9 for other cases.
- ABBOTT 00c search for scalar leptoquarks using  $\mu jj$ ,  $\mu\nu jj$ , and  $\nu\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV. The limit above assumes  $B(\mu q) = 1$ . For  $B(\mu q) = 0.5$  and 0, the bound becomes 180 and 79 GeV respectively. Bounds for vector leptoquarks are also given.
- AFFOLDER 00k search for scalar leptoquark using  $\nu\nu cc$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV. The quoted limit assumes  $B(\nu c) = 1$ . Bounds for vector leptoquarks are also given.
- AFFOLDER 00k search for scalar leptoquark using  $\nu\nu bb$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV. The quoted limit assumes  $B(\nu b) = 1$ . Bounds for vector leptoquarks are also given.
- ABBOTT 99j search for leptoquarks using  $\mu\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV. The quoted limit is for a scalar leptoquark with  $B(\mu q) = B(\nu q) = 0.5$ . Limits on vector leptoquarks range from 240 to 290 GeV.
- ABBOTT 98E search for scalar leptoquarks using  $e\nu jj$ ,  $e\bar{e}jj$ , and  $\nu\nu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV. The limit above assumes  $B(eq) = 1$ . For  $B(eq) = 0.5$  and 0, the bound becomes 204 and 79 GeV, respectively.
- ABBOTT 98j search for charge  $-1/3$  third generation scalar and vector leptoquarks in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV. The quoted limit is for scalar leptoquark with  $B(\nu b) = 1$ .
- ABE 98s search for scalar leptoquarks using  $\mu jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV. The limit is for  $B(\mu q) = 1$ . For  $B(\mu q) = B(\nu q) = 0.5$ , the limit is  $> 160$  GeV.
- GROSS-PILCHER 98 is the combined limit of the CDF and DØ Collaborations as determined by a joint CDF/DØ working group and reported in this FNAL Technical Memo. Original data published in ABE 97x and ABBOTT 98E.
- ABE 97f search for third generation scalar and vector leptoquarks in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV. The quoted limit is for scalar leptoquark with  $B(\tau b) = 1$ .
- ABE 97x search for scalar leptoquarks using  $e\bar{e}jj$  events in  $p\bar{p}$  collisions at  $E_{cm} = 1.8$  TeV. The limit is for  $B(eq) = 1$ .
- Limit is for charge  $-1/3$  isospin-0 leptoquark with  $B(\ell q) = 2/3$ .
- First and second generation leptoquarks are assumed to be degenerate. The limit is slightly lower for each generation.
- Limits are for charge  $-1/3$ , isospin-0 scalar leptoquarks decaying to  $\ell^+q$  or  $\nu q$  with any branching ratio. See paper for limits for other charge-isospin assignments of leptoquarks.
- KIM 90 assume pair production of charge 2/3 scalar-leptoquark via photon exchange. The decay of the first (second) generation leptoquark is assumed to be any mixture of  $d\bar{e}^+$  and  $u\bar{\nu}$  ( $s\mu^+$  and  $c\tau$ ). See paper for limits for specific branching ratios.
- BARTEL 87b limit is valid when a pair of charge 2/3 spinless leptoquarks X is produced with point coupling, and when they decay under the constraint  $B(X \rightarrow c\bar{\nu}_\mu) + B(X \rightarrow s\mu^+) = 1$ .
- BEHREND 86b assumed that a charge 2/3 spinless leptoquark,  $\chi$ , decays either into  $s\mu^+$  or  $c\tau$ :  $B(X \rightarrow s\mu^+) + B(X \rightarrow c\tau) = 1$ .

## MASS LIMITS for Leptoquarks from Single Production

These limits depend on the  $q$ - $\ell$ -leptoquark coupling  $g_{LQ}$ . It is often assumed that  $g_{LQ}^2/4\pi = 1/137$ . Limits shown are for a scalar, weak isoscalar, charge  $-1/3$  leptoquark.

- ABRAMOWICZ 12A limit is for a scalar, weak isoscalar, charge  $-1/3$  leptoquark coupled with  $e_R$ . See their Figs. 12-17 and Table 4 for states with different quantum numbers.
- Limit from single production in Z decay. The limit is for a leptoquark coupling of electromagnetic strength and assumes  $B(\ell q) = 2/3$ . The limit is 77 GeV if first and second leptoquarks are degenerate.
- AARON 11A search for various leptoquarks with lepton-flavor violating couplings. See their Figs. 2-3 and Tables 1-4 for detailed limits.
- The quoted limit is for a scalar, weak isoscalar, charge  $-1/3$  leptoquark coupled with  $e_R$ . See their Figs. 3-5 for limits on states with different quantum numbers.
- ABAZOV 07E search for leptoquark single production through  $qg$  fusion process in  $p\bar{p}$  collisions. See their Fig. 4 for exclusion plot in mass-coupling plane.
- AKTAS 05B limit is for a scalar, weak isoscalar, charge  $-1/3$  leptoquark coupled with  $e_R$ . See their Fig. 3 for limits on states with different quantum numbers.
- CHEKANOV 05 search for various leptoquarks with lepton-flavor violating couplings. See their Figs. 6-10 and Tables 1-8 for detailed limits.

# Gauge & Higgs Boson Particle Listings

## New Heavy Bosons

- <sup>8</sup> CHEKANOV 03B limit is for a scalar, weak isoscalar, charge  $-1/3$  leptoquark coupled with  $e_p$ . See their Figs. 11–12 and Table 5 for limits on states with different quantum numbers.
- <sup>9</sup> For limits on states with different quantum numbers and the limits in the mass-coupling plane, see their Fig. 4 and Fig. 5.
- <sup>10</sup> CHEKA NOV 02 search for various leptoquarks with lepton-flavor violating couplings. See their Figs. 6–7 and Tables 5–6 for detailed limits.
- <sup>11</sup> For limits on states with different quantum numbers and the limits in the mass-coupling plane, see their Fig. 3.
- <sup>12</sup> See their Fig. 14 for limits in the mass-coupling plane.
- <sup>13</sup> BREITWEG 00E search for  $F=0$  leptoquarks in  $e^+p$  collisions. For limits in mass-coupling plane, see their Fig. 11.
- <sup>14</sup> ABREU 99G limit obtained from process  $e\gamma \rightarrow LQ+q$ . For limits on vector and scalar states with different quantum numbers and the limits in the coupling-mass plane, see their Fig. 4 and Table 2.
- <sup>15</sup> For limits on states with different quantum numbers and the limits in the mass-coupling plane, see their Fig. 13 and Fig. 14. ADLOFF 99 also search for leptoquarks with lepton-flavor violating couplings. ADLOFF 99 supersedes AID 96B.
- <sup>16</sup> DERRICK 97 search for various leptoquarks with lepton-flavor violating couplings. See their Figs. 5–8 and Table 1 for detailed limits.
- <sup>17</sup> DERRICK 93 search for single leptoquark production in  $ep$  collisions with the decay  $e q$  and  $\nu q$ . The limit is for leptoquark coupling of electromagnetic strength and assumes  $B(eq) = B(\nu q) = 1/2$ . The limit for  $B(eq) = 1$  is 176 GeV. For limits on states with different quantum numbers, see their Table 3.

- <sup>1</sup> SAKAKI 13 explain the  $B \rightarrow D^{(*)}\tau\bar{\nu}$  anomaly using Wilson coefficients of leptoquark-induced four-fermion operators.
- <sup>2</sup> KOSNIK 12 obtains limits on leptoquark induced four-fermion interactions from  $b \rightarrow s\ell^+\ell^-$  decays.
- <sup>3</sup> AARON 11c limit is for weak isotriplet spin-0 leptoquark at strong coupling  $\lambda = \sqrt{4\pi}$ . For the limits of leptoquarks with different quantum numbers, see their Table 3. Limits are derived from bounds of  $eq$  contact interactions.
- <sup>4</sup> DORSNER 11 give bounds on scalar, weak singlet, charge 4/3 leptoquark from  $K, B, \tau$  decays, meson mixings,  $LFV, g-2$  and  $Z \rightarrow b\bar{b}$ .
- <sup>5</sup> AKTAS 07A search for lepton-flavor violation in  $ep$  collision. See their Tables 4–7 for limits on lepton-flavor violating four-fermion interactions induced by various leptoquarks.
- <sup>6</sup> SCHAEEL 07A limit is for the weak-isoscalar spin-0 left-handed leptoquark with the coupling of electromagnetic strength. For the limits of leptoquarks with different quantum numbers, see their Table 35.
- <sup>7</sup> SMIRNOV 07 obtains mass limits for the vector and scalar chiral leptoquark states from  $K \rightarrow e\mu, B \rightarrow e\tau$  decays.
- <sup>8</sup> CHEKA NOV 05 search for various leptoquarks with lepton-flavor violating couplings. See their Figs. 6–10 and Tables 1–8 for detailed limits.
- <sup>9</sup> ADLOFF 03 limit is for the weak isotriplet spin-0 leptoquark at strong coupling  $\lambda = \sqrt{4\pi}$ . For the limits of leptoquarks with different quantum numbers, see their Table 3. Limits are derived from bounds on  $e^\pm q$  contact interactions.
- <sup>10</sup> The bound is derived from  $B(B^0 \rightarrow e^\pm\mu^\mp) < 1.7 \times 10^{-7}$ .
- <sup>11</sup> CHEKANOV 02 search for lepton-flavor violation in  $ep$  collisions. See their Tables 1–4 for limits on lepton-flavor violating and four-fermion interactions induced by various leptoquarks.

- <sup>12</sup> CHEUNG 01B quoted limit is for a scalar, weak isoscalar, charge  $-1/3$  leptoquark with a coupling of electromagnetic strength. The limit is derived from bounds on contact interactions in a global electroweak analysis. For the limits of leptoquarks with different quantum numbers, see Table 5.
- <sup>13</sup> ACCIARRI 00P limit is for the weak isoscalar spin-0 leptoquark with the coupling of electromagnetic strength. For the limits of leptoquarks with different quantum numbers, see their Table 4.
- <sup>14</sup> ADLOFF 00 limit is for the weak isotriplet spin-0 leptoquark at strong coupling,  $\lambda = \sqrt{4\pi}$ . For the limits of leptoquarks with different quantum numbers, see their Table 2. ADLOFF 00 limits are from the  $Q^2$  spectrum measurement of  $e^+p \rightarrow e^+X$ .
- <sup>15</sup> BARATE 00I search for deviations in cross section and jet-charge asymmetry in  $e^+e^- \rightarrow \bar{q}q$  due to  $t$ -channel exchange of a leptoquark at  $\sqrt{s}=130$  to 183 GeV. Limits for other scalar and vector leptoquarks are also given in their Table 22.
- <sup>16</sup> BARGER 00 explain the deviation of atomic parity violation in cesium atoms from prediction is explained by scalar leptoquark exchange.
- <sup>17</sup> GABRIELLI 00 calculate various process with lepton flavor violation in leptoquark models.
- <sup>18</sup> ZARNECKI 00 limit is derived from data of HERA, LEP, and Tevatron and from various low-energy data including atomic parity violation. Leptoquark coupling with electromagnetic strength is assumed.
- <sup>19</sup> ABBIENDI 99 limits are from  $e^+e^- \rightarrow q\bar{q}$  cross section at 130–136, 161–172, 183 GeV. See their Fig. 8 and Fig. 9 for limits in mass-coupling plane.
- <sup>20</sup> ABE 98V quoted limit is from  $B(B_S \rightarrow e^\pm\mu^\mp) < 8.2 \times 10^{-6}$ . ABE 98V also obtain a similar limit on  $M_{LQ} > 20.4$  TeV from  $B(B_d \rightarrow e^\pm\mu^\mp) < 4.5 \times 10^{-6}$ . Both bounds assume the non-canonical association of the  $b$  quark with electrons or muons under SU(4).
- <sup>21</sup> ACCIARRI 98J limit is from  $e^+e^- \rightarrow q\bar{q}$  cross section at  $\sqrt{s}=130$ –172 GeV which can be affected by the  $t$ - and  $u$ -channel exchanges of leptoquarks. See their Fig. 4 and Fig. 5 for limits in the mass-coupling plane.
- <sup>22</sup> ACKERSTAFF 98V limits are from  $e^+e^- \rightarrow q\bar{q}$  and  $e^+e^- \rightarrow b\bar{b}$  cross sections at  $\sqrt{s} = 130$ –172 GeV, which can be affected by the  $t$ - and  $u$ -channel exchanges of leptoquarks. See their Fig. 21 and Fig. 22 for limits of leptoquarks in mass-coupling plane.
- <sup>23</sup> DEANDREA 97 limit is for  $\tilde{R}_2$  leptoquark obtained from atomic parity violation (APV). The coupling of leptoquark is assumed to be electromagnetic strength. See Table 2 for limits of the four-fermion interactions induced by various scalar leptoquark exchange. DEANDREA 97 combines APV limit and limits from Tevatron and HERA. See Fig. 1–4 for combined limits of leptoquark in mass-coupling plane.
- <sup>24</sup> DERRICK 97 search for lepton-flavor violation in  $ep$  collision. See their Tables 2–5 for limits on lepton-flavor violating four-fermion interactions induced by various leptoquarks.
- <sup>25</sup> GROSSMAN 97 estimate the upper bounds on the branching fraction  $B \rightarrow \tau^+\tau^-(X)$  from the absence of the  $B$  decay with large missing energy. These bounds can be used to constrain leptoquark induced four-fermion interactions.
- <sup>26</sup> JADACH 97 limit is from  $e^+e^- \rightarrow q\bar{q}$  cross section at  $\sqrt{s}=172.3$  GeV which can be affected by the  $t$ - and  $u$ -channel exchanges of leptoquarks. See their Fig. 1 for limits on vector leptoquarks in mass-coupling plane.
- <sup>27</sup> KUZNETSOV 95B use  $\pi, K, B, \tau$  decays and  $\mu e$  conversion and give a list of bounds on the leptoquark mass and the fermion mixing matrix in the Pati-Salam model. The quoted limit is from  $K_L \rightarrow \mu e$  decay assuming zero mixing.
- <sup>28</sup> MIZUKOSHI 95 calculate the one-loop radiative correction to the  $Z$ -physics parameters in various scalar leptoquark models. See their Fig. 4 for the exclusion plot of third generation leptoquark models in mass-coupling plane.
- <sup>29</sup> BHATTACHARYYA 94 limit is from one-loop radiative correction to the leptonic decay width of the  $Z$ .  $m_H=250$  GeV,  $\alpha_s(m_Z)=0.12$ ,  $m_t=180$  GeV, and the electroweak strength of leptoquark coupling are assumed. For leptoquark coupled to  $\bar{\nu}_L t_R, \bar{\nu}_L \tau, \bar{\nu}_L \tau$ , see Fig. 2 in BHATTACHARYYA 94B erratum and Fig. 3.
- <sup>30</sup> DAVIDSON 94 gives an extensive list of the bounds on leptoquark-induced four-fermion interactions from  $\pi, K, D, B, \mu, \tau$  decays and meson mixings, etc. See Table 15 of DAVIDSON 94 for detail.
- <sup>31</sup> KUZNETSOV 94 gives mixing independent bound of the Pati-Salam leptoquark from the cosmological limit on  $\pi^0 \rightarrow \nu\nu$ .
- <sup>32</sup> LEURER 94, LEURER 94B limits are obtained from atomic parity violation and apply to any chiral leptoquark which couples to the first generation with electromagnetic strength. For a nonchiral leptoquark, universality in  $\pi_{e2}$  decay provides a much more stringent bound.
- <sup>33</sup> MAHANTA 94 gives bounds of  $P$ - and  $T$ -violating scalar-leptoquark couplings from atomic and molecular experiments.
- <sup>34</sup> From  $(\pi \rightarrow e\nu)/(\pi \rightarrow \mu\nu)$  ratio. SHANKER 82 assumes the leptoquark induced four-fermion coupling  $4g^2/M^2 (\bar{\nu}_L e_L u_R) (\bar{d}_L e_R)$  with  $g=0.004$  for spin-0 leptoquark and  $g^2/M^2 (\bar{\nu}_L e_L \gamma_\mu u_L) (\bar{d}_R \gamma^\mu e_R)$  with  $g=0.6$  for spin-1 leptoquark.

- 1 CHATRCHYAN 13A search for new resonance decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 7$  TeV.
- 2 CHATRCHYAN 13As search for new resonance decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 8$  TeV.
- 3 AALTONEN 13R search for new resonance decaying to  $\sigma\sigma$ , with hypothetical strongly interacting  $\sigma$  particle subsequently decaying to 2 jets, in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV, using data corresponding to an integrated luminosity of  $6.6 \text{ fb}^{-1}$ . For  $50 \text{ GeV} < m_\sigma < m_{g_A}/2$ , axigluons in mass range 150–400 GeV are excluded.
- 4 CHATRCHYAN 13AU search for the pair produced color-octet vector bosons decaying to  $q\bar{q}$  pairs in  $pp$  collisions. The quoted limit is for  $B(g_A \rightarrow q\bar{q}) = 1$ .
- 5 ABAZOV 12R search for massive color octet vector particle decaying to  $t\bar{t}$ . The quoted limit assumes  $g_A$  couplings with light quarks are suppressed by 0.2.
- 6 CHATRCHYAN 11Y search for new resonance decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 7$  TeV.
- 7 AALTONEN 10L search for massive color octet non-chiral vector particle decaying into  $t\bar{t}$  pair with mass in the range  $400 \text{ GeV} < M < 800 \text{ GeV}$ . See their Fig. 6 for limit in the mass-coupling plane.
- 8 KHACHATRYAN 10 search for new resonance decaying to dijets in  $pp$  collisions at  $\sqrt{s} = 7$  TeV.
- 9 AALTONEN 09AC search for new narrow resonance decaying to dijets.
- 10 CHOUDHURY 07 limit is from the  $t\bar{t}$  production cross section measured at CDF.
- 11 DONCHESKI 98 compare  $\alpha_s$  derived from low-energy data and that from  $\Gamma(Z \rightarrow \text{hadrons})/\Gamma(Z \rightarrow \text{leptons})$ .
- 12 ABE 97G search for new particle decaying to dijets.
- 13 ABE 95N assume axigluons decaying to quarks in the Standard Model only.
- 14 ABE 93G assume  $\Gamma(g_A) = N\alpha_s m_{g_A}/6$  with  $N = 10$ .
- 15 CUYPERS 91 compare  $\alpha_s$  measured in  $T$  decay and that from  $R$  at PEP/PETRA energies.
- 16 ABE 90H assumes  $\Gamma(g_A) = N\alpha_s m_{g_A}/6$  with  $N = 5$  ( $\Gamma(g_A) = 0.09 m_{g_A}$ ). For  $N = 10$ , the excluded region is reduced to 120–150 GeV.
- 17 ROBINETT 89 result demands partial-wave unitarity of  $J = 0$   $t\bar{t} \rightarrow t\bar{t}$  scattering amplitude and derives a limit  $m_{g_A} > 0.5 m_t$ . Assumes  $m_t > 56 \text{ GeV}$ .
- 18 ALBAJAR 88b result is from the nonobservation of a peak in two-jet invariant mass distribution.  $\Gamma(g_A) < 0.4 m_{g_A}$  assumed. See also BAGGER 88.
- 19 CUYPERS 88 requires  $\Gamma(T \rightarrow g g_A) < \Gamma(T \rightarrow g g g)$ . A similar result is obtained by DONCHESKI 88.
- 20 DONCHESKI 88b requires  $\Gamma(T \rightarrow g q\bar{q})/\Gamma(T \rightarrow g g g) < 0.25$ , where the former decay proceeds via axigluon exchange. A more conservative estimate of  $< 0.5$  leads to  $m_{g_A} > 21 \text{ GeV}$ .

### MASS LIMITS for Color-Octet Scalar Bosons

VALUE (GeV)	CL%	DOCUMENT ID	TECN	COMMENT
none 150–287	95	1 AAD 13k	ATLS	$pp \rightarrow S_8 S_8 X, S_8 \rightarrow 2$ jets
• • • We do not use the following data for averages, fits, limits, etc. • • •				
		1 AAD 13k		search for pair production of color-octet scalar particles in $pp$ collisions at $\sqrt{s} = 7$ TeV. Cross section limits are interpreted as mass limits on scalar partners of a Dirac gluino.

### $X^0$ (Heavy Boson) Searches in $Z$ Decays

Searches for radiative transition of  $Z$  to a lighter spin-0 state  $X^0$  decaying to hadrons, a lepton pair, a photon pair, or invisible particles as shown in the comments. The limits are for the product of branching ratios.

- 1 BARATE 98u obtain limits on  $B(Z \rightarrow \gamma X^0)B(X^0 \rightarrow \ell\bar{\ell}, q\bar{q}, g\bar{g}, \gamma\gamma, \nu\bar{\nu})$ . See their Fig. 17.
- 2 See Fig. 4 of ACCIARRI 97Q for the upper limit on  $B(Z \rightarrow \gamma X^0; E_\gamma > E_{\min})$  as a function of  $E_{\min}$ .
- 3 ACTON 93E give  $\sigma(e^+e^- \rightarrow X^0 \gamma)B(X^0 \rightarrow \gamma\gamma) < 0.4 \text{ pb}$  (95%CL) for  $m_{X^0} = 60 \pm 2.5 \text{ GeV}$ . If the process occurs via  $s$ -channel  $\gamma$  exchange, the limit translates to  $\Gamma(X^0) \cdot B(X^0 \rightarrow \gamma\gamma)^2 < 20 \text{ MeV}$  for  $m_{X^0} = 60 \pm 1 \text{ GeV}$ .
- 4 ABREU 92D give  $\sigma_Z \cdot B(Z \rightarrow \gamma X^0) \cdot B(X^0 \rightarrow \text{hadrons}) < (3-10) \text{ pb}$  for  $m_{X^0} = 10-78 \text{ GeV}$ . A very similar limit is obtained for spin-1  $X^0$ .
- 5 ADRIANI 92F search for isolated  $\gamma$  in hadronic  $Z$  decays. The limit  $\sigma_Z \cdot B(Z \rightarrow \gamma X^0) \cdot B(X^0 \rightarrow \text{hadrons}) < (2-10) \text{ pb}$  (95%CL) is given for  $m_{X^0} = 25-85 \text{ GeV}$ .
- 6 ACTON 91 searches for  $Z \rightarrow Z^* X^0, Z^* \rightarrow e^+e^-, \mu^+\mu^-, \text{ or } \nu\bar{\nu}$ . Excludes any new scalar  $X^0$  with  $m_{X^0} < 9.5 \text{ GeV}/c$  if it has the same coupling to  $ZZ^*$  as the MSM Higgs boson.
- 7 ACTON 91B limits are for  $m_{X^0} = 60-85 \text{ GeV}$ .
- 8 ADEVA 91D limits are for  $m_{X^0} = 30-89 \text{ GeV}$ .
- 9 ADEVA 91D limits are for  $m_{X^0} = 30-86 \text{ GeV}$ .
- 10 AKRAWAY 90J give  $\Gamma(Z \rightarrow \gamma X^0) \cdot B(X^0 \rightarrow \text{hadrons}) < 1.9 \text{ MeV}$  (95%CL) for  $m_{X^0} = 32-80 \text{ GeV}$ . We divide by  $\Gamma(Z) = 2.5 \text{ GeV}$  to get product of branching ratios. For nonresonant transitions, the limit is  $B(Z \rightarrow \gamma q\bar{q}) < 8.2 \text{ MeV}$  assuming three-body phase space distribution.

- 1 ODAKA 89 looked for a narrow or wide scalar resonance in  $e^+e^- \rightarrow \text{hadrons}$  at  $E_{\text{cm}} = 55.0-60.8 \text{ GeV}$ .
- 2 DERRICK 86 found no deviation from the Standard Model Bhabha scattering at  $E_{\text{cm}} = 29 \text{ GeV}$  and set limits on the possible scalar boson  $e^+e^-$  coupling. See their figure 4 for excluded region in the  $\Gamma(X^0 \rightarrow e^+e^-) \cdot m_{X^0}$  plane. Electronic chiral invariance requires a parity doublet of  $X^0$ , in which case the limit applies for  $\Gamma(X^0 \rightarrow e^+e^-) = 3 \text{ MeV}$ .
- 3 ADEVA 85 first limit is from  $2\gamma, \mu^+\mu^-, \text{ hadrons}$  assuming  $X^0$  is a scalar. Second limit is from  $e^+e^-$  channel.  $E_{\text{cm}} = 40-47 \text{ GeV}$ . Supersedes ADEVA 84.
- 4 BERGER 85B looked for effect of spin-0 boson exchange in  $e^+e^- \rightarrow e^+e^- + \mu^+\mu^-$  at  $E_{\text{cm}} = 34.7 \text{ GeV}$ . See Fig. 5 for excluded region in the  $m_{X^0} - \Gamma(X^0)$  plane.
- 5 ADEVA 84 and BEHREND 84c have  $E_{\text{cm}} = 39.8-45.5 \text{ GeV}$ . MARK-J searched  $X^0$  in  $e^+e^- \rightarrow \text{hadrons}, 2\gamma, \mu^+\mu^-, e^+e^-$  and CELLO in the same channels plus  $\tau$  pair. No narrow or broad  $X^0$  is found in the energy range. They also searched for the effect of  $X^0$  with  $m_X > E_{\text{cm}}$ . The second limits are from Bhabha data and for spin-0 singlet. The same limits apply for  $\Gamma(X^0 \rightarrow e^+e^-) = 2 \text{ MeV}$  if  $X^0$  is a spin-0 doublet. The second limit of BEHREND 84c was read off from their figure 2. The original papers also list limits in other channels.

### Search for $X^0$ Resonance in $e^+e^-$ Collisions

The limit is for  $\Gamma(X^0 \rightarrow e^+e^-) \cdot B(X^0 \rightarrow f)$ , where  $f$  is the specified final state. Spin 0 is assumed for  $X^0$ .

## Axions ( $A^0$ ) and Other Very Light Bosons

### Axions ( $A^0$ ) and Other Very Light Bosons, Searches for

#### AXIONS AND OTHER SIMILAR PARTICLES

Revised April 2014 by A. Ringwald (DESY), L.J. Rosenberg and G. Rybka (U. of Washington).

#### Introduction

In this section, we list coupling-strength and mass limits for light neutral scalar or pseudoscalar bosons that couple weakly to normal matter and radiation. Such bosons may arise from a global spontaneously broken U(1) symmetry, resulting in a massless Nambu-Goldstone (NG) boson. If there is a small explicit symmetry breaking, either already in the Lagrangian or due to quantum effects such as anomalies, the boson acquires a mass and is called a pseudo-NG boson. Typical examples are axions ( $A^0$ ) [1,2], familons [3] and Majorons [4], associated, respectively, with a spontaneously broken Peccei-Quinn, family and lepton-number symmetry.

A common characteristic among these light bosons  $\phi$  is that their coupling to Standard-Model particles is suppressed by the energy scale that characterizes the symmetry breaking, *i.e.*, the decay constant  $f$ . The interaction Lagrangian is

$$\mathcal{L} = f^{-1} J^\mu \partial_\mu \phi, \quad (1)$$

where  $J^\mu$  is the Noether current of the spontaneously broken global symmetry. If  $f$  is very large, these new particles interact very weakly. Detecting them would provide a window to physics far beyond what can be probed at accelerators.

Axions are of particular interest because the Peccei-Quinn (PQ) mechanism remains perhaps the most credible scheme to preserve CP in QCD. Moreover, the cold dark matter of the universe may well consist of axions and they are searched for in dedicated experiments with a realistic chance of discovery.

Originally it was assumed that the PQ scale  $f_A$  was related to the electroweak symmetry-breaking scale  $v_{\text{weak}} = (\sqrt{2}G_F)^{-1/2} = 247$  GeV. However, the associated “standard” and “variant” axions were quickly excluded—we refer to the Listings for detailed limits. Here we focus on “invisible axions” with  $f_A \gg v_{\text{weak}}$  as the main possibility.

Axions have a characteristic two-photon vertex, inherited from their mixing with  $\pi^0$  and  $\eta$ . It allows for the main search strategy based on axion-photon conversion in external magnetic fields [5], an effect that also can be of astrophysical interest. While for axions the product “ $A\gamma\gamma$  interaction strength  $\times$  mass” is essentially fixed by the corresponding  $\pi^0$  properties, one may consider more general axion-like particles (ALPs) where the two parameters are independent. Several experiments have recently explored this more general parameter space. ALPs populating the latter are predicted to arise generically, in addition to the axion, in low-energy effective field theories emerging from string theory [6]. The latter often contain also very light Abelian vector bosons under which the Standard-Model particles are not charged: so-called hidden-sector photons, dark photons

or paraphotons. They share a lot of the phenomenological features with the axion and ALPs, notably the possibility of hidden photon - photon conversion. Their physics case and the current constraints are compiled in Ref. [7].

#### I. THEORY

##### I.1 Peccei-Quinn mechanism and axions

The QCD Lagrangian includes a CP-violating term  $\mathcal{L}_\Theta = \bar{\Theta} (\alpha_s/8\pi) G^{\mu\nu a} \tilde{G}_{\mu\nu}^a$ , where  $-\pi \leq \bar{\Theta} \leq +\pi$  is the effective  $\Theta$  parameter after diagonalizing quark masses,  $G$  is the color field strength tensor, and  $\tilde{G}$  its dual. Limits on the neutron electric dipole moment [8] imply  $|\bar{\Theta}| \lesssim 10^{-10}$  even though  $\bar{\Theta} = \mathcal{O}(1)$  is otherwise completely satisfactory. The spontaneously broken global Peccei-Quinn symmetry U(1)<sub>PQ</sub> was introduced to solve this “strong CP problem” [1], an axion being the pseudo-NG boson of U(1)<sub>PQ</sub> [2]. This symmetry is broken due to the axion’s anomalous triangle coupling to gluons,

$$\mathcal{L} = \left( \bar{\Theta} - \frac{\phi_A}{f_A} \right) \frac{\alpha_s}{8\pi} G^{\mu\nu a} \tilde{G}_{\mu\nu}^a, \quad (2)$$

where  $\phi_A$  is the axion field and  $f_A$  the axion decay constant. Color anomaly factors have been absorbed in the normalization of  $f_A$  which is defined by this Lagrangian. Thus normalized,  $f_A$  is the quantity that enters all low-energy phenomena [9]. Non-perturbative QCD effects induce a potential for  $\phi_A$  whose minimum is at  $\phi_A = \bar{\Theta} f_A$ , thereby canceling the  $\bar{\Theta}$  term in the QCD Lagrangian and thus restoring CP symmetry.

The resulting axion mass is given by  $m_A f_A \approx m_\pi f_\pi$  where  $m_\pi = 135$  MeV and  $f_\pi \approx 92$  MeV. In more detail one finds

$$m_A = \frac{z^{1/2}}{1+z} \frac{f_\pi m_\pi}{f_A} = \frac{0.60 \text{ meV}}{f_A/10^{10} \text{ GeV}}, \quad (3)$$

where  $z = m_u/m_d$ . We have used the canonical value  $z = 0.56$  [10], although the range  $z = 0.35-0.60$  is plausible [11].

Originally one assumed  $f_A \sim v_{\text{weak}}$  [1,2]. Tree-level flavor conservation fixes the axion properties in terms of a single parameter  $\tan\beta$ , the ratio of the vacuum expectation values of two Higgs fields that appear as a minimal ingredient. This “standard axion” is excluded after extensive searches [12]. A narrow peak structure observed in positron spectra from heavy ion collisions [13] suggested an axion-like particle of mass 1.8 MeV that decays into  $e^+e^-$ , but extensive follow-up searches were negative. “Variant axion models” were proposed which keep  $f_A \sim v_{\text{weak}}$  while dropping the constraint of tree-level flavor conservation [14], but these models are also excluded [15].

Axions with  $f_A \gg v_{\text{weak}}$  evade all current experimental limits. One generic class of models invokes “hadronic axions” where new heavy quarks carry U(1)<sub>PQ</sub> charges, leaving ordinary quarks and leptons without tree-level axion couplings. The prototype is the KSVZ model [16], where in addition the heavy quarks are electrically neutral. Another generic class requires at least two Higgs doublets and ordinary quarks and leptons carry PQ charges, the prototype being the DFSZ model [17]. All of these models contain at least one electroweak singlet

See key on page 547

## Gauge & Higgs Boson Particle Listings Axions ( $A^0$ ) and Other Very Light Bosons

scalar that acquires a vacuum expectation value and thereby breaks the PQ symmetry. The KSVZ and DFSZ models are frequently used as generic examples, but other models exist where both heavy quarks and Higgs doublets carry PQ charges. In supersymmetric models, the axion is part of a supermultiplet and thus inevitably accompanied by a spin-0 saxion and a spin-1 axino, which both also have couplings suppressed by  $f_A$ , but are expected to have large masses due to supersymmetry breaking [18].

### 1.2 Model-dependent axion couplings

Although the generic axion interactions scale approximately with  $f_\pi/f_A$  from the corresponding  $\pi^0$  couplings, there are non-negligible model-dependent factors and uncertainties. The axion's two-photon interaction plays a key role for many searches,

$$\mathcal{L}_{A\gamma\gamma} = \frac{G_{A\gamma\gamma}}{4} F_{\mu\nu} \tilde{F}^{\mu\nu} \phi_A = -G_{A\gamma\gamma} \mathbf{E} \cdot \mathbf{B} \phi_A, \quad (4)$$

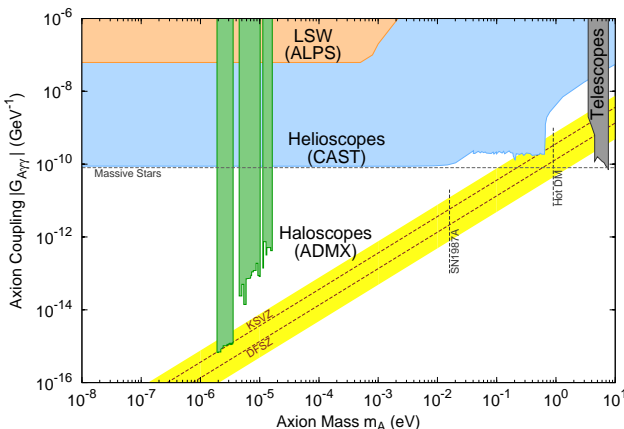

where  $F$  is the electromagnetic field-strength tensor and  $\tilde{F}$  its dual. The coupling constant is

$$\begin{aligned} G_{A\gamma\gamma} &= \frac{\alpha}{2\pi f_A} \left( \frac{E}{N} - \frac{2}{3} \frac{4+z}{1+z} \right) \\ &= \frac{\alpha}{2\pi} \left( \frac{E}{N} - \frac{2}{3} \frac{4+z}{1+z} \right) \frac{1+z}{z^{1/2}} \frac{m_A}{m_\pi f_\pi}, \end{aligned} \quad (5)$$

where  $E$  and  $N$  are the electromagnetic and color anomalies of the axial current associated with the axion. In grand unified models, and notably for DFSZ [17],  $E/N = 8/3$ , whereas for KSVZ [16]  $E/N = 0$  if the electric charge of the new heavy quark is taken to vanish. In general, a broad range of  $E/N$  values is possible [19], as indicated by the yellow band in Figure 1. The two-photon decay width is

$$\Gamma_{A \rightarrow \gamma\gamma} = \frac{G_{A\gamma\gamma}^2 m_A^3}{64\pi} = 1.1 \times 10^{-24} \text{ s}^{-1} \left( \frac{m_A}{\text{eV}} \right)^5. \quad (6)$$

The second expression uses Eq. (5) with  $z = 0.56$  and  $E/N = 0$ . Axions decay faster than the age of the universe if  $m_A \gtrsim 20$  eV.

**Figure 1:** Exclusion plot for axion-like particles as described in the text.

The interaction with fermions  $f$  has derivative form and is invariant under a shift  $\phi_A \rightarrow \phi_A + \phi_0$  as behoves a NG boson,

$$\mathcal{L}_{Aff} = \frac{C_f}{2f_A} \bar{\Psi}_f \gamma^\mu \gamma_5 \Psi_f \partial_\mu \phi_A. \quad (7)$$

Here,  $\Psi_f$  is the fermion field,  $m_f$  its mass, and  $C_f$  a model-dependent coefficient. The dimensionless combination  $g_{Aff} \equiv C_f m_f / f_A$  plays the role of a Yukawa coupling and  $\alpha_{Aff} \equiv g_{Aff}^2 / 4\pi$  of a “fine-structure constant.” The often-used pseudoscalar form  $\mathcal{L}_{Aff} = -i(C_f m_f / f_A) \bar{\Psi}_f \gamma_5 \Psi_f \phi_A$  need not be equivalent to the appropriate derivative structure, for example when two NG bosons are attached to one fermion line as in axion emission by nucleon bremsstrahlung [20].

In the DFSZ model [17], the tree-level coupling coefficient to electrons is

$$C_e = \frac{\cos^2 \beta}{3}, \quad (8)$$

where  $\tan \beta$  is the ratio of two Higgs vacuum expectation values that are generic to this and similar models.

For nucleons,  $C_{n,p}$  are related to axial-vector current matrix elements by generalized Goldberger-Treiman relations,

$$\begin{aligned} C_p &= (C_u - \eta) \Delta u + (C_d - \eta z) \Delta d + (C_s - \eta w) \Delta s, \\ C_n &= (C_u - \eta) \Delta d + (C_d - \eta z) \Delta u + (C_s - \eta w) \Delta s. \end{aligned} \quad (9)$$

Here,  $\eta = (1+z+w)^{-1}$  with  $z = m_u/m_d$  and  $w = m_u/m_s \ll z$  and the  $\Delta q$  are given by the axial vector current matrix element  $\Delta q S_\mu = \langle p | \bar{q} \gamma_\mu \gamma_5 q | p \rangle$  with  $S_\mu$  the proton spin.

Neutron beta decay and strong isospin symmetry considerations imply  $\Delta u - \Delta d = F + D = 1.269 \pm 0.003$ , whereas hyperon decays and flavor SU(3) symmetry imply  $\Delta u + \Delta d - 2\Delta s = 3F - D = 0.586 \pm 0.031$  [21]. The strange-quark contribution is  $\Delta s = -0.08 \pm 0.01_{\text{stat}} \pm 0.05_{\text{sys}}$  from the COMPASS experiment [22], and  $\Delta s = -0.085 \pm 0.008_{\text{exp}} \pm 0.013_{\text{theor}} \pm 0.009_{\text{evol}}$  from HERMES [21], in agreement with each other and with an early estimate of  $\Delta s = -0.11 \pm 0.03$  [23]. We thus adopt  $\Delta u = 0.84 \pm 0.02$ ,  $\Delta d = -0.43 \pm 0.02$  and  $\Delta s = -0.09 \pm 0.02$ , very similar to what was used in the axion literature.

The uncertainty of the axion-nucleon couplings is dominated by the uncertainty  $z = m_u/m_d = 0.35\text{--}0.60$  that we mentioned earlier. For hadronic axions  $C_{u,d,s} = 0$  so that  $-0.51 < C_p < -0.36$  and  $0.10 > C_n > -0.05$ . Therefore it is well possible that  $C_n = 0$  whereas  $C_p$  does not vanish within the plausible  $z$  range. In the DFSZ model,  $C_u = \frac{1}{3} \sin^2 \beta$  and  $C_d = \frac{1}{3} \cos^2 \beta$  and  $C_n$  and  $C_p$  as functions of  $\beta$  and  $z$  do not vanish simultaneously.

The axion-pion interaction is given by the Lagrangian [24]

$$\mathcal{L}_{A\pi} = \frac{C_{A\pi}}{f_\pi f_A} (\pi^0 \pi^+ \partial_\mu \pi^- + \pi^0 \pi^- \partial_\mu \pi^+ - 2\pi^+ \pi^- \partial_\mu \pi^0) \partial_\mu \phi_A, \quad (10)$$

where  $C_{A\pi} = (1-z)/[3(1+z)]$  in hadronic models. The chiral symmetry-breaking Lagrangian provides an additional term  $\mathcal{L}'_{A\pi} \propto (m_\pi^2 / f_\pi f_A) (\pi^0 \pi^0 + 2\pi^- \pi^+) \pi^0 \phi_A$ . For hadronic axions it vanishes identically, in contrast to the DFSZ model (Roberto Peccei, private communication).

## Axions ( $A^0$ ) and Other Very Light Bosons

### II. LABORATORY SEARCHES

#### II.1 Light shining through walls

Searching for “invisible axions” is extremely challenging. The most promising approaches rely on the axion-two-photon vertex, allowing for axion-photon conversion in external electric or magnetic fields [5]. For the Coulomb field of a charged particle, the conversion is best viewed as a scattering process,  $\gamma + Ze \leftrightarrow Ze + A$ , called Primakoff effect [25]. In the other extreme of a macroscopic field, usually a large-scale  $B$ -field, the momentum transfer is small, the interaction coherent over a large distance, and the conversion is best viewed as an axion-photon oscillation phenomenon in analogy to neutrino flavor oscillations [26].

Photons propagating through a transverse magnetic field, with incident  $\mathbf{E}_\gamma$  and magnet  $\mathbf{B}$  parallel, may convert into axions. For  $m_A^2 L/2\omega \ll 2\pi$ , where  $L$  is the length of the  $B$  field region and  $\omega$  the photon energy, the resultant axion beam is coherent with the incident photon beam and the conversion probability is  $\Pi \sim (1/4)(G_{A\gamma\gamma}BL)^2$ . A practical realization uses a laser beam propagating down the bore of a superconducting dipole magnet (like the bending magnets in high-energy accelerators). If another magnet is in line with the first, but shielded by an optical barrier, then photons may be regenerated from the pure axion beam [27]. The overall probability is  $P(\gamma \rightarrow A \rightarrow \gamma) = \Pi^2$ .

The first such experiment utilized two magnets of length  $L = 4.4$  m and  $B = 3.7$  T and found  $G_{A\gamma\gamma} < 6.7 \times 10^{-7}$  GeV $^{-1}$  at 95% CL for  $m_A < 1$  meV [28]. More recently, several such experiments were performed (see Listings) [29,30]. The current best limit,  $G_{A\gamma\gamma} < 0.7 \times 10^{-7}$  GeV $^{-1}$  at 95% CL for  $m_A \lesssim 0.5$  meV, has been achieved by the ALPS (Any Light Particle Search) experiment, which exploited a superconducting HERA dipole magnet and a Fabry-Perot cavity to enhance the laser power on the production side [30], cf. Figure 1. Some of these experiments have also reported limits for scalar bosons where the photon  $\mathbf{E}_\gamma$  must be chosen perpendicular to the magnet  $\mathbf{B}$ .

The concept of resonantly enhanced photon regeneration may open unexplored regions of coupling strength [31]. In this scheme, both the production and detection magnets are within Fabry-Perot optical cavities and actively locked in frequency. The  $\gamma \rightarrow A \rightarrow \gamma$  rate is enhanced by a factor  $2\mathcal{F}\mathcal{F}'/\pi^2$  relative to a single-pass experiment, where  $\mathcal{F}$  and  $\mathcal{F}'$  are the finesses of the two cavities. The resonant enhancement could be of order  $10^{(10-12)}$ , improving the  $G_{A\gamma\gamma}$  sensitivity by  $10^{(2.5-3)}$ . A detailed technical design for ALPS-II, based on this concept and aiming at an improvement of the current laboratory bound on  $G_{A\gamma\gamma}$  by a factor  $\sim 3 \times 10^3$ , has recently been published [32].

Resonantly enhanced photon regeneration has already been exploited in experiments searching for “radiowaves shining through a shielding” [33,34]. For  $m_A \lesssim 10^{-5}$  eV, the upper bound on  $G_{A\gamma\gamma}$  established by the CROWS (CERN Resonant Weakly Interacting sub-eV Particle Search) experiment [35] is comparable to the one set by ALPS.

#### II.2 Photon polarization

An alternative to regenerating the lost photons is to use the beam itself to detect conversion: the polarization of light propagating through a transverse  $B$  field suffers dichroism and birefringence [36]. Dichroism: The  $E_\parallel$  component, but not  $E_\perp$ , is depleted by axion production, causing a small rotation of linearly polarized light. For  $m_A^2 L/2\omega \ll 2\pi$ , the effect is independent of  $m_A$ . For heavier axions, it oscillates and diminishes as  $m_A$  increases, and it vanishes for  $m_A > \omega$ . Birefringence: This rotation occurs because there is mixing of virtual axions in the  $E_\parallel$  state, but not for  $E_\perp$ . Hence, linearly polarized light will develop elliptical polarization. Higher-order QED also induces vacuum birefringence. A search for these effects was performed in the same dipole magnets in the early experiment above [37]. The dichroic rotation gave a stronger limit than the ellipticity rotation:  $G_{A\gamma\gamma} < 3.6 \times 10^{-7}$  GeV $^{-1}$  at 95% CL for  $m_A < 5 \times 10^{-4}$  eV. The ellipticity limits are better at higher masses, as they fall off smoothly and do not terminate at  $m_A$ .

In 2006 the PVLAS collaboration reported a signature of magnetically induced vacuum dichroism that could be interpreted as the effect of a pseudoscalar with  $m_A = 1-1.5$  meV and  $G_{A\gamma\gamma} = (1.6-5) \times 10^{-6}$  GeV $^{-1}$  [38]. Since then, these findings are attributed to instrumental artifacts [39]. This particle interpretation is also excluded by the above photon regeneration searches that were perhaps inspired by the original PVLAS result.

#### II.3 Long-range forces

New bosons would mediate long-range forces, which are severely constrained by “fifth force” experiments [40]. Those looking for new mass-spin couplings provide significant constraints on pseudoscalar bosons [41]. Presently, the most restrictive limits are obtained from combining long-range force measurements with stellar cooling arguments [42]. For the moment, any of these limits are far from realistic values expected for axions. Still, these efforts provide constraints on more general low-mass bosons.

### III. AXIONS FROM ASTROPHYSICAL SOURCES

#### III.1 Stellar energy-loss limits:

Low-mass weakly-interacting particles (neutrinos, gravitons, axions, baryonic or leptonic gauge bosons, *etc.*) are produced in hot astrophysical plasmas, and can thus transport energy out of stars. The coupling strength of these particles with normal matter and radiation is bounded by the constraint that stellar lifetimes or energy-loss rates not conflict with observation [43-45].

We begin this discussion with our Sun and concentrate on hadronic axions. They are produced predominantly by the Primakoff process  $\gamma + Ze \rightarrow Ze + A$ . Integrating over a standard solar model yields the axion luminosity [46]

$$L_A = G_{10}^2 1.85 \times 10^{-3} L_\odot, \quad (11)$$

See key on page 547

## Gauge & Higgs Boson Particle Listings Axions ( $A^0$ ) and Other Very Light Bosons

where  $G_{10} = G_{A\gamma\gamma} \times 10^{10}$  GeV. The maximum of the spectrum is at 3.0 keV, the average at 4.2 keV, and the number flux at Earth is  $G_{10}^2 3.75 \times 10^{11}$  cm $^{-2}$  s $^{-1}$ . The solar photon luminosity is fixed, so axion losses require enhanced nuclear energy production and thus enhanced neutrino fluxes. The all-flavor measurements by SNO together with a standard solar model imply  $L_A \lesssim 0.10 L_\odot$ , corresponding to  $G_{10} \lesssim 7$  [47], mildly superseding a similar limit from helioseismology [48].

A more restrictive limit derives from globular-cluster (GC) stars that allow for detailed tests of stellar-evolution theory. The stars on the horizontal branch (HB) in the color-magnitude diagram have reached helium burning with a core-averaged energy release of about 80 erg g $^{-1}$  s $^{-1}$ , compared to Primakoff axion losses of  $G_{10}^2 30$  erg g $^{-1}$  s $^{-1}$ . The accelerated consumption of helium reduces the HB lifetime by about 80/(80+30  $G_{10}^2$ ). Number counts of HB stars in 15 GCs compared with the number of red giants (that are not much affected by Primakoff losses) reveal agreement with expectations within 20–40% in any one GC and overall on the 10% level [44]. Therefore, a reasonably conservative limit is

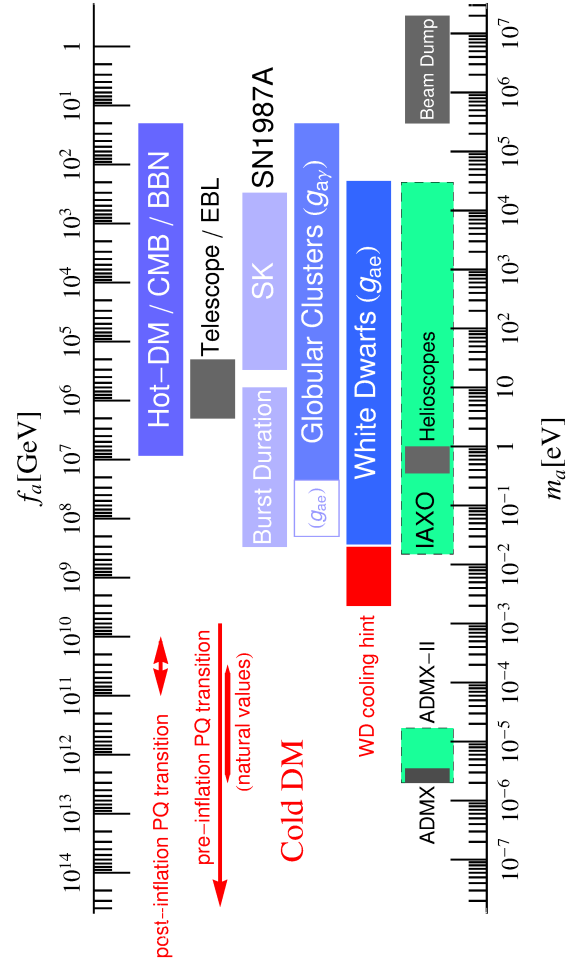

$$G_{A\gamma\gamma} \lesssim 1 \times 10^{-10} \text{ GeV}^{-1}, \quad (12)$$

although a detailed error budget is not available.

Recently, it has been argued that for  $G_{A\gamma\gamma} > 0.8 \times 10^{-10}$  GeV $^{-1}$  the Primakoff flux of axions would shorten the helium-burning phase of massive stars so much that Cepheids could not be observed, thereby excluding such values of the photon coupling [49], cf. Figure 1.

We translate the conservative constraint, Equation 12, on  $G_{A\gamma\gamma}$  to  $f_A > 2.3 \times 10^7$  GeV ( $m_A < 0.3$  eV), using  $z = 0.56$  and  $E/N = 0$  as in the KSVZ model, and show the excluded range in Figure 2. For the DFSZ model with  $E/N = 8/3$ , the corresponding limits are slightly less restrictive,  $f_A > 0.8 \times 10^7$  GeV ( $m_A < 0.7$  eV). The exact high-mass end of the exclusion range has not been determined. The relevant temperature is around 10 keV and the average photon energy is therefore around 30 keV. The excluded  $m_A$  range thus certainly extends beyond the shown 100 keV.

If axions couple directly to electrons, the dominant emission processes are atomic axio-recombination and axio-deexcitation, axio-bremsstrahlung in electron-ion or electron-electron collisions, and Compton scattering [51]. Bremsstrahlung is efficient in white dwarfs (WDs), where the Primakoff and Compton processes are suppressed by the large plasma frequency. The enhanced energy losses would delay helium ignition in GC stars, implying  $\alpha_{Aee} \lesssim 0.5 \times 10^{-26}$  [52]. Enhanced WD cooling led to a similar limit from the WD luminosity function [53]. Based on much better data and detailed WD cooling treatment, today it appears that the WD luminosity function fits better with a new energy-loss channel that can be interpreted in terms of axion losses corresponding to  $\alpha_{Aee} \sim 10^{-27}$  [54]. For pulsationally unstable WDs (ZZ Ceti stars), the period decrease  $\dot{P}/P$  is a measure of the cooling speed. The corresponding observations of the pulsating WDs G117-B15A and R548 imply

**Figure 2:** Exclusion ranges as described in the text. The dark intervals are the approximate CAST and ADMX search ranges, with green regions indicating the planned reach of future upgrades. Limits on coupling strengths are translated into limits on  $m_A$  and  $f_A$  using  $z = 0.56$  and the KSVZ values for the coupling strengths. The “Beam Dump” bar is a rough representation of the exclusion range for standard or variant axions. The “Globular Clusters” and “White Dwarfs” ranges uses the DFSZ model with an axion-electron coupling corresponding to  $\cos^2 \beta = 1/2$ . The Cold Dark Matter exclusion range is particularly uncertain; ranges for pre-inflation and post-inflation Peccei-Quinn transitions are shown. Figure adapted from [49].

additional cooling that can be interpreted in terms of similar axion losses [55]. At the moment we prefer to interpret these results as an upper limit  $\alpha_{Aee} \lesssim 10^{-27}$  shown in Figure 2.

Similar constraints derive from the measured duration of the neutrino signal of the supernova SN 1987A. Numerical simulations for a variety of cases, including axions and Kaluza-Klein gravitons, reveal that the energy-loss rate of a nuclear medium at the density  $3 \times 10^{14}$  g cm $^{-3}$  and temperature 30 MeV should

# Gauge & Higgs Boson Particle Listings

## Axions ( $A^0$ ) and Other Very Light Bosons

not exceed about  $1 \times 10^{19}$  erg  $\text{g}^{-1}$   $\text{s}^{-1}$  [44]. The energy-loss rate from nucleon bremsstrahlung,  $N + N \rightarrow N + N + A$ , is  $(C_N/2f_A)^2(T^4/\pi^2m_N)F$ . Here  $F$  is a numerical factor that represents an integral over the dynamical spin-density structure function because axions couple to the nucleon spin. For realistic conditions, even after considerable effort, one is limited to a heuristic estimate leading to  $F \approx 1$  [45].

The SN 1987A limits are of particular interest for hadronic axions where the bounds on  $\alpha_{Aee}$  are moot. Within uncertainties of  $z = m_u/m_d$  a reasonable choice for the coupling constants is then  $C_p = -0.4$  and  $C_n = 0$ . Using a proton fraction of 0.3,  $F = 1$ , and  $T = 30$  MeV one finds [45]

$$f_A \gtrsim 4 \times 10^8 \text{ GeV} \quad \text{and} \quad m_A \lesssim 16 \text{ meV}. \quad (13)$$

If axions interact sufficiently strongly they are trapped. Only about three orders of magnitude in  $g_{ANN}$  or  $m_A$  are excluded, a range shown somewhat schematically in Figure 2. For even larger couplings, the axion flux would have been negligible, yet it would have triggered additional events in the detectors, excluding a further range [56]. A possible gap between these two SN 1987A arguments was discussed as the “hadronic axion window” under the assumption that  $G_{A\gamma\gamma}$  was anomalously small [57]. This range is now excluded by hot dark matter bounds (see below).

The very tentative indication for additional WD cooling by axion emission described above is not in conflict with SN 1987A bounds. Still, if the WD interpretation were correct, SNe would lose a large fraction of their energy as axions. This would lead to a diffuse SN axion background (DSAB) in the universe with an energy density comparable to the extra-galactic background light [58]. However, there is no apparent way of detecting it or the axion burst from the next nearby SN.

### III.2 Searches for solar axions and ALPs

Instead of using stellar energy losses to derive axion limits, one can also search directly for these fluxes, notably from the Sun. The main focus has been on axion-like particles with a two-photon vertex. They are produced by the Primakoff process with a flux given by Equation 11 and an average energy of 4.2 keV, and can be detected at Earth with the reverse process in a macroscopic  $B$ -field (“axion helioscope”) [5]. In order to extend the sensitivity in mass towards larger values, one can endow the photon with an effective mass in a gas,  $m_\gamma = \omega_{\text{plas}}$ , thus matching the axion and photon dispersion relations [59].

An early implementation of these ideas used a conventional dipole magnet, with a conversion volume of variable-pressure gas with a xenon proportional chamber as x-ray detector [60]. The conversion magnet was fixed in orientation and collected data for about 1000 s/day. Axions were excluded for  $G_{A\gamma\gamma} < 3.6 \times 10^{-9}$   $\text{GeV}^{-1}$  for  $m_A < 0.03$  eV, and  $G_{A\gamma\gamma} < 7.7 \times 10^{-9}$   $\text{GeV}^{-1}$  for  $0.03 < m_A < 0.11$  eV at 95% CL.

Later, the Tokyo axion helioscope used a superconducting magnet on a tracking mount, viewing the Sun continuously.

They reported  $G_{A\gamma\gamma} < 6 \times 10^{-10}$   $\text{GeV}^{-1}$  for  $m_A < 0.3$  eV [61]. This experiment was recommissioned and a similar limit for masses around 1 eV was reported [62].

The most recent helioscope CAST (CERN Axion Solar Telescope) uses a decommissioned LHC dipole magnet on a tracking mount. The hardware includes grazing-incidence x-ray optics with solid-state x-ray detectors, as well as a novel x-ray Micromegas position-sensitive gaseous detector. CAST has established a 95% CL limit  $G_{A\gamma\gamma} < 8.8 \times 10^{-11}$   $\text{GeV}^{-1}$  for  $m_A < 0.02$  eV [46]. To cover larger masses, the magnet bores are filled with a gas at varying pressure. The runs with  $^4\text{He}$  cover masses up to about 0.4 eV [63], providing the  $^4\text{He}$  limits shown in Figure 1. To cover yet larger masses,  $^3\text{He}$  was used to achieve a larger pressure at cryogenic temperatures. Limits up to 1.17 eV were recently published [64], allowing CAST to “cross the axion line” for the KSVZ model (Figure 1).

Going to yet larger masses in a helioscope search is not well motivated because of the cosmic hot dark matter bound of  $m_A \lesssim 0.7$  eV (see below). Sensitivity to significantly smaller values of  $G_{A\gamma\gamma}$  can be achieved with a next-generation axion helioscope with a much larger magnetic-field cross section. Realistic design options for this “International Axion Observatory” (IAXO) have been studied in some detail [65]. Such a next-generation axion helioscope may also push the sensitivity in the product of couplings to photons and to electrons,  $G_{A\gamma\gamma}g_{Aee}$ , into a range beyond stellar energy-loss limits and test the hypothesis that WD cooling is dominated by axion emission [66].

Other Primakoff searches for solar axions and ALPs have been carried out using crystal detectors, exploiting the coherent conversion of axions into photons when the axion angle of incidence satisfies a Bragg condition with a crystal plane [67]. However, none of these limits is more restrictive than the one derived from the constraint on the solar axion luminosity ( $L_A \lesssim 0.10 L_\odot$ ) discussed earlier.

Another idea is to look at the Sun with an x-ray satellite when the Earth is in between. Solar axions and ALPs would convert in the Earth magnetic field on the far side and could be detected [68]. The sensitivity to  $G_{A\gamma\gamma}$  could be comparable to CAST, but only for much smaller  $m_A$ . Deep solar x-ray measurements with existing satellites, using the solar magnetosphere as conversion region, have reported preliminary limits on  $G_{A\gamma\gamma}$  [69].

### III.3 Conversion of astrophysical photon fluxes

Large-scale  $B$  fields exist in astrophysics that can induce axion-photon oscillations. In practical cases,  $B$  is much smaller than in the laboratory, whereas the conversion region  $L$  is much larger. Therefore, while the product  $BL$  can be large, realistic sensitivities are usually restricted to very low-mass particles, far away from the “axion band” in a plot like Figure 1.

One example is SN 1987A, which would have emitted a burst of axion-like particles (ALPs) due to the Primakoff production in its core. They would have partially converted into  $\gamma$ -rays in the galactic  $B$ -field. The absence of a  $\gamma$ -ray

See key on page 547

## Gauge & Higgs Boson Particle Listings Axions ( $A^0$ ) and Other Very Light Bosons

burst in coincidence with SN 1987A neutrinos provides a limit  $G_{A\gamma\gamma} \lesssim 1 \times 10^{-11} \text{ GeV}^{-1}$  for  $m_A \lesssim 10^{-9} \text{ eV}$  [70].

Magnetically induced oscillations between photons and axion-like particles (ALPs) can modify the photon fluxes from distant sources in various ways, featuring (i) frequency-dependent dimming, (ii) modified polarization, and (iii) avoiding absorption by propagation in the form of axions.

For example, dimming of SNe Ia could influence the interpretation in terms of cosmic acceleration [71], although it has become clear that photon-ALP conversion could only be a subdominant effect [72]. Searches for linearly polarised emission from magnetised white dwarfs [73] and changes of the linear polarisation from radio galaxies (see, e.g., Ref. [74]) provide limits close to  $G_{A\gamma\gamma} \sim 10^{-11} \text{ GeV}^{-1}$ , for masses  $m_A \lesssim 10^{-7} \text{ eV}$  and  $m_A \lesssim 10^{-15} \text{ eV}$ , respectively, albeit with uncertainties related to the underlying assumptions. Even stronger limits,  $G_{A\gamma\gamma} \lesssim 2 \times 10^{-13} \text{ GeV}^{-1}$ , for  $m_A \lesssim 10^{-14} \text{ eV}$ , have been obtained by exploiting high-precision measurements of quasar polarisations [75].

Remarkably, it appears that the universe could be too transparent to TeV  $\gamma$ -rays that should be absorbed by pair production on the extra-galactic background light [76]. The situation is not conclusive at present, but the possible role of photon-ALP oscillations in TeV  $\gamma$ -ray astronomy is tantalizing [77]. Fortunately, the region in ALP parameter space,  $G_{A\gamma\gamma} \sim 10^{-12} - 10^{-10} \text{ GeV}^{-1}$  for  $m_A \lesssim 10^{-7} \text{ eV}$  [78], required to explain the anomalous TeV transparency of the universe, could be conceivably probed by the next generation of laboratory experiments (ALPS-II) and helioscopes (IAXO) mentioned above.

### IV. COSMIC AXIONS

#### IV.1 Cosmic axion populations

In the early universe, axions are produced by processes involving quarks and gluons [79]. After color confinement, the dominant thermalization process is  $\pi + \pi \leftrightarrow \pi + A$  [24]. The resulting axion population would contribute a hot dark matter component in analogy to massive neutrinos. Cosmological precision data provide restrictive constraints on a possible hot dark-matter fraction that translate into  $m_A \lesssim 0.9 \text{ eV}$  [80], but in detail depend on the used data set and assumed cosmological model.

For  $m_A \gtrsim 20 \text{ eV}$ , axions decay fast on a cosmic time scale, removing the axion population while injecting photons. This excess radiation provides additional limits up to very large axion masses [81]. An anomalously small  $G_{A\gamma\gamma}$  provides no loophole because suppressing decays leads to thermal axions overdominating the mass density of the universe.

The main cosmological interest in axions derives from their possible role as cold dark matter (CDM). In addition to thermal processes, axions are abundantly produced by the “vacuum re-alignment mechanism” [82] and the decay of topological defects (axion strings and domain walls) [83]. After the breakdown of the PQ symmetry, the axion field relaxes somewhere in the

“bottom of the wine bottle” potential. Near the QCD epoch, instanton effects explicitly break the PQ symmetry, the very effect that causes dynamical PQ symmetry restoration. This “tilting of the wine bottle” drives the axion field toward the CP-conserving minimum, thereby exciting coherent oscillations of the axion field that ultimately represent a condensate of CDM, with a density that depends on the initial value of the field before the start of the oscillations,  $-\pi \leq \bar{\Theta}_i = \phi_A(t_i)/f_A \leq \pi$ . Moreover, discrete domains, with vacuum angles differing by  $2\pi$ , form after the QCD transition and at their borders topological defects form. These defects decay and radiate non-relativistic axions which eventually add up to the re-alignment population.

The expected cosmic mass density axions depends on whether inflation happens after or before the PQ symmetry breakdown. In the former case, the topological defects are diluted away and the fractional cosmic mass density in axions is solely produced by the vacuum re-alignment mechanism [84],

$$\begin{aligned} \Omega_A^{\text{vr}} h^2 &\approx 0.11 \left( \frac{f_A}{5 \times 10^{11} \text{ GeV}} \right)^{1.184} F \bar{\Theta}_i^2 \\ &= 0.11 \left( \frac{12 \text{ } \mu\text{eV}}{m_A} \right)^{1.184} F \bar{\Theta}_i^2, \end{aligned} \quad (14)$$

and depends on the initial value  $\bar{\Theta}_i$  attained in the causally connected region which evolved into today’s observable universe. Here,  $h$  is today’s Hubble expansion parameter in units of  $100 \text{ km s}^{-1} \text{ Mpc}^{-1}$ , and  $F = F(\bar{\Theta}_i, f_A)$  is a factor accounting for anharmonicities in the axion potential. For  $F \bar{\Theta}_i^2 = \mathcal{O}(1)$ ,  $m_A$  should be above  $\sim 10 \text{ } \mu\text{eV}$  in order that the cosmic axion density does not exceed the observed CDM density,  $\Omega_{\text{CDM}} h^2 = 0.11$ . However, much smaller axion masses (much higher PQ scales) would still be possible if the initial value  $\bar{\Theta}_i$  was small (“anthropic axion window” [85]).

However, this window may have been closed recently by measurements of fluctuations in the cosmic microwave background. In fact, if the PQ phase transition happens before inflation, the axion field is present during inflation and thus subject to quantum fluctuations, leading to isocurvature fluctuations that are severely constrained by observations [86]. These isocurvature constraints, combined with the recent measurement of a tensor to scalar ratio  $r = 0.2_{-0.05}^{+0.07}$  by the cosmic microwave background polarimeter experiment BICEP2 [87] strongly disfavor scenarios with preinflationary PQ symmetry breaking [88], i.e. for which

$$f_A > \frac{H_I}{2\pi} \simeq 1.8 \times 10^{13} \text{ GeV} \left( \frac{r}{0.2} \right)^{1/2}, \quad m_A \lesssim 0.3 \text{ } \mu\text{eV} \left( \frac{r}{0.2} \right)^{-1/2},$$

where  $H_I$  is the Hubble scale during inflation. It remains to be seen whether the BICEP2 observations will be confirmed by PLANCK later in this year.

This tentatively leaves us either with scenarios in which there is no PQ symmetry during inflation and no phase transition at all [89] or scenarios in which the PQ symmetry breakdown takes place after inflation. In the latter case,  $\bar{\Theta}_i$

## Gauge & Higgs Boson Particle Listings Axions ( $A^0$ ) and Other Very Light Bosons

will take on different values in different patches of the universe, resulting in an average contribution from the vacuum re-alignment mechanism of [84]

$$\Omega_A^{\text{vr}} h^2 \approx 0.11 \left( \frac{40 \mu\text{eV}}{m_A} \right)^{1.184}. \quad (15)$$

However, the additional contribution from the decay of topological defects suffers from significant uncertainties. According to Sikivie and collaborators, these populations are comparable to the re-alignment contribution [83]. Other groups find a significantly enhanced axion density [90] or rather, a larger  $m_A$  value for axions providing CDM,

$$\Omega_A^{\text{td}} h^2 \approx 0.11 \left( \frac{400 \mu\text{eV}}{m_A} \right)^{1.184}. \quad (16)$$

Moreover, the spatial axion density variations are large at the QCD transition and they are not erased by free streaming. When matter begins to dominate the universe, gravitationally bound “axion mini clusters” form promptly [91]. A significant fraction of CDM axions can reside in these bound objects.

In R-parity conserving supersymmetric models, more possibilities arise: cold dark matter might be a mixture of axions along with the lightest SUSY particle (LSP) [18]. Candidates for the LSP include the lightest neutralino, the gravitino, the axino, or a sneutrino. In the case of a neutralino LSP, saxion and axino production in the early universe have a strong impact on the neutralino and axion abundance. The former almost always gets increased beyond its thermal-production-only value, favoring then models with higgsino-like or wino-like neutralinos [92]. For large values of  $f_A$ , saxions from the vacuum re-alignment mechanism may produce large relic dilution via entropy dumping, thus allowing for much larger values of  $f_A$ , sometimes as high as approaching the GUT scale,  $\sim 10^{16}$  GeV, for natural values of the initial re-alignment angle. Then the dark matter may be either neutralino- or axion-dominated, or a comparable mixture. In such scenarios, one might expect eventual direct detection of both relic neutralinos and relic axions.

Finally, it is worth mentioning that the non-thermal production mechanisms attributed to axions are indeed generic to bosonic weakly interacting ultra-light particles such as ALPs: a wide range in  $G_{A\gamma\gamma} - m_A$  parameter space outside the axion band can generically contain models with adequate CDM density [93].

### IV.2 Telescope searches

The two-photon decay is extremely slow for axions with masses in the CDM regime, but could be detectable for eV masses. The signature would be a quasi-monochromatic emission line from galaxies and galaxy clusters. The expected optical line intensity for DFSZ axions is similar to the continuum night emission. An early search in three rich Abell clusters [94], and a recent search in two rich Abell clusters [95], exclude the “Telescope” range in Figure 1 and Figure 2 unless the axion-photon coupling is strongly suppressed. Of course,

axions in this mass range would anyway provide an excessive hot DM contribution.

Very low-mass axions in halos produce a weak quasi-monochromatic radio line. Virial velocities in undisrupted dwarf galaxies are very low, and the axion decay line would therefore be extremely narrow. A search with the Haystack radio telescope on three nearby dwarf galaxies provided a limit  $G_{A\gamma\gamma} < 1.0 \times 10^{-9}$  GeV $^{-1}$  at 96% CL for  $298 < m_A < 363$   $\mu\text{eV}$  [96]. However, this combination of  $m_A$  and  $G_{A\gamma\gamma}$  does not exclude plausible axion models.

### IV.3 Microwave cavity experiments

The limits of Figure 2 suggest that axions, if they exist, provide a significant fraction or even perhaps all of the cosmic CDM. In a broad range of the plausible  $m_A$  range for CDM, galactic halo axions may be detected by their resonant conversion into a quasi-monochromatic microwave signal in a high-Q electromagnetic cavity permeated by a strong static  $B$  field [5,97]. The cavity frequency is tunable, and the signal is maximized when the frequency is the total axion energy, rest mass plus kinetic energy, of  $\nu = (m_A/2\pi) [1 + \mathcal{O}(10^{-6})]$ , the width above the rest mass representing the virial distribution in the galaxy. The frequency spectrum may also contain finer structure from axions more recently fallen into the galactic potential and not yet completely virialized [98].

The feasibility of this technique was established in early experiments of relatively small sensitive volume,  $\mathcal{O}(1)$  liter), with HFET-based amplifiers, setting limits in the range  $4.5 < m_A < 16.3$   $\mu\text{eV}$  [99], but lacking by 2–3 orders of magnitude the sensitivity required to detect realistic axions. Later, ADMX ( $B \sim 8$  T,  $V \sim 200$  liters) has achieved sensitivity to KSVZ axions, assuming they saturate the local dark matter density and are well virialized, over the mass range 1.9–3.3  $\mu\text{eV}$  [100]. Should halo axions have a significant component not yet virialized, ADMX is sensitive to DFSZ axions [101]. The corresponding 90% CL exclusion regions shown in Figure 3 are normalized to an assumed local CDM density of  $7.5 \times 10^{-25}$  g cm $^{-3}$  (450 MeV cm $^{-3}$ ). More recently the ADMX experiment commissioned an upgrade [102] that replaces the microwave HFET amplifiers by near quantum-limited low-noise dc SQUID microwave amplifiers [103], allowing for a significantly improved sensitivity [104]. This apparatus is also sensitive to other hypothetical light bosons, such as hidden photons or chameleons, over a limited parameter space [93,105]. Alternatively, a Rydberg atom single-photon detector [106] can in principle evade the standard quantum limit for coherent photon detection.

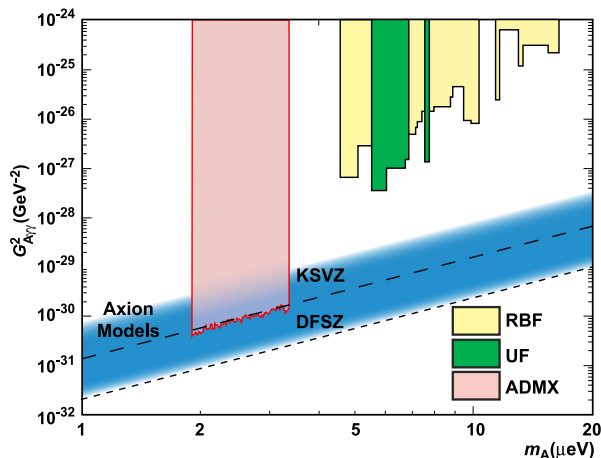

Other new concepts for searching for axion dark matter are also being investigated. Photons from dark matter axions or ALPs could be focused in a manner similar to a dish antenna instead of a resonant cavity [107]. The oscillating galactic dark matter axion field induces extremely small oscillating nuclear electric dipole moments. Conceivably these could be detected by exploiting NMR techniques or molecular interferometry [108], which are most sensitive in the range of low

See key on page 547

### Axions ( $A^0$ ) and Other Very Light Bosons

**Figure 3:** Exclusion region reported from the microwave cavity experiments RBF and UF [99] and ADMX [100]. A local dark-matter density of  $450 \text{ MeV cm}^{-3}$  is assumed.

oscillation frequencies corresponding to sub-neV axion masses. The reach of these techniques in practice remains to be seen.

#### Conclusions

There is a strengthening physics case for very weakly coupled ultralight particles beyond the Standard Model. The elegant solution of the strong CP problem proposed by Peccei and Quinn yields a particularly strong motivation for the axion. In many theoretically appealing ultraviolet completions of the Standard Model axions and axion-like particles occur automatically. Moreover, they are natural cold dark matter candidates. May be the first hints of their existence has already been seen in the anomalous cooling of white dwarfs and the anomalous transparency of the Universe for VHE gamma rays. Interestingly, a significant portion of previously unexplored, but phenomenologically very interesting and theoretically very well motivated axion and ALP parameter space can be tackled in the foreseeable future by a number of terrestrial experiments searching for axion/ALP dark matter, for solar axions/ALPs, and for light apparently shining through a wall.

#### $A^0$ (Axion) MASS LIMITS from Astrophysics and Cosmology

These bounds depend on model-dependent assumptions (i.e. — on a combination of axion parameters).

VALUE (MeV)	DOCUMENT ID	TECN	COMMENT
>0.2	BARROSO 82	ASTR	Standard Axion
>0.25	<sup>1</sup> RAFFELT 82	ASTR	Standard Axion
>0.2	<sup>2</sup> DICUS 78c	ASTR	Standard Axion
>0.3	MIKAELIAN 78	ASTR	Stellar emission
>0.2	<sup>2</sup> SATO 78	ASTR	Standard Axion
>0.2	VYSOTSKII 78	ASTR	Standard Axion

<sup>1</sup> Lower bound from 5.5 MeV  $\gamma$ -ray line from the sun.

<sup>2</sup> Lower bound from requiring the red giants' stellar evolution not be disrupted by axion emission.

#### $A^0$ (Axion) and Other Light Boson ( $X^0$ ) Searches in Hadron Decays

Limits are for branching ratios.

<sup>1</sup> Limits between  $2.0 \times 10^{-5}$  and  $1.5 \times 10^{-6}$  are obtained for  $m_{X^0} = 20-100$  MeV (see their Fig. 8). Angular momentum conservation requires that  $X^0$  has spin  $\geq 1$ .

<sup>2</sup> The limit is for  $B(\phi \rightarrow \eta X^0) \cdot B(X^0 \rightarrow e^+e^-)$  and applies to  $m_{X^0} = 410$  MeV. It is derived by analyzing  $\eta \rightarrow \pi^0 \pi^0 \pi^0$  and  $\pi^- \pi^+ \pi^0$ . Limits between  $1 \times 10^{-6}$  and  $2 \times 10^{-8}$  are obtained for  $m_{X^0} \leq 450$  MeV (see their Fig. 6).

# Gauge & Higgs Boson Particle Listings

## Axions ( $A^0$ ) and Other Very Light Bosons

- <sup>3</sup> ARCHILLI 12 analyzed  $\eta \rightarrow \pi^+ \pi^- \pi^0$  decays. Derived limits on  $\alpha'/\alpha < 2 \times 10^{-5}$  for  $m_{X^0} = 50\text{--}420$  MeV at 90% CL. See their Fig. 8 for mass-dependent limits.
- <sup>4</sup> This limit is for  $B(\pi^0 \rightarrow \gamma X^0) \cdot B(X^0 \rightarrow e^+ e^-)$  and applies for  $m_{X^0} = 90$  MeV and  $\tau_{X^0} \simeq 1 \times 10^{-8}$  sec. Limits between  $10^{-8}$  and  $2 \times 10^{-15}$  are obtained for  $m_{X^0} = 3\text{--}120$  MeV and  $\tau_{X^0} = 1 \times 10^{-11}\text{--}1$  sec. See their Fig. 3 for limits at different masses and lifetimes.
- <sup>5</sup> This limit is for  $B(\eta \rightarrow \gamma X^0) \cdot B(X^0 \rightarrow e^+ e^-)$  and applies for  $m_{X^0} = 100$  MeV and  $\tau_{X^0} \simeq 6 \times 10^{-9}$  sec. Limits between  $10^{-5}$  and  $3 \times 10^{-14}$  are obtained for  $m_{X^0} \lesssim 550$  MeV and  $\tau_{X^0} = 10^{-10}\text{--}10$  sec. See their Fig. 5 for limits at different mass and lifetime and for  $\eta'$  decays.
- <sup>6</sup> This limit applies for a mass near 180 MeV. For other masses in the range  $m_{X^0} = 150\text{--}250$  MeV the limit is less restrictive, but still improves ADLER 02c and ATIYA 93b.
- <sup>7</sup> ANISIMOVSKY 04 bound is for  $m_{X^0} = 0$ .
- <sup>8</sup> ADLER 02c bound is for  $m_{X^0} < 60$  MeV. See Fig. 2 for limits at higher masses.
- <sup>9</sup> The quoted limit is for  $m_{X^0} = 0\text{--}80$  MeV. See their Fig. 5 for the limit at higher mass. The branching fraction limit assumes pure phase space decay distributions.
- <sup>10</sup> ALTEGOER 98 looked for  $X^0$  from  $\pi^0$  decay which penetrate the shielding and convert to  $\pi^0$  in the external Coulomb field of a nucleus.
- <sup>11</sup> KITCHING 97 limit is for  $B(K^+ \rightarrow \pi^+ X^0) \cdot B(X^0 \rightarrow \gamma\gamma)$  and applies for  $m_{X^0} \simeq 50$  MeV,  $\tau_{X^0} < 10^{-10}$  s. Limits are provided for  $0 < m_{X^0} < 100$  MeV,  $\tau_{X^0} < 10^{-8}$  s.
- <sup>12</sup> ADLER 96 looked for a peak in missing-mass distribution. This work is an update of ADLER 93. The limit is for massless stable  $X^0$  particles and extends to  $m_{X^0} = 80$  MeV at the same level. See paper for dependence on finite lifetime.
- <sup>13</sup> AMSLER 94b and AMSLER 96b looked for a peak in missing-mass distribution.
- <sup>14</sup> The MEIJERDREES 94 limit is based on inclusive photon spectrum and is independent of  $X^0$  decay modes. It applies to  $\tau(X^0) > 10^{-23}$  sec.
- <sup>15</sup> ATIYA 93b looked for a peak in missing mass distribution. The bound applies for stable  $X^0$  of  $m_{X^0} = 150\text{--}250$  MeV, and the limit becomes stronger ( $10^{-8}$ ) for  $m_{X^0} = 180\text{--}240$  MeV.
- <sup>16</sup> NG 93 studied the production of  $X^0$  via  $\gamma\gamma \rightarrow \pi^0 \rightarrow \gamma X^0$  in the early universe at  $T \simeq 1$  MeV. The bound on extra neutrinos from nucleosynthesis  $\Delta N_\nu < 0.3$  (WALKER 91) is employed. It applies to  $m_{X^0} \ll 1$  MeV in order to be relativistic down to nucleosynthesis temperature. See paper for heavier  $X^0$ .
- <sup>17</sup> ALLIEGRO 92 limit applies for  $m_{X^0} = 150\text{--}340$  MeV and is the branching ratio times the decay probability. Limit is  $< 1.5 \times 10^{-8}$  at 99% CL.
- <sup>18</sup> ATIYA 92 looked for a peak in missing mass distribution. The limit applies to  $m_{X^0} = 0\text{--}130$  MeV in the narrow resonance limit. See paper for the dependence on lifetime. Covariance requires  $X^0$  to be a vector particle.
- <sup>19</sup> MEIJERDREES 92 limit applies for  $\tau_{X^0} = 10^{-23}\text{--}10^{-11}$  sec. Limits between  $2 \times 10^{-4}$  and  $4 \times 10^{-6}$  are obtained for  $m_{X^0} = 25\text{--}120$  MeV. Angular momentum conservation requires that  $X^0$  has spin  $\geq 1$ .
- <sup>20</sup> ATIYA 90b limit is for  $B(K^+ \rightarrow \pi^+ X^0) \cdot B(X^0 \rightarrow \gamma\gamma)$  and applies for  $m_{X^0} = 50$  MeV,  $\tau_{X^0} < 10^{-10}$  s. Limits are also provided for  $0 < m_{X^0} < 100$  MeV,  $\tau_{X^0} < 10^{-8}$  s.
- <sup>21</sup> KORENCHENKO 87 limit assumes  $m_{A^0} = 1.7$  MeV,  $\tau_{A^0} \lesssim 10^{-12}$  s, and  $B(A^0 \rightarrow e^+ e^-) = 1$ .
- <sup>22</sup> EICHLER 86 looked for  $\pi^+ \rightarrow e^+ \nu A^0$  followed by  $A^0 \rightarrow e^+ e^-$ . Limits on the branching fraction depend on the mass and and lifetime of  $A^0$ . The quoted limits are valid when  $\tau(A^0) \gtrsim 3 \times 10^{-10}$  s if the decays are kinematically allowed.
- <sup>23</sup> YAMAZAKI 84 looked for a discrete line in  $K^+ \rightarrow \pi^+ X$ . Sensitive to wide mass range (5–300 MeV), independent of whether X decays promptly or not.
- <sup>24</sup> ASANO 82 at KEK set limits for  $B(K^+ \rightarrow \pi^+ X^0)$  for  $m_{X^0} < 100$  MeV as  $BR < 4 \times 10^{-8}$  for  $\tau(X^0 \rightarrow n\gamma) > 1 \times 10^{-9}$  s,  $BR < 1.4 \times 10^{-6}$  for  $\tau < 1 \times 10^{-9}$  s.
- <sup>25</sup> ASANO 81b is KEK experiment. Set  $B(K^+ \rightarrow \pi^+ X^0) < 3.8 \times 10^{-8}$  at CL = 90%.
- <sup>26</sup> ZHITNITSKII 79 argue that a heavy axion predicted by YANG 78 ( $3 < m < 40$  MeV) contradicts experimental muon anomalous magnetic moments.

### $A^0$ (Axion) Searches in Quarkonium Decays

Decay or transition of quarkonium. Limits are for branching ratio.

VALUE	CL%	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
$< 4.0 \times 10^{-5}$	90	<sup>1</sup> ANTREASIAN 90c	CBAL	$\Upsilon(1S) \rightarrow A^0 \gamma$
$< 5 \times 10^{-5}$	90	<sup>2</sup> DRUZHININ 87	ND	$\phi \rightarrow A^0 \gamma (A^0 \rightarrow e^+ e^-)$
$< 2 \times 10^{-3}$	90	<sup>3</sup> DRUZHININ 87	ND	$\phi \rightarrow A^0 \gamma (A^0 \rightarrow \gamma\gamma)$
$< 7 \times 10^{-6}$	90	<sup>4</sup> DRUZHININ 87	ND	$\phi \rightarrow A^0 \gamma (A^0 \rightarrow \text{missing})$
$< 1.4 \times 10^{-5}$	90	<sup>5</sup> EDWARDS 82	CBAL	$J/\psi \rightarrow A^0 \gamma$
<sup>1</sup> ANTREASIAN 90c assume that $A^0$ does not decay in the detector.				
<sup>2</sup> The first DRUZHININ 87 limit is valid when $\tau_{A^0}/m_{A^0} < 3 \times 10^{-13}$ s/MeV and $m_{A^0} < 20$ MeV.				
<sup>3</sup> The second DRUZHININ 87 limit is valid when $\tau_{A^0}/m_{A^0} < 5 \times 10^{-13}$ s/MeV and $m_{A^0} < 20$ MeV.				
<sup>4</sup> The third DRUZHININ 87 limit is valid when $\tau_{A^0}/m_{A^0} > 7 \times 10^{-12}$ s/MeV and $m_{A^0} < 20$ MeV.				
<sup>5</sup> EDWARDS 82 looked for $J/\psi \rightarrow \gamma A^0$ decays by looking for events with a single $\gamma$ [of energy $\sim 1/2$ the $J/\psi(1S)$ mass], plus nothing else in the detector. The limit is inconsistent with the axion interpretation of the FAISSNER 81b result.				

### $A^0$ (Axion) Searches in Positronium Decays

Decay or transition of positronium. Limits are for branching ratio.

VALUE	CL%	DOCUMENT ID	TECN	COMMENT

		<sup>7</sup> AMALDI	85	CNTR	Ortho-positronium
		<sup>8</sup> CARBONI	83	CNTR	Ortho-positronium

- <sup>1</sup> BADERTSCHER 02 looked for a three-body decay of ortho-positronium into a photon and two penetrating (neutral or milli-charged) particles.
- <sup>2</sup> The ASAI 94 limit is based on inclusive photon spectrum and is independent of  $A^0$  decay modes.
- <sup>3</sup> The AKOPYAN 91 limit applies for a short-lived  $A^0$  with  $\tau_{A^0} < 10^{-13} m_{A^0}$  [keV]s.
- <sup>4</sup> ASAI 91 limit translates to  $g_{A^0 e^+ e^-}^2 / 4\pi < 1.1 \times 10^{-11}$  (90% CL) for  $m_{A^0} < 800$  keV.
- <sup>5</sup> The TSUCHIAKI 90 limit is based on inclusive photon spectrum and is independent of  $A^0$  decay modes.
- <sup>6</sup> ORITO 89 limit translates to  $g_{A^0 e^+ e^-}^2 / 4\pi < 6.2 \times 10^{-10}$ . Somewhat more sensitive limits are obtained for larger  $m_{A^0}$ :  $B < 7.6 \times 10^{-6}$  at 100 keV.
- <sup>7</sup> AMALDI 85 set limits  $B(A^0 \gamma) / B(\gamma\gamma) < (1\text{--}5) \times 10^{-6}$  for  $m_{A^0} = 900\text{--}100$  keV which are about 1/10 of the CARBONI 83 limits.
- <sup>8</sup> CARBONI 83 looked for ortho-positronium  $\rightarrow A^0 \gamma$ . Set limit for  $A^0$  electron coupling squared,  $g(eA^0)^2 / (4\pi) < 6 \times 10^{-10}\text{--}7 \times 10^{-9}$  for  $m_{A^0}$  from 150–900 keV (CL = 99.7%). This is about 1/10 of the bound from  $g\text{--}2$  experiments.

### $A^0$ (Axion) Search in Photoproduction

VALUE	DOCUMENT ID	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •		
	<sup>1</sup> BASSOMPIERRE... 95	$m_{A^0} = 1.8 \pm 0.2 \text{ MeV}$

<sup>1</sup> BASSOMPIERRE 95 is an extension of BASSOMPIERRE 93. They looked for a peak in the invariant mass of  $e^+ e^-$  pairs in the region  $m_{e^+ e^-} = 1.8 \pm 0.2$  MeV. They obtained bounds on the production rate  $A^0$  for  $\tau(A^0) = 10^{-18}\text{--}10^{-9}$  sec. They also found an excess of events in the range  $m_{e^+ e^-} = 2.1\text{--}3.5$  MeV.

### $A^0$ (Axion) Production in Hadron Collisions

Limits are for  $\sigma(A^0) / \sigma(\pi^0)$ .

- 1 JAIN 07 claims evidence for  $A^0 \rightarrow e^+e^-$  produced in  $^{207}\text{Pb}$  collision on nuclear emulsion (Ag/Br) for  $m(A^0) = 7 \pm 1$  or  $19 \pm 1$  MeV and  $\tau(A^0) \leq 10^{-13}$  s.
- 2 AHMAD 97 reports a result of APEX Collaboration which studied positron production in  $^{238}\text{U} \rightarrow ^{232}\text{Ta}$  and  $^{238}\text{U} \rightarrow ^{181}\text{Ta}$  collisions, without requiring a coincident electron. No narrow lines were found for  $250 < E_{e^+} < 750$  keV.
- 3 LEINBERGER 97 (ORANGE Collaboration) at GSI looked for a narrow sum-energy  $e^+e^-$  line at  $\sim 635$  keV in  $^{238}\text{U} \rightarrow ^{181}\text{Ta}$  collision. Limits on the production probability for a narrow sum-energy  $e^+e^-$  line are set. See their Table 2.
- 4 GANZ 96 (EPOS II Collaboration) has placed upper bounds on the production cross section of  $e^+e^-$  pairs from  $^{238}\text{U} \rightarrow ^{181}\text{Ta}$  and  $^{238}\text{U} \rightarrow ^{232}\text{Th}$  collisions at GSI. See Table 2 for limits both for back-to-back and isotropic configurations of  $e^+e^-$  pairs. These limits rule out the existence of peaks in the  $e^+e^-$  sum-energy distribution, reported by an earlier version of this experiment.
- 5 KAMEL 96 looked for  $e^+e^-$  pairs from the collision of  $^{32}\text{S}$  (200 GeV/nucleon) and emulsion. No evidence of mass peaks is found in the region of sensitivity  $m_{ee} > 2$  MeV.
- 6 BLUEMLEIN 92 is a proton beam dump experiment at Serpukhov with a secondary target to induce Bethe-Heitler production of  $e^+e^-$  or  $\mu^+\mu^-$  from the produce  $A^0$ . See Fig. 5 for the excluded region in  $m_{A^0}$ - $x$  plane. For the standard axion,  $0.3 < x < 25$  is excluded at 95% CL. If combined with BLUEMLEIN 91,  $0.008 < x < 32$  is excluded.
- 7 MEIJERDREES 92 give  $\Gamma(\pi^-\rho \rightarrow nA^0) \cdot \text{B}(A^0 \rightarrow e^+e^-) / \Gamma(\pi^-\rho \rightarrow \text{all}) < 10^{-5}$  (90% CL) for  $m_{A^0} = 100$  MeV,  $\tau_{A^0} = 10^{-11} - 10^{-23}$  sec. Limits ranging from  $2.5 \times 10^{-3}$  to  $10^{-7}$  are given for  $m_{A^0} = 25-136$  MeV.
- 8 BLUEMLEIN 91 is a proton beam dump experiment at Serpukhov. No candidate event for  $A^0 \rightarrow e^+e^-$ ,  $2\gamma$  are found. Fig. 6 gives the excluded region in  $m_{A^0}$ - $x$  plane ( $x = \tan\beta = v_2/v_1$ ). Standard axion is excluded for  $0.2 < m_{A^0} < 3.2$  MeV for most  $x > 1$ ,  $0.2-11$  MeV for most  $x < 1$ .
- 9 FAISSNER 89 searched for  $A^0 \rightarrow e^+e^-$  in a proton beam dump experiment at SIN. No excess of events was observed over the background. A standard axion with mass  $2m_e - 20$  MeV is excluded. Lower limit on  $f_{A^0}$  of  $\sim 10^4$  GeV is given for  $m_{A^0} = 2m_e - 20$  MeV.
- 10 DEBOER 88 reanalyze EL-NADI 88 data and claim evidence for three distinct states with mass  $\sim 1.1$ ,  $\sim 2.1$ , and  $\sim 9$  MeV, lifetimes  $10^{-16} - 10^{-15}$  s decaying to  $e^+e^-$  and note the similarity of the data with those of a cosmic-ray experiment by Bristol group (B.M. Anand, Proc. of the Royal Society of London, Section A **A22** 183 (1953)). For a criticism see PERKINS 89, who suggests that the events are compatible with  $\pi^0$  Dalitz decay. DEBOER 89b is a reply which contests the criticism.
- 11 EL-NADI 88 claim the existence of a neutral particle decaying into  $e^+e^-$  with mass  $1.60 \pm 0.59$  MeV, lifetime  $(0.15 \pm 0.01) \times 10^{-14}$  s, which is produced in heavy ion interactions with emulsion nuclei at  $\sim 4$  GeV/c/nucleon.
- 12 FAISSNER 88 is a proton beam dump experiment at SIN. They found no candidate event for  $A^0 \rightarrow \gamma\gamma$ . A standard axion decaying to  $2\gamma$  is excluded except for a region  $x \approx 1$ . Lower limit on  $f_{A^0}$  of  $10^2 - 10^3$  GeV is given for  $m_{A^0} = 0.1-1$  MeV.
- 13 BADIER 86 did not find long-lived  $A^0$  in 300 GeV  $\pi^-$  Beam Dump Experiment that decays into  $e^+e^-$  in the mass range  $m_{A^0} = (20-200)$  MeV, which excludes the  $A^0$  decay constant  $f(A^0)$  in the interval (60-600) GeV. See their figure 6 for excluded region on  $f(A^0)-m_{A^0}$  plane.
- 14 BERGSMAN 85 look for  $A^0 \rightarrow 2\gamma, e^+e^-, \mu^+\mu^-$ . First limit above is for  $m_{A^0} = 1$  MeV; second is for 200 MeV. See their figure 4 for excluded region on  $f_{A^0}-m_{A^0}$  plane, where  $f_{A^0}$  is  $A^0$  decay constant. For Peccei-Quinn PECCER 77  $A^0, m_{A^0} < 180$  keV and  $\tau > 0.037$  s. (CL = 90%). For the axion of FAISSNER 81B at 250 keV, BERGSMAN 85 expect 15 events but observe zero.
- 15 FAISSNER 83 observed 19  $1-\gamma$  and 12  $2-\gamma$  events where a background of 4.8 and 2.3 respectively is expected. A small-angle peak is observed even if iron wall is set in front of the decay region.
- 16 FAISSNER 83b extrapolate SIN  $\gamma$  signal to LAMPF  $\nu$  experimental condition. Resulting 370  $\gamma$ 's are not at variance with LAMPF upper limit of 450  $\gamma$ 's. Derived from LAMPF limit that  $[d\sigma(A^0)/d\omega \text{ at } 90^\circ] m_{A^0} / \tau_{A^0} < 14 \times 10^{-35} \text{ cm}^2 \text{ sr}^{-1} \text{ MeV ms}^{-1}$ . See comment on FRANK 83b.
- 17 FRANK 83b stress the importance of LAMPF data bins with negative net signal. By statistical analysis say that LAMPF and SIN-A0 are at variance when extrapolation by phase-space model is done. They find LAMPF upper limit is 248 not 450  $\gamma$ 's. See comment on FAISSNER 83b.
- 18 HOFFMAN 83 set CL = 90% limit  $d\sigma/dt \text{ B}(e^+e^-) < 3.5 \times 10^{-32} \text{ cm}^2/\text{GeV}^2$  for 140  $< m_{A^0} < 160$  MeV. Limit assumes  $\tau(A^0) < 10^{-9}$  s.
- 19 FETSCHER 82 reanalyzes SIN beam-dump data of FAISSNER 81. Claims no evidence for axion since  $2-\gamma$  peak rate remarkably decreases if iron wall is set in front of the decay region.
- 20 FAISSNER 81 see excess  $\mu e$  events. Suggest axion interactions.
- 21 FAISSNER 81B is SIN 590 MeV proton beam dump. Observed  $14.5 \pm 5.0$  events of  $2\gamma$  decay of long-lived neutral penetrating particle with  $m_{2\gamma} \lesssim 1$  MeV. Axion interpretation with  $\eta-A^0$  mixing gives  $m_{A^0} = 250 \pm 25$  keV,  $\tau(2\gamma) = (7.3 \pm 3.7) \times 10^{-3}$  s from above rate. See critical remarks below in comments of FETSCHER 82, FAISSNER 83, FAISSNER 83b, FRANK 83b, and BERGSMAN 85. Also see in the next subsection ALEKSEEV 82b, CAVAIIGNAC 83, and ANANEV 85.
- 22 KIM 81 analyzed 8 candidates for  $A^0 \rightarrow 2\gamma$  obtained by Aachen-Padova experiment at CERN with 26 GeV protons on Be. Estimated axion mass is about 300 keV and lifetime is  $(0.86 - 5.6) \times 10^{-3}$  s depending on models. Faissner (private communication), says axion production underestimated and mass overestimated. Correct value around 200 keV.

- 23 FAISSNER 80 is SIN beam dump experiment with 590 MeV protons looking for  $A^0 \rightarrow e^+e^-$  decay. Assuming  $A^0/\pi^0 = 5.5 \times 10^{-7}$ , obtained decay rate limit  $20/(A^0 \text{ mass}) \text{ MeV/s}$  (CL = 90%), which is about  $10^{-7}$  below theory and interpreted as upper limit to  $m_{A^0} < 2m_e$ .
- 24 JACQUES 80 is a BNL beam dump experiment. First limit above comes from nonobservation of excess neutral-current-type events  $[\sigma(\text{production})\sigma(\text{interaction}) < 7. \times 10^{-68} \text{ cm}^4, \text{ CL} = 90\%]$ . Second limit is from nonobservation of axion decays into  $2\gamma$ 's or  $e^+e^-$ , and for axion mass a few MeV.
- 25 SOUKAS 80 at BNL observed no excess of neutral-current-type events in beam dump.
- 26 BECHIS 79 looked for the axion production in low energy electron Bremsstrahlung and the subsequent decay into either  $2\gamma$  or  $e^+e^-$ . No signal found. CL = 90% limits for model parameter(s) are given.
- 27 COTEUS 79 is a beam dump experiment at BNL.
- 28 DISHAW 79 is a calorimetric experiment and looks for low energy tail of energy distributions due to energy lost to weakly interacting particles.
- 29 BELLOTTI 78 first value comes from search for  $A^0 \rightarrow e^+e^-$ . Second value comes from search for  $A^0 \rightarrow 2\gamma$ , assuming mass  $< 2m_e$ . For any mass satisfying this, limit is above value  $\times (\text{mass}^{-4})$ . Third value uses data of PL 60B 401 and quotes  $\sigma(\text{production})\sigma(\text{interaction}) < 10^{-67} \text{ cm}^4$ .
- 30 BOSETTI 78B quotes  $\sigma(\text{production})\sigma(\text{interaction}) < 2. \times 10^{-67} \text{ cm}^4$ .
- 31 DONNELLY 78 examines data from reactor neutrino experiments of REINES 76 and GURR 74 as well as SLAC beam dump experiment. Evidence is negative.
- 32 MICELMACHER 78 finds no evidence of axion existence in reactor experiments of REINES 76 and GURR 74. (See reference under DONNELLY 78 below).
- 33 VYSOTSKII 78 derived lower limit for the axion mass 25 keV from luminosity of the sun and 200 keV from red supergiants.

### $A^0$ (Axion) Searches in Reactor Experiments

VALUE	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •			
1	CHANG 07		Primakoff or Compton
2	ALTMANN 95	CNTR	Reactor; $A^0 \rightarrow e^+e^-$
3	KETOV 86	SPEC	Reactor; $A^0 \rightarrow \gamma\gamma$
4	KOCH 86	SPEC	Reactor; $A^0 \rightarrow \gamma\gamma$
5	DATAR 82	CNTR	Light water reactor
6	VUILLEUMIER 81	CNTR	Reactor; $A^0 \rightarrow 2\gamma$

- 1 CHANG 07 looked for monochromatic photons from Primakoff or Compton conversion of axions from the Kuo-Sheng reactor due to axion coupling to photon or electron, respectively. The search places model-independent limits on the products  $G_{A\gamma\gamma} G_{ANN}$  and  $G_{Aee} G_{ANN}$  for  $m(A^0)$  less than the MeV range.
- 2 ALTMANN 95 looked for  $A^0$  decaying into  $e^+e^-$  from the Bugey 5 nuclear reactor. They obtain an upper limit on the  $A^0$  production rate of  $\omega(A^0)/\omega(\gamma) \times \text{B}(A^0 \rightarrow e^+e^-) < 10^{-16}$  for  $m_{A^0} = 1.5$  MeV at 90% CL. The limit is weaker for heavier  $A^0$ . In the case of a standard axion, this limit excludes a mass in the range  $2m_e < m_{A^0} < 4.8$  MeV at 90% CL. See Fig. 5 of their paper for exclusion limits of axion-like resonances  $Z^0$  in the  $(m_{X^0}, f_{X^0})$  plane.
- 3 KETOV 86 searched for  $A^0$  at the Rovno nuclear power plant. They found an upper limit on the  $A^0$  production probability of  $0.8 [100 \text{ keV}/m_{A^0}]^6 \times 10^{-6}$  per fission. In the standard axion model, this corresponds to  $m_{A^0} > 150$  keV. Not valid for  $m_{A^0} \gtrsim 1$  MeV.
- 4 KOCH 86 searched for  $A^0 \rightarrow \gamma\gamma$  at nuclear power reactor Biblis A. They found an upper limit on the  $A^0$  production rate of  $\omega(A^0)/\omega(\gamma(M1)) < 1.5 \times 10^{-10}$  (CL=95%). Standard axion with  $m_{A^0} = 250$  keV gives  $10^{-9}$  for the ratio. Not valid for  $m_{A^0} > 1022$  keV.
- 5 DATAR 82 looked for  $A^0 \rightarrow 2\gamma$  in neutron capture ( $n p \rightarrow d A^0$ ) at Tarapur 500 MW reactor. Sensitive to sum of  $l = 0$  and  $l = 1$  amplitudes. With ZEHNDER 81 [ $(l = 0) - (l = 1)$ ] result, assert nonexistence of standard  $A^0$ .
- 6 VUILLEUMIER 81 is at Grenoble reactor. Set limit  $m_{A^0} < 280$  keV.

### $A^0$ (Axion) and Other Light Boson ( $X^0$ ) Searches in Nuclear Transitions

Limits are for branching ratio.

VALUE	CL%	DOCUMENT ID	TECN	COMMENT

- <sup>1</sup> DERBIN 02 looked for the axion emission in an M1 transition in  ${}^{125}\text{mTe}$  decay. They looked for a possible presence of a shifted energy spectrum in gamma rays due to the undetected axion.
- <sup>2</sup> DEBOER 97C reanalyzed the existent data on Nuclear M1 transitions and find that a 9 MeV boson decaying into  $e^+e^-$  would explain the excess of events with large opening angles. See also DEBOER 01 for follow-up experiments.
- <sup>3</sup> TSUNODA 95 looked for axion emission when  ${}^{252}\text{Cf}$  undergoes a spontaneous fission, with the axion decaying into  $e^+e^-$ . The bound is for  $m_{A^0}=40$  MeV. It improves to  $2.5 \times 10^{-5}$  for  $m_{A^0}=200$  MeV.
- <sup>4</sup> MINOWA 93 studied chain process,  ${}^{139}\text{Ce} \rightarrow {}^{139}\text{La}^*$  by electron capture and M1 transition of  ${}^{139}\text{La}^*$  to the ground state. It does not assume decay modes of  $A^0$ . The bound applies for  $m_{A^0} < 166$  keV.
- <sup>5</sup> HICKS 92 bound is applicable for  $\tau_{X^0} < 4 \times 10^{-11}$  sec.
- <sup>6</sup> The ASANUMA 90 limit is for the branching fraction of  $X^0$  emission per  ${}^{241}\text{Am}$   $\alpha$  decay and valid for  $\tau_{X^0} < 3 \times 10^{-11}$  s.
- <sup>7</sup> The DEBOER 90 limit is for the branching ratio  ${}^8\text{Be}^* (18.15 \text{ MeV}, 1^+) \rightarrow {}^8\text{Be} A^0, A^0 \rightarrow e^+e^-$  for the mass range  $m_{A^0} = 4\text{--}15$  MeV.
- <sup>8</sup> The BINI 89 limit is for the branching fraction of  ${}^{16}\text{O}^* (6.05 \text{ MeV}, 0^+) \rightarrow {}^{16}\text{O} X^0, X^0 \rightarrow e^+e^-$  for  $m_{X^0} = 1.5\text{--}3.1$  MeV.  $\tau_{X^0} \lesssim 10^{-11}$  s is assumed. The spin-parity of  $X$  is restricted to  $0^+$  or  $1^-$ .
- <sup>9</sup> AVIGNONE 88 looked for the 1115 keV transition  $\text{C}^* \rightarrow \text{Cu} A^0$ , either from  $A^0 \rightarrow 2\gamma$  in-flight decay or from the secondary  $A^0$  interactions by Compton and by Primakoff processes. Limits for axion parameters are obtained for  $m_{A^0} < 1.1$  MeV.
- <sup>10</sup> DATAR 88 rule out light pseudoscalar particle emission through its decay  $A^0 \rightarrow e^+e^-$  in the mass range 1.02–2.5 MeV and lifetime range  $10^{-13}\text{--}10^{-8}$  s. The above limit is for  $\tau = 5 \times 10^{-13}$  s and  $m = 1.7$  MeV; see the paper for the  $\tau$ - $m$  dependence of the limit.
- <sup>11</sup> The limit is for the branching fraction of  ${}^{16}\text{O}^* (6.05 \text{ MeV}, 0^+) \rightarrow {}^{16}\text{O} X^0, X^0 \rightarrow e^+e^-$  against internal pair conversion for  $m_{X^0} = 1.7$  MeV and  $\tau_{X^0} < 10^{-11}$  s. Similar limits are obtained for  $m_{X^0} = 1.3\text{--}3.2$  MeV. The spin parity of  $X^0$  must be either  $0^+$  or  $1^-$ . The limit at 1.7 MeV is translated into a limit for the  $X^0$ -nucleon coupling constant:  $g_{X^0 N N}^2/4\pi < 2.3 \times 10^{-9}$ .
- <sup>12</sup> The DOEHNER 88 limit is for  $m_{A^0} = 1.7$  MeV,  $\tau(A^0) < 10^{-10}$  s. Limits less than  $10^{-4}$  are obtained for  $m_{A^0} = 1.2\text{--}2.2$  MeV.
- <sup>13</sup> SAVAGE 88 looked for  $A^0$  that decays into  $e^+e^-$  in the decay of the 9.17 MeV  $J^P = 2^+$  state in  ${}^{14}\text{N}$ , 17.64 MeV state  $J^P = 1^+$  in  ${}^8\text{Be}$ , and the 18.15 MeV state  $J^P = 1^+$  in  ${}^8\text{Be}$ . This experiment constrains the isovector coupling of  $A^0$  to hadrons, if  $m_{A^0} = (1.1 \rightarrow 2.2)$  MeV and the isoscalar coupling of  $A^0$  to hadrons, if  $m_{A^0} = (1.1 \rightarrow 2.6)$  MeV. Both limits are valid only if  $\tau(A^0) \lesssim 1 \times 10^{-11}$  s.
- <sup>14</sup> Limits are for  $\Gamma(A^0(1.8 \text{ MeV}))/\Gamma(\pi\text{M1})$ ; i.e., for 1.8 MeV axion emission normalized to the rate for internal emission of  $e^+e^-$  pairs. Valid for  $\tau_{A^0} < 2 \times 10^{-11}$  s.  ${}^6\text{Li}$  isovector decay data strongly disfavor PECCEI 86 model I, whereas the  ${}^{10}\text{B}$  and  ${}^{14}\text{N}$  isoscalar decay data strongly reject PECCEI 86 model II and III.
- <sup>15</sup> SAVAGE 86B looked for  $A^0$  that decays into  $e^+e^-$  in the decay of the 9.17 MeV  $J^P = 2^+$  state in  ${}^{14}\text{N}$ . Limit on the branching fraction is valid if  $\tau_{A^0} \lesssim 1 \times 10^{-11}$  s for  $m_{A^0} = (1.1\text{--}1.7)$  MeV. This experiment constrains the iso-vector coupling of  $A^0$  to hadrons.
- <sup>16</sup> ANANEV 85 with IBR-2 pulsed reactor exclude standard  $A^0$  at CL = 95% masses below 470 keV ( $\text{Li}^*$  decay) and below  $2m_d$  for deuteron\* decay.
- <sup>17</sup> CAVAIGNAC 83 at Bugey reactor exclude axion at any  $m_{97}\text{Nb}^*$  decay and axion with  $m_{A^0}$  between 275 and 288 keV (deuteron\* decay).
- <sup>18</sup> ALEKSEEV 82 with IBR-2 pulsed reactor exclude standard  $A^0$  at CL = 95% mass-ranges  $m_{A^0} < 400$  keV ( $\text{Li}^*$  decay) and 330 keV  $< m_{A^0} < 2.2$  MeV. (deuteron\* decay).
- <sup>19</sup> LEHMANN 82 obtained  $A^0 \rightarrow 2\gamma$  rate  $< 6.2 \times 10^{-5}/\text{s}$  (CL = 95%) excluding  $m_{A^0}$  between 100 and 1000 keV.
- <sup>20</sup> ZEHNDER 82 used Gosgen 2.8GW light-water reactor to check  $A^0$  production. No  $2\gamma$  peak in  $\text{Li}^*$ ,  $\text{Nb}^*$  decay (both single  $p$  transition) nor in  $n$  capture (combined with previous  $\text{Ba}^*$  negative result) rules out standard  $A^0$ . Set limit  $m_{A^0} < 60$  keV for any  $A^0$ .
- <sup>21</sup> ZEHNDER 81 looked for  $\text{Ba}^* \rightarrow A^0\text{Ba}$  transition with  $A^0 \rightarrow 2\gamma$ . Obtained  $2\gamma$  coincidence rate  $< 2.2 \times 10^{-5}/\text{s}$  (CL = 95%) excluding  $m_{A^0} > 160$  keV (or 200 keV depending on Higgs mixing). However, see BARROSO 81.
- <sup>22</sup> CALAPRICE 79 saw no axion emission from excited states of carbon. Sensitive to axion mass between 1 and 15 MeV.

$\text{none } 4 \times 10^{-16}\text{--}4.5 \times 10^{-12}$	90	1 BROSS	91 BDMP	$e N \rightarrow e A^0 N (A^0 \rightarrow ee)$
		2 GUO	90 BDMP	$e N \rightarrow e A^0 N (A^0 \rightarrow ee)$
		3 BJORKEN	88 CALO	$A \rightarrow e^+e^-$ or $2\gamma$
$\text{none } 1 \times 10^{-14}\text{--}1 \times 10^{-10}$	90	4 BLINOV	88 MD1	$ee \rightarrow ee A^0 (A^0 \rightarrow ee)$
$\text{none } 1 \times 10^{-14}\text{--}1 \times 10^{-11}$	90	5 RIORDAN	87 BDMP	$e N \rightarrow e A^0 N (A^0 \rightarrow ee)$
$\text{none } 6 \times 10^{-14}\text{--}9 \times 10^{-11}$	95	6 BROWN	86 BDMP	$e N \rightarrow e A^0 N (A^0 \rightarrow ee)$
$\text{none } 3 \times 10^{-13}\text{--}1 \times 10^{-7}$	90	7 DAVIER	86 BDMP	$e N \rightarrow e A^0 N (A^0 \rightarrow ee)$
		8 KONAKA	86 BDMP	$e N \rightarrow e A^0 N (A^0 \rightarrow ee)$

- <sup>1</sup> The listed BROSS 91 limit is for  $m_{A^0} = 1.14$  MeV.  $B(A^0 \rightarrow e^+e^-) = 1$  assumed. Excluded domain in the  $\tau_{A^0}\text{--}m_{A^0}$  plane extends up to  $m_{A^0} \approx 7$  MeV (see Fig. 5). Combining with electron  $g\text{--}2$  constraint, axions coupling only to  $e^+e^-$  ruled out for  $m_{A^0} < 4.8$  MeV (90% CL).
- <sup>2</sup> GUO 90 use the same apparatus as BROWN 86 and improve the previous limit in the shorter lifetime region. Combined with  $g\text{--}2$  constraint, axions coupling only to  $e^+e^-$  are ruled out for  $m_{A^0} < 2.7$  MeV (90% CL).
- <sup>3</sup> BJORKEN 88 reports limits on axion parameters ( $f_A, m_A, \tau_A$ ) for  $m_{A^0} < 200$  MeV from electron beam-dump experiment with production via Primakoff photoproduction, bremsstrahlung from electrons, and resonant annihilation of positrons on atomic electrons.
- <sup>4</sup> BLINOV 88 assume zero spin,  $m = 1.8$  MeV and lifetime  $< 5 \times 10^{-12}$  s and find  $\Gamma(A^0 \rightarrow \gamma\gamma)B(A^0 \rightarrow e^+e^-) < 2$  eV (CL=90%).
- <sup>5</sup> Assumes  $A^0\gamma\gamma$  coupling is small and hence Primakoff production is small. Their figure 2 shows limits on axions for  $m_{A^0} < 15$  MeV.
- <sup>6</sup> Uses electrons in hadronic showers from an incident 800 GeV proton beam. Limits for  $m_{A^0} < 15$  MeV are shown in their figure 3.
- <sup>7</sup>  $m_{A^0} = 1.8$  MeV assumed. The excluded domain in the  $\tau_{A^0}\text{--}m_{A^0}$  plane extends up to  $m_{A^0} \approx 14$  MeV, see their figure 4.
- <sup>8</sup> The limits are obtained from their figure 3. Also given is the limit on the  $A^0\gamma\gamma\text{--}A^0e^+e^-$  coupling plane by assuming Primakoff production.

### Search for $A^0$ (Axion) Resonance in Bhabha Scattering

The limit is for  $\Gamma(A^0)[B(A^0 \rightarrow e^+e^-)]^2$ .

$< 2500$	90	MILLS	87 CNTR	$m_{A^0} = 1.8$ MeV
		10 VONWIMMER	.87 CNTR	

- <sup>1</sup> HALLIN 92 quote limits on lifetime,  $8 \times 10^{-14}\text{--}5 \times 10^{-13}$  sec depending on mass, assuming  $B(A^0 \rightarrow e^+e^-) = 100\%$ . They say that TSERTOS 91 overstated their sensitivity by a factor of 3.
- <sup>2</sup> HENDERSON 92C exclude axion with lifetime  $\tau_{A^0} = 1.4 \times 10^{-12}\text{--}4.0 \times 10^{-10}$  s, assuming  $B(A^0 \rightarrow e^+e^-) = 100\%$ . HENDERSON 92C also exclude a vector boson with  $\tau = 1.4 \times 10^{-12}\text{--}6.0 \times 10^{-10}$  s.
- <sup>3</sup> WU 92 quote limits on lifetime  $> 3.3 \times 10^{-13}$  s assuming  $B(A^0 \rightarrow e^+e^-) = 100\%$ . They say that TSERTOS 89 overestimate the limit by a factor of  $\pi/2$ . WU 92 also quote a bound for vector boson,  $\tau > 8.2 \times 10^{-13}$  s.
- <sup>4</sup> WIDMANN 91 bound applies exclusively to the case  $B(A^0 \rightarrow e^+e^-) = 1$ , since the detection efficiency varies substantially as  $\Gamma(A^0)_{\text{total}}$  changes. See their Fig. 6.
- <sup>5</sup> JUDGE 90 excludes an elastic pseudoscalar  $e^+e^-$  resonance for  $4.5 \times 10^{-13}$  s  $< \tau(A^0) < 7.5 \times 10^{-12}$  s (95% CL) at  $m_{A^0} = 1.832$  MeV. Comparable limits can be set for  $m_{A^0} = 1.776\text{--}1.856$  MeV.
- <sup>6</sup> See also TSERTOS 88B in references.
- <sup>7</sup> The upper limit listed in TSERTOS 88 is too large by a factor of 4. See TSERTOS 88B, footnote 3.
- <sup>8</sup> VANKLINKEN 88 looked for relatively long-lived resonance ( $\tau = 10^{-10}\text{--}10^{-12}$  s). The sensitivity is not sufficient to exclude such a narrow resonance.
- <sup>9</sup> MAIER 87 obtained limits  $R\Gamma \lesssim 60$  eV (100 eV) at  $m_{A^0} \approx 1.64$  MeV (1.83 MeV) for energy resolution  $\Delta E_{\text{cm}} \approx 3$  keV, where  $R$  is the resonance cross section normalized

### $A^0$ (Axion) Limits from Its Electron Coupling

Limits are for  $\tau(A^0 \rightarrow e^+e^-)$ .

	<sup>16</sup> DICUS	83	COSM	$\nu(\text{hvy}) \rightarrow \nu(\text{light}) X^0$

- <sup>1</sup>LATTANZI 13 use WMAP 9 year data as well as X-ray and  $\gamma$ -ray observations to derive limits on decaying majoron dark matter. A limit on the decay width  $\Gamma(X^0 \rightarrow \nu\bar{\nu}) < 6.4 \times 10^{-19} \text{ s}^{-1}$  at 95% CL is found if majorons make up all of the dark matter.
- <sup>2</sup>LESSA 07 consider decays of the form Meson  $\rightarrow \ell\nu$  Majoron and  $\ell \rightarrow \ell'\nu\bar{\nu}$  Majoron and use existing data to derive limits on the neutrino-Majoron Yukawa couplings  $g_{\alpha\beta}$  ( $\alpha, \beta = e, \mu, \tau$ ). Their best limits are  $|g_{e\alpha}|^2 < 5.5 \times 10^{-6}$ ,  $|g_{\mu\alpha}|^2 < 4.5 \times 10^{-5}$ ,  $|g_{\tau\alpha}|^2 < 5.5 \times 10^{-2}$  at CL = 90%.
- <sup>3</sup>DIAZ 98 studied models of spontaneously broken lepton number with both singlet and triplet Higgses. They obtain limits on the parameter space from invisible decay  $Z \rightarrow H^0 A^0 \rightarrow X^0 X^0 X^0 X^0$  and  $e^+e^- \rightarrow Z H^0$  with  $H^0 \rightarrow X^0 X^0$ .
- <sup>4</sup>BOBRAKOV 91 searched for anomalous magnetic interactions between polarized electrons expected from the exchange of a massless pseudoscalar boson (axion). A limit  $x_e^2 < 2 \times 10^{-4}$  (95%CL) is found for the effective anomalous magneton parametrized as  $x_e(G_F/8\pi\sqrt{2})^{1/2}$ .
- <sup>5</sup>ALBRECHT 90E limits are for  $B(\tau \rightarrow \ell X^0)/B(\tau \rightarrow \ell\nu\bar{\nu})$ . Valid for  $m_{X^0} < 100$  MeV. The limits rise to 7.1% (for  $\mu$ ), 5.0% (for  $e$ ) for  $m_{X^0} = 500$  MeV.
- <sup>6</sup>ATIYA 90 limit is for  $m_{X^0} = 0$ . The limit  $B < 1 \times 10^{-8}$  holds for  $m_{X^0} < 95$  MeV. For the reduction of the limit due to finite lifetime of  $X^0$ , see their Fig. 3.
- <sup>7</sup>BOLTON 88 limit corresponds to  $F > 3.1 \times 10^9$  GeV, which does not depend on the chirality property of the coupling.
- <sup>8</sup>CHANDA 88 find  $v_T < 10$  MeV for the weak-triplet Higgs vacuum expectation value in Gelmini-Roncadelli model, and  $v_S > 5.8 \times 10^6$  GeV in the singlet Majoron model.
- <sup>9</sup>CHOI 88 used the observed neutrino flux from the supernova SN 1987A to exclude the neutrino Majoron Yukawa coupling  $h$  in the range  $2 \times 10^{-5} < h < 3 \times 10^{-4}$  for the interaction  $L_{int} = \frac{1}{2} i h \bar{\psi}_\nu \gamma_5 \psi_\nu \phi_X$ . For several families of neutrinos, the limit applies for  $(\Sigma h_i^2)^{1/4}$ .
- <sup>10</sup>PICCIOTTO 88 limit applies when  $m_{X^0} < 55$  MeV and  $\tau_{X^0} > 2$  ns, and it decreases to  $4 \times 10^{-7}$  at  $m_{X^0} = 125$  MeV, beyond which no limit is obtained.
- <sup>11</sup>GOLDMAN 87 limit corresponds to  $F > 2.9 \times 10^9$  GeV for the family symmetry breaking scale from the Lagrangian  $L_{int} = (1/F) \bar{\psi}_\mu \gamma^\mu (a + b\gamma_5) \psi_e \phi_\mu \phi_{X^0}$  with  $a^2 + b^2 = 1$ . This is not as sensitive as the limit  $F > 9.9 \times 10^9$  GeV derived from the search for  $\mu^+ \rightarrow e^+ X^0$  by JODIDIO 86, but does not depend on the chirality property of the coupling.
- <sup>12</sup>Limits are for  $\Gamma(\mu \rightarrow e X^0)/\Gamma(\mu \rightarrow e\nu\bar{\nu})$ . Valid when  $m_{X^0} = 0$ – $93.4$ ,  $98.1$ – $103.5$  MeV.
- <sup>13</sup>EICHLER 86 looked for  $\mu^+ \rightarrow e^+ X^0$  followed by  $X^0 \rightarrow e^+e^-$ . Limits on the branching fraction depend on the mass and lifetime of  $X^0$ . The quoted limits are valid when  $\tau_{X^0} \lesssim 3 \times 10^{-10}$  s if the decays are kinematically allowed.
- <sup>14</sup>JODIDIO 86 corresponds to  $F > 9.9 \times 10^9$  GeV for the family symmetry breaking scale with the parity-conserving effective Lagrangian  $L_{int} = (1/F) \bar{\psi}_\mu \gamma^\mu \psi_e \phi_\mu \phi_{X^0}$ .
- <sup>15</sup>BALTRUSAITIS 85 search for light Goldstone boson ( $X^0$ ) of broken U(1). CL = 95% limits are  $B(\tau \rightarrow \mu^+ X^0)/B(\tau \rightarrow \mu^+ \nu\bar{\nu}) < 0.125$  and  $B(\tau \rightarrow e^+ X^0)/B(\tau \rightarrow e^+ \nu\bar{\nu}) < 0.04$ . Inferred limit for the symmetry breaking scale is  $m > 3000$  TeV.
- <sup>16</sup>The primordial heavy neutrino must decay into  $\nu$  and familon,  $f_A$ , early so that the red-shifted decay products are below critical density, see their table. In addition,  $K \rightarrow \pi f_A$  and  $\mu \rightarrow e f_A$  are unseen. Combining these excludes  $m_{\text{heavy}\nu}$  between  $5 \times 10^{-5}$  and  $5 \times 10^{-4}$  MeV ( $\mu$  decay) and  $m_{\text{heavy}\nu}$  between  $5 \times 10^{-5}$  and 0.1 MeV ( $K$ -decay).

### Majoron Searches in Neutrinoless Double $\beta$ Decay

Limits are for the half-life of neutrinoless  $\beta\beta$  decay with a Majoron emission. No experiment currently claims any such evidence. Only the best or comparable limits for each isotope are reported. Also see the reviews ZUBER 98 and FAESSLER 98B.

# Gauge & Higgs Boson Particle Listings

## Axions ( $A^0$ ) and Other Very Light Bosons

- scale structure, Lyman  $\alpha$ , and the prior Hubble parameter from HST Key Project. A  $\chi^2$  statistic is used. Neutrinos are assumed not to contribute to hot dark matter.
- <sup>13</sup> MORIO 98 points out that a KSVZ axion of this mass range (see CHANG 93) can be a viable hot dark matter of Universe, as long as the model-dependent  $g_{A\gamma}$  is accidentally small enough as originally emphasized by KAPLAN 85; see Fig. 1.
- <sup>14</sup> BORISOV 97 bound is on the axion-electron coupling  $g_{ae} < 1 \times 10^{-13}$  from the photo-production of axions off of magnetic fields in the outer layers of neutron stars.
- <sup>15</sup> KACHELRIESS 97 bound is on the axion-electron coupling  $g_{ae} < 1 \times 10^{-10}$  from the production of axions in strongly magnetized neutron stars. The authors also quote a stronger limit,  $g_{ae} < 9 \times 10^{-13}$  which is strongly dependent on the strength of the magnetic field in white dwarfs.
- <sup>16</sup> KEIL 97 uses new measurements of the axial-vector coupling strength of nucleons, as well as a reanalysis of many-body effects and pion-emission processes in the core of the neutron star, to update limits on the invisible-axion mass.
- <sup>17</sup> RAFFELT 95 reexamined the constraints on axion emission from red giants due to the axion-electron coupling. They improve on DEARBORN 86 by taking into proper account degeneracy effects in the bremsstrahlung rate. The limit comes from requiring the red giant core mass at helium ignition not to exceed its standard value by more than 5% (0.025 solar masses).
- <sup>18</sup> ALTHERR 94 bound is on the axion-electron coupling  $g_{ae} < 1.5 \times 10^{-13}$ , from energy loss via axion emission.
- <sup>19</sup> CHANG 93 updates ENGEL 90 bound with the Kaplan-Manohar ambiguity in  $z=m_u/m_d$  (see the Note on the Quark Masses in the Quark Particle Listings). It leaves the window  $f_A=3 \times 10^5-3 \times 10^6$  GeV open. The constraint from Big-Bang Nucleosynthesis is satisfied in this window as well.
- <sup>20</sup> BERSHADY 91 searched for a line at wave length from 3100–8300 Å expected from 2 $\gamma$  decays of relic thermal axions in intergalactic light of three rich clusters of galaxies.
- <sup>21</sup> KIM 91c argues that the bound from the mass density of the universe will change drastically for the supersymmetric models due to the entropy production of saxion (scalar component in the axionic chiral multiplet) decay. Note that it is an *upperbound* rather than a lowerbound.
- <sup>22</sup> RAFFELT 91b argue that previous SN1987A bounds must be relaxed due to corrections to nucleon bremsstrahlung processes.
- <sup>23</sup> RESSELL 91 uses absence of any intracuster line emission to set limit.
- <sup>24</sup> ENGEL 90 rule out  $10^{-10} \lesssim g_{AN} \lesssim 10^{-3}$ , which for a hadronic axion with EMC motivated axion-nucleon couplings corresponds to  $2.5 \times 10^{-3} \text{ eV} \lesssim m_{A^0} \lesssim 2.5 \times 10^4 \text{ eV}$ . The constraint is loose in the middle of the range, i.e. for  $g_{AN} \sim 10^{-6}$ .
- <sup>25</sup> RAFFELT 90d is a re-analysis of DEARBORN 86.
- <sup>26</sup> The region  $m_{A^0} \gtrsim 2 \text{ eV}$  is also allowed.
- <sup>27</sup> ERICSON 89 considered various nuclear corrections to axion emission in a supernova core, and found a reduction of the previous limit (MAYLE 88) by a large factor.
- <sup>28</sup> MAYLE 89 limit based on naive quark model couplings of axion to nucleons. Limit based on couplings motivated by EMC measurements is 2–4 times weaker. The limit from axion-electron coupling is weak: see HATSUDA 88b.
- <sup>29</sup> RAFFELT 88b derives a limit for the energy generation rate by exotic processes in helium-burning stars  $\epsilon < 100 \text{ erg g}^{-1} \text{ s}^{-1}$ , which gives a firmer basis for the axion limits based on red giant cooling.
- <sup>30</sup> RAFFELT 87 also gives a limit  $g_{A\gamma} < 1 \times 10^{-10} \text{ GeV}^{-1}$ .
- <sup>31</sup> DEARBORN 86 also gives a limit  $g_{A\gamma} < 1.4 \times 10^{-11} \text{ GeV}^{-1}$ .
- <sup>32</sup> RAFFELT 86 gives a limit  $g_{A\gamma} < 1.1 \times 10^{-10} \text{ GeV}^{-1}$  from red giants and  $< 2.4 \times 10^{-9} \text{ GeV}^{-1}$  from the sun.
- <sup>33</sup> KAPLAN 85 says  $m_{A^0} < 23 \text{ eV}$  is allowed for a special choice of model parameters.
- <sup>34</sup> FUKUGITA 82 gives a limit  $g_{A\gamma} < 2.3 \times 10^{-10} \text{ GeV}^{-1}$ .

### Search for Relic Invisible Axions

Limits are for  $[G_{A\gamma\gamma}/m_{A^0}^2]^2 \rho_A$  where  $G_{A\gamma\gamma}$  denotes the axion two-photon coupling,

$L_{\text{int}} = -\frac{G_{A\gamma\gamma}}{4} \phi_A F_{\mu\nu} \tilde{F}^{\mu\nu} = G_{A\gamma\gamma} \phi_A \mathbf{E} \cdot \mathbf{B}$ , and  $\rho_A$  is the axion energy density near the earth.

$< 5.5 \times 10^{-43}$	90	4 DUFFY 06	ADMX	$m_{A^0} = 1.98-2.17 \times 10^{-6} \text{ eV}$
		5 ASZTALOS 04	ADMX	$m_{A^0} = 1.9-3.3 \times 10^{-6} \text{ eV}$
$< 2 \times 10^{-41}$		6 KIM 98	THEO	
$< 1.3 \times 10^{-42}$	95	7 HAGMANN 90	CNTR	$m_{A^0} = (5.4-5.9) 10^{-6} \text{ eV}$
$< 2 \times 10^{-41}$	95	8 WUENSCH 89	CNTR	$m_{A^0} = (4.5-10.2) 10^{-6} \text{ eV}$
		8 WUENSCH 89	CNTR	$m_{A^0} = (11.3-16.3) 10^{-6} \text{ eV}$

- <sup>1</sup> BECK 13 argues that dark-matter axions passing through Earth may generate a small observable signal in resonant S/N/S Josephson junctions. A measurement by HOFFMANN 04 [Physical Review B70 180503 (2004)] is interpreted in terms of subdominant dark matter axions with  $m_{A^0} = 0.11 \text{ meV}$ .
- <sup>2</sup> HOSKINS 11 is analogous to DUFFY 06. See Fig. 4 for the mass-dependent limit in terms of the local density.
- <sup>3</sup> ASZTALOS 10 used the upgraded detector of ASZTALOS 04 to search for halo axions. See their Fig. 5 for the  $m_{A^0}$  dependence of the limit.
- <sup>4</sup> DUFFY 06 used the upgraded detector of ASZTALOS 04, while assuming a smaller velocity dispersion than the isothermal model as in Eq. (8) of their paper. See Fig. 10 of their paper on the axion mass dependence of the limit.
- <sup>5</sup> ASZTALOS 04 looked for a conversion of halo axions to microwave photons in magnetic field. At 90% CL, the KSVZ axion cannot have a local halo density more than  $0.45 \text{ GeV/cm}^3$  in the quoted mass range. See Fig. 7 of their paper on the axion mass dependence of the limit.
- <sup>6</sup> KIM 98 calculated the axion-to-photon couplings for various axion models and compared them to the HAGMANN 90 bounds. This analysis demonstrates a strong model dependence of  $G_{A\gamma\gamma}$  and hence the bound from relic axion search.

<sup>7</sup> HAGMANN 90 experiment is based on the proposal of SIKIVIE 83.

<sup>8</sup> WUENSCH 89 looks for condensed axions near the earth that could be converted to photons in the presence of an intense electromagnetic field via the Primakoff effect, following the proposal of SIKIVIE 83. The theoretical prediction with  $[G_{A\gamma\gamma}/m_{A^0}^2]^2 = 2 \times 10^{-14} \text{ MeV}^{-4}$  (the three generation DFSZ model) and  $\rho_A = 300 \text{ MeV/cm}^3$  that makes up galactic halos gives  $(G_{A\gamma\gamma}/m_{A^0}^2)^2 \rho_A = 4 \times 10^{-44}$ . Note that our definition of  $G_{A\gamma\gamma}$  is  $(1/4\pi)$  smaller than that of WUENSCH 89.

### Invisible $A^0$ (Axion) Limits from Photon Coupling

Limits are for the axion-two-photon coupling  $G_{A\gamma\gamma}$  defined by  $L = G_{A\gamma\gamma} \phi_A \mathbf{E} \cdot \mathbf{B}$ .

For scalars  $S^0$  the limit is on the coupling constant in  $L = G_{S\gamma\gamma} \phi_S (\mathbf{E}^2 - \mathbf{B}^2)$ .

<sup>1</sup> ABRAMOWSKI 13A look for irregularities in the energy spectrum of the BL Lac object PKS 2155–304 measured by H.E.S.S. The limits depend on assumed magnetic field around the source. See their Fig. 7 for mass-dependent limits.

<sup>2</sup> ARMENGAUD 13 is analogous to AVIGNONE 98. See Fig. 6 for the limit.

<sup>3</sup> BETZ 13 performed a microwave-based light shining through the wall experiment. See their Fig. 13 for mass-dependent limits.

<sup>4</sup> FRIEDLAND 13 derived the limit by considering blue-loop suppression of the evolution of red giants with 7–12 solar masses.

<sup>5</sup> MEYER 13 attributed to axion-photon oscillations the observed excess of very high-energy  $\gamma$ -rays with respect to predictions based on extragalactic background light models. See their Fig. 4 for mass-dependent lower limits for various magnetic field configurations.

<sup>6</sup> CADAMURO 12 derived cosmological limits on  $G_{A\gamma\gamma}$  for axion-like particles. See their Fig. 1 for mass-dependent limits.

<sup>7</sup> PAYEZ 12 derive limits from polarization measurements of quasar light (see their Fig. 3). The limits depend on assumed magnetic field strength in galaxy clusters. The limits depend on assumed magnetic field and electron density in the local galaxy supercluster.

<sup>8</sup> ARIK 11 search for solar axions using  $^3\text{He}$  buffer gas in CAST, continuing from the  $^4\text{He}$  version of ARIK 09. See Fig. 2 for the exact mass-dependent limits.

<sup>9</sup> ALPS is a photon regeneration experiment. See their Fig. 4 for mass-dependent limits on scalar and pseudoscalar bosons.

<sup>10</sup> AHMED 09A is analogous to AVIGNONE 98.

<sup>11</sup> ARIK 09 is the  $^4\text{He}$  filling version of the CAST axion helioscope in analogy to INOUE 02 and INOUE 08. See their Fig. 7 for mass-dependent limits.

<sup>12</sup> CHOU 09 use the GammeV apparatus in the afterglow mode to search for chameleons, (pseudo)scalar bosons with a mass depending on the environment. For pseudoscalars they exclude at  $3\sigma$  the range  $2.6 \times 10^{-7} \text{ GeV}^{-1} < G_{A\gamma\gamma} < 4.2 \times 10^{-6} \text{ GeV}^{-1}$  for vacuum  $m_{A^0}$  roughly below 6 meV for density scaling index exceeding 0.8.

<sup>13</sup> GONDOLO 09 use the all-flavor measured solar neutrino flux to constrain solar interior temperature and thus energy losses.

<sup>14</sup> LIPSS photon regeneration experiment, assuming scalar particle  $S^0$ . See Fig. 4 for mass-dependent limits.

# Gauge & Higgs Boson Particle Listings

## Axions ( $A^0$ ) and Other Very Light Bosons

- <sup>15</sup> CHOU 08 perform a variable-baseline photon regeneration experiment. See their Fig. 3 for mass-dependent limits. Excludes the PVLAS result of ZAVATTINI 06.
- <sup>16</sup> FOCHE 08 is an update of ROBILLIARD 07. See their Fig. 12 for mass-dependent limits.
- <sup>17</sup> INOUE 08 is an extension of INOUE 02 to larger axion masses, using the Tokyo axion helioscope. See their Fig. 4 for mass-dependent limits.
- <sup>18</sup> ZAVATTINI 08 is an upgrade of ZAVATTINI 06, see their Fig. 8 for mass-dependent limits. They now exclude the parameter range where ZAVATTINI 06 had seen a positive signature.
- <sup>19</sup> ANDRIAMONJE 07 looked for Primakoff conversion of solar axions in 9T superconducting magnet into X-rays. Supersedes ZIOUTAS 05.
- <sup>20</sup> ROBILLIARD 07 perform a photon regeneration experiment with a pulsed laser and pulsed magnetic field. See their Fig. 4 for mass-dependent limits. Excludes the PVLAS result of ZAVATTINI 06 with a CL exceeding 99.9%.
- <sup>21</sup> ZAVATTINI 06 propagate a laser beam in a magnetic field and observe dichroism and birefringence effects that could be attributed to an axion-like particle. This result is now excluded by ROBILLIARD 07, ZAVATTINI 08, and CHOU 08.
- <sup>22</sup> INOUE 02 looked for Primakoff conversion of solar axions in 4T superconducting magnet into X ray.
- <sup>23</sup> MORALES 02b looked for the coherent conversion of solar axions to photons via the Primakoff effect in Germanium detector.
- <sup>24</sup> BERNABEI 01b looked for Primakoff coherent conversion of solar axions into photons via Bragg scattering in NaI crystal in DAMA dark matter detector.
- <sup>25</sup> ASTIER 00b looked for production of axions from the interaction of high-energy photons with the horn magnetic field and their subsequent re-conversion to photons via the interaction with the NOMAD dipole magnetic field.
- <sup>26</sup> MASSO 00 studied limits on axion-proton coupling using the induced axion-photon coupling through the proton loop and CAMERON 93 bound on the axion-photon coupling using optical rotation. They obtained the bound  $g_{p\gamma}^2/4\pi < 1.7 \times 10^{-9}$  for the coupling  $g_{p\gamma}^2 P_{\gamma}^2 \rho_A$ .
- <sup>27</sup> AVIGNONE 98 result is based on the coherent conversion of solar axions to photons via the Primakoff effect in a single crystal germanium detector.
- <sup>28</sup> Based on the conversion of solar axions to X-rays in a strong laboratory magnetic field.
- <sup>29</sup> Experiment based on proposal by MAIANI 86.
- <sup>30</sup> Experiment based on proposal by VANBIBBER 87.
- <sup>31</sup> LAZARUS 92 experiment is based on proposal found in VANBIBBER 89.
- <sup>32</sup> RUOSO 92 experiment is based on the proposal by VANBIBBER 87.
- <sup>33</sup> SEMERTZIDIS 90 experiment is based on the proposal of MAIANI 86. The limit is obtained by taking the noise amplitude as the upper limit. Limits extend to  $m_{A^0} = 4 \times 10^{-3}$  where  $G_{A\gamma\gamma} < 1 \times 10^{-4}$  GeV $^{-1}$ .

### Limit on Invisible $A^0$ (Axion) Electron Coupling

The limit is for  $G_{Aee} \partial_{\mu} \phi_A \bar{e} \gamma^{\mu} e$  in GeV $^{-1}$ , or equivalently, the dipole-dipole potential  $\frac{G_{Aee}^2}{4\pi} ((\sigma_1 \cdot \sigma_2) - 3(\sigma_1 \cdot \mathbf{n})(\sigma_2 \cdot \mathbf{n}))/r^3$  where  $\mathbf{n} = \mathbf{r}/r$ .

- <sup>1</sup> ABE 13D is analogous to DERBIN 12, using the XMASS detector.
- <sup>2</sup> ARMENGAUD 13 is similar to AALSETH 11. See their Fig. 10 for limits between 3 keV  $< m_{A^0} < 100$  keV.
- <sup>3</sup> ARMENGAUD 13 is similar to DERBIN 12, and take account of axio-recombination and axio-deexcitation effects. See their Fig. 12 for mass-dependent limits.
- <sup>4</sup> BARTH 13 search for solar axions produced by axion-electron coupling, and obtained the limit,  $G_{Aee} \cdot G_{A\gamma\gamma} < 7.9 \times 10^{-20}$  GeV $^{-2}$  at 95%CL.
- <sup>5</sup> DERBIN 13 looked for 5.5 MeV solar axions produced in  $pd \rightarrow {}^3\text{He } A^0$  in a BGO detector through the axioelectric effect. See their Fig. 4 for mass-dependent limits.
- <sup>6</sup> HECKEL 13 studied the influence of 2 or 4 stationary sources each containing  $6.0 \times 10^{24}$  polarized electrons, on a rotating torsion pendulum containing  $9.8 \times 10^{24}$  polarized electrons. See their Fig. 4 for mass-dependent limits.
- <sup>7</sup> VIAUX 13A constrain axion emission using the observed brightness of the tip of the red-giant branch in the globular cluster M5.
- <sup>8</sup> CORSICO 12 attributed the excessive cooling rate of the pulsating white dwarf R548 to emission of axions with  $G_{Aee} \approx 5 \times 10^{-10}$ .
- <sup>9</sup> DERBIN 12 look for solar axions with the axio-electric effect in a Si(Li) detector. The solar production is based on Compton and bremsstrahlung processes.
- <sup>10</sup> AALSETH 11 is analogous to AHMED 09A. See their Fig. 4 for mass-dependent limits.

- <sup>11</sup> AHMED 09A assume keV-mass pseudoscalars are the local dark matter and constrain the axio-electric effect in the CDMS detector. See their Fig. 5 for mass-dependent limits.
- <sup>12</sup> DAVOUDIASL 09 use geophysical constraints on Earth cooling by axion emission.
- <sup>13</sup> These experiments measured induced magnetization of a bulk material by the spin-dependent potential generated from other bulk material with aligned electron spins, where the magnetic field is shielded with superconductor.
- <sup>14</sup> These experiments used a torsion pendulum to measure the potential between two bulk matter objects where the spins are polarized but without a net magnetic field in either of them.
- <sup>15</sup> WINELAND 91 looked for an effect of bulk matter with aligned electron spins on atomic hyperfine splitting using nuclear magnetic resonance.

### Invisible $A^0$ (Axion) Limits from Nucleon Coupling

Limits are for the axion mass in eV.

VALUE (eV)	CL%	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
$< 2.50 \times 10^2$	95	<sup>1</sup> ALESSANDRIA 13	CNTR	Solar axion
$< 1.55 \times 10^2$	90	<sup>2</sup> ARMENGAUD 13	EDEL	Solar axion
$< 8.6 \times 10^3$	90	<sup>3</sup> BELLI	12	CNTR Solar axion
$< 1.41 \times 10^2$	90	<sup>4</sup> BELLINI	12B	BORX Solar axion
$< 1.45 \times 10^2$	95	<sup>5</sup> DERBIN	11	CNTR Solar axion
		<sup>6</sup> BELLINI	08	CNTR Solar axion
		<sup>7</sup> ADELBERGER 07		Test of Newton's law

- <sup>1</sup> ALESSANDRIA 13 used the CUORE experiment to look for 14.4 keV solar axions produced from the M1 transition of thermally excited  ${}^{57}\text{Fe}$  nuclei in the solar core, using the axio-electric effect. The limit assumes the hadronic axion model. See their Fig. 4 for the limit on product of axion couplings to electrons and nucleons.
- <sup>2</sup> ARMENGAUD 13 is analogous to ALESSANDRIA 13. The limit assumes the hadronic axion model. See their Fig. 8 for the limit on product of axion couplings to electrons and nucleons.
- <sup>3</sup> BELLI 12 looked for solar axions emitted by the M1 transition of  ${}^7\text{Li}^*$  (478 keV) after the electron capture of  ${}^7\text{Be}$ , using the resonant excitation of  ${}^7\text{Li}$  in the LiF crystal. The mass bound assumes  $m_U/m_D = 0.55$ ,  $m_U/m_S = 0.029$ , and the flavor-singlet axial vector matrix element  $S = 0.4$ .
- <sup>4</sup> BELLINI 12b looked for 5.5 MeV solar axions produced in the  $pd \rightarrow {}^3\text{He } A^0$ . The limit assumes the hadronic axion model. See their Figs. 4 and 5 for mass-dependent limits on products of axion couplings to photons, electrons, and nucleons.
- <sup>5</sup> DERBIN 11 looked for solar axions emitted by the M1 transition of thermally excited  ${}^{57}\text{Fe}$  nuclei in the Sun, using their possible resonant capture on  ${}^{57}\text{Fe}$  in the laboratory. The mass bound assumes  $m_U/m_D = 0.56$  and the flavor-singlet axial vector matrix element  $S = 3F - D \approx 0.5$ .
- <sup>6</sup> BELLINI 08 consider solar axions emitted in the M1 transition of  ${}^7\text{Li}^*$  (478 keV) and look for a peak at 478 keV in the energy spectra of the Counting Test Facility (CTF), a Borexino prototype. For  $m_{A^0} < 450$  keV they find mass-dependent limits on products of axion couplings to photons, electrons, and nucleons.
- <sup>7</sup> ADELBERGER 07 use precision tests of Newton's law to constrain a force contribution from the exchange of two pseudoscalars. See their Fig. 5 for limits on the pseudoscalar coupling to nucleons, relevant for  $m_{A^0}$  below about 1 meV.

### Axion Limits from $T$ -violating Medium-Range Forces

The limit is for the coupling  $g = g_p g_s$  in a  $T$ -violating potential between nucleons or nucleon and electron of the form  $V = \frac{g\hbar^2}{8\pi m_p} (\boldsymbol{\sigma} \cdot \hat{\mathbf{r}}) \left( \frac{1}{r^2} + \frac{1}{\lambda r} \right) e^{-r/\lambda}$ , where  $g_p$  and  $g_s$  are dimensionless scalar and pseudoscalar coupling constants and  $\lambda = \hbar/(m_A c)$  is the range of the force.

	<sup>12</sup> POSPELOV	98	THEO neutron EDM
	<sup>13</sup> YODIN	96	
	<sup>14</sup> RITTER	93	torsion pendulum
	<sup>15</sup> VENEMA	92	nuclear spin-precession frequencies
	<sup>16</sup> WINELAND	91	NMR

- <sup>1</sup> BULATOWICZ 13 looked for NMR frequency shifts in polarized  ${}^{129}\text{Xe}$  and  ${}^{131}\text{Xe}$  when a zirconia rod is positioned near the NMR cell, and find  $g < 1 \times 10^{-19} - 1 \times 10^{-24}$  for  $\lambda = 0.01-1$  cm. See their Fig. 4 for their limits.
- <sup>2</sup> CHU 13 look for a shift of the spin precession frequency of polarized  ${}^3\text{He}$  in the presence of an unpolarized mass, in analogy to YODIN 96. See Fig. 3 for limits on  $g$  in the approximate  $m_{A^0}$  range 0.02-2 meV.
- <sup>3</sup> RAFFELT 12 show that the pseudoscalar couplings to electron and nucleon and the scalar coupling to nucleon are individually constrained by stellar energy-loss arguments and searches for anomalous monopole-monopole forces, together providing restrictive constraints on  $g$ . See their Figs. 2 and 3 for results.
- <sup>4</sup> HOEDL 11 use a novel torsion pendulum to study the force by the polarized electrons of an external magnet. In their Fig. 3 they show restrictive limits on  $g$  in the approximate  $m_{A^0}$  range 0.03-10 meV.

See key on page 547

Gauge & Higgs Boson Particle Listings  
Axions ( $A^0$ ) and Other Very Light Bosons

- <sup>5</sup> PETUKHOV 10 use spin relaxation of polarized  $^3\text{He}$  and find  $g < 3 \times 10^{-23} \text{ (cm}/\lambda)^2$  at 95% CL for the force range  $\lambda = 10^{-4}$ –1 cm.
- <sup>6</sup> SEREBROV 10 use spin precession of ultracold neutrons close to bulk matter and find  $g < 2 \times 10^{-21} \text{ (cm}/\lambda)^2$  at 95% CL for the force range  $\lambda = 10^{-4}$ –1 cm.
- <sup>7</sup> IGNATOVICH 09 use data on depolarization of ultracold neutrons in material traps. They show  $\lambda$ -dependent limits in their Fig. 1.
- <sup>8</sup> SEREBROV 09 uses data on depolarization of ultracold neutrons stored in material traps and finds  $g < 2.96 \times 10^{-21} \text{ (cm}/\lambda)^2$  for the force range  $\lambda = 10^{-3}$ –1 cm and  $g < 3.9 \times 10^{-22} \text{ (cm}/\lambda)^2$  for  $\lambda = 10^{-4}$ – $10^{-3}$  cm, each time at 95% CL, significantly improving on BAESSLER 07.
- <sup>9</sup> BAESSLER 07 use the observation of quantum states of ultracold neutrons in the Earth's gravitational field to constrain  $g$  for an interaction range  $1 \mu\text{m}$ –a few nm. See their Fig. 3 for results.
- <sup>10</sup> HECKEL 06 studied the influence of unpolarized bulk matter, including the laboratory's surroundings or the Sun, on a torsion pendulum containing about  $9 \times 10^{22}$  polarized electrons. See their Fig. 4 for limits on  $g$  as a function of interaction range.
- <sup>11</sup> NI 99 searched for a  $T$ -violating medium-range force acting on paramagnetic  $\text{Tb F}_3$  salt. See their Fig. 1 for the result.
- <sup>12</sup> POSPELOV 98 studied the possible contribution of  $T$ -violating Medium-Range Force to the neutron electric dipole moment, which is possible when axion interactions violate CP. The size of the force among nucleons must be smaller than gravity by a factor of  $2 \times 10^{-10} \text{ (1 cm}/\lambda_A)$ , where  $\lambda_A = \hbar/m_A c$ .
- <sup>13</sup> YODIN 96 compared the precession frequencies of atomic  $^{199}\text{Hg}$  and Cs when a large mass is positioned near the cells, relative to an applied magnetic field. See Fig. 3 for their limits.
- <sup>14</sup> RITTER 93 studied the influence of bulk mass with polarized electrons on an unpolarized torsion pendulum, providing limits in the interaction range from 1 to 100 cm.
- <sup>15</sup> VENEMA 92 looked for an effect of Earth's gravity on nuclear spin-precession frequencies of  $^{199}\text{Hg}$  and  $^{201}\text{Hg}$  atoms.
- <sup>16</sup> WINELAND 91 looked for an effect of bulk matter with aligned electron spins on atomic hyperfine resonances in stored  $^9\text{Be}^+$  ions using nuclear magnetic resonance.

## Hidden Photons: Kinetic Mixing Parameter Limits

Hidden photons limits are listed for the first time, including only the most recent papers. Suggestions for previous important results are welcome. Limits are on the kinetic mixing parameter  $\chi$  which is defined by the Lagrangian

$$L = -\frac{1}{4} F_{\mu\nu} F^{\mu\nu} - \frac{1}{4} F'_{\mu\nu} F'^{\mu\nu} - \frac{\chi}{2} F_{\mu\nu} F'^{\mu\nu} + \frac{m^2}{2} A'_\mu A'^\mu,$$

where  $A_\mu$  and  $A'_\mu$  are the photon and hidden-photon fields with field strengths  $F_{\mu\nu}$  and  $F'_{\mu\nu}$ , respectively, and  $m_\gamma$  is the hidden-photon mass.

VALUE	CL%	DOCUMENT ID	TECN	COMMENT

- <sup>1</sup> AN 13B examined the stellar production of hidden photons, correcting an important error of the production rate of the longitudinal mode which now dominates. See their Fig. 2 for mass-dependent limits based on solar energy loss.
- <sup>2</sup> AN 13c use the solar flux of hidden photons to set a limit on the atomic ionization rate in the XENON10 experiment. They find  $\chi < 3 \times 10^{-12} \text{ (} m_\gamma/1 \text{ eV)}$  for  $m_\gamma < 1 \text{ eV}$ . See their Fig. 2 for mass-dependent limits.
- <sup>3</sup> HORVAT 13 look for hidden-photo-electric effect in HPGe detectors induced by solar hidden photons. See their Fig. 3 for mass-dependent limits.
- <sup>4</sup> INADA 13 search for hidden photons using an intense X-ray beamline at SPring-8. See their Fig. 4 for mass-dependent limits.
- <sup>5</sup> MIZUMOTO 13 look for solar hidden photons. See their Fig. 5 for mass-dependent limits.
- <sup>6</sup> PARKER 13 look for hidden photons using a cryogenic resonant microwave cavity. See their Fig. 5 for mass-dependent limits.
- <sup>7</sup> PARKER 13 derived a limit for the hidden photon CDM with a randomly oriented hidden photon field.
- <sup>8</sup> REDONDO 13 examined the solar emission of hidden photons including the enhancement factor for the longitudinal mode pointed out by AN 13b, and also updated stellar-energy loss arguments. See their Fig. 3 for mass-dependent limits, including a review of the currently best limits from other arguments.

$$J = \frac{1}{2}$$

## e MASS (atomic mass units u)

The primary determination of an electron's mass comes from measuring the ratio of the mass to that of a nucleus, so that the result is obtained in u (atomic mass units). The conversion factor to MeV is more uncertain than the mass of the electron in u; indeed, the recent improvements in the mass determination are not evident when the result is given in MeV. In this datablock we give the result in u, and in the following datablock in MeV.

VALUE (10 <sup>-6</sup> u)	DOCUMENT ID	TECN	COMMENT

<sup>2</sup> FARNHAM 95 compares cyclotron frequency of trapped electrons with that of a single trapped <sup>12</sup>C<sup>6+</sup> ion.

## e MASS

2010 CODATA (MOHR 12) gives the conversion factor from u (atomic mass units, see the above datablock) to MeV as 931.494 061 (21). Earlier values use the then-current conversion factor. The conversion error dominates the uncertainty of the masses given below.

VALUE (MeV)	DOCUMENT ID	TECN	COMMENT
<b>0.510998928 ± 0.00000011</b>	MOHR 12	RVUE	2010 CODATA value

<sup>14</sup> HUDSON 11 gives a measurement corresponding to this limit as  $(-2.4 \pm 5.7 \pm 1.5) \times 10^{-28}$  ecm.

<sup>15</sup> ECKEL 12 gives a measurement corresponding to this limit as  $(-1.07 \pm 3.06 \pm 1.74) \times 10^{-25}$  ecm.

<sup>16</sup> ABDULLAH 90, COMMINS 94, and REGAN 02 use the relativistic enhancement of a valence electron's electric dipole moment in a high-Z atom.

e<sup>-</sup> MEAN LIFE / BRANCHING FRACTION

A test of charge conservation. See the "Note on Testing Charge Conservation and the Pauli Exclusion Principle" following this section in our 1992 edition (Physical Review **D45** S1 (1992), p. VI.10).

Most of these experiments are one of three kinds: Attempts to observe (a) the 25.5 keV gamma ray produced in  $e^- \rightarrow \nu_e \gamma$ , (b) the (K) shell x-ray produced when an electron decays without additional energy deposit, e.g.,  $e^- \rightarrow \nu_e \bar{\nu}_e \nu_e$  ("disappearance" experiments), and (c) nuclear de-excitation gamma rays after the electron disappears from an atomic shell and the nucleus is left in an excited state. The last can include both weak boson and photon mediating processes. We use the best  $e^- \rightarrow \nu_e \gamma$  limit for the Summary Tables.

Note that we use the mean life rather than the half life, which is often reported.

e<sup>-</sup> → ν<sub>e</sub> γ and astrophysical limits

VALUE (yr)	CL%	DOCUMENT ID	TECN	COMMENT
<b>&gt; 4.6 × 10<sup>26</sup></b>	90	BACK 02	BORX	$e^- \rightarrow \nu \gamma$
• • • We do not use the following data for averages, fits, limits, etc. • • •

 $\mu$  MASS (atomic mass units u)

The muon's mass is obtained from the muon-electron mass ratio as determined from the measurement of Zeeman transition frequencies in muonium ( $\mu^+e^-$  atom). Since the electron's mass is most accurately known in u, the muon's mass is also most accurately known in u. The conversion factor to MeV has approximately the same relative uncertainty as the mass of the muon in u. In this datablock we give the result in u, and in the following datablock in MeV.

$\mu/p$  MAGNETIC MOMENT RATIO

This ratio is used to obtain a precise value of the muon mass and to reduce experimental muon Larmor frequency measurements to the muon magnetic moment anomaly. Measurements with an error  $> 0.00001$  have been omitted. By convention, the minus sign on this ratio is omitted. CODATA values were fitted using their selection of data, plus other data from multiparameter fits.

## THE MUON ANOMALOUS MAGNETIC MOMENT

Updated August 2013 by A. Hoecker (CERN), and W.J. Marciano (BNL).

The Dirac equation predicts a muon magnetic moment,  $\vec{M} = g_\mu \frac{e}{2m_\mu} \vec{S}$ , with gyromagnetic ratio  $g_\mu = 2$ . Quantum loop effects lead to a small calculable deviation from  $g_\mu = 2$ , parameterized by the anomalous magnetic moment

$$a_\mu \equiv \frac{g_\mu - 2}{2}. \quad (1)$$

That quantity can be accurately measured and, within the Standard Model (SM) framework, precisely predicted. Hence, comparison of experiment and theory tests the SM at its quantum loop level. A deviation in  $a_\mu^{\text{exp}}$  from the SM expectation would signal effects of new physics, with current sensitivity reaching up to mass scales of  $\mathcal{O}(\text{TeV})$  [1,2]. For recent and very thorough muon  $g - 2$  reviews, see Refs. [3–5].

The E821 experiment at Brookhaven National Lab (BNL) studied the precession of  $\mu^+$  and  $\mu^-$  in a constant external magnetic field as they circulated in a confining storage ring. It found [7]<sup>1</sup>

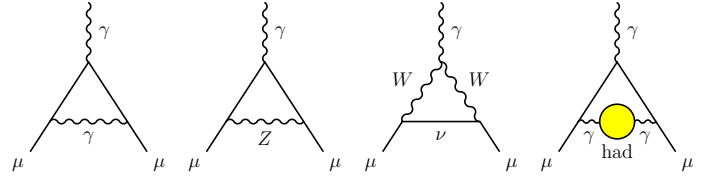

$$\begin{aligned} a_{\mu^+}^{\text{exp}} &= 11\,659\,204(6)(5) \times 10^{-10}, \\ a_{\mu^-}^{\text{exp}} &= 11\,659\,215(8)(3) \times 10^{-10}, \end{aligned} \quad (2)$$

where the first errors are statistical and the second systematic. Assuming CPT invariance and taking into account correlations between systematic uncertainties, one finds for their average [6,7]

$$a_\mu^{\text{exp}} = 11\,659\,209.1(5.4)(3.3) \times 10^{-10}. \quad (3)$$

These results represent about a factor of 14 improvement over the classic CERN experiments of the 1970's [8]. Improvement of the measurement in Eq. (3) by a factor of four by moving the

<sup>1</sup> The original results reported by the experiment have been updated in Eq. (2) and Eq. (3) to the newest value for the absolute muon-to-proton magnetic ratio  $\lambda = 3.183345107(84)$  [6]. The change induced in  $a_\mu^{\text{exp}}$  with respect to the value of  $\lambda = 3.18334539(10)$  used in Ref. 7 amounts to  $+1.12 \times 10^{-10}$ .

**Figure 1:** Representative diagrams contributing to  $a_\mu^{\text{SM}}$ . From left to right: first order QED (Schwinger term), lowest-order weak, lowest-order hadronic.

E821 storage ring to Fermilab, and utilizing a cleaner and more intense muon beam is in progress. An even more ambitious precision goal is set by an experiment based on a beam of ultra-cold muons proposed at the Japan Proton Accelerator Research Complex.

The SM prediction for  $a_\mu^{\text{SM}}$  is generally divided into three parts (see Fig. 1 for representative Feynman diagrams)

$$a_\mu^{\text{SM}} = a_\mu^{\text{QED}} + a_\mu^{\text{EW}} + a_\mu^{\text{Had}}. \quad (4)$$

The QED part includes all photonic and leptonic ( $e, \mu, \tau$ ) loops starting with the classic  $\alpha/2\pi$  Schwinger contribution. It has been computed through 5 loops [9]

$$\begin{aligned} a_\mu^{\text{QED}} &= \frac{\alpha}{2\pi} + 0.765\,857\,425(17) \left(\frac{\alpha}{\pi}\right)^2 + 24.050\,509\,96(32) \left(\frac{\alpha}{\pi}\right)^3 \\ &\quad + 130.879\,6(6.3) \left(\frac{\alpha}{\pi}\right)^4 + 753.3(1.0) \left(\frac{\alpha}{\pi}\right)^5 + \dots \end{aligned} \quad (5)$$

with a few significant changes in the coefficients since our previous update of this review in 2011. Employing<sup>2</sup>  $\alpha^{-1} = 137.035\,999\,049(90)$ , obtained [6] from the precise measurements of  $h/m_{\text{Rb}}$  [11], the Rydberg constant and  $m_{\text{Rb}}/m_e$  [6], leads to [9]

$$a_\mu^{\text{QED}} = 116\,584\,718.95(0.08) \times 10^{-11}, \quad (6)$$

where the small error results mainly from the uncertainty in  $\alpha$ .

Loop contributions involving heavy  $W^\pm, Z$  or Higgs particles are collectively labeled as  $a_\mu^{\text{EW}}$ . They are suppressed by at least a factor of  $\frac{\alpha}{\pi} \frac{m_\mu^2}{m_W^2} \simeq 4 \times 10^{-9}$ . At 1-loop order [12]

$$\begin{aligned} a_\mu^{\text{EW}}[1\text{-loop}] &= \frac{G_\mu m_\mu^2}{8\sqrt{2}\pi^2} \left[ \frac{5}{3} + \frac{1}{3} (1 - 4\sin^2\theta_W)^2 \right. \\ &\quad \left. + \mathcal{O}\left(\frac{m_\mu^2}{M_Z^2}\right) + \mathcal{O}\left(\frac{m_\mu^2}{m_H^2}\right) \right], \\ &= 194.8 \times 10^{-11}, \end{aligned} \quad (7)$$

for  $\sin^2\theta_W \equiv 1 - M_W^2/M_Z^2 \simeq 0.223$ , and where  $G_\mu \simeq 1.166 \times 10^{-5} \text{ GeV}^{-2}$  is the Fermi coupling constant. Two-loop

<sup>2</sup> In the previous versions of this review we used the precise  $\alpha$  value determined from the electron  $a_e$  measurement [9,10]. With the new measurement [11] of the recoil velocity of Rubidium,  $h/m_{\text{Rb}}$ , an  $a_e$ -independent determination of  $\alpha$  with sufficient precision is available and preferred.

# Lepton Particle Listings

## $\mu$

corrections are relatively large and negative [13]. For a Higgs boson mass of  $\simeq 126$  GeV [13]

$$a_{\mu}^{\text{EW}[2\text{-loop}]} = -41.2(1.0) \times 10^{-11}, \quad (8)$$

where the uncertainty stems from quark triangle loops. The 3-loop leading logarithms are negligible [13,14],  $\mathcal{O}(10^{-12})$ , implying in total

$$a_{\mu}^{\text{EW}} = 153.6(1.0) \times 10^{-11}. \quad (9)$$

Hadronic (quark and gluon) loop contributions to  $a_{\mu}^{\text{SM}}$  give rise to its main theoretical uncertainties. At present, those effects are not calculable from first principles, but such an approach, at least partially, may become possible as lattice QCD matures. Instead, one currently relies on a dispersion relation approach to evaluate the lowest-order (*i.e.*,  $\mathcal{O}(\alpha^2)$ ) hadronic vacuum polarization contribution  $a_{\mu}^{\text{Had}}[\text{LO}]$  from corresponding cross section measurements [15]

$$a_{\mu}^{\text{Had}}[\text{LO}] = \frac{1}{3} \left( \frac{\alpha}{\pi} \right)^2 \int ds \frac{K(s)}{s} R^{(0)}(s), \quad (10)$$

where  $K(s)$  is a QED kernel function [16], and where  $R^{(0)}(s)$  denotes the ratio of the bare<sup>3</sup> cross section for  $e^+e^-$  annihilation into hadrons to the pointlike muon-pair cross section at center-of-mass energy  $\sqrt{s}$ . The function  $K(s) \sim 1/s$  in Eq. (10) gives a strong weight to the low-energy part of the integral. Hence,  $a_{\mu}^{\text{Had}}[\text{LO}]$  is dominated by the  $\rho(770)$  resonance.

Currently, the available  $\sigma(e^+e^- \rightarrow \text{hadrons})$  data give a leading-order hadronic vacuum polarization (representative) contribution of [17]

$$a_{\mu}^{\text{Had}}[\text{LO}] = 6\,923(42)(3) \times 10^{-11}, \quad (11)$$

where the first error is experimental (dominated by systematic uncertainties), and the second due to perturbative QCD, which is used at intermediate and large energies to predict the contribution from the quark-antiquark continuum. New multi-hadron data from the BABAR experiment have increased the constraints on unmeasured exclusive final states and led to a small reduction in the hadronic contribution compared to the 2009 PDG value.

Alternatively, one can use precise vector spectral functions from  $\tau \rightarrow \nu_{\tau} + \text{hadrons}$  decays [18] that can be related to isovector  $e^+e^- \rightarrow \text{hadrons}$  cross sections by isospin symmetry. Replacing  $e^+e^-$  data in the two-pion and four-pion channels by the corresponding isospin-transformed  $\tau$  data, and applying isospin-violating corrections (from QED and  $m_d - m_u \neq 0$ ), one finds [17]

$$a_{\mu}^{\text{Had}}[\text{LO}] = 7\,015(42)(19)(3) \times 10^{-11} (\tau), \quad (12)$$

<sup>3</sup> The bare cross section is defined as the measured cross section corrected for initial-state radiation, electron-vertex loop contributions and vacuum-polarization effects in the photon propagator. However, QED effects in the hadron vertex and final state, as photon radiation, are included.

where the first error is experimental, the second estimates the uncertainty in the isospin-breaking corrections applied to the  $\tau$  data, and the third error is due to perturbative QCD. The current discrepancy between the  $e^+e^-$  and  $\tau$ -based determinations of  $a_{\mu}^{\text{Had}}[\text{LO}]$  has been reduced to  $1.8\sigma$  with respect to earlier evaluations. New  $e^+e^-$  and  $\tau$  data from the  $B$ -factory experiments BABAR and Belle have increased the experimental information. Reevaluated isospin-breaking corrections have also contributed to this improvement [19]. BABAR reported good agreement with the  $\tau$  data in the most important two-pion channel [20]. The remaining discrepancy with the older  $e^+e^-$  and  $\tau$  datasets may be indicative of problems with one or both data sets. It may also suggest the need for additional isospin-violating corrections to the  $\tau$  data. Several evaluations of  $a_{\mu}^{\text{Had}}[\text{LO}]$  have been published leading to similar results (see Fig. 2). The low-energy contribution to  $a_{\mu}^{\text{Had}}[\text{LO}]$  has also been evaluated with the use of additional theory or model constraints in Refs. [22] and [23], respectively.

Higher order,  $\mathcal{O}(\alpha^3)$ , hadronic contributions are obtained from dispersion relations using the same  $e^+e^- \rightarrow \text{hadrons}$  data [18,21,24], giving  $a_{\mu}^{\text{Had,Disp}}[\text{NLO}] = (-98.4 \pm 0.6) \times 10^{-11}$ , along with model-dependent estimates of the hadronic light-by-light scattering contribution,  $a_{\mu}^{\text{Had,LBL}}[\text{NLO}]$ , motivated by large- $N_C$  QCD [25–31].<sup>4</sup> Following [29], one finds for the sum of the two terms

$$a_{\mu}^{\text{Had}}[\text{NLO}] = 7(26) \times 10^{-11}, \quad (13)$$

where the error is dominated by hadronic light-by-light uncertainties.

Adding Eqs. (6), (9), (11) and (13) gives the representative  $e^+e^-$  data based SM prediction

$$a_{\mu}^{\text{SM}} = 116\,591\,803(1)(42)(26) \times 10^{-11}, \quad (14)$$

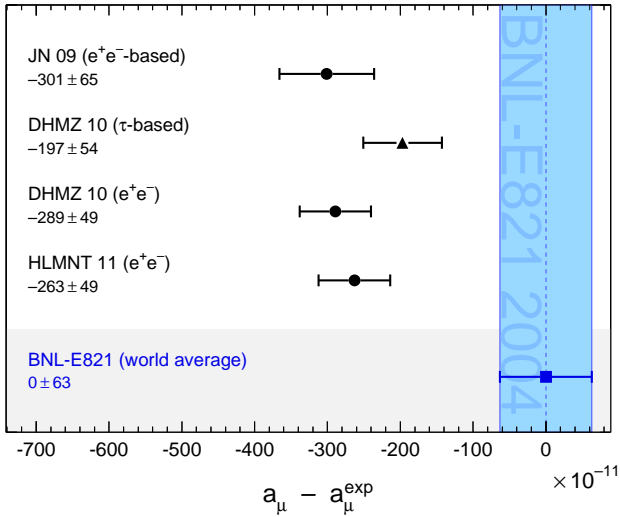

where the errors are due to the electroweak, lowest-order hadronic, and higher-order hadronic contributions, respectively. The difference between experiment and theory

$$\Delta a_{\mu} = a_{\mu}^{\text{exp}} - a_{\mu}^{\text{SM}} = 288(63)(49) \times 10^{-11}, \quad (15)$$

(with all errors combined in quadrature) represents an interesting but not yet conclusive discrepancy of 3.6 times the estimated  $1\sigma$  error. All the recent estimates for the hadronic contribution compiled in Fig. 2 exhibit similar discrepancies. Switching to  $\tau$  data reduces the discrepancy to  $2.4\sigma$ , assuming the isospin-violating corrections are under control within the estimated uncertainties (see Ref. 32 for an analysis leading to a different conclusion).

An alternate interpretation is that  $\Delta a_{\mu}$  may be a new physics signal with supersymmetric particle loops as the leading candidate explanation. Such a scenario is quite natural, since

<sup>4</sup> Some representative recent estimates of the hadronic light-by-light scattering contribution,  $a_{\mu}^{\text{Had,LBL}}[\text{NLO}]$ , that followed after the sign correction of [27], are:  $105(26) \times 10^{-11}$  [29],  $110(40) \times 10^{-11}$  [25],  $136(25) \times 10^{-11}$  [26].

**Figure 2:** Compilation of recent published results for  $a_\mu$  (in units of  $10^{-11}$ ), subtracted by the central value of the experimental average (3). The shaded band indicates the size of the experimental uncertainty. The SM predictions are taken from: JN [4], DHMZ [17], HMNT [21]. Note that the quoted errors in the figure do not include the uncertainty on the subtracted experimental value. To obtain for each theory calculation a result equivalent to Eq. (15), the errors from theory and experiment must be added in quadrature.

generically, supersymmetric models predict [1] an additional contribution to  $a_\mu^{\text{SM}}$

$$a_\mu^{\text{SUSY}} \simeq \text{sign}(\mu) \cdot 130 \times 10^{-11} \cdot \left( \frac{100 \text{ GeV}}{m_{\text{SUSY}}} \right)^2 \tan\beta, \quad (16)$$

where  $m_{\text{SUSY}}$  is a representative supersymmetric mass scale,  $\tan\beta \simeq 3\text{--}40$  a potential enhancement factor, and  $\text{sign}(\mu) = \pm 1$ . Supersymmetric particles in the mass range 100–500 GeV could be the source of the deviation  $\Delta a_\mu$ . If so, those particles should be directly observed at the Large Hadron Collider at CERN.

New physics effects [1] other than supersymmetry could also explain a non-vanishing  $\Delta a_\mu$ . A recent popular scenario involves the “dark photon”, a relatively light hypothetical vector boson from the dark matter sector that couples to our world of particle physics through mixing with the ordinary photon [33–35]. As a result, it couples to ordinary charged particles with strength  $\varepsilon \cdot e$  and gives rise to an additional muon anomalous magnetic moment contribution

$$a_\mu^{\text{dark photon}} = \frac{\alpha}{2\pi} \varepsilon^2 F(m_V/m_\mu), \quad (17)$$

where  $F(x) = \int_0^1 2z(1-z)^2 / [(1-z)^2 + x^2z] dz$ . For values of  $\varepsilon \sim 1\text{--}2 \cdot 10^{-3}$  and  $m_V \sim 10\text{--}100$  MeV, the dark photon, which was originally motivated by cosmology, can provide a viable solution to the muon  $g - 2$  discrepancy. Searches for the dark photon in that mass range are currently underway at Jefferson Lab, USA, and MAMI in Mainz, Germany.

### $\mu$ MAGNETIC MOMENT ANOMALY

The parity-violating decay of muons in a storage ring is observed. The difference frequency  $\omega_3$  between the muon spin precession and the orbital angular frequency ( $e/m_\mu c$ )( $B$ ) is measured, as is the free proton NMR frequency  $\omega_p$ , thus determining the ratio  $R = \omega_3/\omega_p$ . Given the magnetic moment ratio  $\lambda = \mu_\mu/\mu_p$  (from hyperfine structure in muonium),  $(g-2)/2 = R/(\lambda-R)$ .

$$\mu_\mu/(e\hbar/2m_\mu) - 1 = (g_\mu - 2)/2$$

-3.7 ± 3.4	<sup>11</sup> BAILEY	78	CNTR ±	Storage ring
8.6 ± 4.5	BAILEY	78	CNTR +	Storage ring
0.8 ± 4.3	BAILEY	78	CNTR -	Storage ring

<sup>10</sup>This is the combination of the two BENNETT 09 results quoted here separately for  $\mu^+$  and  $\mu^-$ . BENNETT 09 uses the convention  $d = 1/2 \cdot (d_{\mu^-} - d_{\mu^+})$ .

<sup>11</sup>This is the combination of the two BAILEY 78 results quoted here separately for  $\mu^+$  and  $\mu^-$ . BAILEY 78 uses the convention  $d = 1/2 \cdot (d_{\mu^+} - d_{\mu^-})$  and reports  $3.7 \pm 3.4$ . We convert their result to use the same convention as BENNETT 09.

### MUON-ELECTRON CHARGE RATIO ANOMALY $q_{\mu^+}/q_{e^-} + 1$

VALUE	DOCUMENT ID	TECN	CHG	COMMENT
<b>(1.1 ± 2.1) × 10<sup>-9</sup></b>	<sup>12</sup> MEYER	00	CNTR +	1s-2s muonium interval

<sup>12</sup>MEYER 00 measure the 1s-2s muonium interval, and then interpret the result in terms of muon-electron charge ratio  $q_{\mu^+}/q_{e^-}$ .

### $\mu^-$ DECAY MODES

$\mu^+$  modes are charge conjugates of the modes below.

Mode	Fraction ( $\Gamma_i/\Gamma$ )	Confidence level
$\Gamma_1$ $e^- \bar{\nu}_e \nu_\mu$	$\approx 100\%$	
$\Gamma_2$ $e^- \bar{\nu}_e \nu_\mu \gamma$	[a] (1.4 ± 0.4) %	
$\Gamma_3$ $e^- \bar{\nu}_e \nu_\mu e^+ e^-$	[b] (3.4 ± 0.4) × 10 <sup>-5</sup>	

### Lepton Family number (LF) violating modes

$\Gamma_4$ $e^- \nu_e \bar{\nu}_\mu$	LF	[c] < 1.2	%	90%
$\Gamma_5$ $e^- \gamma$	LF	< 5.7	× 10 <sup>-13</sup>	90%
$\Gamma_6$ $e^- e^+ e^-$	LF	< 1.0	× 10 <sup>-12</sup>	90%
$\Gamma_7$ $e^- 2\gamma$	LF	< 7.2	× 10 <sup>-11</sup>	90%

[a] This only includes events with the  $\gamma$  energy > 10 MeV. Since the  $e^- \bar{\nu}_e \nu_\mu$  and  $e^- \bar{\nu}_e \nu_\mu \gamma$  modes cannot be clearly separated, we regard the latter mode as a subset of the former.

[b] See the Particle Listings below for the energy limits used in this measurement.

[c] A test of additive vs. multiplicative lepton family number conservation.

### MUON DECAY PARAMETERS

Revised September 2013 by W. Fetscher and H.-J. Gerber (ETH Zürich).

**Introduction:** All measurements in direct muon decay,  $\mu^- \rightarrow e^- + 2$  neutrals, and its inverse,  $\nu_\mu + e^- \rightarrow \mu^- +$  neutral, are successfully described by the “ $V-A$  interaction,” which is a particular case of a local, derivative-free, lepton-number-conserving, four-fermion interaction [1]. As shown below, within this framework, the Standard Model assumptions, such as the  $V-A$  form and the nature of the neutrals ( $\nu_\mu$  and  $\bar{\nu}_e$ ), and hence the doublet assignments ( $(\nu_e e^-)_L$  and  $(\nu_\mu \mu^-)_L$ ), have been determined from experiments [2,3]. All considerations on muon decay are valid for the leptonic tau decays  $\tau \rightarrow \ell + \nu_\tau + \bar{\nu}_e$  with the replacements  $m_\mu \rightarrow m_\tau$ ,  $m_e \rightarrow m_\ell$ .

**Parameters:** The differential decay probability to obtain an  $e^\pm$  with (reduced) energy between  $x$  and  $x + dx$ , emitted in the direction  $\hat{x}_3$  at an angle between  $\vartheta$  and  $\vartheta + d\vartheta$  with respect to the muon polarization vector  $\mathbf{P}_\mu$ , and with its spin parallel

# Lepton Particle Listings

$\mu$

to the arbitrary direction  $\hat{\zeta}$ , neglecting radiative corrections, is given by

$$\frac{d^2\Gamma}{dx d\cos\vartheta} = \frac{m_\mu}{4\pi^3} W_{e\mu}^4 G_F^2 \sqrt{x^2 - x_0^2} \times (F_{\text{IS}}(x) \pm P_\mu \cos\vartheta F_{\text{AS}}(x)) \times [1 + \hat{\zeta} \cdot \mathbf{P}_e(x, \vartheta)] . \quad (1)$$

Here,  $W_{e\mu} = \max(E_e) = (m_\mu^2 + m_e^2)/2m_\mu$  is the maximum  $e^\pm$  energy,  $x = E_e/W_{e\mu}$  is the reduced energy,  $x_0 = m_e/W_{e\mu} = 9.67 \times 10^{-3}$ , and  $P_\mu = |\mathbf{P}_\mu|$  is the degree of muon polarization.  $\hat{\zeta}$  is the direction in which a perfect polarization-sensitive electron detector is most sensitive. The isotropic part of the spectrum,  $F_{\text{IS}}(x)$ , the anisotropic part  $F_{\text{AS}}(x)$ , and the electron polarization,  $\mathbf{P}_e(x, \vartheta)$ , may be parametrized by the Michel parameter  $\rho$  [1], by  $\eta$  [4], by  $\xi$  and  $\delta$  [5,6], *etc.* These are bilinear combinations of the coupling constants  $g_{e\mu}^2$ , which occur in the matrix element (given below).

If the masses of the neutrinos as well as  $x_0^2$  are neglected, the energy and angular distribution of the electron in the rest frame of a muon ( $\mu^\pm$ ) measured by a polarization insensitive detector, is given by

$$\frac{d^2\Gamma}{dx d\cos\vartheta} \sim x^2 \cdot \left\{ 3(1-x) + \frac{2\rho}{3}(4x-3) + 3\eta x_0(1-x)/x \pm P_\mu \cdot \xi \cdot \cos\vartheta \left[ 1 - x + \frac{2\delta}{3}(4x-3) \right] \right\} . \quad (2)$$

Here,  $\vartheta$  is the angle between the electron momentum and the muon spin, and  $x \equiv 2E_e/m_\mu$ . For the Standard Model coupling, we obtain  $\rho = \xi\delta = 3/4$ ,  $\xi = 1$ ,  $\eta = 0$  and the differential decay rate is

$$\frac{d^2\Gamma}{dx d\cos\vartheta} = \frac{G_F^2 m_\mu^5}{192\pi^3} [3 - 2x \pm P_\mu \cos\vartheta(2x-1)] x^2 . \quad (3)$$

The coefficient in front of the square bracket is the total decay rate.

If only the neutrino masses are neglected, and if the  $e^\pm$  polarization is detected, then the functions in Eq. (1) become

$$\begin{aligned} F_{\text{IS}}(x) &= x(1-x) + \frac{2}{9}\rho(4x^2 - 3x - x_0^2) + \eta \cdot x_0(1-x) \\ F_{\text{AS}}(x) &= \frac{1}{3}\xi \sqrt{x^2 - x_0^2} \\ &\quad \times [1 - x + \frac{2}{3}\delta(4x - 3 + (\sqrt{1 - x_0^2} - 1))] \\ \mathbf{P}_e(x, \vartheta) &= P_{T_1} \cdot \hat{\mathbf{x}}_1 + P_{T_2} \cdot \hat{\mathbf{x}}_2 + P_L \cdot \hat{\mathbf{x}}_3 . \end{aligned} \quad (4)$$

Here  $\hat{\mathbf{x}}_1$ ,  $\hat{\mathbf{x}}_2$ , and  $\hat{\mathbf{x}}_3$  are orthogonal unit vectors defined as follows:

$$\begin{aligned} \hat{\mathbf{x}}_3 &\text{ is along the } e \text{ momentum } \mathbf{p}_e \\ \frac{\hat{\mathbf{x}}_3 \times \mathbf{P}_\mu}{|\hat{\mathbf{x}}_3 \times \mathbf{P}_\mu|} &= \hat{\mathbf{x}}_2 \text{ is transverse to } \mathbf{p}_e \text{ and perpendicular to the "decay plane"} \\ \hat{\mathbf{x}}_2 \times \hat{\mathbf{x}}_3 &= \hat{\mathbf{x}}_1 \text{ is transverse to the } \mathbf{p}_e \text{ and in the "decay plane."} \end{aligned}$$

The components of  $\mathbf{P}_e$  then are given by

$$\begin{aligned} P_{T_1}(x, \vartheta) &= P_\mu \sin\vartheta \cdot F_{T_1}(x) / (F_{\text{IS}}(x) \pm P_\mu \cos\vartheta \cdot F_{\text{AS}}(x)) \\ P_{T_2}(x, \vartheta) &= P_\mu \sin\vartheta \cdot F_{T_2}(x) / (F_{\text{IS}}(x) \pm P_\mu \cos\vartheta \cdot F_{\text{AS}}(x)) \\ P_L(x, \vartheta) &= \left( \pm F_{\text{IP}}(x) + P_\mu \cos\vartheta \right. \\ &\quad \left. \times F_{\text{AP}}(x) \right) / (F_{\text{IS}}(x) \pm P_\mu \cos\vartheta \cdot F_{\text{AS}}(x)) , \end{aligned}$$

where

$$\begin{aligned} F_{T_1}(x) &= \frac{1}{12} \left\{ -2 \left[ \xi'' + 12(\rho - \frac{3}{4}) \right] (1-x)x_0 - 3\eta(x^2 - x_0^2) + \eta''(-3x^2 + 4x - x_0^2) \right\} \\ F_{T_2}(x) &= \frac{1}{3} \sqrt{x^2 - x_0^2} \left\{ 3\frac{\alpha'}{A}(1-x) + 2\frac{\beta'}{A} \sqrt{1-x_0^2} \right\} \\ F_{\text{IP}}(x) &= \frac{1}{54} \sqrt{x^2 - x_0^2} \left\{ 9\xi' \left( -2x + 2 + \sqrt{1-x_0^2} \right) + 4\xi(\delta - \frac{3}{4})(4x - 4 + \sqrt{1-x_0^2}) \right\} \\ F_{\text{AP}}(x) &= \frac{1}{6} \left\{ \xi''(2x^2 - x - x_0^2) + 4(\rho - \frac{3}{4})(4x^2 - 3x - x_0^2) + 2\eta''(1-x)x_0 \right\} . \end{aligned} \quad (5)$$

For the experimental values of the parameters  $\rho$ ,  $\xi$ ,  $\xi'$ ,  $\xi''$ ,  $\delta$ ,  $\eta$ ,  $\eta''$ ,  $\alpha/A$ ,  $\beta/A$ ,  $\alpha'/A$ ,  $\beta'/A$ , which are not all independent, see the Data Listings below. Experiments in the past have also been analyzed using the parameters  $a$ ,  $b$ ,  $c$ ,  $a'$ ,  $b'$ ,  $c'$ ,  $\alpha/A$ ,  $\beta/A$ ,  $\alpha'/A$ ,  $\beta'/A$  (and  $\eta = (\alpha - 2\beta)/2A$ ), as defined by Kinoshita and Sirlin [5,6]. They serve as a model-independent summary of all possible measurements on the decay electron (see Listings below). The relations between the two sets of parameters are

$$\begin{aligned} \rho - \frac{3}{4} &= \frac{3}{4}(-a + 2c)/A , \\ \eta &= (\alpha - 2\beta)/A , \\ \eta'' &= (3\alpha + 2\beta)/A , \\ \delta - \frac{3}{4} &= \frac{9}{4} \cdot \frac{(a' - 2c')/A}{1 - [a + 3a' + 4(b + b') + 6c - 14c']/A} , \\ 1 - \xi \frac{\delta}{\rho} &= 4 \frac{[(b + b') + 2(c - c')]/A}{1 - (a - 2c)/A} , \\ 1 - \xi' &= [(a + a') + 4(b + b') + 6(c + c')]/A , \\ 1 - \xi'' &= (-2a + 20c)/A , \end{aligned}$$

where

$$A = a + 4b + 6c . \quad (6)$$

The differential decay probability to obtain a *left-handed*  $\nu_e$  with (reduced) energy between  $y$  and  $y + dy$ , neglecting radiative corrections as well as the masses of the electron and of the neutrinos, is given by [7]

$$\frac{d\Gamma}{dy} = \frac{m_\mu^5 G_F^2}{16\pi^3} \cdot Q_L^{\nu_e} \cdot y^2 \left\{ (1-y) - \omega_L \cdot (y - \frac{3}{4}) \right\} . \quad (7)$$

Here,  $y = 2 E_{\nu_e}/m_\mu$ .  $Q_L^{\nu_e}$  and  $\omega_L$  are parameters.  $\omega_L$  is the neutrino analog of the spectral shape parameter  $\rho$  of Michel. Since in the Standard Model,  $Q_L^{\nu_e} = 1$ ,  $\omega_L = 0$ , the measurement of  $d\Gamma/dy$  has allowed a null-test of the Standard Model (see Listings below).

**Matrix element:** All results in direct muon decay (energy spectra of the electron and of the neutrinos, polarizations, and angular distributions), and in inverse muon decay (the reaction cross section) at energies well below  $m_W c^2$ , may be parametrized in terms of amplitudes  $g_{\varepsilon\mu}^\gamma$  and the Fermi coupling constant  $G_F$ , using the matrix element

$$\frac{4G_F}{\sqrt{2}} \sum_{\substack{\gamma=S,V,T \\ \varepsilon,\mu=R,L}} g_{\varepsilon\mu}^\gamma \langle \bar{e}_\varepsilon | \Gamma^\gamma | (\nu_e)_n \rangle \langle (\bar{\nu}_\mu)_m | \Gamma_\gamma | \mu_\mu \rangle. \quad (8)$$

We use the notation of Fetscher *et al.* [2], who in turn use the sign conventions and definitions of Scheck [8]. Here,  $\gamma = S, V, T$  indicates a scalar, vector, or tensor interaction; and  $\varepsilon, \mu = R, L$  indicate a right- or left-handed chirality of the electron or muon. The chiralities  $n$  and  $m$  of the  $\nu_e$  and  $\bar{\nu}_\mu$  are then determined by the values of  $\gamma, \varepsilon$ , and  $\mu$ . The particles are represented by fields of definite chirality [9].

As shown by Langacker and London [10], explicit lepton-number nonconservation still leads to a matrix element equivalent to Eq. (8). They conclude that it is not possible, even in principle, to test lepton-number conservation in (leptonic) muon decay if the final neutrinos are massless and are not observed.

The ten complex amplitudes  $g_{\varepsilon\mu}^\gamma$  ( $g_{RR}^T$  and  $g_{LL}^T$  are identically zero) and  $G_F$  constitute 19 independent (real) parameters to be determined by experiment. The Standard Model interaction corresponds to one single amplitude  $g_{LL}^V$  being unity and all the others being zero.

The (direct) muon decay experiments are compatible with an arbitrary mix of the scalar and vector amplitudes  $g_{LL}^S$  and  $g_{LL}^V$  – in the extreme even with purely scalar  $g_{LL}^S = 2$ ,  $g_{LL}^V = 0$ . The decision in favour of the Standard Model comes from the quantitative observation of inverse muon decay, which would be forbidden for pure  $g_{LL}^S$  [2].

**Experimental determination of V–A:** In order to determine the amplitudes  $g_{\varepsilon\mu}^\gamma$  uniquely from experiment, the following set of equations, where the left-hand sides represent experimental results, has to be solved.

$$\begin{aligned} a &= 16(|g_{RL}^V|^2 + |g_{LR}^V|^2) + |g_{RL}^S + 6g_{RR}^T|^2 + |g_{LR}^S + 6g_{LR}^T|^2 \\ a' &= 16(|g_{RL}^V|^2 - |g_{LR}^V|^2) + |g_{RL}^S + 6g_{RR}^T|^2 - |g_{LR}^S + 6g_{LR}^T|^2 \\ \alpha &= 8\text{Re} \left\{ g_{RL}^V (g_{LR}^{S*} + 6g_{LR}^{T*}) + g_{LR}^V (g_{RL}^{S*} + 6g_{RL}^{T*}) \right\} \\ \alpha' &= 8\text{Im} \left\{ g_{LR}^V (g_{RL}^{S*} + 6g_{RL}^{T*}) - g_{RL}^V (g_{LR}^{S*} + 6g_{LR}^{T*}) \right\} \\ b &= 4(|g_{RR}^V|^2 + |g_{LL}^V|^2) + |g_{RR}^S|^2 + |g_{LL}^S|^2 \\ b' &= 4(|g_{RR}^V|^2 - |g_{LL}^V|^2) + |g_{RR}^S|^2 - |g_{LL}^S|^2 \\ \beta &= -4\text{Re} \left\{ g_{RR}^V g_{LL}^{S*} + g_{LL}^V g_{RR}^{S*} \right\} \\ \beta' &= 4\text{Im} \left\{ g_{RR}^V g_{LL}^{S*} - g_{LL}^V g_{RR}^{S*} \right\} \\ c &= \frac{1}{2} \left\{ |g_{RL}^S - 2g_{RL}^T|^2 + |g_{LR}^S - 2g_{LR}^T|^2 \right\} \\ c' &= \frac{1}{2} \left\{ |g_{RL}^S - 2g_{RL}^T|^2 - |g_{LR}^S - 2g_{LR}^T|^2 \right\} \end{aligned}$$

and

$$\begin{aligned} Q_L^{\nu_e} &= 1 - \left\{ \frac{1}{4}|g_{LR}^S|^2 + \frac{1}{4}|g_{LL}^S|^2 + |g_{RR}^V|^2 + |g_{RL}^V|^2 + 3|g_{LR}^T|^2 \right\} \\ \omega_L &= \frac{3}{4} \frac{\{|g_{RR}^S|^2 + 4|g_{LR}^V|^2 + |g_{RL}^S + 2g_{RL}^T|^2\}}{|g_{RL}^S|^2 + |g_{RR}^S|^2 + 4|g_{LL}^V|^2 + 4|g_{LR}^V|^2 + 12|g_{RL}^T|^2}. \end{aligned}$$

It has been noted earlier by C. Jarlskog [11], that certain experiments observing the decay electron are especially informative if they yield the  $V$ - $A$  values. The complete solution is now found as follows. Fetscher *et al.* [2] introduced four probabilities  $Q_{\varepsilon\mu}(\varepsilon, \mu = R, L)$  for the decay of a  $\mu$ -handed muon into an  $\varepsilon$ -handed electron, and showed that there exist upper bounds on  $Q_{RR}$ ,  $Q_{LR}$ , and  $Q_{RL}$ , and a lower bound on  $Q_{LL}$ . These probabilities are given in terms of the  $g_{\varepsilon\mu}^\gamma$ 's by

$$Q_{\varepsilon\mu} = \frac{1}{4}|g_{\varepsilon\mu}^S|^2 + |g_{\varepsilon\mu}^V|^2 + 3(1 - \delta_{\varepsilon\mu})|g_{\varepsilon\mu}^T|^2, \quad (9)$$

where  $\delta_{\varepsilon\mu} = 1$  for  $\varepsilon = \mu$ , and  $\delta_{\varepsilon\mu} = 0$  for  $\varepsilon \neq \mu$ . They are related to the parameters  $a$ ,  $b$ ,  $c$ ,  $a'$ ,  $b'$ , and  $c'$  by

$$\begin{aligned} Q_{RR} &= 2(b + b')/A, \\ Q_{LR} &= [(a - a') + 6(c - c')]/2A, \\ Q_{RL} &= [(a + a') + 6(c + c')]/2A, \\ Q_{LL} &= 2(b - b')/A, \end{aligned} \quad (10)$$

with  $A = 16$ . In the Standard Model,  $Q_{LL} = 1$  and the others are zero.

Since the upper bounds on  $Q_{RR}$ ,  $Q_{LR}$ , and  $Q_{RL}$  are found to be small, and since the helicity of the  $\nu_\mu$  in pion decay is known from experiment [12,13] to very high precision to be  $-1$  [14], the cross section  $S$  of *inverse* muon decay, normalized to the  $V$ - $A$  value, yields [2]

$$|g_{LL}^S|^2 \leq 4(1 - S) \quad (11)$$

and

$$|g_{LL}^V|^2 = S. \quad (12)$$

Thus the Standard Model assumption of a pure  $V$ - $A$  leptonic charged weak interaction of  $e$  and  $\mu$  is derived (within errors) from experiments at energies far below mass of the  $W^\pm$ : Eq. (12) gives a lower limit for  $V$ - $A$ , and Eqs. (9) and (11) give upper limits for the other four-fermion interactions. The existence of such upper limits may also be seen from  $Q_{RR} + Q_{RL} = (1 - \xi')/2$  and  $Q_{RR} + Q_{LR} = \frac{1}{2}(1 + \xi/3 - 16 \xi\delta/9)$ . Table 1 gives the current experimental limits on the magnitudes of the  $g_{\varepsilon\mu}^\gamma$ 's. More stringent limits on the six coupling constants  $g_{LR}^S$ ,  $g_{LR}^V$ ,  $g_{LR}^T$ ,  $g_{RL}^S$ ,  $g_{RL}^V$ , and  $g_{RL}^T$  have been derived from upper limits on the neutrino mass [18]. Limits on the “charge retention” coordinates, as used in the older literature (*e.g.*, Ref. 19), are given by Burkard *et al.* [20].

## Lepton Particle Listings

 $\mu$ 

**Table 1.** Coupling constants  $g_{e\mu}^\gamma$  and some combinations of them. Ninety-percent confidence level experimental limits. The limits on  $|g_{LL}^S|$  and  $|g_{LL}^V|$  are from Ref. 15, and the others from a general analysis of muon decay measurements. Top three rows: Ref. 22, fourth row: Ref. 16, next three rows: Ref. 17, last row: Ref. 21. The experimental uncertainty on the muon polarization in pion decay is included. Note that, by definition,  $|g_{e\mu}^S| \leq 2$ ,  $|g_{e\mu}^V| \leq 1$  and  $|g_{e\mu}^T| \leq 1/\sqrt{3}$ .

$ g_{RR}^S  < 0.035$	$ g_{RR}^V  < 0.017$	$ g_{RR}^T  \equiv 0$
$ g_{LR}^S  < 0.050$	$ g_{LR}^V  < 0.023$	$ g_{LR}^T  < 0.015$
$ g_{RL}^S  < 0.420$	$ g_{RL}^V  < 0.105$	$ g_{RL}^T  < 0.105$
$ g_{LL}^S  < 0.550$	$ g_{LL}^V  > 0.960$	$ g_{LL}^T  \equiv 0$
$ g_{LR}^S + 6g_{LR}^T  < 0.143$	$ g_{RL}^S + 6g_{RL}^T  < 0.418$	
$ g_{LR}^S + 2g_{LR}^T  < 0.108$	$ g_{RL}^S + 2g_{RL}^T  < 0.417$	
$ g_{LR}^S - 2g_{LR}^T  < 0.070$	$ g_{RL}^S - 2g_{RL}^T  < 0.418$	
$Q_{RR} + Q_{LR} < 8.2 \times 10^{-4}$

 $\tau$ 

$$J = \frac{1}{2}$$

$\tau$  discovery paper was PERL 75.  $e^+e^- \rightarrow \tau^+\tau^-$  cross-section threshold behavior and magnitude are consistent with pointlike spin-1/2 Dirac particle. BRANDELIK 78 ruled out pointlike spin-0 or spin-1 particle. FELDMAN 78 ruled out  $J=3/2$ . KIRKBY 79 also ruled out  $J=\text{integer}$ ,  $J=3/2$ .

 $\tau$  MASS

• • • We do not use the following data for averages, fits, limits, etc. • • •

1777.8 ± 0.7 ± 1.7	35k	<sup>6</sup> BALEST	93 CLEO	Repl. by ANASTASSOV 97
1776.9 <sup>+0.4</sup> ± 0.2	14	<sup>7</sup> BAI	92 BES	Repl. by BAI 96

<sup>1</sup>AUBERT 09AK and BELOUS 07 fit  $\tau$  pseudomass spectrum in  $\tau \rightarrow \pi^+\pi^-\nu_\tau$  decays. Result assumes  $m_{\nu_\tau}=0$ .

<sup>2</sup>ABBIENDI 00A fit  $\tau$  pseudomass spectrum in  $\tau \rightarrow \pi^\pm \leq 2\pi^0 \nu_\tau$  and  $\tau \rightarrow \pi^\pm \pi^+\pi^- \leq 1\pi^0 \nu_\tau$  decays. Result assumes  $m_{\nu_\tau}=0$ .

<sup>3</sup>BAI 96 fit  $\sigma(e^+e^- \rightarrow \tau^+\tau^-)$  at different energies near threshold.

<sup>4</sup>ALBRECHT 92M fit  $\tau$  pseudomass spectrum in  $\tau^- \rightarrow 2\pi^-\pi^+\nu_\tau$  decays. Result assumes  $m_{\nu_\tau}=0$ .

<sup>5</sup>BACINO 78B value comes from  $e^\pm \chi^\mp$  threshold. Published mass 1782 MeV increased by 1 MeV using the high precision  $\psi(2S)$  mass measurement of ZHOLENTZ 80 to eliminate the absolute SPEAR energy calibration uncertainty.

<sup>6</sup>BALEST 93 fit spectra of minimum kinematically allowed  $\tau$  mass in events of the type  $e^+e^- \rightarrow \tau^+\tau^- \rightarrow (\pi^+n\pi^0\nu_\tau)(\pi^-m\pi^0\nu_\tau)$   $n \leq 2, m \leq 2, 1 \leq n+m \leq 3$ . If  $m_{\nu_\tau} \neq 0$ , result increases by  $(m_{\nu_\tau}^2/1100 \text{ MeV})$ .

<sup>7</sup>BAI 92 fit  $\sigma(e^+e^- \rightarrow \tau^+\tau^-)$  near threshold using  $e\mu$  events.

 $(m_{\tau^+} - m_{\tau^-})/m_{\text{average}}$ 

A test of CPT invariance.

- 1 ABDALLAH 04k limit is derived from  $e^+e^- \rightarrow e^+e^-\tau^+\tau^-$  total cross-section measurements at  $\sqrt{s}$  between 183 and 208 GeV. In addition to the limits, the authors also quote a value of  $-0.018 \pm 0.017$ .
- 2 ACHARD 04G limit is derived from  $e^+e^- \rightarrow e^+e^-\tau^+\tau^-$  total cross-section measurements at  $\sqrt{s}$  between 189 and 206 GeV, and is on the absolute value of the magnetic moment anomaly.
- 3 GONZALEZ-SPRINBERG 00 use data on tau lepton production at LEP1, SLC, and LEP2, and data from colliders and LEP2 to determine limits. Assume imaginary component is zero.
- 4 ACCIARRI 98E use  $Z \rightarrow \tau^+\tau^-\gamma$  events. In addition to the limits, the authors also quote a value of  $0.004 \pm 0.027 \pm 0.023$ .
- 5 ACKERSTAFF 98N use  $Z \rightarrow \tau^+\tau^-\gamma$  events. The limit applies to an average of the form factor for off-shell  $\tau$ 's having  $p^2$  ranging from  $m_\tau^2$  to  $(M_Z - m_\tau)^2$ .
- 6 ESCRIBANO 97 use preliminary experimental results.
- 7 ESCRIBANO 93 limit derived from  $\Gamma(Z \rightarrow \tau^+\tau^-)$ , and is on the absolute value of the magnetic moment anomaly.
- 8 SILVERMAN 83 limit is derived from  $e^+e^- \rightarrow \tau^+\tau^-$  total cross-section measurements for  $q^2$  up to  $(37 \text{ GeV})^2$ .

**$\tau$  ELECTRIC DIPOLE MOMENT ( $d_\tau$ )**

A nonzero value is forbidden by both  $T$  invariance and  $P$  invariance.

The  $q^2$  dependence is expected to be small providing no thresholds are nearby.

**Re( $d_\tau$ )**

- 1 INAMI 03 use  $e^+e^- \rightarrow \tau^+\tau^-$  events.
- 2 GROZIN 09A calculate the contribution to the electron electric dipole moment from the  $\tau$  electric dipole moment appearing in loops, which is  $\Delta d_e = 6.9 \times 10^{-12} d_\tau$ . Dividing the REGAN 02 upper limit  $|d_e| \leq 1.6 \times 10^{-27}$  e cm at CL=90% by  $6.9 \times 10^{-12}$  gives this limit.
- 3 ABDALLAH 04k limit is derived from  $e^+e^- \rightarrow e^+e^-\tau^+\tau^-$  total cross-section measurements at  $\sqrt{s}$  between 183 and 208 GeV and is on the absolute value of  $d_\tau$ .
- 4 ACHARD 04G limit is derived from  $e^+e^- \rightarrow e^+e^-\tau^+\tau^-$  total cross-section measurements at  $\sqrt{s}$  between 189 and 206 GeV, and is on the absolute value of  $d_\tau$ .
- 5 ALBRECHT 00 use  $e^+e^- \rightarrow \tau^+\tau^-$  events. Limit is on the absolute value of Re( $d_\tau$ ).
- 6 ACKERSTAFF 98N use  $Z \rightarrow \tau^+\tau^-\gamma$  events. The limit applies to an average of the form factor for off-shell  $\tau$ 's having  $p^2$  ranging from  $m_\tau^2$  to  $(M_Z - m_\tau)^2$ .
- 7 ESCRIBANO 97 derive the relationship  $|d_\tau| = \cot \theta_W |d_\tau^W|$  using effective Lagrangian methods, and use a conference result  $|d_\tau^W| < 5.8 \times 10^{-18}$  e cm at 95% CL (L. Silvestris, ICHEP96) to obtain this result.
- 8 ESCRIBANO 97 use preliminary experimental results.
- 9 ESCRIBANO 93 limit derived from  $\Gamma(Z \rightarrow \tau^+\tau^-)$ , and is on the absolute value of the electric dipole moment.

**Lepton Family number (LF), Lepton number (L), or Baryon number (B) violating modes**

L means lepton number violation (e.g.  $\tau^- \rightarrow e^+\pi^-\pi^-$ ). Following common usage, LF means lepton family violation and not lepton number violation (e.g.  $\tau^- \rightarrow e^-\pi^+\pi^-$ ). B means baryon number violation.

[a] Basis mode for the  $\tau$ .

[b] See the Particle Listings below for the energy limits used in this measurement.

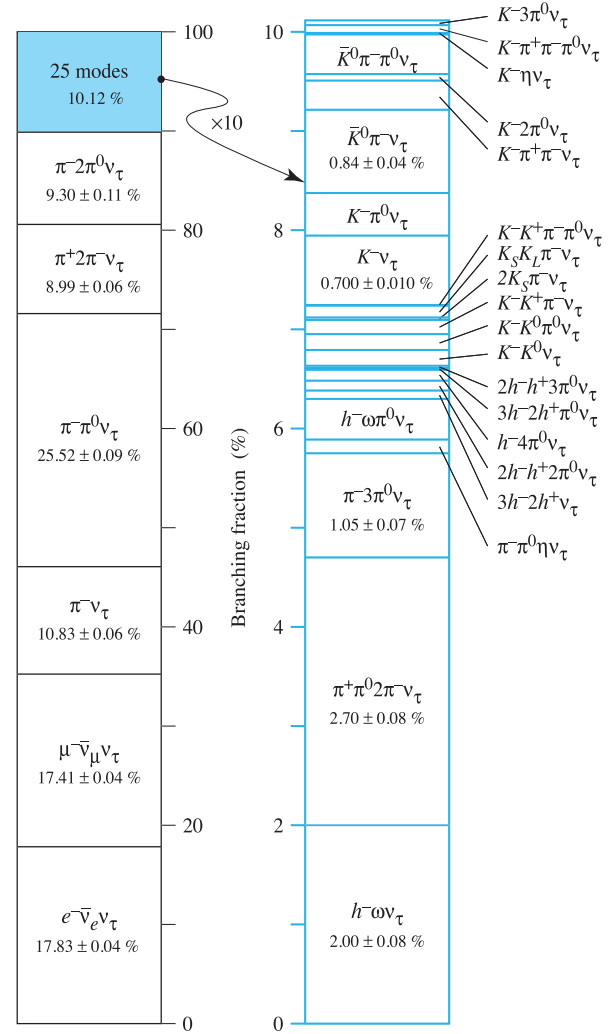

1996 edition of this *Review* [1] for a complete description of our notation for naming  $\tau$ -decay modes and the selection of the basis modes. For each edition since the 1996 edition, the changes in the selected basis modes from the previous edition are described in the  $\tau$  Branching Fractions Review. Figure 1 illustrates the basis mode branching fractions from the 2013 fit.

**Table 1:** Basis modes and fit values(%) for the 2013 fit to  $\tau$  branching fraction data.

$e^- \bar{\nu}_e \nu_\tau$	$17.83 \pm 0.04$
$\mu^- \bar{\nu}_\mu \nu_\tau$	$17.41 \pm 0.04$
$\pi^- \nu_\tau$	$10.83 \pm 0.06$
$\pi^- \pi^0 \nu_\tau$	$25.52 \pm 0.09$
$\pi^- 2\pi^0 \nu_\tau$ (ex. $K^0$ )	$9.30 \pm 0.11$
$\pi^- 3\pi^0 \nu_\tau$ (ex. $K^0$ )	$1.05 \pm 0.07$
$h^- 4\pi^0 \nu_\tau$ (ex. $K^0, \eta$ )	$0.11 \pm 0.04$
$K^- \nu_\tau$	$0.700 \pm 0.010$
$K^- \pi^0 \nu_\tau$	$0.429 \pm 0.015$

In selecting the basis modes, assumptions and choices must be made. For example, we assume the decays  $\tau^- \rightarrow \pi^- K^+ \pi^- \geq 0\pi^0 \nu_\tau$  and  $\tau^- \rightarrow \pi^+ K^- K^- \geq 0\pi^0 \nu_\tau$  have negligible branching fractions. This is consistent with standard model predictions for  $\tau$  decay, although the experimental limits for these branching fractions are not very stringent. The 95% confidence level upper limits for these branching fractions in the current Listings are  $B(\tau^- \rightarrow \pi^- K^+ \pi^- \geq 0\pi^0 \nu_\tau) < 0.25\%$  and  $B(\tau^- \rightarrow \pi^+ K^- K^- \geq 0\pi^0 \nu_\tau) < 0.09\%$ , values not so different from measured branching fractions for allowed 3-prong modes containing charged kaons. Although our usual goal is to impose

**Figure 1:** Basis mode branching fractions of the  $\tau$ . Six modes account for 90% of the decays, 25 modes account for the last 10%. The list of excluded intermediate states for each basis mode has been suppressed.

as few theoretical constraints as possible so that the world averages and fit results can be used to test the theoretical constraints (*i.e.*, we do not make use of the theoretical constraint from lepton universality on the ratio of the  $\tau$ -leptonic branching fractions  $B(\tau^- \rightarrow \mu^- \bar{\nu}_\mu \nu_\tau) / B(\tau^- \rightarrow e^- \bar{\nu}_e \nu_\tau) = 0.9726$ ), the experimental challenge to identify charged prongs in 3-prong  $\tau$  decays is sufficiently difficult that experimenters have been forced to make these assumptions when measuring the branching fractions of the allowed decays. We are constrained by the assumptions made by the experimenters.

There are several  $\tau$ -decay modes with small but well-measured ( $> 2.5$  sigma from zero) branching fractions [2] which cannot be expressed in terms of the selected basis modes and are therefore left out of the fit:

## Lepton Particle Listings

 $\tau$ 

$$\begin{aligned} B(\tau^- \rightarrow \pi^- K_S^0 K_L^0 \pi^0 \nu_\tau) &= (3.1 \pm 1.2) \times 10^{-4} \\ B(\tau^- \rightarrow 2K^- K^+ \nu_\tau) &= (0.21 \pm 0.08) \times 10^{-4} \\ B(\tau^- \rightarrow \eta K^- \pi^0 \nu_\tau) &= (0.48 \pm 0.12) \times 10^{-4} \\ B(\tau^- \rightarrow \eta \bar{K}^0 \pi^- \nu_\tau) &= (0.93 \pm 0.15) \times 10^{-4}. \end{aligned}$$

Certain components of other small but well-measured  $\tau$ -decay modes cannot be expressed in terms of the selected basis modes and therefore are also left out of the fit:

$$\begin{aligned} B(\tau^- \rightarrow \eta \pi^- \pi^0 \pi^0 \nu_\tau) \times \\ B(\eta \rightarrow \gamma \gamma \text{ or } \eta \rightarrow \pi^+ \pi^- \gamma \text{ or } \eta \rightarrow 3\pi^0) &= (1.4 \pm 0.2) \times 10^{-4}, \\ B(\tau^- \rightarrow \eta \pi^- \pi^+ \pi^- \nu_\tau) \times \\ B(\eta \rightarrow \gamma \gamma \text{ or } \eta \rightarrow \pi^+ \pi^- \gamma) &= (0.99 \pm 0.06) \times 10^{-4}, \\ B(\tau^- \rightarrow \phi K^- \nu_\tau) \times \\ B(\phi \rightarrow K_S^0 K_L^0 \text{ or } \phi \rightarrow \eta \gamma) &= (0.13 \pm 0.01) \times 10^{-4}, \\ B(\tau^- \rightarrow f_1(1285) \pi^- \nu_\tau) B(f_1(1285) \rightarrow \rho^0 \gamma) &= (0.22 \pm 0.06) \times 10^{-4}, \\ B(\tau^- \rightarrow h^- \omega \pi^0 \pi^0 \nu_\tau) B(\omega \rightarrow \pi^0 \gamma) &= (0.12 \pm 0.04) \times 10^{-4}, \\ B(\tau^- \rightarrow 2h^- h^+ \omega \nu_\tau) B(\omega \rightarrow \pi^0 \gamma) &= (0.10 \pm 0.02) \times 10^{-4}. \end{aligned}$$

The sum of these excluded branching fractions is  $(0.08 \pm 0.01)\%$ . This is near our goal of 0.1% for the internal consistency of the  $\tau$  Listings for this edition, and thus for simplicity we do not include these small branching fraction decay modes in the basis set.

Beginning with the 2002 edition, the fit algorithm has been improved to allow for correlations between branching fraction measurements used in the fit. If only a few measurements are correlated, the correlation coefficients are listed in the footnote for each measurement. If a large number of measurements are correlated, then the full correlation matrix is listed in the footnote to the measurement that first appears in the  $\tau$  Listings. Footnotes to the other measurements refer to the first measurement. For example, the large correlation matrices for the branching fraction measurements contained in Refs. [3,4] are listed in Footnotes to the  $\Gamma(e^- \bar{\nu}_e \nu_\tau)/\Gamma_{\text{total}}$  and  $\Gamma(h^- \nu_\tau)/\Gamma_{\text{total}}$  measurements respectively. Sometimes experimental papers contain correlation coefficients between measurements using only statistical errors without including systematic errors. We usually cannot make use of these correlation coefficients.

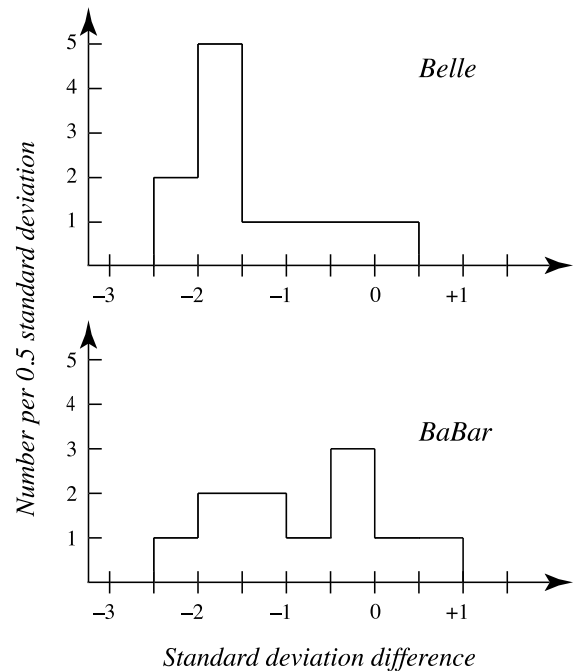

The 2013 constrained fit has a  $\chi^2$  of 128.9 for 109 degrees of freedom, and is essentially unchanged from the 2012 fit.

### Inconsistencies in the $\tau$ -lepton Branching Fraction Data:

Several inconsistencies are known to exist in the branching fraction measurements that are used to determine the  $\tau$ -lepton branching fractions. The sources of the inconsistencies are unknown. The treatment of discrepant data used for fits and averages is described in the introduction of this *Review*. Of the 82 branching fractions that are derived from the constrained fit, 12 (15%) have scale factors that are 1.5 or larger, and the largest is 2.7. Of the 49 branching fractions that are not derived from the constrained fit, 32 make use of only one measurement. Of the 17 averages that make use of more than one measurement, 4 (24%) have scale factors that are 1.5 or larger, and the

largest is 5.4. Ideograms for 8 branching fractions are currently displayed in the  $\tau$  Listings.

The  $\tau$  branching fraction measurements by BaBar and Belle tend to be smaller than the non- $B$ -factory measurements. There are 22  $B$ -factory branching fraction measurements of  $\tau$ -decay modes for which older non- $B$ -factory measurements exist. Comparing the  $B$ -factory branching fraction measurements to the earlier non- $B$ -factory measurements reveals a systematic discrepancy between the two sets of measurements. Figure 2 shows a histogram of the normalized difference ( $B$ -factory value minus non- $B$ -factory value)/estimated uncertainty in the difference) for the 22 measurements. The value used for the non- $B$ -factory measurement is the value listed in the latest edition of this *Review* prior to the first  $B$ -factory measurement for that decay mode. Nineteen of the 22  $B$ -factory branching fraction measurements are smaller than the non- $B$ -factory values. The average normalized difference between the two sets of measurements is -1.08 (-1.41 for the 11 Belle measurements and -0.75 for the 11 BaBar measurements). The Heavy Flavor Averaging Group (HFAG) analysis of  $\tau$  branching fractions includes a similar comparison of the  $B$ -factory and non- $B$ -factory measurements [6].

**Figure 2:** Distribution of the normalized difference between the 22  $B$ -factory measurements of conventional  $\tau$ -decay branching fractions and non- $B$ -factory measurements. The Belle and BaBar collaborations have each published 11 measurements of  $\tau$ -decay branching fractions for which older non- $B$ -factory measurements exist.

Belle and BaBar have each published branching fraction measurements for the six  $\tau$ -decay modes listed in Table 2. The normalized difference between the two measured values is calculated by subtracting the Belle value from the BaBar value and dividing this difference by the quadratic sum of the statistical and systematic errors for each measurement. When a measurement has asymmetric errors, the larger of the two values is used in the quadratic sum. It is apparent from the values in Table 2 that the Belle and BaBar values differ significantly for several of the  $\tau$ -decay modes.

**Table 2:** Comparison of the Belle and Babar branching fraction measurements for the six  $\tau$ -decay modes that both experiments have measured. The normalized difference is the difference between the Belle and BaBar branching fraction values divided by the quadratic sum of the statistical and systematic errors for both measurements.

Mode	BaBar – Belle Normalized Difference ( $\#\sigma$ )
$\pi^- \pi^+ \pi^- \nu_\tau$ (ex. $K^0$ )	+1.4
$K^- \pi^+ \pi^- \nu_\tau$ (ex. $K^0$ )	-2.9
$K^- K^+ \pi^- \nu_\tau$	-2.9
$K^- K^+ K^- \nu_\tau$	-5.4
$\eta K^- \nu_\tau$	-1.0
$\phi K^- \nu_\tau$	-1.3

**Overconsistency of Leptonic Branching Fraction Measurements:** To minimize the effects of older experiments which often have larger systematic errors and sometimes make assumptions that have later been shown to be invalid, we exclude old measurements in decay modes which contain at least several newer data of much higher precision. As a rule, we exclude those experiments with large errors which together would contribute no more than 5% of the weight in the average. This procedure leaves five measurements for  $B_e \equiv B(\tau^- \rightarrow e^- \bar{\nu}_e \nu_\tau)$  and five measurements for  $B_\mu \equiv B(\tau^- \rightarrow \mu^- \bar{\nu}_\mu \nu_\tau)$ . For both  $B_e$  and  $B_\mu$ , the selected measurements are considerably more consistent with each other than should be expected from the quoted errors on the individual measurements. The  $\chi^2$  from the calculation of the average of the selected measurements is 0.34 for  $B_e$  and 0.08 for  $B_\mu$ . Assuming normal errors, the probability of a smaller  $\chi^2$  is 1.3% for  $B_e$  and 0.08% for  $B_\mu$ .

The charged particle here can be e,  $\mu$ , or hadron. In many analyses, the sum of the topological branching fractions (1, 3, and 5 prongs) is constrained to be unity. Since the 5-prong fraction is very small, the measured 1-prong and 3-prong fractions are highly correlated and cannot be treated as independent quantities in our overall fit. We arbitrarily choose to use the 3-prong fraction in our fit, and leave the 1-prong fraction out. We do, however, use these 1-prong measurements in our average below. The measurements used only for the average are marked "avg," whereas "&a" marks a result used for the fit and the average.

<sup>3</sup> WU 90 reports  $\Gamma(\mu^- \bar{\nu}_\mu \nu_\tau \gamma)/\Gamma(\mu^- \bar{\nu}_\mu \nu_\tau) = 0.013 \pm 0.006$ , which is converted to  $\Gamma(\mu^- \bar{\nu}_\mu \nu_\tau \gamma)/\Gamma_{\text{total}}$  using  $\Gamma(\mu^- \bar{\nu}_\mu \nu_\tau \gamma)/\Gamma_{\text{total}} = 17.35\%$ . Requirements on detected  $\gamma$ 's correspond to a  $\tau$  rest frame energy cutoff  $E_\gamma > 37$  MeV.

$\Gamma(e^- \bar{\nu}_e \nu_\tau)/\Gamma_{\text{total}}$   $\Gamma_5/\Gamma$   
To minimize the effect of experiments with large systematic errors, we exclude experiments which together would contribute 5% of the weight in the average.

 $\tau$ -DECAY PARAMETERS $\tau$ -LEPTON DECAY PARAMETERS

Updated August 2011 by A. Stahl (RWTH Aachen).

The purpose of the measurements of the decay parameters (*i.e.*, Michel parameters) of the  $\tau$  is to determine the structure (spin and chirality) of the current mediating its decays.

**Leptonic Decays:** The Michel parameters are extracted from the energy spectrum of the charged daughter lepton  $\ell = e, \mu$  in the decays  $\tau \rightarrow \ell \nu_\ell \nu_\tau$ . Ignoring radiative corrections, neglecting terms of order  $(m_\ell/m_\tau)^2$  and  $(m_\tau/\sqrt{s})^2$ , and setting the neutrino masses to zero, the spectrum in the laboratory frame reads

$$\frac{d\Gamma}{dx} = \frac{G_{\tau\ell}^2 m_\tau^5}{192 \pi^3} \times \left\{ f_0(x) + \rho f_1(x) + \eta \frac{m_\ell}{m_\tau} f_2(x) - P_\tau [\xi g_1(x) + \xi \delta g_2(x)] \right\}, \quad (1)$$

with

$$\begin{aligned} f_0(x) &= 2 - 6x^2 + 4x^3 \\ f_1(x) &= -\frac{4}{9} + 4x^2 - \frac{32}{9}x^3 & g_1(x) &= -\frac{2}{3} + 4x - 6x^2 + \frac{8}{3}x^3 \\ f_2(x) &= 12(1-x)^2 & g_2(x) &= \frac{4}{9} - \frac{16}{3}x + 12x^2 - \frac{64}{9}x^3. \end{aligned}$$

# Lepton Particle Listings

$\tau$

The quantity  $x$  is the fractional energy of the daughter lepton  $\ell$ , *i.e.*,  $x = E_\ell/E_{\ell,max} \approx E_\ell/(\sqrt{s}/2)$  and  $P_\tau$  is the polarization of the tau leptons. The integrated decay width is given by

$$\Gamma = \frac{G_{\tau\ell}^2 m_\tau^5}{192 \pi^3} \left( 1 + 4\eta \frac{m_\ell}{m_\tau} \right). \quad (2)$$

The situation is similar to muon decays  $\mu \rightarrow e\nu_e\nu_\mu$ . The generalized matrix element with the couplings  $g_{\varepsilon\mu}^{\tilde{\gamma}}$  and their relations to the Michel parameters  $\rho$ ,  $\eta$ ,  $\xi$ , and  $\delta$  have been described in the “Note on Muon Decay Parameters.” The Standard Model expectations are 3/4, 0, 1, and 3/4, respectively. For more details, see Ref. 1.

**Hadronic Decays:** In the case of hadronic decays  $\tau \rightarrow h\nu_\tau$ , with  $h = \pi, \rho$ , or  $a_1$ , the ansatz is restricted to purely vectorial currents. The matrix element is

$$\frac{G_{\tau h}}{\sqrt{2}} \sum_{\lambda=R,L} g_\lambda \langle \bar{\Psi}_\omega(\nu_\tau) | \gamma^\mu | \Psi_\lambda(\tau) \rangle J_\mu^h \quad (3)$$

with the hadronic current  $J_\mu^h$ . The neutrino chirality  $\omega$  is uniquely determined from  $\lambda$ . The spectrum depends only on a single parameter  $\xi_h$

$$\frac{d^n \Gamma}{dx_1 dx_2 \dots dx_n} = f(\vec{x}) + \xi_h P_\tau g(\vec{x}), \quad (4)$$

with  $f$  and  $g$  being channel-dependent functions of the  $n$  observables  $\vec{x} = (x_1, x_2, \dots, x_n)$  (see Ref. 2). The parameter  $\xi_h$  is related to the couplings through

$$\xi_h = |g_L|^2 - |g_R|^2. \quad (5)$$

$\xi_h$  is the negative of the chirality of the  $\tau$  neutrino in these decays. In the Standard Model,  $\xi_h = 1$ . Also included in the Data Listings for  $\xi_h$  are measurements of the neutrino helicity which coincide with  $\xi_h$ , if the neutrino is massless (ASNER 00, ACKERSTAFF 97R, AKERS 95P, ALBRECHT 93C, and ALBRECHT 90I).

**Combination of Measurements:** The individual measurements are combined, taking into account the correlations between the parameters. In a first fit, universality between the two leptonic decays, and between all hadronic decays, is assumed. A second fit is made without these assumptions. The results of the two fits are provided as OUR FIT in the Data Listings below in the tables whose title includes “(e or mu)” or “(all hadronic modes),” and “(e),” “(mu)” *etc.*, respectively. The measurements show good agreement with the Standard Model. The  $\chi^2$  values with respect to the Standard model predictions are 24.1 for 41 degrees of freedom and 26.8 for 56 degrees of freedom, respectively. The correlations are reduced through this combination to less than 20%, with the exception of  $\rho$  and  $\eta$  which are correlated by +23%, for the fit with universality and by +70% for  $\tau \rightarrow \mu\nu_\mu\nu_\tau$ .

**Model-independent Analysis:** From the Michel parameters, limits can be derived on the couplings  $g_{\varepsilon\lambda}^k$  without further model assumptions. In the Standard model  $g_{LL}^V = 1$  (leptonic

decays), and  $g_L = 1$  (hadronic decays) and all other couplings vanish. First, the partial decay widths have to be compared to the Standard Model predictions to derive limits on the normalization of the couplings  $A_x = G_{\tau x}^2/G_F^2$  with Fermi’s constant  $G_F$ :

$$\begin{aligned} A_e &= 1.0029 \pm 0.0046, \\ A_\mu &= 0.981 \pm 0.018, \\ A_\pi &= 1.0020 \pm 0.0073. \end{aligned} \quad (6)$$

Then limits on the couplings (95% CL) can be extracted (see Ref. 3 and Ref. 4). Without the assumption of universality, the limits given in Table 1 are derived.

**Table 1:** Coupling constants  $g_{\varepsilon\mu}^{\tilde{\gamma}}$ , 95% confidence level experimental limits. The limits include the quoted values of  $A_e$ ,  $A_\mu$ , and  $A_\pi$  and assume  $A_\rho = A_{a_1} = 1$ .

$\tau \rightarrow e\nu_e\nu_\tau$		
$ g_{RR}^S  < 0.70$	$ g_{RR}^V  < 0.17$	$ g_{RR}^T  \equiv 0$
$ g_{LR}^S  < 0.99$	$ g_{LR}^V  < 0.13$	$ g_{LR}^T  < 0.082$
$ g_{RL}^S  < 2.01$	$ g_{RL}^V  < 0.52$	$ g_{RL}^T  < 0.51$
$ g_{LL}^S  < 2.01$	$ g_{LL}^V  < 1.005$	$ g_{LL}^T  \equiv 0$
$\tau \rightarrow \mu\nu_\mu\nu_\tau$		
$ g_{RR}^S  < 0.72$	$ g_{RR}^V  < 0.18$	$ g_{RR}^T  \equiv 0$
$ g_{LR}^S  < 0.95$	$ g_{LR}^V  < 0.12$	$ g_{LR}^T  < 0.079$
$ g_{RL}^S  < 2.01$	$ g_{RL}^V  < 0.52$	$ g_{RL}^T  < 0.51$
$ g_{LL}^S  < 2.01$	$ g_{LL}^V  < 1.005$	$ g_{LL}^T  \equiv 0$
$\tau \rightarrow \pi\nu_\tau$		
$ g_R^V  < 0.15$	$ g_L^V  > 0.992$	
$\tau \rightarrow \rho\nu_\tau$		
$ g_R^V  < 0.10$	$ g_L^V  > 0.995$	
$\tau \rightarrow a_1\nu_\tau$		
$ g_R^V  < 0.16$	$ g_L^V  > 0.987$	

**Model-dependent Interpretation:** More stringent limits can be derived assuming specific models. For example, in the framework of a two Higgs doublet model, the measurements correspond to a limit of  $m_{H^\pm} > 1.9 \text{ GeV} \times \tan \beta$  on the mass of the charged Higgs boson, or a limit of 253 GeV on the mass of the second  $W$  boson in left-right symmetric models for arbitrary mixing (both 95% CL). See Ref. 4 and Ref. 5.

<sup>1</sup> Combined fit to ARGUS tau decay parameter measurements in ALBRECHT 98, ALBRECHT 95c, ALBRECHT 93G, and ALBRECHT 94E. ALBRECHT 98 use tau pair events of the type  $\tau^- \tau^+ \rightarrow (\ell^- \bar{\nu}_\ell \nu_\tau)(\pi^+ \pi^0 \bar{\nu}_\tau)$ , and their charged conjugates.

<sup>2</sup> ABE 97o assume  $\eta = 0$  in their fit. Letting  $\eta$  vary in the fit gives a  $\rho$  value of  $0.69 \pm 0.13 \pm 0.05$ .

<sup>3</sup> Value is from a simultaneous fit for the  $\rho$  and  $\eta$  decay parameters to the lepton energy spectrum. Not independent of ALBRECHT 90E  $\rho(e \text{ or } \mu)$  value which assumes  $\eta = 0$ . Result is strongly correlated with ALBRECHT 95c.

<sup>4</sup> Combined fit to ARGUS tau decay parameter measurements in ALBRECHT 95c, ALBRECHT 93G, and ALBRECHT 94E.

 **$\rho(e)$  PARAMETER** $(V-A)$  theory predicts  $\rho = 0.75$ .

See key on page 547

- 1 HEISTER 01E quote  $0.992 \pm 0.007 \pm 0.006 \pm 0.005$  where the errors are statistical, systematic, and an uncertainty due to the final state model. We combine the systematic error and model uncertainty. They use  $\tau \rightarrow \pi\nu_\tau, \tau \rightarrow K\nu_\tau, \tau \rightarrow \rho\nu_\tau$ , and  $\tau \rightarrow a_1\nu_\tau$  decays.
- 2 ABREU 00L use  $\tau^- \rightarrow h^- \geq 0\pi^0\nu_\tau$  decays.
- 3 ASNER 00 use  $\tau^- \rightarrow \pi^- 2\pi^0\nu_\tau$  decays.
- 4 ACCIARRI 98R use  $\tau \rightarrow \pi\nu_\tau, \tau \rightarrow K\nu_\tau$ , and  $\tau \rightarrow \rho\nu_\tau$  decays.
- 5 ACKERSTAFF 97R use  $\tau \rightarrow a_1\nu_\tau$  decays.
- 6 ALEXANDER 97F use  $\tau \rightarrow \rho\nu_\tau$  decays.
- 7 COAN 97 use  $h^+h^-$  energy correlations.
- 8 Combined fit to ARGUS tau decay parameter measurements in ALBRECHT 95C, ALBRECHT 93G, and ALBRECHT 94E.
- 9 Uses  $\tau \rightarrow a_1\nu_\tau$  decays. Replaced by ALBRECHT 95C.
- 10 ACCIARRI 96H use  $\tau \rightarrow \pi\nu_\tau, \tau \rightarrow K\nu_\tau$ , and  $\tau \rightarrow \rho\nu_\tau$  decays.
- 11 AKERS 95P use  $\tau \rightarrow a_1\nu_\tau$  decays.
- 12 BUSKULIC 95D use  $\tau \rightarrow \pi\nu_\tau, \tau \rightarrow \rho\nu_\tau$ , and  $\tau \rightarrow a_1\nu_\tau$  decays.
- 13 ALBRECHT 94E measure the square of this quantity and use the sign determined by ALBRECHT 90I to obtain the quoted result. Uses  $\tau \rightarrow a_1\nu_\tau$  decays. Replaced by ALBRECHT 95C.
- 14 BUSKULIC 94D use  $\tau \rightarrow \pi\nu_\tau$  and  $\tau \rightarrow \rho\nu_\tau$  decays. Superseded by BUSKULIC 95D.

## Heavy Charged Lepton Searches

### Charged Heavy Lepton MASS LIMITS

#### Sequential Charged Heavy Lepton ( $L^\pm$ ) MASS LIMITS

These experiments assumed that a fourth generation  $L^\pm$  decayed to a fourth generation  $\nu_L$  (or  $L^0$ ) where  $\nu_L$  was stable, or that  $L^\pm$  decays to a light  $\nu_\rho$  via mixing.

See the "Quark and Lepton Compositeness, Searches for" Listings for limits on radiatively decaying excited leptons, i.e.  $\ell^* \rightarrow \ell\gamma$ . See the "WIMPs and other Particle Searches" section for heavy charged particle search limits in which the charged particle could be a lepton.

- ACCIARRI 96G assumes LEP result that the associated neutral heavy lepton mass  $> 40$  GeV.
- The AHMED 94 limits are from a search for neutral and charged sequential heavy leptons at HERA via the decay channels  $L^- \rightarrow e\gamma$ ,  $L^- \rightarrow \nu W^-$ ,  $L^- \rightarrow eZ$ ; and  $L^0 \rightarrow \nu\gamma$ ,  $L^0 \rightarrow e^-W^+$ ,  $L^0 \rightarrow \nu Z$ , where the  $W$  decays to  $\ell\nu_\rho$ , or to jets, and  $Z$  decays to  $\ell^+ \ell^-$  or jets.
- RILES 90 limits were the result of a special analysis of the data in the case where the mass difference  $m_{L^-} - m_{L^0}$  was allowed to be quite small, where  $L^0$  denotes the neutrino into which the sequential charged lepton decays. With a slightly reduced  $m_{L^\pm}$  range, the mass difference extends to about 4 GeV.
- STOKER 89 (Mark II at PEP) gives bounds on charged heavy lepton ( $L^\pm$ ) mass for the generalized case in which the corresponding neutral heavy lepton ( $L^0$ ) in the SU(2) doublet is not of negligible mass.
- ABE 88 search for  $L^\pm$  and  $L^- \rightarrow$  hadrons looking for acoplanar jets. The bound is valid for  $m_\nu < 10$  GeV.
- ADACHI 88B search for hadronic decays giving acoplanar events with large missing energy.  $E_{cm}^{ee} = 52$  GeV.
- Assumes associated neutrino is approximately massless.
- ADEVA 85 analyze one-isolated-muon data and sensitive to  $\tau < 10$  nanosec. Assume  $B(\text{lepton}) = 0.30$ .  $E_{cm} = 40-47$  GeV.
- BARTEL 83 limit is from PETRA  $e^+e^-$  experiment with average  $E_{cm} = 34.2$  GeV.
- BERGER 81B is DESY DORIS and PETRA experiment. Looking for  $e^+e^- \rightarrow L^+L^-$ .
- BRANDELIK 81 is DESY-PETRA experiment. Looking for  $e^+e^- \rightarrow L^+L^-$ .
- AZIMOV 80 estimated probabilities for  $M + N$  type events in  $e^+e^- \rightarrow L^+L^-$  deducing semi-hadronic decay multiplicities of  $L$  from  $e^+e^-$  annihilation data at  $E_{cm} = (2/3)m_L$ . Obtained above limit comparing these with  $e^+e^-$  data (BRANDELIK 80).
- BARBER 80B looked for  $e^+e^- \rightarrow L^+L^-$ ,  $L^- \rightarrow \nu^+X$  with MARK-J at DESY-PETRA.
- ROTHER 69 examines previous data on  $\mu$  pair production and  $\pi$  and  $K$  decays.

### Stable Charged Heavy Lepton ( $L^\pm$ ) MASS LIMITS

VALUE (GeV)	CL%	DOCUMENT ID	TECN
>102.6	95	ACHARD	01B L3
••• We do not use the following data for averages, fits, limits, etc. •••

## Neutrino Properties

## INTRODUCTION TO THE NEUTRINO PROPERTIES LISTINGS

Revised August 2013 by P. Vogel (Caltech) and A. Piepke (University of Alabama).

The following Listings concern measurements of various properties of neutrinos. Nearly all of the measurements, all of which so far are limits, actually concern superpositions of the mass eigenstates  $\nu_i$ , which are in turn related to the weak eigenstates  $\nu_\ell$ , via the neutrino mixing matrix

$$|\nu_\ell\rangle = \sum_i U_{\ell i} |\nu_i\rangle.$$

In the analogous case of quark mixing via the CKM matrix, the smallness of the off-diagonal terms (small mixing angles) permits a “dominant eigenstate” approximation. However, the results of neutrino oscillation searches show that the mixing matrix contains two large mixing angles and a third angle that is not exceedingly small. We cannot, therefore, associate any particular state  $|\nu_i\rangle$  with any particular lepton label  $e, \mu$  or  $\tau$ . Nevertheless, note that in the standard labeling the  $|\nu_1\rangle$  has the largest  $|\nu_e\rangle$  component ( $\sim 2/3$ ),  $|\nu_2\rangle$  contains  $\sim 1/3$  of the  $|\nu_e\rangle$  component and  $|\nu_3\rangle$  contains only a small  $\sim 2.5\%$   $|\nu_e\rangle$  component.

Neutrinos are produced in weak decays with a definite lepton flavor, and are typically detected by the charged current weak interaction again associated with a specific lepton flavor. Hence, the listings for the neutrino mass that follow are

separated into the three associated charged lepton categories. Other properties (mean lifetime, magnetic moment, charge and charge radius) are no longer separated this way. If needed, the associated lepton flavor is reported in the footnotes.

Measured quantities (mass-squared, magnetic moments, mean lifetimes, *etc.*) all depend upon the mixing parameters  $|U_{\ell i}|^2$ , but to some extent also on experimental conditions (*e.g.*, on energy resolution). Most of these observables, in particular mass-squared, cannot distinguish between Dirac and Majorana neutrinos, and are unaffected by  $CP$  phases.

Direct neutrino mass measurements are usually based on the analysis of the kinematics of charged particles (leptons, pions) emitted together with neutrinos (flavor states) in various weak decays. The most sensitive neutrino mass measurement to date, involving electron type antineutrinos, is based on fitting the shape of the beta spectrum. The quantity  $\langle m_\beta^2 \rangle = \sum_i |U_{ei}|^2 m_{\nu_i}^2$  is determined or constrained, where the sum is over all mass eigenvalues  $m_{\nu_i}$  that are too close together to be resolved experimentally. If the energy resolution is better than  $\Delta m_{ij}^2 \equiv m_{\nu_i}^2 - m_{\nu_j}^2$ , the corresponding heavier  $m_{\nu_i}$  and mixing parameter could be determined by fitting the resulting spectral anomaly (step or kink).

A limit on  $\langle m_\beta^2 \rangle$  implies an upper limit on the minimum value  $m_{\nu_{min}}^2$  of  $m_{\nu_i}^2$ , independent of the mixing parameters  $U_{ei}$ :  $m_{\nu_{min}}^2 \leq \langle m_\beta^2 \rangle$ . However, if and when the value of  $\langle m_\beta^2 \rangle$  is determined then its combination with the results derived from neutrino oscillations that give us the values of the neutrino mass-squared differences  $\Delta m_{ij}^2 \equiv m_i^2 - m_j^2$  and the mixing parameters  $|U_{ei}|^2$ , the individual neutrino mass squares  $m_{\nu_j}^2 = \langle m_\beta^2 \rangle - \sum_i |U_{ei}|^2 \Delta m_{ij}^2$  can be determined.

So far solar, reactor, atmospheric and accelerator neutrino oscillation experiments can be consistently described using three active neutrino flavors, i.e. two mass splittings and three mixing angles. However, several experiments with radioactive sources, reactors, and accelerators imply the possible existence of one or more non-interacting neutrino species that might be observable since they couple weakly to the flavor neutrinos  $|\nu_l\rangle$ .

Combined three neutrino analyses determine the squared mass differences and all three mixing angles to within reasonable accuracy. For given  $|\Delta m_{ij}^2|$  a limit on  $\langle m_\beta^2 \rangle$  from beta decay defines an upper limit on the maximum value  $m_{\nu_{max}}$  of  $m_{\nu_i}$ :  $m_{\nu_{max}}^2 \leq \langle m_\beta^2 \rangle + \sum_{i < j} |\Delta m_{ij}^2|$ . The analysis of the low energy beta decay of tritium, combined with the oscillation results, thus limits all active neutrino masses. Traditionally, experimental neutrino mass limits obtained from pion decay  $\pi^+ \rightarrow \mu^+ + \nu_\mu$  or the shape of the spectrum of decay products of the  $\tau$  lepton did not distinguish between flavor and mass eigenstates. These results are reported as limits of the  $\mu$  and  $\tau$  based neutrino mass. After the determination of the  $|\Delta m_{ij}^2|$ 's and the mixing angles  $\theta_{ij}$ , the corresponding neutrino mass limits are no longer competitive with those derived from low energy beta decays.

# Lepton Particle Listings

## Neutrino Properties

The spread of arrival times of the neutrinos from SN1987A, coupled with the measured neutrino energies, provided a time-of-flight limit on a quantity similar to  $\langle m_{\beta} \rangle \equiv \sqrt{\langle m_{\beta}^2 \rangle}$ . This statement, clothed in various degrees of sophistication, has been the basis for a very large number of papers. The resulting limits, however, are no longer comparable with the limits from tritium beta decay.

Constraint on the sum of the neutrino masses can be obtained from the analysis of the cosmic microwave background anisotropy, combined with the galaxy redshift surveys and other data. These limits are reported in a separate table (Sum of Neutrino Masses,  $m_{tot}$ ). Discussion concerning the model dependence of this limit is continuing.

### $\overline{m}$ MASS (electron based)

Those limits given below are for the square root of  $m_{\nu_e}^{2(\text{eff})} \equiv \sum_i |U_{ei}|^2 m_{\nu_i}^2$ . Limits that come from the kinematics of  ${}^3\text{H} \beta\text{-}\overline{m}$  decay are the square roots of the limits for  $m_{\nu_e}^{2(\text{eff})}$ . Obtained from the measurements reported in the Listings for " $\overline{m}$  Mass Squared," below.

<sup>1</sup> ASEEV 11 report the analysis of the entire beta endpoint data, taken with the Troitsk integrating electrostatic spectrometer between 1997 and 2002 (some of the earlier runs were rejected), using a windowless gaseous tritium source. The fitted value of  $m_{\nu_e}$ , based on the method of Feldman and Cousins, is obtained from the upper limit of the fit for  $m_{\nu_e}^2$ . Previous analysis problems were resolved by careful monitoring of the tritium gas column density. Supersedes LOBASHEV 99 and BELESEV 95.

<sup>2</sup> KRAUS 05 is a continuation of the work reported in WEINHEIMER 99. This result represents the final analysis of data taken from 1997 to 2001. Various sources of systematic uncertainties have been identified and quantified. The background has been reduced compared to the initial running period. A spectral anomaly at the endpoint, reported in LOBASHEV 99, was not observed.

<sup>3</sup> PAGLIAROLI 10 is critical of the likelihood method used by LOREDO 02.

<sup>4</sup> ARNABOLDI 03A *et al.* report kinematical neutrino mass limit using  $\beta$ -decay of <sup>187</sup>Re. Bolometric AgReO<sub>4</sub> micro-calorimeters are used. Mass bound is substantially weaker than those derived from tritium  $\beta$ -decays but has different systematic uncertainties.

<sup>5</sup> LOREDO 02 updates LOREDO 89.

<sup>6</sup> LOBASHEV 99 report a new measurement which continues the work reported in BELESEV 95. This limit depends on phenomenological fit parameters used to derive their best fit to  $m_{\nu_e}^2$ , making unambiguous interpretation difficult. See the footnote under " $\overline{m}$  Mass Squared."

<sup>7</sup> WEINHEIMER 99 presents two analyses which exclude the spectral anomaly and result in an acceptable  $m_{\nu_e}^2$ . We report the most conservative limit, but the other is nearly the same. See the footnote under " $\overline{m}$  Mass Squared."

<sup>8</sup> BELESEV 95 (Moscow) use an integral electrostatic spectrometer with adiabatic magnetic collimation and a gaseous tritium sources. A fit to a normal Kurie plot above 18300–18350 eV (to avoid a low-energy anomaly) plus a monochromatic line 7–15 eV below the endpoint yields  $m_{\nu_e}^2 = -4.1 \pm 10.9 \text{ eV}^2$ , leading to this Bayesian limit.

<sup>9</sup> CHING 95 quotes results previously given by SUN 93; no experimental details are given. A possible explanation for consistently negative values of  $m_{\nu_e}^2$  is given.

<sup>10</sup> HIDDEMANN 95 (Munich) experiment uses atomic tritium embedded in a metal-dioxide lattice. Bayesian limit calculated from the weighted mean  $m_{\nu_e}^2 = 221 \pm 4244 \text{ eV}^2$  from the two runs listed below.

<sup>11</sup> STOEFFL 95 (LLNL) result is the Bayesian limit obtained from the  $m_{\nu_e}^2$  errors given below but with  $m_{\nu_e}^2$  set equal to 0. The anomalous endpoint accumulation leads to a value of  $m_{\nu_e}^2$  which is negative by more than 5 standard deviations.

<sup>12</sup> WEINHEIMER 93 (Mainz) is a measurement of the endpoint of the tritium  $\beta$  spectrum using an electrostatic spectrometer with a magnetic guiding field. The source is molecular tritium frozen onto an aluminum substrate.

<sup>13</sup> HOLZSCHUH 92B (Zurich) result is obtained from the measurement  $m_{\nu_e}^2 = -24 \pm 48 \pm 61$  ( $1\sigma$  errors), in  $\text{eV}^2$ , using the PDG prescription for conversion to a limit in  $m_{\nu_e}$ .

<sup>14</sup> KAWAKAMI 91 (Tokyo) experiment uses tritium-labeled arachidic acid. This result is the Bayesian limit obtained from the  $m_{\nu_e}^2$  limit with the errors combined in quadrature. This was also done in ROBERTSON 91, although the authors report a different procedure.

<sup>15</sup> ROBERTSON 91 (LANL) experiment uses gaseous molecular tritium. The result is in strong disagreement with the earlier claims by the ITP group [LUBIMOV 80, BORIS 87 (+ BORIS 88 erratum)] that  $m_{\nu_e}$  lies between 17 and 40 eV. However, the probability of a positive  $m^2$  is only 3% if statistical and systematic error are combined in quadrature.

<sup>16</sup> See also comment in BORIS 87B and erratum in BORIS 88.

### $\overline{m}^2$ MASS SQUARED (electron based)

Given troubling systematics which result in improbably negative estimates of  $m_{\nu_e}^{2(\text{eff})} \equiv \sum_i |U_{ei}|^2 m_{\nu_i}^2$ , in many experiments, we use only KRAUS 05 and LOBASHEV 99 for our average.

<sup>1</sup> ASEEV 11 report the analysis of the entire beta endpoint data, taken with the Troitsk integrating electrostatic spectrometer between 1997 and 2002, using a windowless gaseous tritium source. The analysis does not use the two additional fit parameters (see LOBASHEV 99) for a step-like structure near the endpoint. Using only the runs where the tritium gas column density was carefully monitored the need for such parameters was eliminated. Supersedes LOBASHEV 99 and BELESEV 95.

<sup>2</sup> KRAUS 05 is a continuation of the work reported in WEINHEIMER 99. This result represents the final analysis of data taken from 1997 to 2001. Problems with significantly negative squared neutrino masses, observed in some earlier experiments, have been resolved in this work.

<sup>3</sup> LOBASHEV 99 report a new measurement which continues the work reported in BELESEV 95. The data were corrected for electron trapping effects in the source, eliminating the dependence of the fitted neutrino mass on the fit interval. The analysis assuming a pure beta spectrum yields significantly negative fitted  $m_{\nu_e}^2 \approx -(20-10) \text{ eV}^2$ . This problem is attributed to a discrete spectral anomaly of about  $6 \times 10^{-11}$  intensity with a time-dependent energy of 5–15 eV below the endpoint. The data analysis accounts for this anomaly by introducing two extra phenomenological fit parameters resulting in a best fit of  $m_{\nu_e}^2 = -1.9 \pm 3.4 \pm 2.2 \text{ eV}^2$  which is used to derive a neutrino mass limit. However, the introduction of phenomenological fit parameters which are correlated with the derived  $m_{\nu_e}^2$  limit makes unambiguous interpretation of this result difficult.

<sup>4</sup> WEINHEIMER 99 is a continuation of the work reported in WEINHEIMER 93. Using a lower temperature of the frozen tritium source eliminated the dewetting of the  $T_2$  film, which introduced a dependence of the fitted neutrino mass on the fit interval in the earlier work. An indication for a spectral anomaly reported in LOBASHEV 99 has been seen, but its time dependence does not agree with LOBASHEV 99. Two analyses, which exclude the spectral anomaly either by choice of the analysis interval or by using a particular data set which does not exhibit the anomaly, result in acceptable  $m_{\nu_e}^2$  fits and are used to derive the neutrino mass limit published by the authors. We list the most conservative of the two.

<sup>5</sup> BELESEV 95 (Moscow) use an integral electrostatic spectrometer with adiabatic magnetic collimation and a gaseous tritium sources. This value comes from a fit to a normal Kurie plot above 18300–18350 eV (to avoid a low-energy anomaly), including the effects of an apparent peak 7–15 eV below the endpoint.

<sup>6</sup> HIDDEMANN 95 (Munich) experiment uses atomic tritium embedded in a metal-dioxide lattice. They quote measurements from two data sets.

<sup>7</sup> STOEFFL 95 (LLNL) uses a gaseous source of molecular tritium. An anomalous pileup of events at the endpoint leads to the negative value for  $m_{\nu_e}^2$ . The authors acknowledge that "the negative value for the best fit of  $m_{\nu_e}^2$  has no physical meaning" and discuss possible explanations for this effect.

<sup>8</sup> SUN 93 uses a tritiated hydrocarbon source. See also CHING 95.

See key on page 547

# Lepton Particle Listings

## Neutrino Properties

- <sup>9</sup>WEINHEIMER 93 (Mainz) is a measurement of the endpoint of the tritium  $\beta$  spectrum using an electrostatic spectrometer with a magnetic guiding field. The source is molecular tritium frozen onto an aluminum substrate.
- <sup>10</sup>HOLZSCHUH 92B (Zurich) source is a monolayer of tritiated hydrocarbon.
- <sup>11</sup>KAWAKAMI 91 (Tokyo) experiment uses tritium-labeled arachidic acid.
- <sup>12</sup>ROBERTSON 91 (LANL) experiment uses gaseous molecular tritium. The result is in strong disagreement with the earlier claims by the ITEP group [LUBIMOV 80, BORIS 87 (+ BORIS 88 erratum)] that  $m_\nu$  lies between 17 and 40 eV. However, the probability of a positive  $m_\nu^2$  is only 3% if statistical and systematic error are combined in quadrature.

### $\nu$ MASS (electron based)

These are measurement of  $m_\nu$  (in contrast to  $m_{\overline{\nu}}$ , given above). The masses can be different for a Dirac neutrino in the absence of CPT invariance. The possible distinction between  $\nu$  and  $\overline{\nu}$  properties is usually ignored elsewhere in these Listings.

<460	68	YASUMI 94	CNTR	<sup>163</sup> Ho decay
<225	95	SPRINGER 87	CNTR	<sup>163</sup> Ho decay

### $\nu$ MASS (muon based)

Limits given below are for the square root of  $m_{\nu_\mu}^{2(\text{eff})} \equiv \sum_i |U_{\mu i}|^2 m_{\nu_i}^2$ .

In some of the COSM papers listed below, the authors did not distinguish between weak and mass eigenstates.

OUR EVALUATION is based on OUR AVERAGE for the  $\pi^\pm$  mass and the ASSAMAGAN 96 value for the muon momentum for the  $\pi^\pm$  decay at rest. The limit is calculated using the unified classical analysis of FELDMAN 98 for a Gaussian distribution near a physical boundary. WARNING: since  $m_{\nu_\mu}^{2(\text{eff})}$  is calculated from the differences of large numbers, it and the corresponding limits are extraordinarily sensitive to small changes in the pion mass, the decay muon momentum, and their errors. For example, the limits obtained using JECKELMANN 94, LENZ 98, and the weighted averages are 0.15, 0.29, and 0.19 MeV, respectively.

VALUE (MeV)	CL%	DOCUMENT ID	TECN	COMMENT
<b>&lt;0.19 (CL = 90%) OUR EVALUATION</b>				
<0.17	90	1 ASSAMAGAN 96	SPEC	$m_\nu^2 = -0.016 \pm 0.023$

<0.65	90	CLARK 74	ASPK	$K_{\mu 3}$ decay

<sup>1</sup>ASSAMAGAN 96 measurement of  $p_\mu$  from  $\pi^\pm \rightarrow \mu^\pm \nu$  at rest combined with JECKELMANN 94 Solution B pion mass yields  $m_\nu^2 = -0.016 \pm 0.023$  with corresponding Bayesian limit listed above. If Solution A is used,  $m_\nu^2 = -0.143 \pm 0.024$  MeV<sup>2</sup>. Replaces ASSAMAGAN 94.

<sup>2</sup>DOLGOV 95 removes earlier assumptions (DOLGOV 93) about thermal equilibrium below  $T_{\text{QCD}}$  for wrong-helicity Dirac neutrinos (ENQVIST 93, FULLER 91) to set more stringent limits.

<sup>3</sup>ENQVIST 93 bases limit on the fact that thermalized wrong-helicity Dirac neutrinos would speed up expansion of early universe, thus reducing the primordial abundance. FULLER 91 exploits the same mechanism but in the older calculation obtains a larger production rate for these states, and hence a lower limit. Neutrino lifetime assumed to exceed nucleosynthesis time,  $\sim 1$  s.

<sup>4</sup>Assumes neutrino lifetime  $>1$  s. For Dirac neutrinos only. See also ENQVIST 93.

<sup>5</sup>ANDERHUB 82 kinematics is insensitive to the pion mass.

### $\nu$ MASS (tau based)

The limits given below are the square roots of limits for  $m_{\nu_\tau}^{2(\text{eff})} \equiv \sum_i |U_{\tau i}|^2 m_{\nu_i}^2$ .

In some of the ASTR and COSM papers listed below, the authors did not distinguish between weak and mass eigenstates.

<sup>1</sup>BARATE 98F result based on kinematics of  $2939 \tau^- \rightarrow 2\pi^- \pi^+ \nu_\tau$  and  $52 \tau^- \rightarrow 3\pi^- 2\pi^+ (\pi^0) \nu_\tau$  decays. If possible 2.5% excited  $a_1$  decay is included in 3-prong sample analysis, limit increases to 19.2 MeV.

<sup>2</sup>ATHANAS 00 bound comes from analysis of  $\tau^- \rightarrow \pi^- \pi^+ \pi^- \pi^0 \nu_\tau$  decays.

<sup>3</sup>ACKERSTAFF 98T use  $\tau^- \rightarrow 5\pi^\pm \nu_\tau$  decays to obtain a limit of 43.2 MeV (95%CL). They combine this with ALEXANDER 96M value using  $\tau^- \rightarrow 3h^\pm \nu_\tau$  decays to obtain quoted limit.

<sup>4</sup>AMMAR 98 limit comes from analysis of  $\tau^- \rightarrow 3\pi^- 2\pi^+ \nu_\tau$  and  $\tau^- \rightarrow 2\pi^- \pi^+ 2\pi^0 \nu_\tau$  decay modes.

<sup>5</sup>ANASTASSOV 97 derive limit by comparing their  $m_\tau$  measurement (which depends on  $m_{\nu_\tau}$ ) to BAL 96  $m_\tau$  threshold measurement.

<sup>6</sup>FIELDS 97 limit for a Dirac neutrino. For a Majorana neutrino the mass region  $< 0.93$  or  $> 31$  MeV is excluded. These bounds assume  $N_\nu < 4$  from nucleosynthesis; a wider excluded region occurs with a smaller  $N_\nu$  upper limit.

<sup>7</sup>SWAIN 97 derive their limit from the Standard Model relationships between the tau mass, lifetime, branching fractions for  $\tau^- \rightarrow e^- \overline{\nu}_e \nu_\tau, \tau^- \rightarrow \mu^- \overline{\nu}_\mu \nu_\tau, \tau^- \rightarrow \pi^- \nu_\tau$ , and  $\tau^- \rightarrow K^- \nu_\tau$ , and the muon mass and lifetime by assuming lepton universality and using world average values. Limit is reduced to 48 MeV when the CLEO  $\tau$  mass measurement (BALEST 93) is included; see CLEO's more recent  $m_{\nu_\tau}$  limit (ANASTASSOV 97). Consideration of mixing with a fourth generation heavy neutrino yields  $\sin^2 \theta_L < 0.016$  (95%CL).

<sup>8</sup>ALEXANDER 96M bound comes from analyses of  $\tau^- \rightarrow 3\pi^- 2\pi^+ \nu_\tau$  and  $\tau^- \rightarrow h^- h^- h^+ \nu_\tau$  decays.

<sup>9</sup>BOTTINO 96 assumes three generations of neutrinos with mixing, finds consistency with massless neutrinos with no mixing based on 1995 data for masses, lifetimes, and leptonic partial widths.

<sup>10</sup>HANNENSTAD 96C limit is on the mass of a Majorana neutrino. This bound assumes  $N_\nu < 4$  from nucleosynthesis. A wider excluded region occurs with a smaller  $N_\nu$  upper limit. This paper is the corrected version of HANNENSTAD 96; see the erratum: HANNENSTAD 96B.

<sup>11</sup>SOBIE 96 derive their limit from the Standard Model relationship between the tau mass, lifetime, and leptonic branching fraction, and the muon mass and lifetime, by assuming lepton universality and using world average values.

<sup>12</sup>BUSKULIC 95H bound comes from a two-dimensional fit of the visible energy and invariant mass distribution of  $\tau^- \rightarrow 5\pi(\pi^0) \nu_\tau$  decays. Replaced by BARATE 98F.

<sup>13</sup>DOLGOV 95 removes earlier assumptions (DOLGOV 93) about thermal equilibrium below  $T_{\text{QCD}}$  for wrong-helicity Dirac neutrinos (ENQVIST 93, FULLER 91) to set more stringent limits. DOLGOV 96 argues that a possible window near 20 MeV is excluded.

<sup>14</sup>SIGL 95 exclude massive Dirac or Majorana neutrinos with lifetimes between  $10^{-3}$  and  $10^8$  seconds if the decay products are predominantly  $\gamma$  or  $e^+ e^-$ .

<sup>15</sup>DODELSON 94 calculate constraints on  $\nu_\tau$  mass and lifetime from nucleosynthesis for 4 generic decay modes. Limits depend strongly on decay mode. Quoted limit is valid for all decay modes of Majorana neutrinos with lifetime greater than about 300 s. For Dirac neutrinos limits change to  $< 0.3$  or  $> 33$ .

<sup>16</sup>KAWASAKI 94 excluded region is for Majorana neutrino with lifetime  $>1000$  s. Other limits are given as a function of  $\nu_\tau$  lifetime for decays of the type  $\nu_\tau \rightarrow \nu_\mu \phi$  where  $\phi$  is a Nambu-Goldstone boson.

<sup>17</sup>PERES 94 used PDG 92 values for parameters to obtain a value consistent with mixing. Reexamination by BOTTINO 96 which included radiative corrections and 1995 PDG parameters resulted in two allowed regions,  $m_3 < 70$  MeV and  $140 \text{ MeV} < m_3 < 149$  MeV.

<sup>18</sup>CINABRO 93 bound comes from analysis of  $\tau^- \rightarrow 3\pi^- 2\pi^+ \nu_\tau$  and  $\tau^- \rightarrow 2\pi^- \pi^+ 2\pi^0 \nu_\tau$  decay modes.

<sup>19</sup>DOLGOV 93 assumes neutrino lifetime  $>100$  s. For Majorana neutrinos, the low mass limit is 0.5 MeV. KAWANO 92 points out that these bounds can be overcome for a Dirac neutrino if it possesses a magnetic moment. See also DOLGOV 96.

<sup>20</sup>ENQVIST 93 bases limit on the fact that thermalized wrong-helicity Dirac neutrinos would speed up expansion of early universe, thus reducing the primordial abundance. FULLER 91 exploits the same mechanism but in the older calculation obtains a larger production rate for these states, and hence a lower limit. Neutrino lifetime assumed to exceed nucleosynthesis time,  $\sim 1$  s.

# Lepton Particle Listings

## Neutrino Properties

<sup>21</sup> ALBRECHT 92M reports measurement of a slightly lower  $\tau$  mass, which has the effect of reducing the  $\nu_\tau$  mass reported in ALBRECHT 88B. Bound is from analysis of  $\tau^- \rightarrow 3\pi^- 2\pi^+ \nu_\tau$  mode.

<sup>22</sup> Assumes neutrino lifetime  $>1$  s. For Dirac neutrinos. See also ENQVIST 93.

<sup>23</sup> KOLB 91 exclusion region is for Dirac neutrino with lifetime  $>1$  s; other limits are given.

Revised September 2013 by K.A. Olive (University of Minnesota).

The limits on low mass ( $m_\nu \lesssim 1$  MeV) neutrinos apply to  $m_{\text{tot}}$  given by

$$m_{\text{tot}} = \sum_\nu (g_\nu/2)m_\nu,$$

where  $g_\nu$  is the number of spin degrees of freedom for  $\nu$  plus  $\bar{\nu}$ :  $g_\nu = 4$  for neutrinos with Dirac masses;  $g_\nu = 2$  for Majorana neutrinos. Stable neutrinos in this mass range make a contribution to the total energy density of the Universe which is given by

$$\rho_\nu = m_{\text{tot}} n_\nu = m_{\text{tot}} (3/11) n_\gamma,$$

where the factor 3/11 is the ratio of (light) neutrinos to photons. Writing  $\Omega_\nu = \rho_\nu/\rho_c$ , where  $\rho_c$  is the critical energy density of the Universe, and using  $n_\gamma = 412 \text{ cm}^{-3}$ , we have

$$\Omega_\nu h^2 = m_{\text{tot}} / (94 \text{ eV}).$$

While an upper limit to the matter density of  $\Omega_m h^2 < 0.12$  would constrain  $m_{\text{tot}} < 11$  eV, much stronger constraints are obtained from a combination of observations of the CMB, the amplitude of density fluctuations on smaller scales from the clustering of galaxies and the Lyman- $\alpha$  forest, baryon acoustic oscillations, and new Hubble parameter data. These combine to give an upper limit of around 0.3 eV, and may, in the near future, be able to provide a lower bound on the sum of the neutrino masses.

### SUM OF THE NEUTRINO MASSES, $m_{\text{tot}}$

(Defined in the above note), of effectively stable neutrinos (i.e., those with mean lives greater than or equal to the age of the universe). These papers assumed Dirac neutrinos. When necessary, we have generalized the results reported so they apply to  $m_{\text{tot}}$ . For other limits, see SZALAY 76, VYSOTSKY 77, BERNSTEIN 81, FREESE 84, SCHRAMM 84, and COWSIK 85.

- Constrains the total mass of neutrinos from Planck CMB data combined with galaxy clustering data from BOSS. Limit is relaxed to 0.49 eV if the dark energy equation of state is allowed to vary.
- Constrains the total mass of neutrinos from observational Hubble parameter data with seven-year WMAP data and the most recent estimate of  $H_0$ .
- Constrains the total mass of neutrinos from the WiggleZ high redshift galaxy sample when combined with seven-year WMAP data. Limit is improved to  $< 0.29$  eV when further combined with a prior on the Hubble parameter and baryon acoustic oscillations.
- Constrains the total mass of neutrinos from the CFHTLS combined with seven-year WMAP data and a prior on the Hubble parameter. Limit is relaxed to 0.41 eV when small scales affected by non-linearities are removed.
- Constrains the total mass of neutrinos from the Sloan Digital Sky Survey and the five-year WMAP data.
- Constrains the total mass of neutrinos from the 7-year WMAP data including SDSS and HST data. Limit relaxes to 1.19 eV when CMB data is used alone. Supersedes HANNESTAD 06.
- Constrains the total mass of neutrinos from a combination of CMB data, a recent measurement of  $H_0$  (SHOES), and baryon acoustic oscillation data from SDSS.
- Constrains the total mass of neutrinos from SDSS MegaZ LRG DR7 galaxy clustering data combined with CMB, HST, supernovae and baryon acoustic oscillation data. Limit relaxes to 0.47 eV when the equation of state parameter,  $w \neq 1$ .
- Constrains the total mass of neutrinos from weak lensing measurements when combined with CMB. Limit improves to 0.54 eV when supernovae and baryon acoustic oscillation observations are included. Assumes  $\Lambda$ CDM model.
- Constrains the total mass of neutrinos from five-year WMAP data. Limit improves to 0.67 eV when supernovae and baryon acoustic oscillation observations are included. Limits quoted assume the  $\Lambda$ CDM model. Supersedes SPERGEL 07.
- Constrains the total mass of neutrinos from weak lensing measurements when combined with CMB. Limit improves to  $0.03 < \Sigma m_\nu < 0.54$  eV when supernovae and baryon acoustic oscillation observations are included. The slight preference for massive neutrinos at the two-sigma level disappears when systematic errors are taken into account. Assumes  $\Lambda$ CDM model.
- Constrains the total mass of neutrinos from recent Chandra X-ray observations of galaxy clusters when combined with CMB, supernovae, and baryon acoustic oscillation measurements. Assumes flat universe and constant dark-energy equation of state,  $w$ .
- Constrains the total mass of neutrinos from recent CMB and SOSS LRG power spectrum data along with bias mass relations from SDSS, DEEP2, and Lyman-Break Galaxies. It assumes  $\Lambda$ CDM model. Limit degrades to 0.59 eV in a more general  $w$ CDM model.
- Constrains the total mass of neutrinos from neutrino oscillation experiments and cosmological data. The most conservative limit uses only WMAP three-year data, while the most stringent limit includes CMB, large-scale structure, supernova, and Lyman-alpha data.
- Constrains the total mass of neutrinos from recent CMB, large scale structure, SN1a, and baryon acoustic oscillation data. The limit relaxes to 1.75 when WMAP data alone is used with no prior. Paper shows results with several combinations of data sets. Supersedes KRISTIANSEN 06.
- Constrains the total mass of neutrinos from the CMB and the large scale structure data. The most conservative limit is obtained when generic initial conditions are allowed.
- Constrains the total mass of neutrinos from recent CMB, large scale structure, Lyman-alpha forest, and SN1a data.
- Constrains the total mass of neutrinos from recent CMB and large scale structure data. See also GOOBAR 06. Superseded by HANNESTAD 10.
- Constrains the total mass of neutrinos from the CMB and the final 2dF Galaxy Redshift Survey.
- Constrains the total mass of neutrinos from the CMB experiments alone, assuming  $\Lambda$ CDM Universe. FUKUGITA 06 show that this result is unchanged by the 3-year WMAP data.
- Constrains the total mass of neutrinos from the power spectrum of fluctuations derived from the Sloan Digital Sky Survey and the 2dF galaxy redshift survey, WMAP and 27 other CMB experiments and measurements by the HST Key project.
- Constrains the total mass of neutrinos from the power spectrum of fluctuations derived from the Sloan Digital Sky Survey, the 2dF galaxy redshift survey, WMAP and ACBAR. The limit is strengthened to 0.6 eV when measurements by the HST Key project and supernovae data are included.
- Constrains the fractional contribution of neutrinos to the total matter density in the Universe from WMAP data combined with other CMB measurements, the 2dFGRS data, and Lyman  $\alpha$  data. The limit does not noticeably change if the Lyman  $\alpha$  data are not used.
- LEWIS 02 constrains the total mass of neutrinos from the power spectrum of fluctuations derived from the CMB, HST Key project, 2dF galaxy redshift survey, supernovae type Ia, and BBN.
- WANG 02 constrains the total mass of neutrinos from the power spectrum of fluctuations derived from the CMB and other cosmological data sets such as galaxy clustering and the Lyman  $\alpha$  forest.
- FUKUGITA 00 is a limit on neutrino masses from structure formation. The constraint is based on the clustering scale  $\sigma_8$  and the COBE normalization and leads to a conservative limit of 0.9 eV assuming 3 nearly degenerate neutrinos. The quoted limit is on the sum of the light neutrino masses.

See key on page 547

Lepton Particle Listings  
Neutrino Properties

<sup>27</sup> CROFT 99 result based on the power spectrum of the Ly  $\alpha$  forest. If  $\Omega_{\text{matter}} < 0.5$ , the limit is improved to  $m_\nu < 2.4 (\Omega_{\text{matter}}/0.17-1) \text{ eV}$ .

<1 $\times 10^{-13}$		7 BERNSTEIN	83 ASTR Solar energy losses

<sup>1</sup> GNINENKO 07 use limit on  $\bar{\nu}_e$  magnetic moment from LI 03b to derive this result. The limit is considerably weaker than the limits on the charge of  $\nu_e$  and  $\bar{\nu}_e$  from various astrophysics considerations.

<sup>2</sup> This RAFFELT 99 limit applies to all neutrino flavors which are light enough (<5 keV) to be emitted from globular-cluster red giants.

<sup>3</sup> This RAFFELT 99 limit is derived from the helioseismological limit on a new energy-loss channel of the Sun, and applies to all neutrino flavors which are light enough (<1 keV) to be emitted from the sun.

<sup>4</sup> BABU 94 use COOPER-SARKAR 92 limit on  $\nu$  magnetic moment to derive quoted result. It applies to  $\nu_\tau$ .

<sup>5</sup> DAVIDSON 91 use data from early SLAC electron beam dump experiment to derive charge limit as a function of neutrino mass. It applies to  $\nu_\tau$ .

<sup>6</sup> Exact BARBIELLINI 87 limit depends on assumptions about the intergalactic or galactic magnetic fields and about the direct distance and time through the field. It applies to  $\nu_e$ .

<sup>7</sup> The limit applies to all flavors.

 **$\nu$  (MEAN LIFE) / MASS**

Measures  $[\sum |U_{ej}|^2 \Gamma_j m_j]^{-1}$ , where the sum is over mass eigenstates which cannot be resolved experimentally. Some of the limits constrain the radiative decay and are based on the limit of the corresponding photon flux. Other apply to the decay of a heavier neutrino into the lighter one and a Majoron or other invisible particle. Many of these limits apply to any  $\nu$  within the indicated mass range.

Limits on the radiative decay are either directly based on the limits of the corresponding photon flux, or are derived from the limits on the neutrino magnetic moments. In the later case the transition rate for  $\nu_i \rightarrow \nu_j + \gamma$

is constrained by  $\Gamma_{ij} = \frac{1}{\tau_{ij}} = \frac{(m_i^2 - m_j^2)^3}{m_i^3} \mu_{ij}^2$  where  $\mu_{ij}$  is the neutrino transition moment in the mass eigenstates basis. Typically, the limits on lifetime based on the magnetic moments are many orders of magnitude more restrictive than limits based on the nonobservation of photons.

<sup>1</sup> KRAKAUER 91 quotes the limit  $\tau/m_{\nu_1} > (0.75a^2 + 21.65a + 26.3) \text{ s/eV}$ , where  $a$  is a parameter describing the asymmetry in the neutrino decay defined as  $dN_\nu/d\cos\theta = (1/2)(1 + a\cos\theta)$ . The parameter  $a = 0$  for a Majorana neutrino, but can vary from  $-1$  to  $1$  for a Dirac neutrino. The bound given by the authors is the most conservative (which applies for  $a = -1$ ).

<sup>2</sup> RAFFELT 85 limit on the radiative decay is from solar x- and  $\gamma$ -ray fluxes. Limit depends on  $\nu$  flux from  $p\bar{p}$ , now established from GALLEX and SAGE to be  $> 0.5$  of expectation.

<sup>3</sup> REINES 74 looked for  $\nu$  of nonzero mass decaying radiatively to a neutral of lesser mass +  $\gamma$ . Used liquid scintillator detector near fission reactor. Finds lab lifetime  $6 \times 10^7$  s or more. Above value of (mean life)/mass assumes average effective neutrino energy of 0.2 MeV. To obtain the limit  $6 \times 10^7$  s REINES 74 assumed that the full  $\bar{\nu}_e$  reactor flux could be responsible for yielding decays with photon energies in the interval 0.1 MeV - 0.5 MeV. This represents some overestimate so their lower limit is an over-estimate of the lab lifetime (VOGEL 84). If so, OBERAUER 87 may be comparable or better.

<sup>4</sup> CECCHINI 11 search for radiative decays of solar neutrinos into visible photons during the 2006 total solar eclipse. The range of (mean life)/mass values corresponds to a range of  $\nu_1$  masses between  $10^{-4}$  and 0.1 eV.

<sup>5</sup> MIRIZZI 07 determine a limit on the neutrino radiative decay from an analysis of the maximum allowed distortion of the CMB spectrum as measured by the COBE/FIRAS. For the decay  $\nu_2 \rightarrow \nu_1$  the lifetime limit is  $\lesssim 4 \times 10^{20}$  s for  $m_{\text{min}} \lesssim 0.14 \text{ eV}$ . For transition with the  $|\Delta m_{31}|$  mass difference the lifetime limit is  $\sim 2 \times 10^{19}$  s for  $m_{\text{min}} \lesssim 0.14 \text{ eV}$  and  $\sim 5 \times 10^{20}$  s for  $m_{\text{min}} \gtrsim 0.14 \text{ eV}$ .

<sup>6</sup> MIRIZZI 07 determine a limit on the neutrino radiative decay from analysis of the cosmic infrared background (CIB) using the Spitzer Observatory data. For transition with the  $|\Delta m_{31}|$  mass difference they obtain the lifetime limit  $\sim 10^{20}$  s for  $m_{\text{min}} \lesssim 0.14 \text{ eV}$ .

<sup>7</sup> WONG 07 use their limit on the neutrino magnetic moment together with the assumed experimental value of  $\Delta m_{13}^2 \sim 2 \times 10^{-3} \text{ eV}^2$  to obtain  $\tau_{13}/m_1^3 > 3.2 \times 10^{27} \text{ s/eV}^3$  for the radiative decay in the case of the inverted mass hierarchy. Similarly to RAFFELT 89 this limit can be violated if electric and magnetic moments are equal to each other. Analogous, but numerically somewhat different limits are obtained for  $\tau_{23}$  and  $\tau_{21}$ .

<sup>8</sup> XIN 05 search for the  $\gamma$  from radiative decay of  $\nu_e$  produced by the electron capture on <sup>51</sup>Cr. No events were seen and the limit on  $\tau/m_\nu$  was derived. This is a weaker limit on the decay of  $\nu_e$  than KRAKAUER 91.

<sup>9</sup> XIN 05 use their limit on the neutrino magnetic moment of  $\nu_e$  together with the assumed experimental value of  $\Delta m_{13}^2 \sim 2 \times 10^{-3} \text{ eV}^2$  to obtain  $\tau_{13}/m_1^3 > 1 \times 10^{23} \text{ s/eV}^3$  for the radiative decay in the case of the inverted mass hierarchy. Similarly to RAFFELT 89 this limit can be violated if electric and magnetic moments are equal to each other. Analogous, but numerically somewhat different limits are obtained for  $\tau_{23}$  and  $\tau_{21}$ . Again, this limit is specific for  $\nu_e$ .

<sup>10</sup> AHARMIM 04 obtained these results from the solar  $\bar{\nu}_e$  flux limit set by the SNO measurement assuming  $\nu_2$  decay through nonradiative process  $\nu_2 \rightarrow \bar{\nu}_1 X$ , where  $X$  is a Majoron or other invisible particle. Limits are given for the cases of quasidegenerate and hierarchical neutrino masses.

<sup>11</sup> CECCHINI 04 obtained this bound through the observations performed on the occasion of the 21 June 2001 total solar eclipse, looking for visible photons from radiative decays of solar neutrinos. Limit is a  $\tau/m_{\nu_2}$  in  $\nu_2 \rightarrow \nu_1 \gamma$ . Limit ranges from  $\sim 100$  to  $10^7 \text{ s/eV}$  for  $0.01 < m_{\nu_1} < 0.1 \text{ eV}$ .

# Lepton Particle Listings

## Neutrino Properties

- <sup>12</sup>EGUCHI 04 obtained these results from the solar  $\bar{\nu}_e$  flux limit set by the KamLAND measurement assuming  $\nu_2$  decay through nonradiative process  $\nu_2 \rightarrow \bar{\nu}_1 X$ , where  $X$  is a Majoron or other invisible particle. Limits are given for the cases of quasidegenerate and hierarchical neutrino masses.
- <sup>13</sup>The ratio of the lifetime over the mass derived by BANDYOPADHYAY 03 is for  $\nu_2$ . They obtained this result using the following solar-neutrino data: total rates measured in Cl and Ga experiments, the Super-Kamiokande's zenith-angle spectra, and SNO's day and night spectra. They assumed that  $\nu_1$  is the lowest mass, stable or nearly stable neutrino state and  $\nu_2$  decays through nonradiative Majoron emission process,  $\nu_2 \rightarrow \bar{\nu}_1 + J$ , or through nonradiative process with all the final state particles being sterile. The best fit is obtained in the region of the LMA solution.
- <sup>14</sup>DERBIN 02B (also BACK 03B) obtained this bound for the radiative decay from the results of background measurements with Counting Test Facility (the prototype of the Borexino detector). The laboratory gamma spectrum is given as  $dN_\nu/d\cos\theta = (1/2)(1 + \alpha\cos\theta)$  with  $\alpha=0$  for a Majorana neutrino, and  $\alpha$  varying to  $-1$  to  $1$  for a Dirac neutrino. The listed bound is for the case of  $\alpha=0$ . The most conservative bound  $1.5 \times 10^3 \text{ s eV}^{-1}$  is obtained for the case of  $\alpha=-1$ .
- <sup>15</sup>The ratio of the lifetime over the mass derived by JOSHUPURA 02B is for  $\nu_2$ . They obtained this result from the total rates measured in all solar neutrino experiments. They assumed that  $\nu_1$  is the lowest mass, stable or nearly stable neutrino state and  $\nu_2$  decays through nonradiative process like Majoron emission decay,  $\nu_2 \rightarrow \nu'_1 + J$  where  $\nu'_1$  state is sterile. The exact limit depends on the specific solution of the solar neutrino problem. The quoted limit is for the LMA solution.
- <sup>16</sup>DOLGOV 99 places limits in the (Majorana)  $\tau$ -associated  $\nu$  mass-lifetime plane based on nucleosynthesis. Results would be considerably modified if neutrino oscillations exist.
- <sup>17</sup>BILLER 98 use the observed TeV  $\gamma$ -ray spectra to set limits on the mean life of any radiatively decaying neutrino between 0.05 and 1 eV. Curve shows  $\tau_\nu/B_\gamma > 0.15 \times 10^{21} \text{ s}$  at 0.05 eV,  $> 1.2 \times 10^{21} \text{ s}$  at 0.17 eV,  $> 3 \times 10^{21} \text{ s}$  at 1 eV, where  $B_\gamma$  is the branching ratio to photons.
- <sup>18</sup>BLUDMAN 92 sets additional limits by this method for higher mass ranges. Cosmological limits are also obtained.
- <sup>19</sup>Limit on the radiative decay based on nonobservation of  $\gamma$ 's in coincidence with  $\nu$ 's from SN1987A.
- <sup>20</sup>DODELSON 92 range is for wrong-helicity keV mass Dirac  $\nu$ 's from the core of neutron star in SN1987A decaying to  $\nu$ 's that would have interacted in KAM2 or IMB detectors.
- <sup>21</sup>GRANEK 91 considers heavy neutrino decays to  $\gamma\nu_L$  and  $3\nu_L$ , where  $m_{\nu_L} < 100 \text{ keV}$ . Lifetime is calculated as a function of heavy neutrino mass, branching ratio into  $\gamma\nu_L$  and  $m_{\nu_L}$ .
- <sup>22</sup>KRAKAUER 91 quotes the limit for  $\nu_e, \tau/m_\nu > (0.3a^2 + 9.8a + 15.9) \text{ s/eV}$ , where  $a$  is a parameter describing the asymmetry in the radiative neutrino decay defined as  $dN_\nu/d\cos\theta = (1/2)(1 + a\cos\theta)$   $a=0$  for a Majorana neutrino, but can vary from  $-1$  to  $1$  for a Dirac neutrino. The bound given by the authors is the most conservative (which applies for  $a = -1$ ).
- <sup>23</sup>WALKER 90 uses SN1987A  $\gamma$  flux limits after 289 days.
- <sup>24</sup>CHUPP 89 should be multiplied by a branching ratio (about 1) and a detection efficiency (about 1/4), and pertains to radiative decay of any neutrino to a lighter or sterile neutrino.
- <sup>25</sup>RAFFELT 89 uses KYULDJIEV 84 to obtain  $\tau m^3 > 3 \times 10^{18} \text{ s eV}^3$  (based on  $\bar{\nu}_e e^-$  cross sections). The bound for the radiative decay is not valid if electric and magnetic transition moments are equal for Dirac neutrinos.
- <sup>26</sup>RAFFELT 89B analyze stellar evolution and exclude the region  $3 \times 10^{12} < \tau m^3 < 3 \times 10^{21} \text{ s eV}^3$ .
- <sup>27</sup>Model-dependent theoretical analysis of SN1987A neutrinos. Quoted limit is for  $[\sum_j |U_{\ell j}|^2 \Gamma_j m_j]^{-1}$ , where  $\ell = \mu, \tau$ . Limit is  $3.3 \times 10^{14} \text{ s/eV}$  for  $\ell = e$ .
- <sup>28</sup>OBERAUER 87 looks for photons and  $e^+e^-$  pairs from radiative decays of reactor neutrinos.
- <sup>29</sup>BINETRUY 84 finds  $\tau < 10^8 \text{ s}$  for neutrinos in a radiation-dominated universe.
- <sup>30</sup>These experiments look for  $\nu_k \rightarrow \nu_j \gamma$  or  $\bar{\nu}_k \rightarrow \bar{\nu}_j \gamma$ .
- <sup>31</sup>STECKER 80 limit based on UV background; result given is  $\tau > 4 \times 10^{22} \text{ s}$  at  $m_\nu = 20 \text{ eV}$ .
- <sup>32</sup>FALK 78 finds lifetime constraints based on supernova energetics.
- <sup>33</sup>COWSIK 77 considers variety of scenarios. For neutrinos produced in the big bang, present limits on optical photon flux require  $\tau > 10^{23} \text{ s}$  for  $m_\nu \sim 1 \text{ eV}$ . See also COWSIK 79 and GOLDMAN 79.

### $\nu$ MAGNETIC MOMENT

The coupling of neutrinos to an electromagnetic field is characterized by a  $3 \times 3$  matrix  $\lambda$  of the magnetic ( $\mu$ ) and electric ( $d$ ) dipole moments ( $\lambda = \mu - id$ ). For Majorana neutrinos the matrix  $\lambda$  is antisymmetric and only transition moments are allowed, while for Dirac neutrinos  $\lambda$  is a general  $3 \times 3$  matrix. In the standard electroweak theory extended to include neutrino masses (see FUJIKAWA 80)  $\mu_\nu = 3eG_F m_\nu / (8\pi^2 \sqrt{2}) = 3.2 \times 10^{-19} (m_\nu/\text{eV}) \mu_B$ , i.e. it is unobservably small given the known small neutrino masses. In more general models there is no longer a proportionality between neutrino mass and its magnetic moment, even though only massive neutrinos have nonvanishing magnetic moments without fine tuning.

Laboratory bounds on  $\lambda$  are obtained via elastic  $\nu$ - $e$  scattering, where the scattered neutrino is not observed. The combinations of matrix elements of  $\lambda$  that are constrained by various experiments depend on the initial neutrino flavor and on its propagation between source and detector (e.g., solar  $\nu_e$  and reactor  $\bar{\nu}_e$  do not constrain the same combinations). The listings below therefore identify the initial neutrino flavor.

Other limits, e.g. from various stellar cooling processes, apply to all neutrino flavors. Analogous flavor independent, but weaker, limits are obtained from the analysis of  $e^+e^- \rightarrow \nu\bar{\nu}\gamma$  collider experiments.

<sup>1</sup>BEDA 13 report  $\bar{\nu}_e e^-$  scattering results, using the Kalinin Nuclear Power Plant and a shielded Ge detector. The recoil electron spectrum is analyzed between 2.5 and 55 keV. Supersedes BEDA 07. Supersedes BEDA 10. This is the most stringent limit on the magnetic moment of reactor  $\bar{\nu}_e$ .

<sup>2</sup>AUERBACH 01 limit is based on the LSND  $\nu_e$  and  $\nu_\mu$  electron scattering measurements. The limit is slightly more stringent than KRAKAUER 90.

<sup>3</sup>SCHWIENHORST 01 quote an experimental sensitivity of  $4.9 \times 10^{-7}$ .

<sup>4</sup>VIAUX 13A constrains the neutrino magnetic moment from observations of the globular cluster M5.

<sup>5</sup>BEDA 10 report  $\bar{\nu}_e e^-$  scattering results, using the Kalinin Nuclear Power Plant and a shielded Ge detector. The recoil electron spectrum is analyzed between 2.9 and 45 keV. Supersedes BEDA 07. Superseded by BEDA 13.

<sup>6</sup>DENIZ 10 observe reactor  $\bar{\nu}_e e^-$  scattering with recoil kinetic energies 3-8 MeV using CsI(Tl) detectors. The observed rate and spectral shape are consistent with the Standard Model prediction, leading to the reported constraint on  $\bar{\nu}_e$  magnetic moment.

<sup>7</sup>KUZNETSOV 09 obtain a limit on the flavor averaged magnetic moment of Dirac neutrinos from the time averaged neutrino signal of SN1987A. Improves and supersedes the analysis of BARBIERI 88 and AYALA 99.

<sup>8</sup>ARPESELLA 08A obtained this limit using the shape of the recoil electron energy spectrum from the Borexino 192 live days of solar neutrino data.

<sup>9</sup>BEDA 07 performed search for electromagnetic  $\bar{\nu}_e e^-$  scattering at Kalininskaya nuclear reactor. A Ge detector with active and passive shield was used and the electron recoil spectrum between 3.0 and 61.3 keV analyzed. Superseded by BEDA 10.

- <sup>10</sup> WONG 07 performed search for non-standard  $\bar{\nu}_e$ -e scattering at the Kuo-Sheng nuclear reactor. Ge detector equipped with active anti-Compton shield is used. Most stringent laboratory limit on magnetic moment of reactor  $\bar{\nu}_e$ . Supersedes LI 03B.
- <sup>11</sup> DARAKTCHIEVA 05 present the final analysis of the search for non-standard  $\bar{\nu}_e$ -e scattering component at Bugey nuclear reactor. Full kinematical event reconstruction of both the kinetic energy above 700 keV and scattering angle of the recoil electron, by use of TPC. Most stringent laboratory limit on magnetic moment. Supersedes DARAKTCHIEVA 03.
- <sup>12</sup> XIN 05 evaluated the  $\nu_e$  flux at the Kuo-Sheng nuclear reactor and searched for non-standard  $\nu_e$ -e scattering. Ge detector equipped with active anti-Compton shield was used. This laboratory limit on magnetic moment is considerably less stringent than the limits for reactor  $\bar{\nu}_e$ , but is specific to  $\nu_e$ .
- <sup>13</sup> GRIFOLS 04 obtained this bound using the SNO data of the solar  $^8\text{B}$  neutrino flux measured with deuteron breakup. This bound applies to  $\mu_{\text{eff}} = (\mu_{21}^2 + \mu_{22}^2 + \mu_{23}^2)^{1/2}$ .
- <sup>14</sup> LIU 04 obtained this limit using the shape of the recoil electron energy spectrum from the Super-Kamiokande-I 1496 days of solar neutrino data. Neutrinos are assumed to have only diagonal magnetic moments,  $\mu_{\nu 1} = \mu_{\nu 2}$ . This limit corresponds to the oscillation parameters in the vacuum oscillation region.
- <sup>15</sup> LIU 04 obtained this limit using the shape of the recoil electron energy spectrum from the Super-Kamiokande-I 1496 live-day solar neutrino data, by limiting the oscillation parameter region in the LMA region allowed by solar neutrino experiments plus KamLAND.  $\mu_{\nu 1} = \mu_{\nu 2}$  is assumed. In the LMA region, the same limit would be obtained even if neutrinos have off-diagonal magnetic moments.
- <sup>16</sup> BACK 03b obtained this bound from the results of background measurements with Counting Test Facility (the prototype of the Borexino detector). Standard Solar Model flux was assumed. This  $\mu_\nu$  can be different from the reactor  $\mu_\nu$  in certain oscillation scenarios (see BEACOM 99).
- <sup>17</sup> DARAKTCHIEVA 03 searched for non-standard  $\bar{\nu}_e$ -e scattering component at Bugey nuclear reactor. Full kinematical event reconstruction by use of TPC. Superseded by DARAKTCHIEVA 05.
- <sup>18</sup> LI 03B used Ge detector in active shield near nuclear reactor to test for nonstandard  $\bar{\nu}_e$ -e scattering.
- <sup>19</sup> GRIMUS 02 obtain stringent bounds on all Majorana neutrino transition moments from a simultaneous fit of LMA-MSW oscillation parameters and transition moments to global solar neutrino data + reactor data. Using only solar neutrino data, a 90% CL bound of  $6.3 \times 10^{-10} \mu_B$  is obtained.
- <sup>20</sup> TANIMOTO 00 combined  $e^+ e^- \rightarrow \nu \bar{\nu} \gamma$  data from VENUS, TOPAZ, and AMY.
- <sup>21</sup> AYALA 99 improves the limit of BARBIERI 88.
- <sup>22</sup> BEACOM 99 obtain the limit using the shape, but not the absolute magnitude which is affected by oscillations, of the solar neutrino spectrum obtained by Superkamiokande (825 days). This  $\mu_\nu$  can be different from the reactor  $\mu_\nu$  in certain oscillation scenarios.
- <sup>23</sup> RAFFELT 99 is an update of RAFFELT 90. This limit applies to all neutrino flavors which are light enough ( $< 5$  keV) to be emitted from globular-cluster red giants. This limit pertains equally to electric dipole moments and magnetic transition moments, and it applies to both Dirac and Majorana neutrinos.
- <sup>24</sup> RAFFELT 99 is essentially an update of BERNSTEIN 63, but is derived from the helioseismological limit on a new energy-loss channel of the Sun. This limit applies to all neutrino flavors which are light enough ( $< 1$  keV) to be emitted from the Sun. This limit pertains equally to electric dipole and magnetic transition moments, and it applies to both Dirac and Majorana neutrinos.
- <sup>25</sup> ACCIARRI 97Q result applies to both direct and transition magnetic moments and for  $q^2=0$ .
- <sup>26</sup> ELMFORS 97 calculate the rate of depolarization in a plasma for neutrinos with a magnetic moment and use the constraints from a big-bang nucleosynthesis on additional degrees of freedom.
- <sup>27</sup> Applies to absolute value of magnetic moment.
- <sup>28</sup> DERBIN 93 determine the cross section for  $0.6$ - $2.0$  MeV electron energy as  $(1.28 \pm 0.63) \times \sigma_{\text{weak}}$ . However, the (reactor on - reactor off)/(reactor off) is only  $\sim 1/100$ .
- <sup>29</sup> COOPER-SARKAR 92 assume  $f_{D_s}/f_\pi = 2$  and  $D_s, \bar{D}_s$  production cross section =  $2.6 \mu\text{b}$  to calculate  $\nu$  flux.
- <sup>30</sup> VIDYAKIN 92 limit is from a  $e\bar{\nu}$  elastic scattering experiment. No experimental details are given except for the cross section from which this limit is derived. Signal/noise was  $1/10$ . The limit uses  $\sin^2 \theta_W = 0.23$  as input.
- <sup>31</sup> DORENBOSCH 91 corrects an incorrect statement in DORENBOSCH 89 that the  $\nu$  magnetic moment is  $< 1 \times 10^{-9}$  at the 95%CL. DORENBOSCH 89 measures both  $\nu_\mu e$  and  $\bar{\nu} e$  elastic scattering and assume  $\mu(\nu) = \mu(\bar{\nu})$ .
- <sup>32</sup> KRAKAUER 90 experiment fully reported in ALLEN 93.
- <sup>33</sup> RAFFELT 90 limit applies for a diagonal magnetic moment of a Dirac neutrino, or for a transition magnetic moment of a Majorana neutrino. In the latter case, the same analysis gives  $< 1.4 \times 10^{-12}$ . Limit at 95%CL obtained from  $\delta M_C$ .
- <sup>34</sup> Significant dependence on details of stellar models.
- <sup>35</sup> FUKUGITA 88 find magnetic dipole moments of any two neutrino species are bounded by  $\mu < 10^{-16} [10^{-9} G/B_0]$  where  $B_0$  is the present-day intergalactic field strength.
- <sup>36</sup> GROTCHE 88 combined data from MAC, ASP, CELLO, and Mark J.
- <sup>37</sup> For  $m_\nu = 8$ - $200$  eV. NUSSINOV 87 examines transition magnetic moments for  $\nu_\mu \rightarrow \nu_e$  and obtain  $< 3 \times 10^{-15}$  for  $m_\nu > 16$  eV and  $< 6 \times 10^{-14}$  for  $m_\nu > 4$  eV.
- <sup>38</sup> We obtain above limit from SUTHERLAND 76 using their limit  $f < 1/3$ .
- <sup>39</sup> KIM 74 is a theoretical analysis of  $\bar{\nu}_\mu$  reaction data.

## NEUTRINO CHARGE RADIUS SQUARED

We report limits on the so-called neutrino charge radius squared. While the straight-forward definition of a neutrino charge radius has been proven to be gauge-dependent and, hence, unphysical (LEE 77C), there have been recent attempts to define a physically observable neutrino charge radius (BERNABEU 00, BERNABEU 02). The issue is still controversial (FUJIKAWA 03, BERNABEU 03). A more general interpretation of the experimental results is that they are limits on certain nonstandard contributions to neutrino scattering.

		<sup>7</sup> GRIFOLS	89B ASTR	SN 1987A

<sup>1</sup> DENIZ 10 observe reactor  $\bar{\nu}_e e$  scattering with recoil kinetic energies 3-8 MeV using CsI(Tl) detectors. The observed rate and spectral shape are consistent with the Standard Model prediction, leading to the reported constraint on  $\bar{\nu}_e$  charge radius.

<sup>2</sup> Based on analysis of CCFR 98 results. Limit is on  $\langle r_V^2 \rangle + \langle r_A^2 \rangle$ . The CHARM II and E734 at BNL results are reanalyzed, and weaker bounds on the charge radius squared than previously published are obtained. The NuTeV result is discussed; when tentatively interpreted as  $\nu_\mu$  charge radius it implies  $\langle r_V^2 \rangle + \langle r_A^2 \rangle = (4.20 \pm 1.64) \times 10^{-33} \text{ cm}^2$ .

<sup>3</sup> Results of LEP-2 are interpreted as limits on the axial-vector charge radius squared of a Majorana  $\nu_\mu$ . Slightly weaker limits for both vector and axial-vector charge radius squared are obtained for the Dirac case, and somewhat weaker limits are obtained from the analysis of lower energy data (LEP-1.5 and TRISTAN).

<sup>4</sup> AUERBACH 01 measure  $\nu_e e$  elastic scattering with LSND detector. The cross section agrees with the Standard Model expectation, including the charge and neutral current interference. The 90% CL applies to the range shown.

<sup>5</sup> VIDYAKIN 92 limit is from a  $e\bar{\nu}$  elastic scattering experiment. No experimental details are given except for the cross section from which this limit is derived. Signal/noise was  $1/10$ . The limit uses  $\sin^2 \theta_W = 0.23$  as input.

<sup>6</sup> Result is obtained from reanalysis given in ALLEN 91, followed by our reduction to obtain  $1\sigma$  errors.

<sup>7</sup> GRIFOLS 89b sets a limit of  $\langle r^2 \rangle < 0.2 \times 10^{-32} \text{ cm}^2$  for right-handed neutrinos.

## Number of Neutrino Types

The neutrinos referred to in this section are those of the Standard  $SU(2) \times U(1)$  Electroweak Model possibly extended to allow nonzero neutrino masses. Light neutrinos are those with  $m < m_Z/2$ . The limits are on the number of neutrino mass eigenstates, including  $\nu_1$ ,  $\nu_2$ , and  $\nu_3$ .

## THE NUMBER OF LIGHT NEUTRINO TYPES FROM COLLIDER EXPERIMENTS

Revised March 2008 by D. Karlen (University of Victoria and TRIUMF).

The most precise measurements of the number of light neutrino types,  $N_\nu$ , come from studies of  $Z$  production in  $e^+e^-$  collisions. The invisible partial width,  $\Gamma_{\text{inv}}$ , is determined by subtracting the measured visible partial widths, corresponding to  $Z$  decays into quarks and charged leptons, from the total  $Z$  width. The invisible width is assumed to be due to  $N_\nu$  light neutrino species each contributing the neutrino partial width  $\Gamma_\nu$  as given by the Standard Model. In order to reduce the model dependence, the Standard Model value for the ratio of the neutrino to charged leptonic partial widths,  $(\Gamma_\nu/\Gamma_\ell)_{\text{SM}} = 1.991 \pm 0.001$ , is used instead of  $(\Gamma_\nu)_{\text{SM}}$  to determine the number of light neutrino types:

$$N_\nu = \frac{\Gamma_{\text{inv}}}{\Gamma_\ell} \left( \frac{\Gamma_\ell}{\Gamma_\nu} \right)_{\text{SM}}. \quad (1)$$

The combined result from the four LEP experiments is  $N_\nu = 2.984 \pm 0.008$  [1].

In the past, when only small samples of  $Z$  decays had been recorded by the LEP experiments and by the Mark II at SLC, the uncertainty in  $N_\nu$  was reduced by using Standard Model

## Number of Neutrino Types

See key on page 547

fits to the measured hadronic cross sections at several center-of-mass energies near the  $Z$  resonance. Since this method is much more dependent on the Standard Model, the approach described above is favored.

Before the advent of the SLC and LEP, limits on the number of neutrino generations were placed by experiments at lower-energy  $e^+e^-$  colliders by measuring the cross section of the process  $e^+e^- \rightarrow \nu\bar{\nu}\gamma$ . The ASP, CELLO, MAC, MARK J, and VENUS experiments observed a total of 3.9 events above background [2], leading to a 95% CL limit of  $N_\nu < 4.8$ . This process has a much larger cross section at center-of-mass energies near the  $Z$  mass and has been measured at LEP by the ALEPH, DELPHI, L3, and OPAL experiments [3]. These experiments have observed several thousand such events, and the combined result is  $N_\nu = 3.00 \pm 0.08$ . The same process has also been measured by the LEP experiments at much higher center-of-mass energies, between 130 and 208 GeV, in searches for new physics [4]. Combined with the lower energy data, the result is  $N_\nu = 2.92 \pm 0.05$ .

Experiments at  $p\bar{p}$  colliders also placed limits on  $N_\nu$  by determining the total  $Z$  width from the observed ratio of  $W^\pm \rightarrow \ell^\pm\nu$  to  $Z \rightarrow \ell^+\ell^-$  events [5]. This involved a calculation that assumed Standard Model values for the total  $W$  width and the ratio of  $W$  and  $Z$  leptonic partial widths, and used an estimate of the ratio of  $Z$  to  $W$  production cross sections. Now that the  $Z$  width is very precisely known from the LEP experiments, the approach is now one of those used to determine the  $W$  width.

Double- $\beta$  Decay

OMITTED FROM SUMMARY TABLE

NEUTRINOLESS DOUBLE- $\beta$  DECAY

Revised August 2013 by P. Vogel (Caltech) and A. Piepke (University of Alabama).

Neutrinoless double-beta ( $0\nu\beta\beta$ ) decay would signal violation of total lepton number conservation. The process can be mediated by an exchange of a light Majorana neutrino, or by an exchange of other particles. However, the existence of  $0\nu\beta\beta$ -decay requires Majorana neutrino mass, no matter what the actual mechanism is. As long as only a limit on the lifetime is available, limits on the effective Majorana neutrino mass, on the lepton-number violating right-handed current or other possible mechanisms mediating  $0\nu\beta\beta$ -decay can be obtained, independently of the actual mechanism. These limits are listed in the next three tables, together with a claimed  $0\nu\beta\beta$ -decay signal reported by part of the Heidelberg-Moscow collaboration. There is tension between that claim and several recent experiments which did not find evidence for  $0\nu\beta\beta$  decay. In the following we assume that the exchange of light Majorana neutrinos ( $m_{\nu_i} \leq 10$  MeV) contributes dominantly to the decay rate.

Besides a dependence on the phase space ( $G^{0\nu}$ ) and the nuclear matrix element ( $M^{0\nu}$ ), the observable  $0\nu\beta\beta$ -decay rate is proportional to the square of the effective Majorana mass  $\langle m_{\beta\beta} \rangle$ ,  $(T_{1/2}^{0\nu})^{-1} = G^{0\nu} \cdot |M^{0\nu}|^2 \cdot \langle m_{\beta\beta} \rangle^2$ , with  $\langle m_{\beta\beta} \rangle^2 = |\sum_i U_{ei}^2 m_{\nu_i}|^2$ . The sum contains, in general, complex  $CP$ -phases in  $U_{ei}^2$ , *i.e.*, cancellations may occur. For three neutrino flavors, there are three physical phases for Majorana neutrinos. There is only one phase if neutrinos are Dirac particles. The two additional Majorana phase differences affect only processes to which lepton-number-changing amplitudes contribute. Given the general  $3 \times 3$  mixing matrix for Majorana neutrinos, one can construct other analogous lepton number violating quantities,  $\langle m_{\ell\ell'} \rangle = \sum_i U_{ei} U_{e'i} m_{\nu_i} (l \text{ or } l' \neq e)$ . However, these are currently much less constrained than  $\langle m_{\beta\beta} \rangle$ .

Nuclear structure calculations are needed to deduce  $\langle m_{\beta\beta} \rangle$  from the decay rate. While  $G^{0\nu}$  can be calculated, the computation of  $M^{0\nu}$  is subject to uncertainty. Comparing different nuclear model evaluations indicates a factor  $\sim 2$  to 3 spread in the calculated nuclear matrix elements. The particle physics quantities to be determined are thus nuclear model-dependent, so the half-life measurements are listed first. Where possible, we reference the nuclear matrix elements used in the subsequent analysis. Since rates for the more conventional  $2\nu\beta\beta$  decay serve to calibrate some nuclear models (e.g. QRPA-based calculations), results for this process are also given.

Oscillation experiments utilizing atmospheric-, accelerator-, solar-, and reactor-produced neutrinos and anti-neutrinos yield strong evidence that at least some neutrinos are massive. However, these findings shed no light on the mass hierarchy (*i.e.*, on the sign of  $\Delta m_{31}^2$ ), the absolute neutrino mass values or the properties of neutrinos under  $CPT$ -conjugation (Dirac or Majorana).

All confirmed oscillation experiments can be consistently described using three interacting neutrino species with two mass splittings and three mixing angles. Full three flavor analyses such as *e.g.* [1] yield:  $|\Delta m_{31}^2| = 2.55_{-0.09}^{+0.06} (2.43_{-0.06}^{+0.07}) \times 10^{-3}$  eV<sup>2</sup> and  $\sin^2 \theta_{23} = 0.613_{-0.040}^{+0.022} (0.600_{-0.031}^{+0.026})$  for the parameters observed in atmospheric and accelerator experiments, where the values correspond to the normal (inverted) hierarchies. Observations of solar  $\nu_e$  and reactor  $\bar{\nu}_e$  lead to  $\Delta m_{21}^2 = 7.62_{-0.19}^{+0.19} \times 10^{-5}$  eV<sup>2</sup> and  $\sin^2 \theta_{12} = 0.320_{-0.017}^{+0.016}$ . The investigation of reactor  $\bar{\nu}_e$  at  $\sim 1.5$  km baseline shows that electron type neutrinos couple only weakly to the third mass eigenstate with  $\sin^2 \theta_{13} = 0.0246_{-0.0028}^{+0.0029} (0.0250_{-0.0027}^{+0.0026})$ . (All errors correspond to  $1\sigma$ .)

Based on the 3-neutrino analysis:  $\langle m_{\beta\beta} \rangle^2 = |\cos^2 \theta_{13} \cos^2 \theta_{12} m_1 + e^{i\Delta\alpha_{21}} \cos^2 \theta_{13} \sin^2 \theta_{12} m_2 + e^{i\Delta\alpha_{31}} \sin^2 \theta_{13} m_3|^2$ , with  $\Delta\alpha_{21}, \Delta\alpha_{31}$  denoting the physically relevant Majorana  $CP$ -phase differences (possible Dirac phase  $\delta$  is absorbed in these  $\Delta\alpha$ ). Given the present knowledge of the neutrino oscillation parameters one can derive the relation between the effective Majorana mass and the mass of the lightest neutrino, as illustrated in the left panel of Fig. 1. The three mass hierarchies

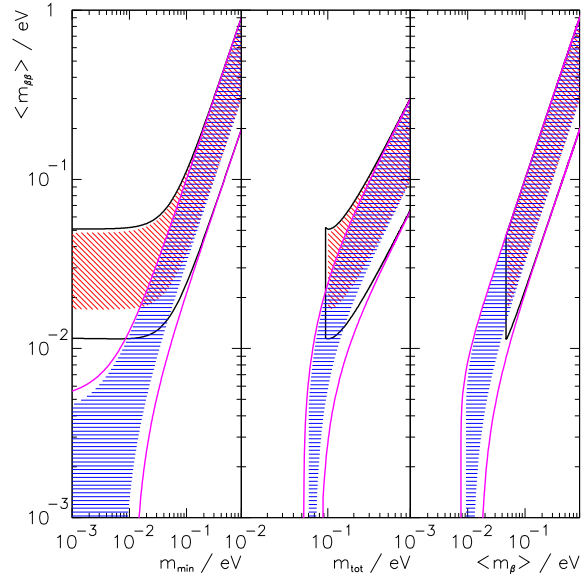

allowed by the oscillation data: normal ( $m_1 < m_2 < m_3$ ), inverted ( $m_3 < m_1 < m_2$ ), and degenerate ( $m_1 \approx m_2 \approx m_3$ ), result in different projections. The width of the innermost hatched bands reflects the uncertainty introduced by the unknown Majorana and Dirac phases. If the experimental errors of the oscillation parameters are taken into account, then the allowed areas are widened as shown by the outer bands of Fig. 1. Because of the overlap of the different mass scenarios a measurement of  $\langle m_{\beta\beta} \rangle$  in the degenerate or inversely hierarchical ranges would not determine the hierarchy. The middle panel of Fig. 1 depicts the relation of  $\langle m_{\beta\beta} \rangle$  with the summed neutrino mass  $m_{tot} = m_1 + m_2 + m_3$ , constrained by observational cosmology. The oscillation data thus allow to test whether observed values of  $\langle m_{\beta\beta} \rangle$  and  $m_{tot}$  are consistent within the 3 neutrino framework and the light neutrino-exchange dominance assumption. The right hand panel of Fig. 1, finally, shows  $\langle m_{\beta\beta} \rangle$  as a function of the kinematical mass  $\langle m_{\beta} \rangle = [\sum |U_{ei}|^2 m_{\nu_i}^2]^{1/2}$  determined through the analysis of the electron energy distribution in low energy beta decays. The rather large intrinsic width of the  $\beta\beta$ -decay constraint essentially does not allow to positively identify the inverted hierarchy, and thus the sign of  $\Delta m_{31}^2$ , even in combination with these other observables. Naturally, if the value of  $\langle m_{\beta\beta} \rangle \leq 0.01$  eV, but non-zero is ever established then normal hierarchy becomes the only possible scenario.

It should be noted that systematic uncertainties of the nuclear matrix elements are not folded into the mass projections shown in Fig. 1. Taking this additional uncertainty into account would further widen the allowed areas. The uncertainties in oscillation parameters affect the width of the allowed bands in an asymmetric manner, as shown in Fig. 1. For example, for the degenerate mass pattern ( $\langle m_{\beta\beta} \rangle \geq 0.1$  eV) the upper edge is simply  $\langle m_{\beta\beta} \rangle \sim m$ , where  $m$  is the common mass of the degenerate multiplet, independent of the oscillation parameters, while the lower edge is  $m \cos(2\theta_{12})$ . Similar arguments explain the other features of Fig. 1.

If the neutrinoless double-beta decay is observed, it will be possible to fix a range of absolute values of the masses  $m_{\nu_i}$ . Unlike the direct neutrino mass measurements, however, a limit on  $\langle m_{\beta\beta} \rangle$  does not allow one to constrain the individual mass values  $m_{\nu_i}$  even when the mass differences  $\Delta m^2$  are known.

Neutrino oscillation data imply, for the first time, the existence of a lower limit  $\sim 0.013$  eV for the Majorana neutrino mass for the inverted hierarchy mass pattern while  $\langle m_{\beta\beta} \rangle$  could, by fine tuning, vanish in the case of the normal mass hierarchy. Several new double beta searches have been proposed to probe the interesting  $\langle m_{\beta\beta} \rangle$  mass range, with the prospect of full coverage of the inverted mass hierarchy region within the next decade.

If lepton-number-violating right-handed current weak interactions exist, their strength can be characterized by the phenomenological coupling constants  $\eta$  and  $\lambda$  ( $\eta$  describes the coupling between the right-handed lepton current and left-handed quark current while  $\lambda$  describes the coupling when both

**Figure 1:** The left panel shows the dependence of  $\langle m_{\beta\beta} \rangle$  on the absolute mass of the lightest neutrino  $m_{min}$ . The middle panel shows  $\langle m_{\beta\beta} \rangle$  as a function of the summed neutrino mass  $m_{tot}$ , while the right panel depicts  $\langle m_{\beta\beta} \rangle$  as a function of the mass  $\langle m_{\beta} \rangle$ . In all panels the width of the hatched areas is due to the unknown Majorana phases and thus irreducible. The allowed areas given by the solid lines are obtained by taking into account the errors of the oscillation parameters (at the  $3\sigma$  level [1]). The two sets of solid lines correspond to the normal and inverted hierarchies. These sets merge into each other for  $\langle m_{\beta\beta} \rangle \geq 0.1$  eV, which corresponds to the degenerate mass pattern.

currents are right-handed). The  $0\nu\beta\beta$  decay rate then depends on  $\langle \eta \rangle = \eta \sum_i U_{ei} V_{ei}$  and  $\langle \lambda \rangle = \lambda \sum_i U_{ei} V_{ei}$  that vanish for massless or unmixed neutrinos ( $V_{\ell j}$  is a matrix analogous to  $U_{\ell j}$  but describing the mixing with the hypothetical right-handed neutrinos). This mechanism of the  $0\nu\beta\beta$  decay could be, in principle, distinguished from the light Majorana neutrino exchange by the observation of the single electron spectra. The limits on  $\langle \eta \rangle$  and  $\langle \lambda \rangle$  are listed in a separate table. The reader is cautioned that a number of earlier experiments did not distinguish between  $\eta$  and  $\lambda$ . In addition, see the section on Majoron searches for additional limits set by these experiments.

## Lepton Particle Listings

Double- $\beta$  DecayHalf-life Measurements and Limits for Double- $\beta$  Decay

In most cases the transitions  $(Z,A) \rightarrow (Z+2,A) + 2e^- + (0 \text{ or } 2) \bar{\nu}_e$  to the  $0^+$  ground state of the final nucleus are listed. However, we also list transitions that increase the nuclear charge ( $2e^+$ ,  $e^+$ /EC and ECEC) and transitions to excited states of the final nuclei ( $0^+_1$ ,  $2^+$ , and  $2^+_1$ ). In the following Listings, only best or comparable limits or lifetimes for each isotope are reported and only those with  $T_{1/2} > 10^{20}$  years that are relevant for particle physics. For  $2\nu$  decay, which is well established, only measured half-lives are reported.

- ALBERT 14 use the EXO-200 tracking detector for a re-measurement of the  $2\nu\beta\beta$ -half life of  $^{136}\text{Xe}$ . A nuclear matrix element of  $0.0218 \pm 0.0003 \text{ MeV}^{-1}$  is derived from this data. Supersedes ACKERMAN 11.
- AGOSTINI 13 use 5.04 kg yr of data collected with bare enriched Ge diodes operated in a liquid argon shield, to determine the half life for the  $0\nu\beta\beta$  decay of  $^{76}\text{Ge}$ . This result is in agreement, and more accurate, than DOERR 03.
- AGOSTINI 13A use 21.6 kg yr of data, collected with GERDA detector array, to place a lower limit on the  $0\nu\beta\beta$ -half life of  $^{76}\text{Ge}$ . This result is in tension with the evidence for  $0\nu\beta\beta$ -decay reported in KLAPDOR-KLEINGROTHAUS 06A. This half-life limit exceeds the limit reported in KLAPDOR-KLEINGROTHAUS 01.
- BELLI 13A use an underground Ge detector to search for the  $2\beta^+$ -decay of  $^{96}\text{Ru}$  via the intensity of the annihilation peak. This method cannot distinguish two from zero neutrino decay.
- BELLI 13A use an underground Ge detector to search for the EC $\beta^+$ -decay of  $^{96}\text{Ru}$  via the intensity of the 778 keV  $\gamma$  de-excitation peak. This method cannot distinguish two from zero neutrino decay. The same analysis provides several limits, ( $\sim 0.1 - 0.3$ )  $10^{21}$  years, for the  $\beta^+$ EC mode leading to the excited  $0^+$  and  $2^+$  states.
- BELLI 13A use an underground Ge detector to search for the  $\beta\beta$ -decay of  $^{104}\text{Ru}$  via the intensity of the 556 keV  $\gamma$  de-excitation peak. This method cannot distinguish two from zero neutrino decay.
- GANDO 13A use the KamLAND detector to search for  $0\nu\beta\beta$ -decay of  $^{136}\text{Xe}$  based on an exposure of 89.5 kg yr. This result is in tension with the evidence of  $0\nu\beta\beta$  reported in KLAPDOR-KLEINGROTHAUS 06A and earlier references to that work. Supersedes GANDO 12A and is more sensitive than BERNABEI 02D.
- GAVRILYAK 13 use a proportional counter filled with Kr gas to search for the  $2\nu 2K$  decay of  $^{78}\text{Kr}$ . Data with the enriched and depleted Kr were used to determine signal and background. A  $2.5\sigma$  excess of events obtained with the enriched sample is interpreted as an indication for the presence of this decay.
- GAVRILYAK 13 use a proportional counter filled with Kr gas to search for the  $0\nu 2K$  decay of  $^{78}\text{Kr}$  into 2828 keV excited state of  $^{78}\text{Se}$ . This transition could be subject to resonant rate enhancement. Data obtained with the enriched and depleted Kr were used to determine signal and background.
- ANDREOTTI 12 use high resolution  $\text{TeO}_2$  bolometric calorimeter to search for the  $0\nu\beta\beta$  decay of  $^{130}\text{Te}$  leading to the excited  $0^+_1$  state at 1793.5 keV.
- AUGER 12 use EXO-200 liquid Xe TPC filled with 79.4 kg (fiducial mass) of  $^{136}\text{Xe}$  to constrain the  $0\nu\beta\beta$ -decay half-life of  $^{136}\text{Xe}$ . This result is more sensitive than BERNABEI 02D and GANDO 12A.

# Lepton Particle Listings

## Double- $\beta$ Decay

See key on page 547

- 12 BELL1 12A use  $^{106}\text{CdWO}_4$  215 g crystal scintillator to search for various  $\beta\beta$  decay modes. The limit for the ECEC mode is derived from the fit to the background spectrum in the 1.8–3.2 MeV energy interval in the run of 6590 hours. The same analysis provides several limits ( $\sim 2\text{--}5 \times 10^{20}$  years) for the ECEC mode leading to the excited  $0^+$  and  $2^+$  states. Also a similar size limits for the possible resonance process populating states at 2718 keV, 2741 keV, and 2748 keV were obtained.
- 13 BELL1 12A use  $^{106}\text{CdWO}_4$  215 g crystal scintillator to search for various  $\beta\beta$  decay modes. The limit for the  $\text{EC}\beta^+$  mode is derived from the fit to the background spectrum in the 2.0–3.0 MeV energy interval in the run of 6590 hours. The same analysis provides several limits ( $\sim 0.5\text{--}1.3 \times 10^{21}$  years) for the  $\text{EC}\beta^+$  mode leading to the excited  $0^+$  and  $2^+$  states.
- 14 BELL1 12A use  $^{106}\text{CdWO}_4$  215 g crystal scintillator to search for various  $\beta\beta$  decay modes. The limit for the  $\beta^+\beta^+$  mode is derived from the fit to the background spectrum in the 0.76–2.8 MeV energy interval in the run of 6590 hours. The same analysis provides the limit ( $1.2 \times 10^{21}$  years) for the  $\beta^+\beta^+$  mode leading to the first excited  $2^+$  state.
- 15 GANDO 12A use a modification of the existing KamLAND detector. The  $\beta\beta$  decay source/detector is 13 tons of enriched  $^{136}\text{Xe}$ -loaded scintillator contained in an inner balloon. The  $2\nu\beta\beta$  decay rate is derived from the fit to the spectrum between 0.5 and 4.8 MeV. This result is in agreement with ACKERMAN 11.
- 16 GANDO 12A use a modification of the existing KamLAND detector. The  $\beta\beta$  decay source/detector is 13 tons of enriched  $^{136}\text{Xe}$ -loaded scintillator contained in an inner balloon. The  $0\nu\beta\beta$  decay rate is derived from the fit where the background rates were allowed to float. Supersedes by GANDO 13A.
- 17 ACKERMAN 11 use the EXO-200 liquid Xe TPC filled with  $\sim 175$  kg of enriched  $^{136}\text{Xe}$  to determine the  $2\nu$  half-life of  $^{136}\text{Xe}$ . Supersedes by ALBERT 14.
- 18 ARNOLD 11 use enriched  $^{130}\text{Te}$  in the NEMO-3 detector to measure the  $2\nu\beta\beta$  decay rate. This result is in agreement with, but more accurate than ARNABOLDI 03.
- 19 ARNOLD 11 use the NEMO-3 detector to obtain a limit for the  $0\nu\beta\beta$  decay. This result is less significant than ARNABOLDI 05.
- 20 BARABASH 11 use 100 g of enriched  $^{112}\text{Sn}$  to determine a limit for the ECEC  $0\nu$  decay to the  $0_1^+$  state of  $^{112}\text{Cd}$  by searching for the de-excitation  $\gamma$  with a Ge detector. This decay mode is a candidate for resonant rate enhancement.
- 21 BARABASH 11 use 100 g of enriched  $^{112}\text{Sn}$  to determine a limit for the ECEC  $0\nu$  decay to the  $0_2^+$  state of  $^{112}\text{Cd}$  by searching for the de-excitation  $\gamma$  with a Ge detector.
- 22 BARABASH 11 use 100 g of enriched  $^{112}\text{Sn}$  to determine a limit for the ECEC  $0\nu$  decay to the  $0_1^+$  state of  $^{112}\text{Cd}$  by searching for the de-excitation  $\gamma$  with a Ge detector.
- 23 BARABASH 11 use 100 g of enriched  $^{112}\text{Sn}$  to determine a limit for the ECEC  $0\nu$  decay to the ground state of  $^{112}\text{Cd}$  by searching for the de-excitation  $\gamma$  with a Ge detector.
- 24 Supersedes DANEVICH 03 and ARNOLD 96.
- 25 Supersedes BRUDANIN 00 and BALYSH 96.
- 26 BARABASH 11A use the NEMO-3 detector to measure  $\beta\beta 2\nu$  rates and place limits on  $\beta\beta 0\nu$  half lives for various nuclides.
- 27 Supersedes ARNABOLDI 03.
- 28 Supersedes ARNOLD 05A, ARNOLD 04, ASHITKOV 01, EJIRI 01, and DASSIE 95.
- 29 Supersedes ARNOLD 05A, ARNOLD 04, ARNOLD 98, and ELLIOTT 92.
- 30 Less restrictive than ARNABOLDI 08.
- 31 Less restrictive than DANEVICH 03.
- 32 Less restrictive than UMEHARA 08 and OGAWA 04.
- 33 BELL1 11D use  $\text{ZnWO}_4$  scintillator calorimeters to search for various  $\beta\beta$  decay modes of  $^{64}\text{Zn}$ ,  $^{70}\text{Zn}$ ,  $^{180}\text{W}$ , and  $^{186}\text{W}$ .
- 34 RUKHADZE 11 uses 13.6 g of enriched  $^{106}\text{Cd}$  to search for the neutrinoless ECEC decay into an excited state of  $^{106}\text{Pd}$  and its characteristic  $\gamma$ -radiation using the TGV2 detector. This decay mode is a candidate for resonant rate enhancement, however, hindered by the large spin difference.
- 35 ARGYRIADES 10 use  $9.4 \pm 0.2$  g of  $^{96}\text{Zr}$  in NEMO-3 detector and identify its  $2\nu\beta\beta$  decay. The result is in agreement and supersedes ARNOLD 99.
- 36 ARGYRIADES 10 use  $9.4 \pm 0.2$  g of  $^{96}\text{Zr}$  in NEMO-3 detector and obtain a limit of the  $0\nu\beta\beta$  decay. The result is in agreement and supersedes ARNOLD 99.
- 37 ARGYRIADES 10 use  $9.4 \pm 0.2$  g of  $^{96}\text{Zr}$  in NEMO-3 detector and obtain a limit of the  $0\nu\beta\beta$  decay into the first excited  $0_1^+$  state in  $^{96}\text{Mo}$ .
- 38 BELL1 10 use enriched  $^{100}\text{Mo}$  with 4 HP Ge detectors to record the 590.8 and 539.5 keV  $\gamma$  rays from the decay of the  $0_1^+$  state in  $^{100}\text{Ru}$  both in singles and coincidences. This result confirms the measurement of KIDD 09 and ARNOLD 07 and supersedes them.
- 39 ARGYRIADES 09 use the NEMO-3 tracking calorimeter containing 36.5 g of  $^{150}\text{Nd}$ , a total exposure of 924.7 days, to derive a limit for the  $0\nu\beta\beta$  half-life. Supersedes DESILVA 97.
- 40 ARGYRIADES 09 use the NEMO-3 tracking calorimeter containing 36.5 g of  $^{150}\text{Nd}$ , a total exposure of 924.7 days, to determine the value of the  $2\nu\beta\beta$  half-life. This result is in marginal agreement, but has somewhat smaller error bars, than DESILVA 97.
- 41 BELL1 09A use  $\text{ZnWO}_4$  scintillating crystals to search for various modes of  $\beta\beta$  decay. This work improves the limits for different modes of  $^{64}\text{Zn}$  decay into the ground state of  $^{64}\text{Ni}$ , in this case for the  $0\nu\beta^+\text{EC}$  mode. Supersedes BELL1 08.
- 42 BELL1 09A use  $\text{ZnWO}_4$  scintillating crystals to search for various modes of  $\beta\beta$  decay. This work improves the limits for different modes of  $^{64}\text{Zn}$  decay into the ground state of  $^{64}\text{Ni}$ , in this case for the  $0\nu$  ECEC mode. Supersedes BELL1 08.
- 43 KIDD 09 combine past and new data with an improved coincidence detection efficiency determination. The result agrees with ARNOLD 95. Supersedes DEBRAECKELEER 01 and BARABASH 95.
- 44 ARNABOLDI 08 use high resolution  $\text{TeO}_2$  bolometer calorimeter to search for double beta decay of  $^{130}\text{Te}$ . Supersedes ARNABOLDI 05.
- 45 BELL1 08 use  $\text{ZnWO}_4$  scintillation calorimeter to search for neutrinoless  $\beta^+$  plus electron capture decay of  $^{64}\text{Zn}$ . The half-life limit for the  $2\nu$  mode is  $2.1 \times 10^{20}$  years.
- 46 BELL1 08B use  $\text{CdWO}_4$  scintillation calorimeter to search for  $0\nu\beta\beta$  decay of  $^{114}\text{Cd}$ .
- 47 UMEHARA 08 use  $\text{CaF}_2$  scintillation calorimeter to search for double beta decay of  $^{48}\text{Ca}$ . Limit is significantly more stringent than quoted sensitivity:  $18 \times 10^{21}$  years.
- 48 First exclusive measurement of  $2\nu$ -decay to the first excited  $0_1^+$ -state of daughter nucleus. ARNOLD 07 use the NEMO-3 tracking calorimeter to detect all particles emitted in decay. Result agrees with the inclusive ( $0\nu + 2\nu$ ) measurement of DEBRAECKELEER 01.
- 49 Limit on  $0\nu$ -decay to the first excited  $0_1^+$ -state of daughter nucleus using NEMO-3 tracking calorimeter. Supersedes DASSIE 95.
- 50 Limit on  $0\nu$ -decay to the first excited  $2^+$ -state of daughter nucleus using NEMO-3 tracking calorimeter.
- 51 BARABASH 07 use Ge calorimeter to search for  $\gamma$ -radiation following double electron capture or  $\beta^+$  plus electron capture decays of  $^{74}\text{Se}$  to the ground state of  $^{74}\text{Ge}$ . This limit is based on the search for the 511 keV annihilation radiation. Various other limits, for the capture from different atomic shells and also to the excited states, are reported in the paper.
- 52 BARABASH 07 use Ge calorimeter to search for  $\gamma$ -radiation following double electron capture decay of  $^{74}\text{Se}$  into the second excited  $2^+$ -state of  $^{74}\text{Ge}$ . That transition has been considered due to a possible resonance enhancement. The  $2\nu$  mode would be suppressed for this decay by its extremely small phase space factor.
- 53 KLAPDOR-KLEINGROTHAUS 06A present re-analysis of data originally published in KLAPDOR-KLEINGROTHAUS 04A. Modified pulse shape analysis leads the authors to claim improved  $6\sigma$  statistical evidence for observation of  $0\nu$ -decay, compared to 4.2 $\sigma$  in KLAPDOR-KLEINGROTHAUS 04A. Analysis of the systematic uncertainty is not presented. This re-analysis is disputed in AGOSTINI 13A and SCHWINGENHEUER 13.
- 54 Supersedes ARNABOLDI 04. Bolometric  $\text{TeO}_2$  detector array CUORICINO is used for high resolution search for  $0\nu\beta\beta$  decay. The half-life limit is derived from 3.09 kg yr  $^{130}\text{Te}$  exposure.
- 55 NEMO-3 tracking calorimeter containing 6.9 kg of enriched  $^{100}\text{Mo}$  is used in ARNOLD 05A. A limit for  $0\nu\beta\beta$  half-life of  $^{100}\text{Mo}$  is reported. Supersedes ARNOLD 04.
- 56 NEMO-3 tracking calorimeter is used in ARNOLD 05A to place limit on  $0\nu\beta\beta$  half-life of  $^{82}\text{Se}$ . Detector contains 0.93 kg of enriched  $^{82}\text{Se}$ . Supersedes ARNOLD 04.
- 57 ARNOLD 05A use the NEMO-3 tracking calorimeter to determine the  $2\nu\beta\beta$  half-life of  $^{100}\text{Mo}$  with high statistics and low background (389 days of data taking). Supersedes ARNOLD 04.
- 58 ARNOLD 05A use the NEMO-3 tracking detector to determine the  $2\nu\beta\beta$  half-life of  $^{82}\text{Se}$  with high statistics and low background (389 days of data taking). Supersedes ARNOLD 04.
- 59 ARNOLD 04 use the NEMO-3 tracking detector to determine the limit for  $0\nu\beta\beta$  half-life of  $^{82}\text{Se}$ . This represents an improvement, by a factor of  $\sim 10$ , when compared with ELLIOTT 92. It supersedes the limit of ARNOLD 98 for this decay using NEMO-2.
- 60 ARNOLD 04 use the NEMO-3 tracking detector to determine the  $2\nu\beta\beta$  half-life of  $^{100}\text{Mo}$  with high statistics and low background. The half-life is determined assuming the Single State Dominance. It is in agreement with, and more accurate than, previous determinations. Supersedes DASSIE 95 determination of this quantity with NEMO-2.
- 61 BARABASH 04 perform an inclusive measurement of the  $\beta\beta$  decay of  $^{150}\text{Nd}$  into the first excited ( $0_1^+$ ) state of  $^{150}\text{Sm}$ . Gamma radiation emitted in decay of the excited state is detected.
- 62 Decay into first excited state of daughter nucleus.
- 63 Two neutrino decay into ground state. Relatively large error mainly due to uncertainties in background determination. Reported value is shorter than the geochemical measurements of KIRSTEN 83 and BERNATOWICZ 92 but in agreement with LIN 88 and TAKAOKA 96.
- 64 Supersedes ALESSANDRELLO 00. Array of  $\text{TeO}_2$  crystals in high resolution cryogenic calorimeter. Some enriched in  $^{128}\text{Te}$ . Ground state to ground state decay.
- 65 Calorimetric measurement of  $2\nu$  ground state decay of  $^{116}\text{Cd}$  using enriched  $\text{CdWO}_4$  scintillators. Agrees with EJIRI 95 and ARNOLD 96. Supersedes DANEVICH 00.
- 66 Limit on  $0\nu$  decay of  $^{116}\text{Cd}$  using enriched  $\text{CdWO}_4$  scintillators. Supersedes DANEVICH 00.
- 67 Limit on  $0\nu$  decay of  $^{116}\text{Cd}$  into first excited  $2^+$  state of daughter nucleus using enriched  $\text{CdWO}_4$  scintillators. Supersedes DANEVICH 00.
- 68 Limit on  $0\nu$  decay of  $^{116}\text{Cd}$  into first excited  $0^+$  state of daughter nucleus using enriched  $\text{CdWO}_4$  scintillators. Supersedes DANEVICH 00.
- 69 Limit on  $0\nu$  decay of  $^{116}\text{Cd}$  into second excited  $0^+$  state of daughter nucleus using enriched  $\text{CdWO}_4$  scintillators. Supersedes DANEVICH 00.
- 70 Limit on the  $0\nu$  ground state decay of  $^{186}\text{W}$  using enriched  $\text{CdWO}_4$  scintillators.
- 71 Limit on the  $0\nu$  decay of  $^{186}\text{W}$  to the first excited  $2^+$  state of the daughter nucleus using enriched  $\text{CdWO}_4$  scintillators.
- 72 Results of the Heidelberg-Moscow experiment (KLAPDOR-KLEINGROTHAUS 01 and GUENTHER 97) are reanalyzed using a new simulation of the complete background spectrum. The  $\beta\beta 2\nu$ -decay rate is deduced from a 41.57 kg-y exposure. The result is in agreement and supersedes the above referenced half-lives with similar statistical and systematic errors.
- 73 AALSETH 02b limit is based on 117 mol-yr of data using enriched Ge detectors. Background reduction by means of pulse shape analysis is applied to part of the data set. Reported limit is slightly less restrictive than that in KLAPDOR-KLEINGROTHAUS 01 However, it excludes part of the allowed half-life range reported in KLAPDOR-KLEINGROTHAUS 01B for the same nuclide. The analysis has been criticized in KLAPDOR-KLEINGROTHAUS 04B. The criticism was addressed and disputed in AALSETH 04.

## Lepton Particle Listings

Double- $\beta$  Decay

- <sup>74</sup> BERNABEI 02b report a limit for the  $0\nu, 0^+ \rightarrow 0^+$  decay of <sup>134</sup>Xe, present in the source at 17%, by considering the maximum number of events for this mode compatible with the fitted smooth background.
- <sup>75</sup> BERNABEI 02b report a limit for the  $0\nu, 0^+ \rightarrow 0^+$  decay of <sup>136</sup>Xe, by considering the maximum number of events for this mode compatible with the fitted smooth background. The quoted sensitivity is  $450 \times 10^{21}$  yr. The Feldman and Cousins method is used to obtain the quoted limit.
- <sup>76</sup> ASHITKOV 01 result for  $0\nu$  of <sup>100</sup>Mo is less stringent than EJIRI 01.
- <sup>77</sup> DANEVICH 01 place limit on  $0\nu$  decay of <sup>160</sup>Gd using Gd<sub>2</sub>SiO<sub>5</sub>:Ce crystal scintillators. The limit is more stringent than KOBAYASHI 95.
- <sup>78</sup> DANEVICH 01 place limits on  $0\nu$  decay of <sup>160</sup>Gd into excited  $2^+$  state of daughter nucleus using Gd<sub>2</sub>SiO<sub>5</sub>:Ce crystal scintillators.
- <sup>79</sup> DEBRACKELEER 01 performed an inclusive measurement of the  $\beta\beta$  decay into the second excited state of the daughter nucleus. A novel coincidence technique counting the de-excitation photons is employed. The result agrees with BARABASH 95.
- <sup>80</sup> KLAPDOR-KLEINGROTHAUS 01 is a continuation of the work published in BAUDIS 99. Isotopically enriched Ge detectors are used in calorimetric measurement. The most stringent bound is derived from the data set in which pulse-shape analysis has been used to reduce background. Exposure time is 35.5 kg y. Supersedes BAUDIS 99 as most stringent result.
- <sup>81</sup> WIESER 01 reports an inclusive geochemical measurement of <sup>96</sup>Zr  $\beta\beta$  half life. Their result agrees within  $2\sigma$  with ARNOLD 99 but only marginally, within  $3\sigma$ , with KAWASHIMA 93.
- <sup>82</sup> BRUDANIN 00 determine the  $2\nu$  half-life of <sup>48</sup>Ca. Their value is less accurate than BALYSH 96.
- <sup>83</sup> ARNOLD 99 measure directly the  $2\nu$  decay of Zr for the first time, using the NEMO-2 tracking detector and an isotopically enriched source. The lifetime is more accurate than the geochemical result of KAWASHIMA 93.
- <sup>84</sup> ARNOLD 98 measure the  $2\nu$  decay of <sup>82</sup>Se by comparing the spectra in an enriched and natural selenium source using the NEMO-2 tracking detector. The measured half-life is in agreement, perhaps slightly shorter, than ELLIOTT 92.
- <sup>85</sup> ARNOLD 98 determine the limit for  $0\nu$  decay to the excited  $2^+$  state of <sup>82</sup>Se using the NEMO-2 tracking detector.
- <sup>86</sup> ALSTON-GARNJOST 97 report evidence for  $2\nu$  decay of <sup>100</sup>Mo. This decay has also been observed by EJIRI 91, DASSIE 95, and DESILVA 97.
- <sup>87</sup> DESILVA 97 result for  $2\nu$  decay of <sup>100</sup>Mo is in agreement with ALSTON-GARNJOST 97 and DASSIE 95. This measurement has the smallest errors.
- <sup>88</sup> DESILVA 97 result for  $2\nu$  decay of <sup>150</sup>Nd is in marginal agreement with ARTEMEV 93. It has smaller errors.
- <sup>89</sup> ARNOLD 96 measure the  $2\nu$  decay of <sup>116</sup>Cd. This result is in agreement with EJIRI 95, but has smaller errors. Supersedes ARNOLD 95.
- <sup>90</sup> BALYSH 96 measure the  $2\nu$  decay of <sup>48</sup>Ca, using a passive source of enriched <sup>48</sup>Ca in a TPC.
- <sup>91</sup> TAKAOKA 96 measure the geochemical half-life of <sup>130</sup>Te. Their value is in disagreement with the quoted values of BERNATOWICZ 92 and KIRSTEN 83; but agrees with several other unquoted determinations, e.g., MANUEL 91.
- <sup>92</sup> BARABASH 95 cannot distinguish  $0\nu$  and  $2\nu$ , but it is inferred indirectly that the  $0\nu$  mode accounts for less than 0.026% of their event sample. They also note that their result disagrees with the previous experiment by the NEMO group (BLUM 92).
- <sup>93</sup> BERNATOWICZ 92 finds <sup>128</sup>Te/<sup>130</sup>Te activity ratio from slope of <sup>128</sup>Xe/<sup>132</sup>Xe vs <sup>130</sup>Xe/<sup>132</sup>Xe ratios during extraction, and normalizes to lead-dated ages for the <sup>130</sup>Te lifetime. The authors state that their results imply that "(a) the double beta decay of <sup>128</sup>Te has been firmly established and its half-life has been determined ... without any ambiguity due to trapped Xe interferences... (b) Theoretical calculations ... underestimate the [long half-lives of <sup>128</sup>Te/<sup>130</sup>Te] by 1 or 2 orders of magnitude, pointing to a real suppression in the  $2\nu$  decay rate of these isotopes. (c) Despite [this], most  $\beta\beta$ -models predict a ratio of  $2\nu$  decay widths ... in fair agreement with observation." Further details of the experiment are given in BERNATOWICZ 93. Our listed half-life has been revised downward from the published value by the authors, on the basis of reevaluated cosmic-ray <sup>128</sup>Xe production corrections.
- <sup>94</sup> TURKEVICH 91 observes activity in old U sample. The authors compare their results with theoretical calculations. They state "Using the phase-space factors of Boehm and Vogel (BOEHM 87) leads to matrix element values for the <sup>238</sup>U transition in the same range as deduced for <sup>130</sup>Te and <sup>76</sup>Ge. On the other hand, the latest theoretical estimates (STAUDT 90) give an upper limit that is 10 times lower. This large discrepancy implies either a defect in the calculations or the presence of a faster path than the standard two-neutrino mode in this case." See BOEHM 87 and STAUDT 90.
- <sup>95</sup> Result agrees with direct determination of ELLIOTT 92.
- <sup>96</sup> Inclusive half life inferred from mass spectroscopic determination of abundance of  $\beta\beta$ -decay product <sup>130</sup>Te in mineral kirkite (NiTeSe). Systematic uncertainty reflects variations in U-Xe gas-retention-age derived from different uranite samples. Agrees with geochemical determination of TAKAOKA 96 and direct measurement of ARNABOLDI 03. Inconsistent with results of KIRSTEN 83 and BERNATOWICZ 92.
- <sup>97</sup> Ratio of inclusive double beta half lives of <sup>128</sup>Te and <sup>130</sup>Te determined from minerals melonite (NiTe<sub>2</sub>) and altaite (PbTe) by means of mass spectroscopic measurement of abundance of  $\beta\beta$ -decay products. As gas-retention-age could not be determined the authors use half life of <sup>130</sup>Te (LIN 88) to infer the half life of <sup>128</sup>Te. No estimate of the systematic uncertainty of this method is given. The directly determined half life ratio agrees with BERNATOWICZ 92. However, the inferred <sup>128</sup>Te half life disagrees with KIRSTEN 83 and BERNATOWICZ 92.
- <sup>98</sup> KIRSTEN 83 reports "2 $\sigma$ " error. References are given to earlier determinations of the <sup>130</sup>Te lifetime.

 $\langle m_{\nu} \rangle$ , The Effective Weighted Sum of Majorana Neutrino Masses Contributing to Neutrinoless Double- $\beta$  Decay

$\langle m_{\nu} \rangle = |\sum U_{ej}^2 m_{\nu_j}|$ , where the sum goes from 1 to  $n$  and where  $n$  = number of neutrino generations, and  $\nu_j$  is a Majorana neutrino. Note that  $U_{ej}^2$ , not  $|U_{ej}|^2$ , occurs in the sum. The possibility of cancellations has been stressed. In the following Listings, only best or comparable limits or lifetimes for each isotope are reported.

- 1 AGOSTINI 13A is based on 21.6 kg yr of data collected by the GERDA detector. The reported range reflects different nuclear matrix elements. This result is in tension with the evidence for  $0\nu\beta\beta$ -decay reported in KLAPDOR-KLEINGROTHAUS 06a and earlier references to that work.
- 2 GANDO 13A limit is based on a combination of KamLAND-Zen and EXO-200 (AUGER 12) data. The reported range reflects different nuclear matrix elements. Supersedes GANDO 12A.
- 3 AUGER 12 limit is based on the EXO-200 data. The reported range reflects different nuclear matrix elements.
- 4 GANDO 12A limit is based on the KamLAND-Zen data. The reported range reflects different nuclear matrix elements. Superseded by GANDO 13A.
- 5 BARABASH 11A limit is based on NEMO-3 data for <sup>100</sup>Mo. The reported range reflects different nuclear matrix elements. Supersedes ARNOLD 05A and ARNOLD 04.
- 6 BARABASH 11A limit is based on NEMO-3 data for <sup>82</sup>Se. The reported range reflects different nuclear matrix elements. Supersedes ARNOLD 05A and ARNOLD 04.
- 7 ARGYRIADES 10 use <sup>96</sup>Zr and the NEMO-3 tracking detector to obtain the reported mass limit. The range reflects the fluctuation of the nuclear matrix elements considered.
- 8 ARGYRIADES 09 limit is based on data taken with the NEMO-3 detector and <sup>150</sup>Nd. A range of nuclear matrix elements that include the effect of nuclear deformation have been used.
- 9 Limit was obtained using high resolution TeO<sub>2</sub> bolometer calorimeter to search for double beta decay of <sup>130</sup>Te. Reported range of limits reflects spread of matrix element calculations used. Supersedes ARNABOLDI 05.
- 10 Limit was obtained using CaF<sub>2</sub> scintillation calorimeter to search for double beta decay of <sup>48</sup>Ca. Reported range of limits reflects spread of QRPA and SM matrix element calculations used. Supersedes OGAWA 04.
- 11 ARNOLD 07 use NEMO-3 half life limit for  $0\nu$ -decay of <sup>100</sup>Mo to the first excited  $0^+_{1-}$  state of daughter nucleus to obtain neutrino mass limit. The spread reflects the choice of two different nuclear matrix elements. This limit is not competitive when compared to the decay to the ground state.
- 12 ARNOLD 07 use NEMO-3 half life limit for  $0\nu$ -decay of <sup>100</sup>Mo to the first excited  $2^+_{-}$  state of daughter nucleus to obtain neutrino mass limit. This limit is not competitive when compared to the decay to the ground state.
- 13 Re-analysis of data originally published in KLAPDOR-KLEINGROTHAUS 04A. Modified pulse shape analysis leads the authors to claim  $6\sigma$  statistical evidence for observation of  $0\nu$ -decay. Authors use matrix element of STAUDT 90. Uncertainty of nuclear matrix element is not reflected in stated error. Supersedes KLAPDOR-KLEINGROTHAUS 04A.
- 14 Supersedes ARNABOLDI 04. Reported range of limits due to use of different nuclear matrix element calculations.

# Lepton Particle Listings

## Double- $\beta$ Decay

See key on page 547

- 15 Mass limits reported in ARNOLD 05A are derived from  $^{100}\text{Mo}$  data, obtained by the NEMO-3 collaboration. The range reflects the spread of matrix element calculations considered in this work. Supersedes ARNOLD 04.
- 16 Neutrino mass limits based on  $^{82}\text{Se}$  data utilizing the NEMO-3 detector. The range reported in ARNOLD 05A reflects the spread of matrix element calculations considered in this work. Supersedes ARNOLD 04.
- 17 Supersedes ARNABOLDI 03. Reported range of limits due to use of different nuclear matrix element calculations.
- 18 ARNOLD 04 limit is based on the nuclear matrix elements of SIMKOVIC 99, STOICA 01 and CIVITARESE 03.
- 19 Supersedes KLAPDOR-KLEINGROTHAUS 02D. Event excess at  $\beta\beta$ -decay energy is used to derive Majorana neutrino mass using the nuclear matrix elements of STAUDT 90. The mass range shown is based on the authors evaluation of the uncertainties of the STAUDT 90 matrix element calculation. If this uncertainty is neglected, and only statistical errors are considered, the range in  $\langle m \rangle$  becomes (0.2–0.6) eV at the  $3\sigma$  level.
- 20 Calorimetric  $\text{CaF}_2$  scintillator. Range of limits reflects authors' estimate of the uncertainty of the nuclear matrix elements. Replaces YOU 91 as the most stringent limit based on  $^{48}\text{Ca}$ .
- 21 Supersedes ALESSANDRELLO 00. Cryogenic calorimeter search. Reported a range reflecting uncertainty in nuclear matrix element calculations.
- 22 Limit for  $\langle m_{\nu} \rangle$  is based on the nuclear matrix elements of STAUDT 90 and ARNOLD 96. Supersedes DANEVICH 00.
- 23 AALSETH 02b reported range of limits on  $\langle m_{\nu} \rangle$  reflects the spread of theoretical nuclear matrix elements. Excludes part of allowed mass range reported in KLAPDOR-KLEINGROTHAUS 01b.
- 24 BERNABEI 02b limit is based on the matrix elements of SIMKOVIC 02. The range of neutrino masses based on a variety of matrix elements is 1.1–2.9 eV.
- 25 KLAPDOR-KLEINGROTHAUS 02D is a detailed description of the analysis of the data collected by the Heidelberg-Moscow experiment, previously presented in KLAPDOR-KLEINGROTHAUS 01b. Matrix elements in STAUDT 90 have been used. See the footnote in the preceding table for further details. See also KLAPDOR-KLEINGROTHAUS 02b.
- 26 The range of the reported  $\langle m_{\nu} \rangle$  values reflects the spread of the nuclear matrix elements. On axis value assuming  $\langle \lambda \rangle = \langle \eta \rangle = 0$ .
- 27 KLAPDOR-KLEINGROTHAUS 01 uses the calculation by STAUDT 90. Using several other models in the literature could worsen the limit up to 1.2 eV. This is the most stringent experimental bound on  $m_{\nu}$ . It supersedes BAUDIS 99b.
- 28 ARNOLD 99 limit based on the nuclear matrix elements of STAUDT 90.
- 29 BERNATOWICZ 92 finds these majorana neutrino mass limits assuming that the measured geochemical decay width is a limit on the  $0\nu$  decay width. The range is the range found using matrix elements from HAXTON 84, TOMODA 87, and SUHONEN 91. Further details of the experiment are given in BERNATOWICZ 93.
- 30 ELLIOTT 92 uses the matrix elements of HAXTON 84.

### Limits on Lepton-Number Violating (V+A) Current Admixture

For reasons given in the discussion at the beginning of this section, we list only results from 1989 and later.  $\langle \lambda \rangle = \lambda \sum U_{ej} V_{ej}$  and  $\langle \eta \rangle = \eta \sum U_{ej} V_{ej}$ , where the sum is over the number of neutrino generations. This sum vanishes for massless or unmixed neutrinos. In the following Listings, only best or comparable limits or lifetimes for each isotope are reported.

$\langle \lambda \rangle$ ( $10^{-6}$ )	CL%	$\langle \eta \rangle$ ( $10^{-8}$ )	CL%	ISOTOPE	METHOD	DOCUMENT ID
<120	90			$^{100}\text{Mo}$	$0^+ \rightarrow 2^+$	1 ARNOLD 07

- 1 ARNOLD 07 use NEMO-3 half life limit for  $0\nu$ -decay of  $^{100}\text{Mo}$  to the first excited  $2^+$ -state of daughter nucleus to limit the right-handed admixture of weak currents  $\langle \lambda \rangle$ . This limit is not competitive when compared to the decay to the ground state.
- 2 Re-analysis of data originally published in KLAPDOR-KLEINGROTHAUS 04A. Modified pulse shape analysis leads the authors to claim  $6\sigma$  statistical evidence for observation of  $0\nu$ -decay. Authors use matrix element of MUTO 89 to determine  $\langle \lambda \rangle$  and  $\langle \eta \rangle$ . Uncertainty of nuclear matrix element is not reflected in stated errors.
- 3 ARNOLD 05A derive limit for  $\langle \lambda \rangle$  based on  $^{100}\text{Mo}$  data collected with NEMO-3 detector. No limit for  $\langle \eta \rangle$  is given. Supersedes ARNOLD 04.
- 4 ARNOLD 05A derive limit for  $\langle \lambda \rangle$  based on  $^{82}\text{Se}$  data collected with NEMO-3 detector. No limit for  $\langle \eta \rangle$  is given. Supersedes ARNOLD 04.
- 5 ARNOLD 04 use the matrix elements of SUHONEN 94 to obtain a limit for  $\langle \lambda \rangle$ , no limit for  $\langle \eta \rangle$  is given. This limit is more stringent than the limit in EJIRI 01 for the same nucleus.
- 6 ARNOLD 04 use the matrix elements of TOMODA 91 and SUHONEN 91 to obtain a limit for  $\langle \lambda \rangle$ , no limit for  $\langle \eta \rangle$  is given.
- 7 Supersedes ALESSANDRELLO 00. Cryogenic calorimeter search. Reported a range reflecting uncertainty in nuclear matrix element calculations.

- 8 Limits for  $\langle \lambda \rangle$  and  $\langle \eta \rangle$  are based on nuclear matrix elements of STAUDT 90. Supersedes DANEVICH 00.
- 9 The range of the reported  $\langle \lambda \rangle$  and  $\langle \eta \rangle$  values reflects the spread of the nuclear matrix elements. On axis value assuming  $\langle m_{\nu} \rangle = 0$  and  $\langle \lambda \rangle = \langle \eta \rangle = 0$ , respectively.
- 10 GUENTHER 97 limits use the matrix elements of STAUDT 90. Supersedes BALLYSH 95 and BALLYSH 92.
- 11 VUILLEUMIER 93 uses the matrix elements of MUTO 89. Based on a half-life limit  $2.6 \times 10^{23}$  y at 90%CL.
- 12 BERNATOWICZ 92 takes the measured geochemical decay width as a limit on the  $0\nu$  width, and uses the SUHONEN 91 coefficients to obtain the least restrictive limit on  $\eta$ . Further details of the experiment are given in BERNATOWICZ 93.

## Double- $\beta$ Decay, Neutrino Mixing

BOEHM	87	Massive Neutrinos	F. Bohm, P. Vogel	(CIT)
Cambridge Univ.		Press, Cambridge		
TOMODA	87	PL B199 475	T. Tomoda, A. Faessler	(TUBIN)
HAXTON	84	PPNP 12 409	W.C. Haxton, G.J. Stevenson	
KIRSTEN	83	PRL 50 474	T. Kirsten, H. Richter, E. Jessberger	(MPIH)

A recent re-evaluation of the spectral conversion of electron to  $\bar{\nu}_e$  in MUELLER 11 results in an upward shift of the reactor  $\bar{\nu}_e$  spectrum by 3% and, thus, might require revisions to the ratios listed in this table.

### Neutrino Mixing

With the exception of a few possible anomalies such as LSND, current neutrino data can be described within the framework of a  $3 \times 3$  mixing matrix between the flavor eigenstates  $\nu_e$ ,  $\nu_\mu$ , and  $\nu_\tau$  and the mass eigenstates  $\nu_1$ ,  $\nu_2$ , and  $\nu_3$ . (See Eq. (14.78) of the review "Neutrino Mass, Mixing, and Oscillations" by K. Nakamura and S.T. Petcov.) The Listings are divided into the following sections:

**(A) Neutrino fluxes and event ratios:** shows measurements which correspond to various oscillation tests for Accelerator, Reactor, Atmospheric, and Solar neutrino experiments. Typically ratios involve a measurement in a realm sensitive to oscillations compared to one for which no oscillation effect is expected.

**(B) Three neutrino mixing parameters:** shows measurements of  $\sin^2(2\theta_{12})$ ,  $\sin^2(2\theta_{23})$ ,  $\Delta m_{21}^2$ ,  $\Delta m_{32}^2$ , and  $\sin^2(2\theta_{13})$  which are all interpretations of data based on the three neutrino mixing scheme described in the review "Neutrino Mass, Mixing, and Oscillations." by K. Nakamura and S.T. Petcov. Many parameters have been calculated in the two-neutrino approximation.

**(C) Other neutrino mixing results:** shows measurements and limits for the probability of oscillation for experiments which might be relevant to the LSND oscillation claim. Included are experiments which are sensitive to  $\nu_\mu \rightarrow \nu_e$ ,  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$ , sterile neutrinos, and CPT tests.

#### (A) Neutrino fluxes and event ratios

##### Events (observed/expected) from accelerator $\nu_\mu$ experiments.

Some neutrino oscillation experiments compare the flux in two or more detectors. This is usually quoted as the ratio of the event rate in the far detector to the expected rate based on an extrapolation from the near detector in the absence of oscillations.

VALUE	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •			
0.71 ± 0.08	1 AHN	06A K2K	K2K to Super-K
0.64 ± 0.05	2 MICHAEL	06 MINS	All charged current events
0.71 $\pm_{-0.09}^{+0.08}$	3 ALIU	05 K2K	KEK to Super-K
0.70 $\pm_{-0.11}^{+0.10}$	4 AHN	03 K2K	KEK to Super-K

<sup>1</sup>Based on the observation of 112 events when  $158.1 \pm_{-8.6}^{+9.2}$  were expected without oscillations. Including not only the number of events but also the shape of the energy distribution, the evidence for oscillation is at the level of about  $4.3 \sigma$ . Supersedes ALIU 05.

<sup>2</sup>This ratio is based on the observation of 215 events compared to an expectation of  $336 \pm 14$  without oscillations. See also ADAMSON 08.

<sup>3</sup>This ratio is based on the observation of 107 events at the far detector 250 km away from KEK, and an expectation of  $151 \pm_{-10}^{+12}$ .

<sup>4</sup>This ratio is based on the observation of 56 events with an expectation of  $80.1 \pm_{-5.4}^{+6.2}$ .

##### Events (observed/expected) from reactor $\bar{\nu}_e$ experiments.

The quoted values are the ratios of the measured reactor  $\bar{\nu}_e$  event rate at the quoted distances, and the rate expected without oscillations. The expected rate is based on the experimental data for the most significant reactor fuels ( $^{235}\text{U}$ ,  $^{239}\text{Pu}$ ,  $^{241}\text{Pu}$ ) and on calculations for  $^{238}\text{U}$ .

0.994 ± 0.010 ± 0.05	ACHKAR	95 CNTR	Bugey reactor, 40 m
0.915 ± 0.132 ± 0.05	ACHKAR	95 CNTR	Bugey reactor, 95 m
0.987 ± 0.014 ± 0.027	11 DECLAIS	94 CNTR	Bugey reactor, 15 m
0.985 ± 0.018 ± 0.034	KUVSHIN...	91 CNTR	Rovno reactor
1.05 ± 0.02 ± 0.05	VUILLEUMIER	82	Gösgen reactor
0.955 ± 0.035 ± 0.110	12 KWON	81	$\bar{\nu}_e p \rightarrow e^+ n$
0.89 ± 0.15	12 BOEHM	80	$\bar{\nu}_e p \rightarrow e^+ n$

<sup>1</sup>AN 13 use six identical detectors, with three placed near the reactor cores (flux-weighted baselines of 470 and 576 m) and the remaining three at the far hall (at the flux averaged distance of 1648 m from all six reactor cores) to determine the mixing angle  $\theta_{13}$  using the  $\bar{\nu}_e$  observed interaction rate ratios. This rate-only analysis excludes the no-oscillation hypothesis at 7.7 standard deviations. The value of  $\Delta m_{31}^2 = 2.32 \times 10^{-3} \text{ eV}^2$  was assumed in the analysis. This is an improved result (2.5 times increase in statistics) compared to AN 12.

<sup>2</sup>ABE 12 determine the  $\bar{\nu}_e$  interaction rate in a single detector, located 1050 m from the cores of two reactors. The rate normalization is fixed by the results of the Bugey4 reactor experiment, thus avoiding any dependence on possible very short baseline oscillations.

<sup>3</sup>AHN 12 use two identical detectors, placed at flux weighted distances of 408.56 m and 1433.99m from six reactor cores, to determine the  $\bar{\nu}_e$  interaction rate ratio.

<sup>4</sup>AN 12 use six identical detectors with three placed near the reactor cores (flux-weighted baselines of 470 m and 576 m) and the remaining three at the far hall (at the flux averaged distance of 1648 m from all six reactor cores) to determine the  $\bar{\nu}_e$  interaction rate ratios. Superseded by AN 13.

<sup>5</sup>DENIZ 10 observe reactor  $\bar{\nu}_e e$  scattering with recoil kinetic energies 3–8 MeV using CsI(Tl) detectors. The observed rate is consistent with the Standard Model prediction, leading to a constraint on  $\sin^2\theta_{\text{eff}} = 0.251 \pm 0.031(\text{stat}) \pm 0.024(\text{sys})$ .

<sup>6</sup>Updated result of KamLAND, including the data used in EGUCHI 03. Note that the survival probabilities for different periods are not directly comparable because the effective baseline varies with power output of the reactor sources involved, and there were large variations in the reactor power production in Japan in 2003.

<sup>7</sup>EGUCHI 03 observe reactor neutrino disappearance at ~180 km baseline to various Japanese nuclear power reactors.

<sup>8</sup>BOEHM 01 search for neutrino oscillations at 0.75 and 0.89 km distance from the Palo Verde reactors.

<sup>9</sup>APOLLONIO 99, APOLLONIO 98 search for neutrino oscillations at 1.1 km fixed distance from Chooz reactors. They use  $\bar{\nu}_e p \rightarrow e^+ n$  in Gd-loaded scintillator target. APOLLONIO 99 supersedes APOLLONIO 98. See also APOLLONIO 03 for detailed description.

<sup>10</sup>GREENWOOD 96 search for neutrino oscillations at 18 m and 24 m from the reactor at Savannah River.

<sup>11</sup>DECLAIS 94 result based on integral measurement of neutrons only. Result is ratio of measured cross section to that expected in standard V-A theory. Replaced by ACHKAR 95.

<sup>12</sup>KWON 81 represents an analysis of a larger set of data from the same experiment as BOEHM 80.

#### Atmospheric neutrinos

Neutrinos and antineutrinos produced in the atmosphere induce  $\mu$ -like and  $e$ -like events in underground detectors. The ratio of the numbers of the two kinds of events is defined as  $\mu/e$ . It has the advantage that systematic effects, such as flux uncertainty, tend to cancel, for both experimental and theoretical values of the ratio. The "ratio of the ratios" of experimental to theoretical  $\mu/e$ ,  $R(\mu/e)$ , or that of experimental to theoretical  $\mu/\text{total}$ ,  $R(\mu/\text{total})$  with  $\text{total} = \mu + e$ , is reported below. If the actual value is not unity, the value obtained in a given experiment may depend on the experimental conditions. In addition, the measured "up-down asymmetry" for  $\mu$  ( $N_{\text{up}}(\mu)/N_{\text{down}}(\mu)$ ) or  $e$  ( $N_{\text{up}}(e)/N_{\text{down}}(e)$ ) is reported. The expected "up-down asymmetry" is nearly unity if there is no neutrino oscillation.

#### $R(\mu/e) = (\text{Measured Ratio } \mu/e) / (\text{Expected Ratio } \mu/e)$

	8	BECKER-SZ...	92B	IMB	Water Cherenkov

<sup>1</sup> ASHIE 05 results are based on an exposure of 92 kton yr during the complete Super-Kamiokande I running period. The analyzed data sample consists of fully-contained single-ring  $e$ -like events with  $0.1 \text{ GeV}/c < p_e$  and  $\mu$ -like events  $0.2 \text{ GeV}/c < p_\mu$ , both having a visible energy  $< 1.33 \text{ GeV}$ . These criteria match the definition used by FUKUDA 94.

<sup>2</sup> ASHIE 05 results are based on an exposure of 92 kton yr during the complete Super-Kamiokande I running period. The analyzed data sample consists of fully-contained single-ring events with visible energy  $> 1.33 \text{ GeV}$  and partially-contained events. All partially-contained events are classified as  $\mu$ -like.

<sup>3</sup> SANCHEZ 03 result is based on an exposure of 5.9 kton yr, and updates ALLISON 99 result. The analyzed data sample consists of fully-contained  $e$ -flavor and  $\mu$ -flavor events having lepton momentum  $> 0.3 \text{ GeV}/c$ .

<sup>4</sup> FUKUDA 96b studied neutron background in the atmospheric neutrino sample observed in the Kamiokande detector. No evidence for the background contamination was found.

<sup>5</sup> DAUM 95 results are based on an exposure of 2.0 kton yr which includes the data used by BERGER 90b. This ratio is for the contained and semicontained events. DAUM 95 also report  $R(\mu/e) = 0.99 \pm 0.13 \pm 0.08$  for the total neutrino induced data sample which includes upward going stopping muons and horizontal muons in addition to the contained and semicontained events.

<sup>6</sup> FUKUDA 94 result is based on an exposure of 7.7 kton yr and updates the HIRATA 92 result. The analyzed data sample consists of fully-contained  $e$ -like events with  $0.1 < p_e < 1.33 \text{ GeV}/c$  and fully-contained  $\mu$ -like events with  $0.2 < p_\mu < 1.5 \text{ GeV}/c$ .

<sup>7</sup> FUKUDA 94 analyzed the data sample consisting of fully contained events with visible energy  $> 1.33 \text{ GeV}$  and partially contained  $\mu$ -like events.

<sup>8</sup> BECKER-SZENDY 92b reports the fraction of nonshowing events (mostly muons from atmospheric neutrinos) as  $0.36 \pm 0.02 \pm 0.02$ , as compared with expected fraction  $0.51 \pm 0.01 \pm 0.05$ . After cutting the energy range to the Kamiokande limits, BEIER 92 finds  $R(\mu/e)$  very close to the Kamiokande value.

### $R(\nu_\mu) = (\text{Measured Flux of } \nu_\mu) / (\text{Expected Flux of } \nu_\mu)$

$0.71 \pm 0.05 \pm 0.19$	<sup>4</sup> AMBROSIO	00	MCRO downgoing partially contained + upgoing stopping
$0.74 \pm 0.036 \pm 0.046$	<sup>5</sup> AMBROSIO	98	MCRO Streamer tubes
	<sup>6</sup> CASPER	91	IMB Water Cherenkov
	<sup>7</sup> AGLIETTA	89	NUSX
$0.95 \pm 0.22$	<sup>8</sup> BOLIEV	81	Baksan
$0.62 \pm 0.17$	CROUCH	78	Case Western /UCI

<sup>1</sup> ADAMSON 06 uses a measurement of 107 total neutrinos compared to an expected rate of  $127 \pm 13$  without oscillations.

<sup>2</sup> AMBROSIO 01 result is based on the upward through-going muon tracks with  $E_\mu > 1 \text{ GeV}$ . The data came from three different detector configurations, but the statistics is largely dominated by the full detector run, from May 1994 to December 2000. The total live time, normalized to the full detector configuration, is 6.17 years. The first error is the statistical error, the second is the systematic error, dominated by the theoretical error in the predicted flux.

<sup>3</sup> AMBROSIO 00 result is based on the upgoing partially contained event sample. It came from 4.1 live years of data taking with the full detector, from April 1994 to February 1999. The average energy of atmospheric muon neutrinos corresponding to this sample is 4 GeV. The first error is statistical, the second is the systematic error, dominated by the 25% theoretical error in the rate (20% in the flux and 15% in the cross section, added in quadrature). Within statistics, the observed deficit is uniform over the zenith angle.

<sup>4</sup> AMBROSIO 00 result is based on the combined samples of downgoing partially contained events and upgoing stopping events. These two subsamples could not be distinguished due to the lack of timing information. The result came from 4.1 live years of data taking with the full detector, from April 1994 to February 1999. The average energy of atmospheric muon neutrinos corresponding to this sample is 4 GeV. The first error is statistical, the second is the systematic error, dominated by the 25% theoretical error in the rate (20% in the flux and 15% in the cross section, added in quadrature). Within statistics, the observed deficit is uniform over the zenith angle.

<sup>5</sup> AMBROSIO 98 result is for all nadir angles and updates AHLEN 95 result. The lower cutoff on the muon energy is 1 GeV. In addition to the statistical and systematic errors, there is a Monte Carlo flux error (theoretical error) of  $\pm 0.13$ . With a neutrino oscillation hypothesis, the fit either to the flux or zenith distribution independently yields  $\sin^2 2\theta = 1.0$  and  $\Delta(m^2) \sim$  a few times  $10^{-3} \text{ eV}^2$ . However, the fit to the observed zenith distribution gives a maximum probability for  $\chi^2$  of only 5% for the best oscillation hypothesis.

<sup>6</sup> CASPER 91 correlates showering/nonshowing signature of single-ring events with parent atmospheric-neutrino flavor. They find nonshowing ( $\approx \nu_\mu$  induced) fraction is  $0.41 \pm 0.03 \pm 0.02$ , as compared with expected  $0.51 \pm 0.05$  (syst).

<sup>7</sup> AGLIETTA 89 finds no evidence for any anomaly in the neutrino flux. They define  $\rho = (\text{measured number of } \nu_e \text{'s}) / (\text{measured number of } \nu_\mu \text{'s})$ . They report  $\rho(\text{measured}) = \rho(\text{expected}) = 0.96 \pm 0.32 \pm 0.28$ .

<sup>8</sup> From this data BOLIEV 81 obtain the limit  $\Delta(m^2) \leq 6 \times 10^{-3} \text{ eV}^2$  for maximal mixing,  $\nu_\mu \leftrightarrow \nu_\mu$  type oscillation.

### $R(\mu/\text{total}) = (\text{Measured Ratio } \mu/\text{total}) / (\text{Expected Ratio } \mu/\text{total})$

$0.71 \pm 0.06$	<sup>1</sup> ADAMSON	12B	MINS contained-vertex muons
$0.551 \pm 0.035 \pm 0.004$	<sup>2</sup> ASHIE	05	SKAM multi-GeV

<sup>1</sup> ADAMSON 12b reports the atmospheric neutrino results obtained with MINOS far detector in 2,553 live days (an exposure of 37.9 kton-yr). This result is obtained with a sample of high resolution contained-vertex muons. The quoted error is statistical only.

<sup>2</sup> ASHIE 05 results are based on an exposure of 92 kton yr during the complete Super-Kamiokande I running period. The analyzed data sample consists of fully-contained single-ring  $\mu$ -like events with visible energy  $> 1.33 \text{ GeV}$  and partially-contained events. All partially-contained events are classified as  $\mu$ -like. Upward-going events are those with  $-1 < \cos(\text{zenith angle}) < -0.2$  and downward-going events are those with  $0.2 < \cos(\text{zenith angle}) < 1$ . The  $\mu$ -like up-down ratio for the multi-GeV data deviates from 1 (the expectation for no atmospheric  $\nu_\mu$  oscillations) by more than 12 standard deviations.

### $N_{\text{up}}(e) / N_{\text{down}}(e)$

## Neutrino Mixing

- <sup>1</sup> ADAMSON 12B reports the atmospheric neutrino results obtained with MINOS far detector in 2,553 live days (an exposure of 37.9 kton-yr). The muon charge ratio  $N(\mu^+)/N(\mu^-)$  represents the  $\overline{\nu}_\mu/\nu_\mu$  ratio. As far as the same oscillation parameters are used for  $\nu_s$  and  $\overline{\nu}_s$ , the expected  $\overline{\nu}_\mu/\nu_\mu$  ratio is almost entirely independent of any input oscillations.
- <sup>2</sup> This result is obtained with a charge-separated sample of high resolution contained-vertex muons.
- <sup>3</sup> This result is obtained with a charge-separated sample of high resolution neutrino-induced rock-muons.
- <sup>4</sup> The charge-separated samples of high resolution contained-vertex muons and neutrino-induced rock-muons are combined to obtain this result which is consistent with unity.
- <sup>5</sup> ADAMSON 07 result is obtained with the MINOS far detector in 854.24 live days, based on neutrino-induced upward-going and horizontal muons. This result is consistent with CP T conservation.
- <sup>6</sup> ADAMSON 06 result is obtained with the MINOS far detector with an exposure of 4.54 kton yr, based on contained events. The expected ratio is calculated by assuming the same oscillation parameters for neutrinos and antineutrinos.

### Solar neutrinos

Solar neutrinos are produced by thermonuclear fusion reactions in the Sun. Radiochemical experiments measure particular combinations of fluxes from various neutrino-producing reactions, whereas water-Cherenkov experiments mainly measure a flux of neutrinos from decay of <sup>8</sup>B. Solar neutrino fluxes are composed of all active neutrino species,  $\nu_e$ ,  $\nu_\mu$ , and  $\nu_\tau$ . In addition, some other mechanisms may cause antineutrino components in solar neutrino fluxes. Each measurement method is sensitive to a particular component or a combination of components of solar neutrino fluxes. For details, see Section 13.4 of Reviews, Tables, and Plots.

### $\nu_e$ Capture Rates from Radiochemical Experiments

1 SNU (Solar Neutrino Unit) =  $10^{-36}$  captures per atom per second.

VALUE (SNU)	DOCUMENT ID	TECN	COMMENT
73.4 $\pm 6.1$ $^{+3.7}_{-4.1}$	<sup>1</sup> KAETHER	10	GALX reanalysis
67.6 $\pm 4.0$ $\pm 3.2$	<sup>2</sup> KAETHER	10	GNO+GALX reanalysis combined
65.4 $\pm 3.1$ $\pm 2.6$ $^{-3.0}_{-2.8}$	<sup>3</sup> ABDURASHITOV	09 SAGE	<sup>71</sup> Ga $\rightarrow$ <sup>71</sup> Ge
62.9 $\pm 5.5$ $\pm 2.5$ $^{-5.3}_{-2.5}$	<sup>4</sup> ALTMANN	05 GNO	<sup>71</sup> Ga $\rightarrow$ <sup>71</sup> Ge
69.3 $\pm 4.1$ $\pm 3.6$	<sup>5</sup> ALTMANN	05 GNO	GNO + GALX combined
77.5 $\pm 6.2$ $\pm 4.3$ $^{-4.7}_{-4.7}$	<sup>6</sup> HAMPEL	99 GALX	<sup>71</sup> Ga $\rightarrow$ <sup>71</sup> Ge
2.56 $\pm 0.16$ $\pm 0.16$	<sup>7</sup> CLEVELAND	98 HOME	<sup>37</sup> Cl $\rightarrow$ <sup>37</sup> Ar

- <sup>1</sup> KAETHER 10 reports the reanalysis results of a complete GALLEX data (GALLEX I+II+III+IV, reported in HAMPEL 99) based on the event selection with a new pulse shape analysis, which provides a better background reduction than the rise time analysis adopted in HAMPEL 99.
- <sup>2</sup> Combined result of GALLEX I+II+III+IV reanalysis and GNO I+II+III (ALTMANN 05).
- <sup>3</sup> ABDURASHITOV 09 reports a combined analysis of 168 extractions of the SAGE solar neutrino experiment during the period January 1990 through December 2007, and updates the ABDURASHITOV 02 result. The data are consistent with the assumption that the solar neutrino production rate is constant in time. Note that a  $\sim 15\%$  systematic uncertainty in the overall normalization may be added to the ABDURASHITOV 09 result, because calibration experiments for gallium solar neutrino measurements using intense <sup>51</sup>Cr (twice by GALLEX and once by SAGE) and <sup>37</sup>Ar (by SAGE) result in an average ratio of  $0.87 \pm 0.05$  of the observed to calculated rates.
- <sup>4</sup> ALTMANN 05 reports the complete result from the GNO solar neutrino experiment (GNO I+II+III), which is the successor project of GALLEX. Experimental technique of GNO is essentially the same as that of GALLEX. The run data cover the period 20 May 1998 through 9 April 2003.
- <sup>5</sup> Combined result of GALLEX I+II+III+IV (HAMPEL 99) and GNO I+II+III.
- <sup>6</sup> HAMPEL 99 report the combined result for GALLEX I+II+III+IV (65 runs in total), which update the HAMPEL 96 result. The GALLEX IV result (12 runs) is  $118.4 \pm 17.8 \pm 6.6$  SNU. (HAMPEL 99 discuss the consistency of partial results with the mean.) The GALLEX experimental program has been completed with these runs. The total run data cover the period 14 May 1991 through 23 January 1997. A total of 300 <sup>71</sup>Ge events were observed. Note that a  $\sim 15\%$  systematic uncertainty in the overall normalization may be added to the HAMPEL 99 result, because calibration experiments for gallium solar neutrino measurements using intense <sup>51</sup>Cr (twice by GALLEX and once by SAGE) and <sup>37</sup>Ar (by SAGE) result in an average ratio of  $0.87 \pm 0.05$  of the observed to calculated rates.
- <sup>7</sup> CLEVELAND 98 is a detailed report of the <sup>37</sup>Cl experiment at the Homestake Mine. The average solar neutrino-induced <sup>37</sup>Ar production rate from 108 runs between 1970 and 1994 updates the DAVIS 89 result.

### $\phi_{ES}$ (<sup>8</sup>B)

<sup>8</sup>B solar-neutrino flux measured via  $\nu e$  elastic scattering. This process is sensitive to all active neutrino flavors, but with reduced sensitivity to  $\nu_\mu$ ,  $\nu_\tau$  due to the cross-section difference,  $\sigma(\nu_{\mu,\tau} e) \sim 0.16\sigma(\nu_e e)$ . If the <sup>8</sup>B solar-neutrino flux involves nonelectron flavor active neutrinos, their contribution to the flux is  $\sim 0.16$  times of  $\nu_e$ .

- <sup>1</sup> ABE 11 reports the Super-Kamiokande-III results for 548 live days from August 4, 2006 to August 18, 2008. The analysis threshold is 5.0 MeV, but the event sample in the 5.0–6.5 MeV total electron range has a total live time of 298 days.
- <sup>2</sup> ABE 11 recalculated the Super-Kamiokande-II results using <sup>8</sup>B spectrum of WINTER 06a.
- <sup>3</sup> ABE 11 recalculated the Super-Kamiokande-I results using <sup>8</sup>B spectrum of WINTER 06a.
- <sup>4</sup> ABE 11B use a 123 kton-day exposure of the KamLAND liquid scintillation detector to measure the <sup>8</sup>B solar neutrino flux. They utilize  $\nu - e$  elastic scattering above a reconstructed-energy threshold of 5.5 MeV, corresponding to 5 MeV electron recoil energy. 299 electron recoil candidate events are reported, of which 157  $\pm 23.6$  are assigned to background.
- <sup>5</sup> BELLINI 10A reports the Borexino result with 3 MeV energy threshold for scattered electrons. The data correspond to 345.3 live days with a target mass of 100 t, between July 15, 2007 and August 23, 2009.
- <sup>6</sup> AHARMIM 08 reports the results from SNO Phase III measurement using an array of <sup>3</sup>He proportional counters to measure the rate of NC interactions in heavy water, over the period between November 27, 2004 and November 28, 2006, corresponding to 385.17 live days. A simultaneous fit was made for the number of NC events detected by the proportional counters and the numbers of NC, CC, and ES events detected by the PMTs, where the spectral distributions of the ES and CC events were not constrained to the <sup>8</sup>B shape.
- <sup>7</sup> CRAVENS 08 reports the Super-Kamiokande-II results for 791 live days from December 2002 to October 2005. The photocathode coverage of the detector is 19% (reduced from 40% of that of Super-Kamiokande-I due to an accident in 2001). The analysis threshold for the average flux is 7 MeV.
- <sup>8</sup> HOSAKA 06 reports the final results for 1496 live days with Super-Kamiokande-I between May 31, 1996 and July 15, 2001, and replace FUKUDA 02 results. The analysis threshold is 5 MeV except for the first 280 live days (6.5 MeV).
- <sup>9</sup> AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, corresponding to 391.4 live days, and update AHMED 04a. The CC, ES, and NC events were statistically separated. In one method, the <sup>8</sup>B energy spectrum was not constrained. In the other method, the constraint of an undistorted <sup>8</sup>B energy spectrum was added for comparison with AHMAD 02 results.
- <sup>10</sup> AHMAD 02 reports the <sup>8</sup>B solar-neutrino flux measured via  $\nu e$  elastic scattering above the kinetic energy threshold of 5 MeV. The data correspond to 306.4 live days with SNO between November 2, 1999 and May 28, 2001, and updates AHMAD 01 results.
- <sup>11</sup> AHMAD 01 reports the <sup>8</sup>B solar-neutrino flux measured via  $\nu e$  elastic scattering above the kinetic energy threshold of 6.75 MeV. The data correspond to 241 live days with SNO between November 2, 1999 and January 15, 2001.
- <sup>12</sup> FUKUDA 96 results are for a total of 2079 live days with Kamiokande II and III from January 1987 through February 1995, covering the entire solar cycle 22, with threshold  $E_e > 9.3$  MeV (first 449 days),  $> 7.5$  MeV (middle 794 days), and  $> 7.0$  MeV (last 836 days). These results update the HIRATA 90 result for the average <sup>8</sup>B solar-neutrino flux and HIRATA 91 result for the day-night variation in the <sup>8</sup>B solar-neutrino flux. The total data sample was also analyzed for short-term variations: within experimental errors, no strong correlation of the solar-neutrino flux with the sunspot numbers was found.

### $\phi_{CC}$ (<sup>8</sup>B)

<sup>8</sup>B solar-neutrino flux measured with charged-current reaction which is sensitive exclusively to  $\nu_e$ .

## Neutrino Mixing

See key on page 547

<sup>1</sup>AHARMIM 08 reports the results from SNO Phase III measurement using an array of <sup>3</sup>He proportional counters to measure the rate of NC interactions in heavy water, over the period between November 27, 2004 and November 28, 2006, corresponding to 385.17 live days. A simultaneous fit was made for the number of NC events detected by the proportional counters and the numbers of NC, CC, and ES events detected by the PMTs, where the spectral distributions of the ES and CC events were not constrained to the <sup>8</sup>B shape.

<sup>2</sup>AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, corresponding to 391.4 live days, and update AHMED 04A. The CC, ES, and NC events were statistically separated. In one method, the <sup>8</sup>B energy spectrum was not constrained. In the other method, the constraint of an undistorted <sup>8</sup>B energy spectrum was added for comparison with AHMAD 02 results.

<sup>3</sup>AHMD 02 reports the SNO result of the <sup>8</sup>B solar-neutrino flux measured with charged-current reaction on deuterium,  $\nu_e d \rightarrow pp e^-$ , above the kinetic energy threshold of 5 MeV. The data correspond to 306.4 live days with SNO between November 2, 1999 and May 28, 2001, and updates AHMAD 01 results. The complete description of the SNO Phase I data set is given in AHARMIM 07.

<sup>4</sup>AHMD 01 reports the first SNO result of the <sup>8</sup>B solar-neutrino flux measured with the charged-current reaction on deuterium,  $\nu_e d \rightarrow pp e^-$ , above the kinetic energy threshold of 6.75 MeV. The data correspond to 241 live days with SNO between November 2, 1999 and January 15, 2001.

### $\phi_{NC}$ (<sup>8</sup>B)

<sup>8</sup>B solar neutrino flux measured with neutral-current reaction, which is equally sensitive to  $\nu_e$ ,  $\nu_\mu$ , and  $\nu_\tau$ .

VALUE ( $10^6 \text{ cm}^{-2}\text{s}^{-1}$ )	DOCUMENT ID	TECN	COMMENT

6.42 ± 1.57 <sup>+0.55</sup> / <sub>-0.58</sub>	<sup>5</sup> AHMAD	02 SNO	average flux; <sup>8</sup> B shape not const.

<sup>1</sup>AHARMIM 13 obtained this result from a combined analysis of the data from all three phases, SNO-I, II, and III. The measurement of the <sup>8</sup>B flux mostly comes from the NC signal, however, CC contribution is included in the fit.

<sup>2</sup>AHARMIM 10 reports this result from a joint analysis of SNO Phase I+II data with the "effective electron kinetic energy" threshold of 3.5 MeV. This result is obtained with a "binned-histogram unconstrained fit" where binned probability distribution functions of the neutrino signal observables were used without any model constraints on the shape of the neutrino spectrum.

<sup>3</sup>AHARMIM 08 reports the results from SNO Phase III measurement using an array of <sup>3</sup>He proportional counters to measure the rate of NC interactions in heavy water, over the period between November 27, 2004 and November 28, 2006, corresponding to 385.17 live days. A simultaneous fit was made for the number of NC events detected by the proportional counters and the numbers of NC, CC, and ES events detected by the PMTs, where the spectral distributions of the ES and CC events were not constrained to the <sup>8</sup>B shape.

<sup>4</sup>AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, corresponding to 391.4 live days, and update AHMED 04A. The CC, ES, and NC events were statistically separated. In one method, the <sup>8</sup>B energy spectrum was not constrained. In the other method, the constraint of an undistorted <sup>8</sup>B energy spectrum was added for comparison with AHMAD 02 results.

<sup>5</sup>AHMAD 02 reports the first SNO result of the <sup>8</sup>B solar-neutrino flux measured with the neutral-current reaction on deuterium,  $\nu_e d \rightarrow np \nu_e$ , above the neutral-current reaction threshold of 2.2 MeV. The data correspond to 306.4 live days with SNO between November 2, 1999 and May 28, 2001. The complete description of the SNO Phase I data set is given in AHARMIM 07.

### $\phi_{\nu_\mu+\nu_\tau}$ (<sup>8</sup>B)

Nonelectron-flavor active neutrino component ( $\nu_\mu$  and  $\nu_\tau$ ) in the <sup>8</sup>B solar-neutrino flux.

VALUE ( $10^6 \text{ cm}^{-2}\text{s}^{-1}$ )	DOCUMENT ID	TECN	COMMENT

<sup>1</sup>CRAVENS 08 reports the Super-Kamiokande-II results for 791 live days from December 2002 to October 2005. The photocathode coverage of the detector is 19% (reduced from 40% of that of Super-Kamiokande-I due to an accident in 2001). The analysis threshold for the day and night fluxes is 7.5 MeV.

<sup>2</sup>HOSAKA 06 reports the final results for 1496 live days with Super-Kamiokande-I between May 31, 1996 and July 15, 2001, and replace FUKUDA 02 results. The analysis threshold is 5 MeV except for the first 280 live days (6.5 MeV).

<sup>3</sup>This result with reduced statistical uncertainty is obtained by assuming two-neutrino oscillations within the LMA (large mixing angle) region and by fitting the time variation of

## Lepton Particle Listings

## Neutrino Mixing

the solar neutrino flux measured via  $\nu_e$  elastic scattering to the variations expected from neutrino oscillations. For details, see SMY 04. There is an additional small systematic error of  $\pm 0.0004$  coming from uncertainty of oscillation parameters.

<sup>4</sup>AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, with 176.5 days of the live time recorded during the day and 214.9 days during the night. This result is obtained with the spectral distribution of the CC events not constrained to the <sup>8</sup>B shape.

<sup>5</sup>AHMAD 02b results are based on the charged-current interactions recorded between November 2, 1999 and May 28, 2001, with the day and night live times of 128.5 and 177.9 days, respectively. The complete description of the SNO Phase I data set is given in AHARMIM 07.

<sup>6</sup>AHMAD 02b results are derived from the charged-current interactions, neutral-current interactions, and  $\nu e$  elastic scattering, with the total flux of active neutrinos constrained to have no asymmetry. The data were recorded between November 2, 1999 and May 28, 2001, with the day and night live times of 128.5 and 177.9 days, respectively. The complete description of the SNO Phase I data set is given in AHARMIM 07.

 **$\phi_{ES} (^7\text{Be})$** 

<sup>7</sup>Be solar-neutrino flux measured via  $\nu_e$  elastic scattering. This process is sensitive to all active neutrino flavors, but with reduced sensitivity to  $\nu_\mu, \nu_\tau$  due to the cross-section difference,  $\sigma(\nu_{\mu,\tau} e) \sim 0.2 \sigma(\nu_e e)$ . If the <sup>7</sup>Be solar-neutrino flux involves non-electron flavor active neutrinos, their contribution to the flux is  $\sim 0.2$  times that of  $\nu_e$ .

**(B) Three-neutrino mixing parameters****INTRODUCTION TO THREE-NEUTRINO MIXING PARAMETERS LISTINGS**

Updated January 2014 by M. Goodman (ANL).

**Introduction and Notation:** With the exception of possible short-baseline anomalies (such as LSND), current accelerator, reactor, solar and atmospheric neutrino data can be described within the framework of a  $3 \times 3$  mixing matrix between the flavor eigenstates  $\nu_e, \nu_\mu$  and  $\nu_\tau$  and mass eigenstates  $\nu_1, \nu_2$  and  $\nu_3$ . (See equation 14.78 of the review “Neutrino Mass, Mixing and Oscillations” by K. Nakamura and S.T. Petcov.) Whether or not this is the ultimately correct framework, it is currently widely used to parametrize neutrino mixing data and to plan new experiments.

The mass differences are called  $\Delta m_{21}^2 \equiv m_2^2 - m_1^2$  and  $\Delta m_{32}^2 \equiv m_3^2 - m_2^2$ . In these listings, we assume

$$\Delta m_{32}^2 \sim \Delta m_{31}^2 \quad (1)$$

even though the experimental error is comparable to the difference  $\Delta m_{31}^2 - \Delta m_{32}^2 = \Delta m_{21}^2$ . The measurements made by  $\nu_\mu$  disappearance at accelerators and by  $\nu_e$  disappearance at reactors are slightly different mixtures of  $\Delta m_{32}^2$  and  $\Delta m_{31}^2$ . The angles are labeled  $\theta_{12}, \theta_{23}$  and  $\theta_{13}$ . The CP violating phase is called  $\delta$ , but that does not yet appear in the listings. The familiar two neutrino form for oscillations is

$$P(\nu_a \rightarrow \nu_b; a \neq b) = \sin^2(2\theta) \sin^2(\Delta m^2 L/4E). \quad (2)$$

Despite the fact that the mixing angles have been measured to be much larger than in the quark sector, the two neutrino form is often a very good approximation and is used in many situations.

The angles appear in the equations below in many forms. They most often appear as  $\sin^2(2\theta)$ . The listings currently use this convention.

**Accelerator neutrino experiments:** Ignoring  $\Delta m_{21}^2$ , CP violation, and matter effects, the equations for the probability of appearance in an accelerator oscillation experiment are:

$$P(\nu_\mu \rightarrow \nu_\tau) = \sin^2(2\theta_{23}) \cos^4(\theta_{13}) \sin^2(\Delta m_{32}^2 L/4E) \quad (3)$$

$$P(\nu_\mu \rightarrow \nu_e) = \sin^2(2\theta_{13}) \sin^2(\theta_{23}) \sin^2(\Delta m_{32}^2 L/4E) \quad (4)$$

$$P(\nu_e \rightarrow \nu_\mu) = \sin^2(2\theta_{13}) \sin^2(\theta_{23}) \sin^2(\Delta m_{32}^2 L/4E) \quad (5)$$

$$P(\nu_e \rightarrow \nu_\tau) = \sin^2(2\theta_{13}) \cos^2(\theta_{23}) \sin^2(\Delta m_{32}^2 L/4E) \quad (6)$$

Current and future long-baseline accelerator experiments are studying non-zero  $\theta_{13}$  through  $P(\nu_\mu \rightarrow \nu_e)$ . Including the CP terms and low mass scale, the equation for neutrino oscillation in vacuum is:

$$\begin{aligned} P(\nu_\mu \rightarrow \nu_e) &= P1 + P2 + P3 + P4 \\ P1 &= \sin^2(\theta_{23}) \sin^2(2\theta_{13}) \sin^2(\Delta m_{32}^2 L/4E) \\ P2 &= \cos^2(\theta_{23}) \sin^2(2\theta_{13}) \sin^2(\Delta m_{21}^2 L/4E) \\ P3 &= -/+ J \sin(\delta) \sin(\Delta m_{32}^2 L/4E) \\ P4 &= J \cos(\delta) \cos(\Delta m_{32}^2 L/4E) \end{aligned} \quad (7)$$

where

$$J = \cos(\theta_{13}) \sin(2\theta_{12}) \sin(2\theta_{13}) \sin(2\theta_{23}) \times \sin(\Delta m_{32}^2 L/4E) \sin(\Delta m_{21}^2 L/4E) \quad (8)$$

and the sign in P3 is negative for neutrinos and positive for anti-neutrinos respectively. For most new long-baseline accelerator experiments, P2 can safely be neglected but the other three terms could be comparable. Also, depending on the distance and the mass hierarchy, matter effects will need to be included.

**Reactor neutrino experiments:** Nuclear reactors are prolific sources of  $\bar{\nu}_e$  with an energy near 4 MeV. The oscillation probability can be expressed

$$\begin{aligned} P(\bar{\nu}_e \rightarrow \bar{\nu}_e) &= 1 - \cos^4(\theta_{13}) \sin^2(2\theta_{12}) \sin^2(\Delta m_{21}^2 L/4E) \\ &\quad - \cos^2(\theta_{12}) \sin^2(2\theta_{13}) \sin^2(\Delta m_{31}^2 L/4E) \\ &\quad - \sin^2(\theta_{12}) \sin^2(2\theta_{13}) \sin^2(\Delta m_{32}^2 L/4E) \end{aligned} \quad (9)$$

not using the approximation in Eq. (1). For short distances ( $L < 5$  km) we can ignore the second term on the right and can reimpose approximation Eq. (1). This takes the familiar two neutrino form with  $\theta_{13}$  and  $\Delta m_{32}^2$ :

$$P(\bar{\nu}_e \rightarrow \bar{\nu}_e) = 1 - \sin^2(2\theta_{13}) \sin^2(\Delta m_{32}^2 L/4E). \quad (10)$$

**Solar and Atmospheric neutrino experiments:** Solar neutrino experiments are sensitive to  $\nu_e$  disappearance and have allowed the measurement of  $\theta_{12}$  and  $\Delta m_{21}^2$ . They are also sensitive to  $\theta_{13}$ . We identify  $\Delta m_{\odot}^2 = \Delta m_{21}^2$  and  $\theta_{\odot} = \theta_{12}$ .

Atmospheric neutrino experiments are primarily sensitive to  $\nu_\mu$  disappearance through  $\nu_\mu \rightarrow \nu_\tau$  oscillations, and have

allowed the measurement of  $\theta_{23}$  and  $\Delta m_{32}^2$ . We identify  $\Delta m_A^2 = \Delta m_{32}^2$  and  $\theta_A = \theta_{23}$ . Despite the large  $\nu_e$  component of the atmospheric neutrino flux, it is difficult to measure  $\Delta m_{21}^2$  effects. This is because of a cancellation between  $\nu_\mu \rightarrow \nu_e$  and  $\nu_e \rightarrow \nu_\mu$  together with the fact that the ratio of  $\nu_\mu$  and  $\nu_e$  atmospheric fluxes, which arise from sequential  $\pi$  and  $\mu$  decay, is near 2.

**Oscillation Parameter Listings:** In Section (B) we encode the three mixing angles  $\theta_{12}$ ,  $\theta_{23}$ ,  $\theta_{13}$  and two mass squared differences  $\Delta m_{21}^2$  and  $\Delta m_{32}^2$ . Our knowledge of  $\theta_{12}$  and  $\Delta m_{21}^2$  comes from the KamLAND reactor neutrino experiment together with solar neutrino experiments. Our knowledge of  $\theta_{23}$  and  $\Delta m_{32}^2$  comes from atmospheric neutrino experiments and long-baseline accelerator experiments. Results on  $\theta_{13}$  come from reactor antineutrino disappearance experiments. There are also results from long-baseline accelerator experiments looking for  $\nu_e$  appearance. The interpretation of both kinds of results depends on  $\Delta m_{32}^2$ , and the accelerator results also depend on the mass hierarchy,  $\theta_{23}$  and the CP violating phase  $\delta$ . We present values for  $\theta_{13}$  at the current best fit value of  $\Delta m_{32}^2$ , but they are not symmetric around that best fit value.

Accelerator and atmospheric experiments are beginning to have some sensitivity to the CP violation phase  $\delta$  through Eq. (7). Note that P3 depends on the sign of  $\Delta m_{32}^2$  so the sensitivity depends on the mass hierarchy. For non-maximal  $\theta_{13}$  mixing, it also depends on the octant of  $\theta_{13}$ , i.e. whether  $\theta_{13} > \pi/4$  or  $\theta_{13} < \pi/4$ .

### $\sin^2(2\theta_{12})$

<sup>1</sup> GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND, global solar neutrino, short-baseline (SBL) reactor, and accelerator data, assuming CPT invariance. Supersedes GANDO 11.

<sup>2</sup> AHARMIM 13 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data.

<sup>3</sup> AHARMIM 13 global solar neutrino data include SNO's all-phases-combined analysis results on the total active <sup>8</sup>B neutrino flux and energy-dependent  $\nu_e$  survival probability parameters, measurements of Cl (CLEVELAND 98), Ga (ABDURASHITOV 09) which contains combined analysis with GNO (ALTMANN 05 and Ph.D. thesis of F. Kaether)), and <sup>7</sup>Be (BELLINI 11A) rates, and <sup>8</sup>B solar-neutrino recoil electron measurements of SK-I (HOSAKA 06) zenith, SK-II (CRAVENS 08) and SK-III (ABE 11) day/night spectra, and Borexino (BELLINI 10A) spectra.

<sup>4</sup> AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{32}^2$  fixed to  $2.45 \times 10^{-3} \text{ eV}^2$ , using global solar neutrino data.

<sup>5</sup> AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{32}^2$  fixed to  $2.45 \times 10^{-3} \text{ eV}^2$ , using global solar neutrino and KamLAND (GANDO 11) data. CPT invariance is assumed.

<sup>6</sup> GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND and global solar neutrino data, assuming CPT invariance. Supersedes GANDO 11.

<sup>7</sup> GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND data. Supersedes GANDO 11.

<sup>8</sup> ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. CPT invariance is assumed.

<sup>9</sup> ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, and SAGE data.

<sup>10</sup> ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{32}^2$  fixed to  $2.4 \times 10^{-3} \text{ eV}^2$ , using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. The normal neutrino mass hierarchy and CPT invariance are assumed.

<sup>11</sup> ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{32}^2$  fixed to  $2.4 \times 10^{-3} \text{ eV}^2$ , using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, and GALLEX/GNO data. The normal neutrino mass hierarchy is assumed.

<sup>12</sup> BELLINI 11A obtained this result by a two-neutrino oscillation analysis using KamLAND, Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal **743** 24 (2011)) with the exception that the <sup>8</sup>B flux was left free. CPT invariance is assumed.

<sup>13</sup> BELLINI 11A obtained this result by a two-neutrino oscillation analysis using Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal **743** 24 (2011)) with the exception that the <sup>8</sup>B flux was left free.

<sup>14</sup> GANDO 11 obtain this result with three-neutrino fit using the KamLAND + solar data. Superseded by GANDO 13.

<sup>15</sup> GANDO 11 obtain this result with three-neutrino fit using the KamLAND data only. Superseded by GANDO 13.

<sup>16</sup> AHARMIM 10 global solar neutrino data include SNO's low-energy-threshold analysis survival probability day/night curves, SNO Phase III integral rates (AHARMIM 08), Cl (CLEVELAND 98), SAGE (ABDURASHITOV 09), Gallex/GNO (HAMPEL 99, ALTMANN 05), Borexino (ARPESELLA 08A), SK-I zenith (HOSAKA 06), and SK-II day/night spectra (CRAVENS 08).

<sup>17</sup> AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data and KamLAND data (ABE 08A). CPT invariance is assumed.

<sup>18</sup> AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data.

<sup>19</sup> AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{31}^2$  fixed to  $2.3 \times 10^{-3} \text{ eV}^2$ , using global solar neutrino data and KamLAND data (ABE 08A). CPT invariance is assumed.

<sup>20</sup> AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{31}^2$  fixed to  $2.3 \times 10^{-3} \text{ eV}^2$ , using global solar neutrino data.

<sup>21</sup> ABE 08A obtained this result by a rate + shape + time combined geoneutrino and reactor two-neutrino fit for  $\Delta m_{21}^2$  and  $\tan^2 \theta_{12}$ , using KamLAND data only. Superseded by GANDO 11.

<sup>22</sup> ABE 08A obtained this result by means of a two-neutrino fit using KamLAND, Homestake, SAGE, GALLEX, GNO, SK (zenith angle and E-spectrum), the SNO  $\chi^2$ -map, and solar flux data. CPT invariance is assumed. Superseded by GANDO 11.

<sup>23</sup> The result given by AHARMIM 08 is  $\theta = (34.4^{+1.3}_{-1.2})^\circ$ . This result is obtained by a two-neutrino oscillation analysis using solar neutrino data including those of Borexino (ARPESELLA 08A) and Super-Kamiokande-I (HOSAKA 06), and KamLAND data (ABE 08A). CPT invariance is assumed.

<sup>24</sup> HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using SK  $\nu_e$  data, CC data from other solar neutrino experiments, and KamLAND data (ARAKI 05). CPT invariance is assumed.

<sup>25</sup> HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the data from Super-Kamiokande, SNO (AHMAD 02 and AHMAD 02b), and KamLAND (ARAKI 05) experiments. CPT invariance is assumed.

<sup>26</sup> HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02b) solar neutrino data.

<sup>27</sup> The result given by AHARMIM 05A is  $\theta = (33.9 \pm 1.6)^\circ$ . This result is obtained by a two-neutrino oscillation analysis using SNO pure deuterium and salt phase data, SK  $\nu_e$  data, Cl and Ga CC data, and KamLAND data (ARAKI 05). CPT invariance is assumed. AHARMIM 05A also quotes  $\theta = (33.9^{+2.4}_{-2.2})^\circ$  as the error enveloping the 68% CL two-dimensional region. This translates into  $\sin^2 2\theta = 0.86^{+0.05}_{-0.06}$ .

<sup>28</sup> AHARMIM 05A obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in figure 35a of AHARMIM 05A. AHARMIM 05A also quotes  $\tan^2 \theta = 0.45^{+0.09}_{-0.08}$  as the error enveloping the 68% CL two-dimensional region. This translates into  $\sin^2 2\theta = 0.86^{+0.05}_{-0.07}$ .

<sup>29</sup> ARAKI 05 obtained this result by a two-neutrino oscillation analysis using KamLAND and solar neutrino data. CPT invariance is assumed. The  $1\sigma$  error shown here is translated from the number provided by the KamLAND collaboration,  $\tan^2 \theta = 0.40^{+0.07}_{-0.05}$ . The corresponding number quoted in ARAKI 05 is  $\tan^2 \theta = 0.40^{+0.10}_{-0.07}$  ( $\sin^2 2\theta = 0.82 \pm 0.07$ ), which envelops the 68% CL two-dimensional region.

<sup>30</sup> The result given by AHMED 04A is  $\theta = (32.5^{+1.7}_{-1.6})^\circ$ . This result is obtained by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (EGUCHI 03). CPT invariance is assumed. AHMED 04A also quotes  $\theta = (32.5^{+2.4}_{-2.3})^\circ$  as the error enveloping the 68% CL two-dimensional region. This translates into  $\sin^2 2\theta = 0.82 \pm 0.06$ .

<sup>31</sup> AHMED 04A obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 5(a) of AHMED 04A. The best-fit point is  $\Delta(m^2) = 6.5 \times 10^{-5} \text{ eV}^2$ ,  $\tan^2 \theta = 0.40$  ( $\sin^2 2\theta = 0.82$ ).

<sup>32</sup> The result given by SMY 04 is  $\tan^2 \theta = 0.44 \pm 0.08$ . This result is obtained by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (IANNI 03). CPT invariance is assumed.

<sup>33</sup> SMY 04 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The  $1\sigma$  errors are read from Fig. 6(a) of SMY 04.

<sup>34</sup> SMY 04 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02b) solar neutrino data. The  $1\sigma$  errors are read from Fig. 6(a) of SMY 04.

<sup>35</sup> AHMAD 02b obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4(b) of AHMAD 02b. The best fit point is  $\Delta(m^2) = 5.0 \times 10^{-5} \text{ eV}^2$  and  $\tan \theta = 0.34$  ( $\sin^2 2\theta = 0.76$ ).

<sup>36</sup> FUKUDA 02 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4 of FUKUDA 02. The best fit point is  $\Delta(m^2) = 6.9 \times 10^{-5} \text{ eV}^2$  and  $\tan^2 \theta = 0.38$  ( $\sin^2 2\theta = 0.80$ ).

<sup>1</sup> GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND, global solar neutrino, short-baseline (SBL) reactor, and accelerator data, assuming CPT invariance. Supersedes GANDO 11.

<sup>2</sup> AHARMIM 13 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data.

<sup>3</sup> AHARMIM 13 global solar neutrino data include SNO's all-phases-combined analysis results on the total active <sup>8</sup>B neutrino flux and energy-dependent  $\nu_e$  survival probability parameters, measurements of Cl (CLEVELAND 98), Ga (ABDURASHITOV 09 which contains combined analysis with GNO (ALTMANN 05 and Ph.D. thesis of F. Kaether)), and <sup>7</sup>Be (BELLINI 11A) rates, and <sup>8</sup>B solar-neutrino recoil electron measurements of SK-I (HOSAKA 06) zenith, SK-II (CRAVENS 08), and SK-III (ABE 11) day/night spectra, and Borexino (BELLINI 10A) spectra.

<sup>4</sup> AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{31}^2$  fixed to  $2.45 \times 10^{-3} \text{ eV}^2$ , using global solar neutrino data.

<sup>5</sup> AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{32}^2$  fixed to  $2.45 \times 10^{-3} \text{ eV}^2$ , using global solar neutrino and KamLAND data (GANDO 11). CPT invariance is assumed.

<sup>6</sup> GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND and global solar neutrino data, assuming CPT invariance. Supersedes GANDO 11.

<sup>7</sup> GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND data. Supersedes GANDO 11.

<sup>8</sup> ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. CPT invariance is assumed.

<sup>9</sup> ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, and SAGE data.

<sup>10</sup> ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{32}^2$  fixed to  $2.4 \times 10^{-3} \text{ eV}^2$ , using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. The normal neutrino mass hierarchy and CPT invariance are assumed.

<sup>11</sup> ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{32}^2$  fixed to  $2.4 \times 10^{-3} \text{ eV}^2$ , using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, and GALLEX/GNO data. The normal neutrino mass hierarchy is assumed.

<sup>12</sup> BELLINI 11A obtained this result by a two-neutrino oscillation analysis using KamLAND, Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal **743** 24 (2011)) with the exception that the <sup>8</sup>B flux was left free. CPT invariance is assumed.

<sup>13</sup> BELLINI 11A obtained this result by a two-neutrino oscillation analysis using Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal **743** 24 (2011)) with the exception that the <sup>8</sup>B flux was left free.

<sup>14</sup> GANDO 11 obtain this result with three-neutrino fit using the KamLAND + solar data. Superseded by GANDO 13.

<sup>15</sup> GANDO 11 obtain this result with three-neutrino fit using the KamLAND data only. Supersedes ABE 08A.

<sup>16</sup> AHARMIM 10 global solar neutrino data include SNO's low-energy-threshold analysis survival probability day/night curves, SNO Phase III integral rates (AHARMIM 08), Cl (CLEVELAND 98), SAGE (ABDURASHITOV 09), Gallex/GNO (HAMPEL 99, ALTMANN 05), Borexino (ARPESELLA 08A), SK-I zenith (HOSAKA 06), and SK-II day/night spectra (CRAVENS 08).

<sup>17</sup> AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data and KamLAND data (ABE 08A). CPT invariance is assumed.

<sup>18</sup> AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data.

<sup>19</sup> AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{31}^2$  fixed to  $2.3 \times 10^{-3} \text{ eV}^2$ , using global solar neutrino data and KamLAND data (ABE 08A). CPT invariance is assumed.

<sup>20</sup> AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{31}^2$  fixed to  $2.3 \times 10^{-3} \text{ eV}^2$ , using global solar neutrino data.

<sup>21</sup> ABE 08A obtained this result by a rate + shape + time combined geoneutrino and reactor two-neutrino fit for  $\Delta m_{21}^2$  and  $\tan^2\theta_{12}$ , using KamLAND data only. Superseded by GANDO 11.

<sup>22</sup> ABE 08A obtained this result by means of a two-neutrino fit using KamLAND, Homestake, SAGE, GALLEX, GNO, SK (zenith angle and E-spectrum), the SNO  $\chi^2$ -map, and solar flux data. CPT invariance is assumed. Superseded by GANDO 11.

<sup>23</sup> AHARMIM 08 obtained this result by a two-neutrino oscillation analysis using all solar neutrino data including those of Borexino (ARPESELLA 08A) and Super-Kamiokande-I (HOSAKA 06), and KamLAND data (ABE 08A). CPT invariance is assumed.

<sup>24</sup> HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (ARAKI 05). CPT invariance is assumed.

<sup>25</sup> HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the data from Super-Kamiokande, SNO (AHMAD 02 and AHMAD 02b), and KamLAND (ARAKI 05) experiments. CPT invariance is assumed.

<sup>26</sup> HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02b) solar neutrino data.

<sup>27</sup> HOSAKA 06 obtained this result from the consistency between the observed and expected day-night flux asymmetry amplitude. The listed 68% CL range is derived from the  $1\sigma$  boundary of the amplitude fit to the data. Oscillation parameters are constrained to be in the LMA region. The mixing angle is fixed at  $\tan^2\theta = 0.44$  because the fit depends only very weakly on it.

<sup>28</sup> AHARMIM 05A obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (ARAKI 05). CPT invariance is assumed. AHARMIM 05A also quotes  $\Delta(m^2) = (8.0^{+0.6}_{-0.4}) \times 10^{-5} \text{ eV}^2$  as the error enveloping the 68% CL two-dimensional region.

<sup>29</sup> AHARMIM 05A obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in figure 35a of AHARMIM 05A. AHARMIM 05A also quotes  $\Delta(m^2) = (6.5^{+4.4}_{-2.3}) \times 10^{-5} \text{ eV}^2$  as the error enveloping the 68% CL two-dimensional region.

<sup>30</sup> ARAKI 05 obtained this result by a two-neutrino oscillation analysis using KamLAND and solar neutrino data. CPT invariance is assumed. The  $1\sigma$  error shown here is provided by the KamLAND collaboration. The error quoted in ARAKI 05,  $\Delta(m^2) = (7.9^{+0.6}_{-0.5}) \times 10^{-5}$ , envelops the 68% CL two-dimensional region.

<sup>31</sup> AHMED 04A obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (EGUCHI 03). CPT invariance is assumed. AHMED 04A also quotes  $\Delta(m^2) = (7.1^{+1.2}_{-0.6}) \times 10^{-5} \text{ eV}^2$  as the error enveloping the 68% CL two-dimensional region.

<sup>32</sup> AHMED 04A obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 5(a) of AHMED 04A. The best-fit point is  $\Delta(m^2) = 6.5 \times 10^{-5} \text{ eV}^2$ ,  $\tan^2\theta = 0.40$  ( $\sin^2 2\theta = 0.82$ ).

<sup>33</sup> SMY 04 obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (IANNI 03). CPT invariance is assumed.

<sup>34</sup> SMY 04 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The  $1\sigma$  errors are read from Fig. 6(a) of SMY 04.

<sup>35</sup> SMY 04 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02b) solar neutrino data. The  $1\sigma$  errors are read from Fig. 6(a) of SMY 04.

<sup>36</sup> AHMAD 02b obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4(b) of AHMAD 02b. The best fit point is  $\Delta(m^2) = 5.0 \times 10^{-5} \text{ eV}^2$  and  $\tan\theta = 0.34$  ( $\sin^2 2\theta = 0.76$ ).

<sup>37</sup> FUKUDA 02 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4 of FUKUDA 02. The best fit point is  $\Delta(m^2) = 6.9 \times 10^{-5} \text{ eV}^2$  and  $\tan^2\theta = 0.38$  ( $\sin^2 2\theta = 0.80$ ).

### $\sin^2(2\theta_{23})$

The reported limits below correspond to the projection onto the  $\sin^2(2\theta_{23})$  axis of the 90% CL contours in the  $\sin^2(2\theta_{23}) - \Delta m_{32}^2$  plane presented by the authors. Unless otherwise specified, the limits are 90% CL and the reported uncertainties are 68% CL. If the result is reported as  $\sin^2(\theta_{23})$  we convert it to  $\sin^2(2\theta_{23})$  and choose the quadrant that represents the more conservative value.

- 1 ABE 14 results are based on  $\nu_{\mu}$  disappearance using three-neutrino oscillation fit. The confidence intervals are derived from one dimensional profiled likelihoods. ABE 14 reported results as  $\sin^2(\theta_{23}) = 0.514 \pm_{-0.056}^{+0.055}$  ( $0.511 \pm 0.055$ ), assuming normal (inverted) mass hierarchy.
- 2 ADAMSON 14 uses a complete set of accelerator and atmospheric data. The analysis combines the  $\nu_{\mu}$  disappearance and  $\nu_e$  appearance data using three-neutrino oscillation fit. The fit results are obtained for normal and inverted mass hierarchy assumptions. The best fit is for lower  $\theta_{23}$  quadrant and inverted mass hierarchy.
- 3 AARTSEN 13b obtained this result by a two-neutrino oscillation analysis using 20–100 GeV muon neutrino sample from a total of 318.9 days of live-time measurement with the low-energy subdetector DeepCore of the IceCube neutrino telescope.
- 4 The best fit value is  $\sin^2(\theta_{23}) = 0.514 \pm 0.082$ . Superseded by ABE 14.
- 5 ADAMSON 13b obtained this result from  $\nu_{\mu}$  and  $\bar{\nu}_{\mu}$  disappearance using  $\nu_{\mu}$  ( $10.71 \times 10^{20}$  POT) and  $\bar{\nu}_{\mu}$  ( $3.36 \times 10^{20}$  POT) beams, and atmospheric ( $37.88$ kton-years) data from MINOS. The fit assumed two-flavor neutrino hypothesis and identical  $\nu_{\mu}$  and  $\bar{\nu}_{\mu}$  oscillation parameters. Superseded by ADAMSON 14.
- 6 ABE 12a obtained this result by a two-neutrino oscillation analysis. The best-fit point is  $\sin^2(2\theta_{23}) = 0.98$ .
- 7 ADAMSON 12 is a two-neutrino oscillation analysis using antineutrinos. The best fit value is  $\sin^2(2\theta_{23}) = 0.95 \pm_{-0.11}^{+0.10} \pm 0.01$ .
- 8 ADAMSON 12b obtained this result by a two-neutrino oscillation analysis of the L/E distribution using 37.9 kton-yr atmospheric neutrino data with the MINOS far detector.
- 9 The best fit point is  $\Delta m^2 = 0.0019 \text{ eV}^2$  and  $\sin^2 2\theta = 0.99$ . The 90% single-parameter confidence interval at the best fit point is  $\sin^2 2\theta > 0.86$ .
- 10 The data are separated into pure samples of  $\nu_s$  and  $\bar{\nu}_s$ , and separate oscillation parameters for  $\nu_s$  and  $\bar{\nu}_s$  are fit to the data. The best fit point is  $(\Delta m^2, \sin^2 2\theta) = (0.0022 \text{ eV}^2, 0.99)$  and  $(\Delta \bar{m}^2, \sin^2 2\bar{\theta}) = (0.0016 \text{ eV}^2, 1.00)$ . The quoted result is taken from the 90% C.L. contour in the  $(\Delta m^2, \sin^2 2\theta)$  plane obtained by minimizing the four parameter log-likelihood function with respect to the other oscillation parameters.
- 11 ADRIAN-MARTINEZ 12 measured the oscillation parameters of atmospheric neutrinos with the ANTARES deep sea neutrino telescope using the data taken from 2007 to 2010 (863 days of total live time).
- 12 ABE 11c obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande-I+II+III atmospheric neutrino data. ABE 11c also reported results under a two-neutrino disappearance model with separate mixing parameters between  $\nu$  and  $\bar{\nu}$ , and obtained  $\sin^2 2\theta > 0.93$  for  $\nu$  and  $\sin^2 2\theta > 0.83$  for  $\bar{\nu}$  at 90% C.L.
- 13 ADAMSON 11b obtained this result by a two-neutrino oscillation analysis of antineutrinos in an antineutrino enhanced beam with  $1.71 \times 10^{20}$  protons on target. This result is consistent with the neutrino measurements of ADAMSON 11 at 2% C.L.
- 14 WENDELL 10 obtained this result ( $\sin^2 \theta_{23} = 0.407\text{--}0.583$ ) by a three-neutrino oscillation analysis using the Super-Kamiokande-I+II+III atmospheric neutrino data, assuming  $\theta_{13} = 0$  but including the solar oscillation parameters  $\Delta m_{21}^2$  and  $\sin^2 \theta_{12}$  in the fit.
- 15 WENDELL 10 obtained this result ( $\sin^2 \theta_{23} = 0.43\text{--}0.61$ ) by a three-neutrino oscillation analysis with one mass scale dominance ( $\Delta m_{21}^2 = 0$ ) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06a result.
- 16 WENDELL 10 obtained this result ( $\sin^2 \theta_{23} = 0.44\text{--}0.63$ ) by a three-neutrino oscillation analysis with one mass scale dominance ( $\Delta m_{21}^2 = 0$ ) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06a result.
- 17 ADAMSON 06 obtained this result by a two-neutrino oscillation analysis of the L/E distribution using 4.54 kton yr atmospheric neutrino data with the MINOS far detector.
- 18 Supercedes ALIU 05.
- 19 MICHAEL 06 best fit is for maximal mixing. See also ADAMSON 08.
- 20 The best fit is for maximal mixing.

- 21 ALLISON 05 result is based upon atmospheric neutrino interactions including upward-stopping muons, with an exposure of 5.9 kton yr. From a two-flavor oscillation analysis the best-fit point is  $\Delta m^2 = 0.0017 \text{ eV}^2$  and  $\sin^2(2\theta) = 0.97$ .
- 22 ASHIE 05 obtained this result by a two-neutrino oscillation analysis using 92 kton yr atmospheric neutrino data from the complete Super-Kamiokande I running period.
- 23 AMBROSIO 04 obtained this result, without using the absolute normalization of the neutrino flux, by combining the angular distribution of upward through-going muon tracks with  $E_{\mu} > 1 \text{ GeV}$ ,  $N_{low}$  and  $N_{high}$ , and the numbers of InDown + UpStop and InUp events. Here,  $N_{low}$  and  $N_{high}$  are the number of events with reconstructed neutrino energies  $< 30 \text{ GeV}$  and  $> 130 \text{ GeV}$ , respectively. InDown and InUp represent events with downward and upward-going tracks starting inside the detector due to neutrino interactions, while UpStop represents entering upward-going tracks which stop in the detector. The best fit is for maximal mixing.
- 24 ASHIE 04 obtained this result from the L(flight length)/E(estimated neutrino energy) distribution of  $\nu_{\mu}$  disappearance probability, using the Super-Kamiokande-I 1489 live-day atmospheric neutrino data.
- 25 There are several islands of allowed region from this K2K analysis, extending to high values of  $\Delta m^2$ . We only include the one that overlaps atmospheric neutrino analyses. The best fit is for maximal mixing.
- 26 AMBROSIO 03 obtained this result on the basis of the ratio  $R = N_{low}/N_{high}$ , where  $N_{low}$  and  $N_{high}$  are the number of upward through-going muon events with reconstructed neutrino energy  $< 30 \text{ GeV}$  and  $> 130 \text{ GeV}$ , respectively. The data came from the full detector run started in 1994. The method of FELDMAN 98 is used to obtain the limits.
- 27 AMBROSIO 03 obtained this result by using the ratio R and the angular distribution of the upward through-going muons. R is given in the previous note and the angular distribution is reported in AMBROSIO 01. The method of FELDMAN 98 is used to obtain the limits. The best fit is to maximal mixing.
- 28 SANCHEZ 03 is based on an exposure of 5.9 kton yr. The result is obtained using a likelihood analysis of the neutrino L/E distribution for a selection  $\mu$  flavor sample while the  $e$ -flavor sample provides flux normalization. The method of FELDMAN 98 is used to obtain the allowed region. The best fit is  $\sin^2(2\theta) = 0.97$ .
- 29 AMBROSIO 01 result is based on the angular distribution of upward through-going muon tracks with  $E_{\mu} > 1 \text{ GeV}$ . The data came from three different detector configurations, but the statistics is largely dominated by the full detector run, from May 1994 to December 2000. The total live time, normalized to the full detector configuration is 6.17 years. The best fit is obtained outside the physical region. The method of FELDMAN 98 is used to obtain the limits. The best fit is for maximal mixing.
- 30 AMBROSIO 01 result is based on the angular distribution and normalization of upward through-going muon tracks with  $E_{\mu} > 1 \text{ GeV}$ . See the previous footnote.
- 31 FUKUDA 99c obtained this result from a total of 537 live days of upward through-going muon data in Super-Kamiokande between April 1996 to January 1998. With a threshold of  $E_{\mu} > 1.6 \text{ GeV}$ , the observed flux is  $(1.74 \pm 0.07 \pm 0.02) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$ . The best fit is  $\sin^2(2\theta) = 0.95$ .
- 32 FUKUDA 99d obtained this result from a simultaneous fitting to zenith angle distributions of upward-stopping and through-going muons. The flux of upward-stopping muons of minimum energy of 1.6 GeV measured between April 1996 and January 1998 is  $(0.39 \pm 0.04 \pm 0.02) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$ . This is compared to the expected flux of  $(0.73 \pm 0.16 \text{ (theoretical error)}) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$ . The best fit is to maximal mixing.
- 33 FUKUDA 99d obtained this result from the zenith dependence of the upward-stopping/through-going flux ratio. The best fit is to maximal mixing.
- 34 FUKUDA 98c obtained this result by an analysis of 33.0 kton yr atmospheric neutrino data. The best fit is for maximal mixing.
- 35 HATAKEYAMA 98 obtained this result from a total of 2456 live days of upward-going muon data in Kamiokande between December 1985 and May 1995. With a threshold of  $E_{\mu} > 1.6 \text{ GeV}$ , the observed flux of upward through-going muons is  $(1.94 \pm 0.10 \pm 0.07) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$ . This is compared to the expected flux of  $(2.46 \pm 0.54 \text{ (theoretical error)}) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$ . The best fit is for maximal mixing.
- 36 HATAKEYAMA 98 obtained this result from a combined analysis of Kamiokande contained events (FUKUDA 94) and upward going muon events. The best fit is  $\sin^2(2\theta) = 0.95$ .
- 37 FUKUDA 94 obtained the result by a combined analysis of sub- and multi-GeV atmospheric neutrino events in Kamiokande. The best fit is for maximal mixing.

 $\Delta m_{32}^2$ 

The sign of  $\Delta m_{32}^2$  is not known at this time. Only the absolute value is quoted below. Unless otherwise specified, the ranges below correspond to the projection onto the  $\Delta m_{32}^2$  axis of the 90% CL contours in the  $\sin^2(2\theta_{23}) - \Delta m_{32}^2$  plane presented by the authors. If uncertainties are reported with the value, they correspond to one standard deviation uncertainty.

- 1 ABE 14 results are based on  $\nu_\mu$  disappearance using three-neutrino oscillation fit. The confidence intervals are derived from one dimensional profiled likelihoods. In ABE 14 the inverted mass hierarchy result is reported as  $\Delta m_{13}^2 = (2.48 \pm 0.10) \times 10^{-3} \text{ eV}^2$  which we converted to  $\Delta m_{32}^2$  by adding PDG 14 value of  $\Delta m_{21}^2 = (7.53 \pm 0.18) \times 10^{-5} \text{ eV}^2$ .
- 2 ADAMSON 14 uses a complete set of accelerator and atmospheric data. The analysis combines the analysis of  $\nu_\mu$  disappearance and  $\nu_e$  appearance data using three-neutrino oscillation fit. The fit results are obtained for normal and inverted mass hierarchy assumptions.
- 3 AN 14 uses six identical detectors, with three placed near the reactor cores (flux-weighted baselines of 512 and 561 m) and the remaining three at the far hall (at the flux averaged distance of 1579 m from all six reactor cores) to determine prompt energy spectra and derive  $\Delta m_{ee}^2 = (2.59^{+0.19}_{-0.20}) \times 10^{-3} \text{ eV}^2$ . Assuming the normal (inverted) hierarchy, the fitted  $\Delta m_{32}^2 = (2.54^{+0.19}_{-0.20}) \times 10^{-3} ((2.64^{+0.19}_{-0.20}) \times 10^{-3}) \text{ eV}^2$ .
- 4 AARTSEN 13B obtained this result by a two-neutrino oscillation analysis using 20-100 GeV muon neutrino sample from a total of 318.9 days of live-time measurement with the low-energy subdetector DeepCore of the IceCube neutrino telescope.
- 5 Based on the observation of 58  $\nu_\mu$  events with 205 ± 17(syst) expected in the absence of neutrino oscillations. Superseded by ABE 14.
- 6 ADAMSON 13B obtained this result from  $\nu_\mu$  and  $\bar{\nu}_\mu$  disappearance using  $\nu_\mu$  (10.71 × 10<sup>20</sup> POT) and  $\bar{\nu}_\mu$  (3.36 × 10<sup>20</sup> POT) beams, and atmospheric (37.88 kton-years) data from MINOS. The fit assumed two-flavor neutrino hypothesis and identical  $\nu_\mu$  and  $\bar{\nu}_\mu$  oscillation parameters.
- 7 ABE 12A obtained this result by a two-neutrino oscillation analysis. The best-fit point is  $\Delta m_{32}^2 = 2.65 \times 10^{-3} \text{ eV}^2$ .
- 8 ADAMSON 12 is a two-neutrino oscillation analysis using antineutrinos.
- 9 ADAMSON 12B obtained this result by a two-neutrino oscillation analysis of the L/E distribution using 37.9 kton-yr atmospheric neutrino data with the MINOS far detector.
- 10 The 90% single-parameter confidence interval at the best fit point is  $\Delta m^2 = 0.0019 \pm 0.0004 \text{ eV}^2$ .
- 11 The data are separated into pure samples of  $\nu_s$  and  $\bar{\nu}_s$ , and separate oscillation parameters for  $\nu_s$  and  $\bar{\nu}_s$  are fit to the data. The best fit point is  $(\Delta m^2, \sin^2 2\theta) = (0.0022 \text{ eV}^2, 0.99)$  and  $(\Delta \bar{m}^2, \sin^2 2\bar{\theta}) = (0.0016 \text{ eV}^2, 1.00)$ . The quoted result is taken from the 90% C.L. contour in the  $(\Delta m^2, \sin^2 2\theta)$  plane obtained by minimizing the four parameter log-likelihood function with respect to the other oscillation parameters.
- 12 ADRIAN-MARTINEZ 12 measured the oscillation parameters of atmospheric neutrinos with the ANTARES deep sea neutrino telescope using the data taken from 2007 to 2010 (863 days of total live time).
- 13 ABE 11C obtained this result by a two-neutrino oscillation analysis with separate mixing parameters between neutrinos and antineutrinos, using the Super-Kamiokande-I+II+III atmospheric neutrino data. The corresponding 90% CL neutrino oscillation parameter range obtained from this analysis is  $\Delta m^2 = 1.7\text{-}3.0 \times 10^{-3} \text{ eV}^2$ .

- 14 ADAMSON 11B obtained this result by a two-neutrino oscillation analysis of antineutrinos in an antineutrino enhanced beam with  $1.71 \times 10^{20}$  protons on target. This result is consistent with the neutrino measurements of ADAMSON 11 at 2% C.L.
- 15 ADAMSON 11C obtains this result based on a study of antineutrinos in a neutrino beam and assumes maximal mixing in the two-flavor approximation.
- 16 WENDELL 10 obtained this result by a three-neutrino oscillation analysis with one mass scale dominance ( $\Delta m_{21}^2 = 0$ ) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06A result.
- 17 ADAMSON 06 obtained this result by a two-neutrino oscillation analysis of the L/E distribution using 4.54 kton yr atmospheric neutrino data with the MINOS far detector.
- 18 The best fit in the physical region is for  $\Delta m^2 = 2.8 \times 10^{-3} \text{ eV}^2$ .
- 19 Supersedes ALIU 05.
- 20 MICHAEL 06 best fit is  $2.74 \times 10^{-3} \text{ eV}^2$ . See also ADAMSON 08.
- 21 ALLISON 05 result is based on an atmospheric neutrino observation with an exposure of 5.9 kton yr. From a two-flavor oscillation analysis the best-fit point is  $\Delta m^2 = 0.0017 \text{ eV}^2$  and  $\sin^2 2\theta = 0.97$ .
- 22 ASHIE 05 obtained this result by a two-neutrino oscillation analysis using 92 kton yr atmospheric neutrino data from the complete Super-Kamiokande I running period. The best fit is for  $\Delta m^2 = 2.1 \times 10^{-3} \text{ eV}^2$ .
- 23 AMBROSIO 04 obtained this result, without using the absolute normalization of the neutrino flux, by combining the angular distribution of upward through-going muon tracks with  $E_\mu > 1 \text{ GeV}$ ,  $N_{low}$  and  $N_{high}$ , and the numbers of InDown + UpStop and InUp events. Here,  $N_{low}$  and  $N_{high}$  are the number of events with reconstructed neutrino energies < 30 GeV and > 130 GeV, respectively. InDown and InUp represent events with downward and upward-going tracks starting inside the detector due to neutrino interactions, while UpStop represents entering upward-going tracks which stop in the detector. The best fit is for  $\Delta m^2 = 2.3 \times 10^{-3} \text{ eV}^2$ .
- 24 ASHIE 04 obtained this result from the L(flight length)/E(estimated neutrino energy) distribution of  $\nu_\mu$  disappearance probability, using the Super-Kamiokande-I 1489 live-day atmospheric neutrino data. The best fit is for  $\Delta m^2 = 2.4 \times 10^{-3} \text{ eV}^2$ .
- 25 There are several islands of allowed region from this K2K analysis, extending to high values of  $\Delta m^2$ . We only include the one that overlaps atmospheric neutrino analyses. The best fit is for  $\Delta m^2 = 2.8 \times 10^{-3} \text{ eV}^2$ .
- 26 AMBROSIO 03 obtained this result on the basis of the ratio  $R = N_{low}/N_{high}$ , where  $N_{low}$  and  $N_{high}$  are the number of upward through-going muon events with reconstructed neutrino energy < 30 GeV and > 130 GeV, respectively. The data came from the full detector run started in 1994. The method of FELDMAN 98 is used to obtain the limits. The best fit is for  $\Delta m^2 = 2.5 \times 10^{-3} \text{ eV}^2$ .
- 27 AMBROSIO 03 obtained this result by using the ratio R and the angular distribution of the upward through-going muons. R is given in the previous note and the angular distribution is reported in AMBROSIO 01. The method of FELDMAN 98 is used to obtain the limits. The best fit is for  $\Delta m^2 = 2.5 \times 10^{-3} \text{ eV}^2$ .
- 28 SANCHEZ 03 is based on an exposure of 5.9 kton yr. The result is obtained using a likelihood analysis of the neutrino L/E distribution for a selection  $\mu$  flavor sample while the  $e$ -flavor sample provides flux normalization. The method of FELDMAN 98 is used to obtain the allowed region. The best fit is for  $\Delta m^2 = 5.2 \times 10^{-3} \text{ eV}^2$ .
- 29 AMBROSIO 01 result is based on the angular distribution of upward through-going muon tracks with  $E_\mu > 1 \text{ GeV}$ . The data came from three different detector configurations, but the statistics is largely dominated by the full detector run, from May 1994 to December 2000. The total live time, normalized to the full detector configuration is 6.17 years. The best fit is obtained outside the physical region. The method of FELDMAN 98 is used to obtain the limits.
- 30 AMBROSIO 01 result is based on the angular distribution and normalization of upward through-going muon tracks with  $E_\mu > 1 \text{ GeV}$ . See the previous footnote.
- 31 FUKUDA 99c obtained this result from a total of 537 live days of upward through-going muon data in Super-Kamiokande between April 1996 to January 1998. With a threshold of  $E_\mu > 1.6 \text{ GeV}$ , the observed flux is  $(1.74 \pm 0.07 \pm 0.02) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$ . The best fit is for  $\Delta m^2 = 5.9 \times 10^{-3} \text{ eV}^2$ .
- 32 FUKUDA 99D obtained this result from a simultaneous fitting to zenith angle distributions of upward-stopping and through-going muons. The flux of upward-stopping muons of minimum energy of 1.6 GeV measured between April 1996 and January 1998 is  $(0.39 \pm 0.04 \pm 0.02) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$ . This is compared to the expected flux of  $(0.73 \pm 0.16 \text{ (theoretical error)}) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$ . The best fit is for  $\Delta m^2 = 3.9 \times 10^{-3} \text{ eV}^2$ .
- 33 FUKUDA 99D obtained this result from the zenith dependence of the upward-stopping/through-going flux ratio. The best fit is for  $\Delta m^2 = 3.1 \times 10^{-3} \text{ eV}^2$ .
- 34 FUKUDA 98c obtained this result by an analysis of 33.0 kton yr atmospheric neutrino data. The best fit is for  $\Delta m^2 = 2.2 \times 10^{-3} \text{ eV}^2$ .
- 35 HATAKEYAMA 98 obtained this result from a total of 2456 live days of upward-going muon data in Kamiokande between December 1985 and May 1995. With a threshold of  $E_\mu > 1.6 \text{ GeV}$ , the observed flux of upward through-going muons is  $(1.94 \pm 0.10^{+0.07}_{-0.06}) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$ . This is compared to the expected flux of  $(2.46 \pm 0.54 \text{ (theoretical error)}) \times 10^{-13} \text{ cm}^{-2}\text{s}^{-1}\text{sr}^{-1}$ . The best fit is for  $\Delta m^2 = 2.2 \times 10^{-3} \text{ eV}^2$ .
- 36 HATAKEYAMA 98 obtained this result from a combined analysis of Kamiokande contained events (FUKUDA 94) and upward going muon events. The best fit is for  $\Delta m^2 = 13 \times 10^{-3} \text{ eV}^2$ .
- 37 FUKUDA 94 obtained the result by a combined analysis of sub- and multi-GeV atmospheric neutrino events in Kamiokande. The best fit is for  $\Delta m^2 = 16 \times 10^{-3} \text{ eV}^2$ .

## Neutrino Mixing

### $\sin^2(2\theta_{13})$

At present time direct measurements of  $\sin^2(2\theta_{13})$  are derived from the reactor  $\bar{\nu}_e$  disappearance at distances corresponding to the  $\Delta m_{32}^2$  value, i.e.  $L \sim 1$  km. Alternatively, limits can also be obtained from the analysis of the solar neutrino data and accelerator-based  $\nu_\mu \rightarrow \nu_e$  experiments.

<sup>1</sup> AN 14 uses six identical detectors, with three placed near the reactor cores (flux-weighted baselines of 512 and 561 m) and the remaining three at the far hall (at the flux averaged distance of 1579 m from all six reactor cores) to determine the mixing angle  $\theta_{13}$  using the  $\bar{\nu}_e$  observed interaction rates and energy spectra and three neutrino mixing analysis. Supersedes AN 13.

<sup>2</sup> ABE 12B determines the neutrino mixing angle  $\theta_{13}$  using a single detector, located 1050 m from the cores of two reactors. This result is based on a spectral shape and rate analysis.

<sup>3</sup> AHN 12 uses two identical detectors, placed at flux weighted distances of 408.56 m and 1433.99 m from six reactor cores, to determine the mixing angle  $\theta_{13}$ . This rate-only analysis excludes the no-oscillation hypothesis at 4.9 standard deviations. The value of  $\Delta m_{31}^2 = (2.32^{+0.12}_{-0.08}) \times 10^{-3} \text{ eV}^2$  was assumed in the analysis.

<sup>4</sup> ABE 13C uses delayed neutron capture on hydrogen instead of on Gd used previously. The fiducial volume is thus three times larger. The fit is based on the rate and shape analysis as in ABE 12B.

<sup>5</sup> ABE 13E assumes maximal  $\theta_{23}$  mixing and CP phase  $\delta = 0$ .

<sup>6</sup> ADAMSON 13A results obtained from  $\nu_e$  appearance, assuming  $\delta = 0$ , and  $\sin^2(2\theta_{23}) = 0.957$ .

<sup>7</sup> AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{32}^2$  fixed to  $2.45 \times 10^{-3} \text{ eV}^2$ , using global solar neutrino data. AHARMIM 13 global solar neutrino data include SNO's all-phases-combined analysis results on the total active  $^8\text{B}$  neutrino flux and energy-dependent  $\nu_e$  survival probability parameters, measurements of Cl (CLEVELAND 98), Ga (ABDURASHITOV 09 which contains combined analysis with GNO (ALTMANN 05 and Ph.D. thesis of F. Kaether)), and  $^7\text{Be}$  (BELLINI 11A) rates, and  $^8\text{B}$  solar-neutrino recoil electron measurements of SK-I (HOSAKA 06) zenith, SK-II (CRAVENS 08) and SK-III (ABE 11) day/night spectra, and Borexino (BELLINI 10A) spectra. AHARMIM 13 also reported a result combining global solar and KamLAND data, which is  $\sin^2(2\theta_{13}) = (9.1^{+2.9}_{-3.1}) \times 10^{-2}$ .

<sup>8</sup> AN 13 uses six identical detectors, with three placed near the reactor cores (flux-weighted baselines of 498 and 555 m) and the remaining three at the far hall (at the flux averaged distance of 1628 m from all six reactor cores) to determine the  $\bar{\nu}_e$  interaction rate ratios. Superseded by AN 14.

<sup>9</sup> ABE 12 determines the  $\bar{\nu}_e$  interaction rate in a single detector, located 1050 m from the cores of two reactors. The rate normalization is fixed by the results of the Bugey4 reactor experiment, thus avoiding any dependence on possible very short baseline oscillations. The value of  $\Delta m_{31}^2 = 2.4 \times 10^{-3} \text{ eV}^2$  is used in the analysis. Superseded by ABE 12B.

<sup>10</sup> AN 12 uses six identical detectors with three placed near the reactor cores (flux-weighted baselines of 470 m and 576 m) and the remaining three at the far hall (at the flux averaged distance of 1648 m from all six reactor cores) to determine the mixing angle  $\theta_{13}$  using the  $\bar{\nu}_e$  observed interaction rate ratios. This rate-only analysis excludes the no-oscillation hypothesis at 5.2 standard deviations. The value of  $\Delta m_{31}^2 = (2.32^{+0.12}_{-0.08}) \times 10^{-3} \text{ eV}^2$  was assumed in the analysis. Superseded by AN 13.

<sup>11</sup> ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{32}^2$  fixed to  $2.4 \times 10^{-3} \text{ eV}^2$ , using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. This result implies an upper bound of  $\sin^2\theta_{13} < 0.059$  (95% CL) or  $\sin^2 2\theta_{13} < 0.22$  (95% CL). The normal neutrino mass hierarchy and CPT invariance are assumed.

<sup>12</sup> ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{32}^2$  fixed to  $2.4 \times 10^{-3} \text{ eV}^2$ , using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, and GALLEX/GNO data. The normal neutrino mass hierarchy is assumed.

<sup>13</sup> The quoted limit is for  $\Delta m_{32}^2 = 2.4 \times 10^{-3} \text{ eV}^2$ ,  $\theta_{23} = \pi/2$ ,  $\delta = 0$ , and the normal mass hierarchy. For other values of  $\delta$ , the 68% region spans from 0.03 to 0.25, and the 90% region from 0.02 to 0.32.

<sup>14</sup> The quoted limit is for  $\Delta m_{32}^2 = 2.4 \times 10^{-3} \text{ eV}^2$ ,  $\theta_{23} = \pi/2$ ,  $\delta = 0$ , and the inverted mass hierarchy. For other values of  $\delta$ , the 68% region spans from 0.04 to 0.30, and the 90% region from 0.02 to 0.39.

<sup>15</sup> The quoted limit is for  $\Delta m_{32}^2 = 2.32 \times 10^{-3} \text{ eV}^2$ ,  $\theta_{23} = \pi/2$ ,  $\delta = 0$ , and the normal mass hierarchy. For other values of  $\delta$ , the 68% region spans from 0.02 to 0.12, and the 90% region from 0 to 0.16.

<sup>16</sup> The quoted limit is for  $\Delta m_{32}^2 = 2.32 \times 10^{-3} \text{ eV}^2$ ,  $\theta_{23} = \pi/2$ ,  $\delta = 0$ , and the inverted mass hierarchy. For other values of  $\delta$ , the 68% region spans from 0.02 to 0.16, and the 90% region from 0 to 0.21.

<sup>17</sup> FOGLI 11 obtained this result from an analysis using the atmospheric, accelerator long baseline, CHOOZ, solar, and KamLAND data. Recently, MUELLER 11 suggested an average increase of about 3.5% in normalization of the reactor  $\bar{\nu}_e$  fluxes, and using these fluxes, the fitted result becomes  $0.10 \pm 0.03$ .

<sup>18</sup> GANDO 11 report  $\sin^2\theta_{13} = 0.020 \pm 0.016$ . This result was obtained with three-neutrino fit using the KamLAND + solar data.

<sup>19</sup> GANDO 11 report  $\sin^2\theta_{13} = 0.032 \pm 0.037$ . This result was obtained with three-neutrino fit using the KamLAND data only.

<sup>20</sup> This result corresponds to the limit of  $<0.12$  at 90% CL for  $\Delta m_{32}^2 = 2.43 \times 10^{-3} \text{ eV}^2$ ,  $\theta_{23} = \pi/2$ , and  $\delta = 0$ . For other values of  $\delta$ , the 90% CL region spans from 0 to 0.16.

<sup>21</sup> This result corresponds to the limit of  $<0.20$  at 90% CL for  $\Delta m_{32}^2 = 2.43 \times 10^{-3} \text{ eV}^2$ ,  $\theta_{23} = \pi/2$ , and  $\delta = 0$ . For other values of  $\delta$ , the 90% CL region spans from 0 to 0.21.

<sup>22</sup> AHARMIM 10 global solar neutrino data include SNO's low-energy-threshold analysis survival probability day/night curves, SNO Phase III integral rates (AHARMIM 08), Cl (CLEVELAND 98), SAGE (ABDURASHITOV 09), Gallex/GNO (HAMPEL 99, ALTMANN 05), Borexino (ARPESELLA 08A), SK-I zenith (HOSAKA 06), and SK-II day/night spectra (CRAVENS 08).

<sup>23</sup> AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{31}^2$  fixed to  $2.3 \times 10^{-3} \text{ eV}^2$ , using global solar neutrino data and KamLAND data (ABE 08A). CPT invariance is assumed. This result implies an upper bound of  $\sin^2\theta_{13} < 0.057$  (95% CL) or  $\sin^2 2\theta_{13} < 0.22$  (95% CL).

<sup>24</sup> AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of  $\Delta m_{31}^2$  fixed to  $2.3 \times 10^{-3} \text{ eV}^2$ , using global solar neutrino data.

<sup>25</sup> WENDELL 10 obtained this result by a three-neutrino oscillation analysis with one mass scale dominance ( $\Delta m_{21}^2 = 0$ ) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06A result.

<sup>26</sup> The quoted limit is for  $\Delta m_{32}^2 = 2.43 \times 10^{-3} \text{ eV}^2$ ,  $\theta_{23} = \pi/2$ , and  $\delta = 0$ . For other values of  $\delta$ , the 68% CL region spans from 0.02 to 0.26.

<sup>27</sup> The quoted limit is for  $\Delta m_{32}^2 = 2.43 \times 10^{-3} \text{ eV}^2$ ,  $\theta_{23} = \pi/2$ , and  $\delta = 0$ . For other values of  $\delta$ , the 68% CL region spans from 0.04 to 0.34.

<sup>28</sup> FOGLI 08 obtained this result from a global analysis of all neutrino oscillation data, that is, solar + KamLAND + atmospheric + accelerator long baseline + CHOOZ.

<sup>29</sup> FOGLI 08 obtained this result from an analysis using the solar and KamLAND neutrino oscillation data.

<sup>30</sup> FOGLI 08 obtained this result from an analysis using the atmospheric, accelerator long baseline, and CHOOZ neutrino oscillation data.

<sup>31</sup> YAMAMOTO 06 searched for  $\nu_\mu \rightarrow \nu_e$  appearance. Assumes  $2 \sin^2(2\theta_{\mu e}) = \sin^2(2\theta_{13})$ . The quoted limit is for  $\Delta m_{32}^2 = 1.9 \times 10^{-3} \text{ eV}^2$ . That value of  $\Delta m_{32}^2$  is the one- $\sigma$  low value for AHN 06A. For the AHN 06A best fit value of  $2.8 \times 10^{-3} \text{ eV}^2$ , the  $\sin^2(2\theta_{13})$  limit is  $< 0.26$ . Supersedes AHN 04.

<sup>32</sup> AHN 04 searched for  $\nu_\mu \rightarrow \nu_e$  appearance. Assuming  $2 \sin^2(2\theta_{\mu e}) = \sin^2(2\theta_{13})$ , a limit on  $\sin^2(2\theta_{\mu e})$  is converted to a limit on  $\sin^2(2\theta_{13})$ . The quoted limit is for  $\Delta m_{32}^2 = 1.9 \times 10^{-3} \text{ eV}^2$ . That value of  $\Delta m_{32}^2$  is the one- $\sigma$  low value for ALIU 05. For the ALIU 05 best fit value of  $2.8 \times 10^{-3} \text{ eV}^2$ , the  $\sin^2(2\theta_{13})$  limit is  $< 0.30$ .

<sup>33</sup> The quoted limit is for  $\Delta m_{32}^2 = 1.9 \times 10^{-3} \text{ eV}^2$ . That value of  $\Delta m_{32}^2$  is the 1- $\sigma$  low value for ALIU 05. For the ALIU 05 best fit value of  $2.8 \times 10^{-3} \text{ eV}^2$ , the  $\sin^2 2\theta_{13}$  limit

See key on page 547

is  $< 0.19$ . In this range, the  $\theta_{13}$  limit is larger for lower values of  $\Delta m_{32}^2$ , and smaller for higher values of  $\Delta m_{32}^2$ .

<sup>34</sup> The quoted limit is for  $\Delta m_{32}^2 = 1.9 \times 10^{-3} \text{ eV}^2$ . That value of  $\Delta m_{32}^2$  is the  $1\text{-}\sigma$  low value for ALIU 05. For the ALIU 05 best fit value of  $2.8 \times 10^{-3} \text{ eV}^2$ , the  $\sin^2 2\theta_{13}$  limit is  $< 0.23$ .

<sup>35</sup> The quoted limit is for  $\Delta m_{32}^2 = 2.43 \times 10^{-3} \text{ eV}^2$ . That value of  $\Delta m_{32}^2$  is the central value for ADAMSON 08. For the ADAMSON 08  $1\text{-}\sigma$  low value of  $2.30 \times 10^{-3} \text{ eV}^2$ , the  $\sin^2 2\theta_{13}$  limit is  $< 0.16$ . See also APOLLONIO 03 for a detailed description of the experiment.

**(C) Other neutrino mixing results**

The LSND collaboration reported in AGUILAR 01 a signal which is consistent with  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$  oscillations. In a three neutrino framework, this would be a measurement of  $\theta_{12}$  and  $\Delta m_{21}^2$ . This does not appear to be consistent with most of the other neutrino data. The MiniBooNE experiment, reported in AGUILAR-AREVALO 07, does a two-neutrino analysis which, assuming  $CP$  conservation, rules out AGUILAR 01. However, the MiniBooNE antineutrino data reported in AGUILAR-AREVALO 13a are consistent with the signal reported in AGUILAR 01. The following listings include results which might be relevant towards understanding these observations. They include searches for  $\nu_\mu \rightarrow \nu_e$ ,  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$ , sterile neutrino oscillations, and  $CPT$  violation.

 **$\Delta(m^2)$  for  $\sin^2(2\theta) = 1$  ( $\nu_\mu \rightarrow \nu_e$ )**

VALUE (eV <sup>2</sup> )	CL%	DOCUMENT ID	TECN	COMMENT

<0.09	90	ANGELINI 86	HLBC	BEBE CERN PS

<sup>1</sup> Based on  $\nu_\mu \rightarrow \nu_e$  appearance of  $162.0 \pm 47.8$  events; marginally compatible with two neutrino oscillations. The best fit value is  $\Delta m^2 = 3.14 \text{ eV}^2$ .

<sup>2</sup> MAHN 12 is a combined spectral fit of MiniBooNE and SciBooNE neutrino data with the range of  $\Delta m^2$  up to  $25 \text{ eV}^2$ . The best limit is  $0.04$  at  $7 \text{ eV}^2$ .

<sup>3</sup> AGUILAR 01 is the final analysis of the LSND full data set. Search is made for the  $\nu_\mu \rightarrow \nu_e$  oscillations using  $\nu_\mu$  from  $\pi^+$  decay in flight by observing beam-on electron events from  $\nu_e C \rightarrow e^- X$ . Present analysis results in  $8.1 \pm 12.2 \pm 1.7$  excess events in the  $60 < E_e < 200 \text{ MeV}$  energy range, corresponding to oscillation probability of  $0.10 \pm 0.16 \pm 0.04\%$ . This is consistent, though less significant, with the previous result of ATHANASSOPOULOS 98, which it supersedes. The present analysis uses selection criteria developed for the decay at rest region, and is less effective in removing the background above  $60 \text{ MeV}$  than ATHANASSOPOULOS 98.

<sup>4</sup> ATHANASSOPOULOS 98 is a search for the  $\nu_\mu \rightarrow \nu_e$  oscillations using  $\nu_\mu$  from  $\pi^+$  decay in flight. The 40 observed beam-on electron events are consistent with  $\nu_e C \rightarrow e^- X$ ; the expected background is  $21.9 \pm 2.1$ . Authors interpret this excess as evidence for an oscillation signal corresponding to oscillations with probability  $(0.26 \pm 0.10 \pm 0.05)\%$ . Although the significance is only  $2.3\sigma$ , this measurement is an important and consistent cross check of ATHANASSOPOULOS 96 who reported evidence for  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$  oscillations from  $\mu^+$  decay at rest. See also ATHANASSOPOULOS 98b.

<sup>5</sup> LOVERRE 96 uses the charged-current to neutral-current ratio from the combined CHARM (ALLABY 86) and CDHS (ABRAMOWICZ 86) data from 1986.

• • • We do not use the following data for averages, fits, limits, etc. • • •

<sup>1</sup> Based on  $\nu_\mu \rightarrow \nu_e$  appearance of  $162.0 \pm 47.8$  events; marginally compatible with two neutrino oscillations. The best fit value is  $\sin^2 2\theta = 0.002$ .

<sup>2</sup> ANTONELLO 13 use the ICARUS T600 detector at LNGS and  $\sim 20 \text{ GeV}$  beam of  $\nu_\mu$  from CERN 730 km away to search for an excess of  $\nu_e$  events. Two events are found with  $3.7 \pm 0.6$  expected from conventional sources. This result excludes some parts of the parameter space expected by LSND. Superseded by ANTONELLO 13a.

<sup>3</sup> Based on four events with a background of  $6.4 \pm 0.9$  from conventional sources with an average energy of  $20 \text{ GeV}$  and  $730 \text{ km}$  from the source of  $\nu_\mu$ .

<sup>4</sup> MAHN 12 is a combined fit of MiniBooNE and SciBooNE neutrino data.

<sup>5</sup> The limit is  $\sin^2 2\theta < 0.9 \times 10^{-3}$  at  $\Delta m^2 = 2 \text{ eV}^2$ . That value of  $\Delta m^2$  corresponds to the smallest mixing angle consistent with the reported signal from LSND in AGUILAR 01.

<sup>6</sup> The limit becomes  $\sin^2 2\theta < 0.15$  at  $\Delta m^2 = 2.8 \times 10^{-3} \text{ eV}^2$ , the best-fit value of the  $\nu_\mu$  disappearance analysis in K2K.

<sup>7</sup> AGUILAR 01 is the final analysis of the LSND full data set of the search for the  $\nu_\mu \rightarrow \nu_e$  oscillations. See footnote in preceding table for further details.

<sup>8</sup> ATHANASSOPOULOS 98 report  $(0.26 \pm 0.10 \pm 0.05)\%$  for the oscillation probability; the value of  $\sin^2 2\theta$  for large  $\Delta m^2$  is deduced from this probability. See footnote in preceding table for further details, and see the paper for a plot showing allowed regions. If effect is due to oscillation, it is most likely to be intermediate  $\sin^2 2\theta$  and  $\Delta m^2$ . See also ATHANASSOPOULOS 98b.

<sup>9</sup> LOVERRE 96 uses the charged-current to neutral-current ratio from the combined CHARM (ALLABY 86) and CDHS (ABRAMOWICZ 86) data from 1986.

<sup>10</sup> VILAIN 94c limit derived by combining the  $\nu_\mu$  and  $\bar{\nu}_\mu$  data assuming  $CP$  conservation.

• • • We do not use the following data for averages, fits, limits, etc. • • •

<sup>1</sup> Based on  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$  appearance of  $78.4 \pm 28.5$  events. The best fit values are  $\Delta m^2 = 0.043 \text{ eV}^2$  and  $\sin^2 2\theta = 0.88$ .

<sup>2</sup> CHENG 12 is a combined fit of MiniBooNE and SciBooNE antineutrino data.

<sup>3</sup> This value is for a two neutrino oscillation analysis for excess antineutrino events with  $E_\nu > 475 \text{ MeV}$ . The best fit is at  $0.07$ . The allowed region is consistent with LSND reported by AGUILAR 01. Supersedes AGUILAR-AREVALO 09b.

<sup>4</sup> This value is for a two neutrino oscillation analysis for excess antineutrino events with  $E_\nu > 200 \text{ MeV}$  with subtraction of the expected 12 events low energy excess seen in the neutrino component of the beam. The best fit value is  $0.007$  for  $\Delta(m^2) = 4.4 \text{ eV}^2$ .

<sup>5</sup> ARMBRUSTER 02 is the final analysis of the KARMEN 2 data for  $17.7 \text{ m}$  distance from the ISIS stopped pion and muon neutrino source. It is a search for  $\bar{\nu}_e$ , detected by the inverse  $\beta$ -decay reaction on protons and  $^{12}\text{C}$ . 15 candidate events are observed, and  $15.8 \pm 0.5$  background events are expected, hence no oscillation signal is detected. The results exclude large regions of the parameter area favored by the LSND experiment.

<sup>6</sup> AGUILAR 01 is the final analysis of the LSND full data set. It is a search for  $\bar{\nu}_e$   $30 \text{ m}$  from LAMPF beam stop. Neutrinos originate mainly from  $\pi^+$  decay at rest.  $\bar{\nu}_e$  are detected through  $\bar{\nu}_e p \rightarrow e^+ n$  ( $20 < E_{e^+} < 60 \text{ MeV}$ ) in delayed coincidence with  $np \rightarrow d\gamma$ . Authors observe  $87.9 \pm 22.4 \pm 6.0$  total excess events. The observation is attributed to  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$  oscillations with the oscillation probability of  $0.264 \pm 0.067 \pm 0.045\%$ , consistent with the previously published result. Taking into account all constraints, the most favored allowed region of oscillation parameters is a band of  $\Delta(m^2)$  from  $0.2\text{--}2.0 \text{ eV}^2$ . Supersedes ATHANASSOPOULOS 95, ATHANASSOPOULOS 96, and ATHANASSOPOULOS 98.

<sup>7</sup> ATHANASSOPOULOS 96 is a search for  $\bar{\nu}_e$   $30 \text{ m}$  from LAMPF beam stop. Neutrinos originate mainly from  $\pi^+$  decay at rest.  $\bar{\nu}_e$  could come from either  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$  or  $\nu_e \rightarrow \bar{\nu}_e$ ; our entry assumes the first interpretation. They are detected through  $\bar{\nu}_e p \rightarrow e^+ n$  ( $20 \text{ MeV} < E_{e^+} < 60 \text{ MeV}$ ) in delayed coincidence with  $np \rightarrow d\gamma$ . Authors observe  $51 \pm 20 \pm 8$  total excess events over an estimated background  $12.5 \pm 2.9$ . ATHANASSOPOULOS 96b is a shorter version of this paper.

<sup>8</sup> ATHANASSOPOULOS 95 error corresponds to the  $1.6\sigma$  band in the plot. The expected background is  $2.7 \pm 0.4$  events. Corresponds to an oscillation probability of  $(0.34 \pm 0.20 \pm 0.18 \pm 0.07)\%$ . For a different interpretation, see HILL 95. Replaced by ATHANASSOPOULOS 96.

<sup>9</sup> HILL 95 is a report by one member of the LSND Collaboration, reporting a different conclusion from the analysis of the data of this experiment (see ATHANASSOPOULOS 95). Contrary to the rest of the LSND Collaboration, Hill finds no evidence for the neutrino oscillation  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$  and obtains only upper limits.

<sup>10</sup> FREEDMAN 93 is a search at LAMPF for  $\bar{\nu}_e$  generated from any of the three neutrino types  $\nu_\mu$ ,  $\bar{\nu}_\mu$ , and  $\nu_e$  which come from the beam stop. The  $\bar{\nu}_e$ 's would be detected by the reaction  $\bar{\nu}_e p \rightarrow e^+ n$ . FREEDMAN 93 replaces DURKIN 88.

- • • We do not use the following data for averages, fits, limits, etc. • • •
- 1 ANTONELLO 13A obtained the limit by assuming  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$  oscillation from the  $\sim 2\%$  of  $\bar{\nu}_\mu$  evnents contamination in the CNGS beam.
- 2 CHENG 12 is a combined fit of MiniBooNE and SciBooNE antineutrino data.
- 3 This value is for a two neutrino oscillation analysis for excess antineutrino events with  $E_\nu > 475$  MeV. At 90% CL there is no solution at high  $\Delta(m^2)$ . The best fit is at maximal mixing. The allowed region is consistent with LSND reported by AGUILAR 01. Supersedes AGUILAR-AREVALO 09B.
- 4 This value is for a two neutrino oscillation analysis for excess antineutrino events with  $E_\nu > 200$  MeV with subtraction of the expected 12 events low energy excess seen in the neutrino component of the beam. At 90% CL there is no solution at high  $\Delta(m^2)$ . The best fit value is 0.007 for  $\Delta(m^2) = 4.4$  eV<sup>2</sup>.
- 5 This result is inconclusive with respect to small amplitude mixing suggested by LSND.
- 6 ARMBRUSTER 02 is the final analysis of the KARMEN2 data. See footnote in the preceding table for further details, and the paper for the exclusion plot.
- 7 AGUILAR 01 is the final analysis of the LSND full data set. The deduced oscillation probability is  $0.264 \pm 0.067 \pm 0.045\%$ ; the value of  $\sin^2 2\theta$  for large  $\Delta(m^2)$  is twice this probability (although these values are excluded by other constraints). See footnote in preceding table for further details, and the paper for a plot showing allowed regions. Supersedes ATHANASSOPOULOS 95, ATHANASSOPOULOS 96, and ATHANASSOPOULOS 98.
- 8 ATHANASSOPOULOS 96 reports  $(0.31 \pm 0.12 \pm 0.05)\%$  for the oscillation probability; the value of  $\sin^2 2\theta$  for large  $\Delta(m^2)$  should be twice this probability. See footnote in preceding table for further details, and see the paper for a plot showing allowed regions.
- 9 ATHANASSOPOULOS 95 error corresponds to the  $1.6\sigma$  band in the plot. The expected background is  $2.7 \pm 0.4$  events. Corresponds to an oscillation probability of  $(0.34 \pm 0.20 \pm 0.18 \pm 0.07)\%$ . For a different interpretation, see HILL 95. Replaced by ATHANASSOPOULOS 96.
- 10 HILL 95 is a report by one member of the LSND Collaboration, reporting a different conclusion from the analysis of the data of this experiment (see ATHANASSOPOULOS 95). Contrary to the rest of the LSND Collaboration, Hill finds no evidence for the neutrino oscillation  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$  and obtains only upper limits.

### Sterile neutrino limits from atmospheric neutrino studies

#### $\Delta(m^2)$ for $\sin^2(2\theta) = 1$ ( $\nu_\mu \rightarrow \nu_s$ )

$\nu_s$  means  $\nu_\tau$  or any sterile (noninteracting)  $\nu$ .

VALUE ( $10^{-5}$ eV <sup>2</sup> )	CL%	DOCUMENT ID	TECN	COMMENT
<3000 (or <550)	90	1 OYAMA	89	KAMI Water Cherenkov
<4.2 (or >54).	90	BIONTA	88	IMB Flux has $\nu_\mu, \bar{\nu}_\mu, \nu_e,$ and $\bar{\nu}_e$

- • • We do not use the following data for averages, fits, limits, etc. • • •
- 1 OYAMA 89 gives a range of limits, depending on assumptions in their analysis. They argue that the region  $\Delta(m^2) = (100-1000) \times 10^{-5}$  eV<sup>2</sup> is not ruled out by any data for large mixing.

#### Search for $\nu_\mu \rightarrow \nu_s$

VALUE	DOCUMENT ID	TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •	1 AMBROSIO 01	MCRO	matter effects
	2 FUKUDA 00	SKAM	neutral currents + matter effects

- 1 AMBROSIO 01 tested the pure 2-flavor  $\nu_\mu \rightarrow \nu_s$  hypothesis using matter effects which change the shape of the zenith-angle distribution of upward through-going muons. With maximum mixing and  $\Delta(m^2)$  around  $0.0024$  eV<sup>2</sup>, the  $\nu_\mu \rightarrow \nu_s$  oscillation is disfavored with 99% confidence level with respect to the  $\nu_\mu \rightarrow \nu_\tau$  hypothesis.
- 2 FUKUDA 00 tested the pure 2-flavor  $\nu_\mu \rightarrow \nu_s$  hypothesis using three complementary atmospheric-neutrino data samples. With this hypothesis, zenith-angle distributions are expected to show characteristic behavior due to neutral currents and matter effects. In the  $\Delta(m^2)$  and  $\sin^2 2\theta$  region preferred by the Super-Kamiokande data, the  $\nu_\mu \rightarrow \nu_s$  hypothesis is rejected at the 99% confidence level, while the  $\nu_\mu \rightarrow \nu_\tau$  hypothesis consistently fits all of the data sample.

### CP violating phase

#### $\delta$ , CP violating phase

Measurements of  $\delta$  come from atmospheric and accelerator experiments looking at  $\nu_e$  appearance. We encode values between 0 and  $2\pi$ , though it is equivalent to use  $-\pi$  to  $\pi$ .

VALUE (rad)	CL%	DOCUMENT ID	TECN	COMMENT
(0.05 to 1.2) $\pi$	90	1 ADAMSON 14	MINS	normal mass hierarchy, $\theta_{23} > \pi/4$
(0 to 1.5) $\pi$ , (1.9 to 2) $\pi$	90	2 ADAMSON 13A	MINS	normal mass hierarchy, $\theta_{23} > \pi/4$

- • • We do not use the following data for averages, fits, limits, etc. • • •
- 1 Based on three-flavor formalism. Likelihood as a function of  $\delta$  is also shown for the other three combinations of hierarchy and  $\theta_{23}$  quadrant; all values of  $\delta$  are allowed at 90% C.L.
- 2 Based on  $\nu_e$  appearance in MINOS and the calculated  $\sin^2(2\theta_{23}) = 0.957$ ,  $\theta_{23} > \pi/4$ , and normal mass hierarchy. Likelihood as a function of  $\delta$  is also shown for the other three combinations of hierarchy and  $\theta_{23}$  quadrant; all values of  $\delta$  are allowed at 90% C.L.

### CPT tests

#### $\langle \Delta m_{21}^2 - \Delta \bar{m}_{21}^2 \rangle$

VALUE ( $10^{-4}$ eV <sup>2</sup> )	CL%	DOCUMENT ID	TECN	COMMENT
<1.1	99.7	1 DEGOUVEA 05	FIT	solar vs. reactor

- • • We do not use the following data for averages, fits, limits, etc. • • •
- 1 DEGOUVEA 05 obtained this bound at the  $3\sigma$  CL from the KamLAND (ARAKI 05) and solar neutrino data.

#### $\langle \Delta m_{32}^2 - \Delta \bar{m}_{32}^2 \rangle$

VALUE ( $10^{-3}$ eV <sup>2</sup> )	CL%	DOCUMENT ID	TECN	COMMENT
$0.6^{+2.4}_{-0.8}$	90	1 ADAMSON 12B	MINS	MINOS atmospheric

- • • We do not use the following data for averages, fits, limits, etc. • • •
- 1 The quoted result is the single-parameter 90% C.L. interval determined from the 90% C.L. contour in the  $(\Delta m^2, \Delta \bar{m}^2)$  plane, which is obtained by minimizing the four parameter log-likelihood function with respect to the other oscillation parameters.

>4.1		GRIEST	87 COSM	Dirac $\nu$

- <sup>5</sup> FARGION 95 bound is sensitive to assumed  $\nu$  concentration in the Galaxy. See also KONOPLICH 94.
- <sup>6</sup> These results assume that neutrinos make up dark matter in the galactic halo.
- <sup>7</sup> Limits based on annihilations in the sun and are due to an absence of high energy neutrinos detected in underground experiments.
- <sup>8</sup> MORI 92B results assume that neutrinos make up dark matter in the galactic halo. Limits based on annihilations in earth are also given.
- <sup>9</sup> REUSSER 91 uses existing  $\beta\beta$  detector (see FISHER 89) to search for CDM Dirac neutrinos.
- <sup>10</sup> ENQVIST 89 argue that there is no cosmological upper bound on heavy neutrinos.

- <sup>11</sup> BRITTON 92B is from a search for additional peaks in the  $e^+$  spectrum from  $\pi^+ \rightarrow e^+ \nu_e$  decay at TRIUMF. See also BRITTON 92.
- <sup>12</sup> BRYMAN 83B obtain upper limits from both direct peak search and analysis of  $B(\pi \rightarrow e\nu)/B(\pi \rightarrow \mu\nu)$ . Latter limits are not listed, except for this entry (i.e. — we list the most stringent limits for given mass).
- <sup>13</sup> Analysis of  $(\pi^+ \rightarrow e^+ \nu_e)/(\pi^+ \rightarrow \mu^+ \nu_\mu)$  and  $(K^+ \rightarrow e^+ \nu_e)/(K^+ \rightarrow \mu^+ \nu_\mu)$  decay ratios.
- <sup>14</sup> Analysis of  $(K^+ \rightarrow e^+ \nu_e)$  spectrum.

##### Kink search in nuclear $\beta$ decay

High-sensitivity follow-up experiments show that indications for a neutrino with mass 17 keV (Simpson, Hime, and others) were not valid. Accordingly, we no longer list the experiments by these authors and some others which made positive claims of 17 keV neutrino emission. Complete listings are given in the 1994 edition (Physical Review **D50** 1173 (1994)) and in the 1998 edition (The European Physical Journal

**C3** 1 (1998)). We list below only the best limits on  $|U_{ex}|^2$  for each  $m_{\nu_x}$ . See WIETFELDT 96 for a comprehensive review.

- <sup>15</sup> TRINCZEK 03 is a search for admixture of heavy neutrino to  $\nu_e$ , in contrast to  $\bar{\nu}_e$  used in many other searches. Full kinematic reconstruction of the neutrino momentum by use of a magneto optical trap.
- <sup>16</sup> GALEAZZI 01 use an cryogenic microcalorimeter to search for mass 50–1000 eV neutrino admixtures using the <sup>187</sup>Re beta spectrum with 2.4 keV endpoint. They derive limits for the admixture of heavy neutrinos, ranging from  $9 \times 10^{-3}$  for mass 1 keV to 0.116 for mass 100 eV. This is a significant improvement with respect to HIDDEMANN 95, especially for masses below  $\sim 500 \text{ MeV}$ , where the limit is about a factor of  $\sim 2$  higher.
- <sup>17</sup> HOLZSCHUH 00 use an iron-free  $\beta$  spectrometer to measure the <sup>35</sup>S  $\beta$  decay spectrum. An analysis of the spectrum in the energy range 56–173 keV is used to derive limits for the admixture of heavy neutrinos. This extends the range of neutrino masses explored in HOLZSCHUH 99.
- <sup>18</sup> DRAGON 99 analyze the  $\beta$  decay spectrum of <sup>241</sup>Pu in the energy range 0.2–9.2 keV to derive limits for the admixture of heavy neutrinos. It is not competitive with HOLZSCHUH 99.
- <sup>19</sup> HOLZSCHUH 99 use an iron-free  $\beta$  spectrometer to measure the <sup>63</sup>Ni  $\beta$  decay spectrum. An analysis of the spectrum in the energy range 33–67.8 keV is used to derive limits for the admixture of heavy neutrinos.
- <sup>20</sup> HINDI 98 obtain a limit on heavy neutrino admixture from EC decay of <sup>37</sup>Ar by measuring the time-of-flight distribution of the recoiling ions in coincidence with x-rays or Auger electrons. The authors report upper limit for  $|U_{ex}|^2$  of  $\approx 3\%$  for  $m_{\nu_x} = 500 \text{ keV}$ ,  $1\%$  for  $m_{\nu_x} = 550 \text{ keV}$ ,  $2\%$  for  $m_{\nu_x} = 600 \text{ keV}$ , and  $4\%$  for  $m_{\nu_x} = 650 \text{ keV}$ . Their reported limits for  $m_{\nu_x} \leq 450 \text{ keV}$  are inferior to the limits of SCHRECKENBACH 83.
- <sup>21</sup> In the beta spectrum from tritium  $\beta$  decay nonvanishing or mixed  $m_{T_1}$  state in the mass region 0.01–4 keV. For  $m_{\nu_x} < 1 \text{ keV}$ , their upper limit on  $|U_{ex}|^2$  becomes less
- <sup>22</sup> KALBFLEISCH 93 extends the 17 keV neutrino search of BAHNAN 92, using an improved proportional chamber to which a small amount of <sup>3</sup>H is added. Systematics are significantly reduced, allowing for an improved upper limit. The authors give a 99% confidence limit on  $|U_{ex}|^2$  as a function of  $m_{\nu_x}$  in the range from 13.5 keV to 17.5 keV. See also the related papers BAHNAN 93, BAHNAN 93b, and BAHNAN 95 on theoretical aspects of beta spectra and fitting methods for heavy neutrinos.
- <sup>23</sup> MORTARA 93 limit is from study using a high-resolution solid-state detector with a superconducting solenoid. The authors note that “The sensitivity to neutrino mass is verified by measurement with a mixed source of <sup>35</sup>S and <sup>14</sup>C, which artificially produces a distortion in the beta spectrum similar to that expected from the massive neutrino.”
- <sup>24</sup> DEUTSCH 90 search for emission of heavy  $\bar{\nu}_e$  in super-allowed beta decay of <sup>20</sup>F by spectral analysis of the electrons.
- <sup>25</sup> This limit was taken from the figure 3 of APALIKOV 85; the text gives a more restrictive limit of  $1.7 \times 10^{-3}$  at CL = 90%.
- <sup>26</sup> SCHRECKENBACH 83 is a combined measurement of the  $\beta^+$  and  $\beta^-$  spectrum.
- <sup>27</sup> SHROCK 80 was a retroactive analysis of data on several superallowed  $\beta$  decays to search for kinks in the Kurie plot.
- <sup>28</sup> Application of test to search for kinks in  $\beta$  decay Kurie plots.

29 BACK 03a searched for heavy neutrinos emitted from  $^8\text{B}$  decay in the Sun using the decay  $\nu_h \rightarrow \nu_e e^+ e^-$  in the Counting Test Facility (the prototype of the Borexino detector) and obtained limits on heavy neutrino admixture for the  $\nu_h$  mass range 1.1-12 MeV.

30 ABREU 97i long-lived  $\nu_x$  analysis. Short-lived analysis extends limit to lower masses with decreasing sensitivity except at 3.5 GeV, where the limit is the same as at 6 GeV.

31 HAGNER 95 obtain limits on heavy neutrino admixture from the decay  $\nu_h \rightarrow \nu_e e^+ e^-$  at a nuclear reactor for the  $\nu_h$  mass range 2-9 MeV.

32 BARANOV 93 is a search for neutrino decays into  $e^+ e^- \nu_e$  using a beam dump experiment at the 70 GeV Serpukhov proton synchrotron. The limits are not as good as those achieved earlier by BERGSMA 83 and BERNARDI 86, BERNARDI 88.

33 BURCHAT 90 includes the analyses reported in JUNG 90, ABRAMS 89c, and WENDT 87.

34 OBERAUER 87 bounds from search for  $\nu \rightarrow \nu' e e$  decay mode using reactor (anti)neutrinos.

35 COOPER-SARKAR 85 also give limits based on model-dependent assumptions for  $\nu_\tau$  flux. We do not list these. Note that for this bound to be nontrivial,  $x$  is not equal to 3, i.e.  $\nu_x$  cannot be the dominant mass eigenstate in  $\nu_\tau$  since  $m_{\nu_3} < 70$  MeV (ALBRECHT 85i). Also, of course,  $x$  is not equal to 1 or 2, so a fourth generation would be required for this bound to be nontrivial.

36 BERGSMA 83b also quote limits on  $|U_{e3}|^2$  where the index 3 refers to the mass eigenstate dominantly coupled to the  $\tau$ . Those limits were based on assumptions about the  $D_S$  mass and  $D_S \rightarrow \tau \nu_\tau$  branching ratio which are no longer valid. See COOPER-SARKAR 85.

Limits on Coupling of  $\mu$  to  $\nu_x$  as Function of  $m_{\nu_x}$

37 ASTIER 02 search for anomalous pion decay into a 33.9 MeV neutral particle. No evidence was found and the sensitivity to the branching ratio  $B(\pi \rightarrow \mu X) \cdot B(X \rightarrow \nu e^+ e^-)$  is as low as  $3.7 \times 10^{-15}$ , depending on the  $X$  lifetime.

38 DAUM 00 search for anomalous pion decay into a 33.9 MeV neutral particle that might be responsible for the time-distribution anomaly observed by the KARMEN Collaboration.

39 FORMAGGIO 00 search for anomalous pion decay into a 33.9 MeV neutral particle  $Q^0$  that might be responsible for the time-distribution anomaly observed by the KARMEN Collaboration. In the E815 (NuTeV) experiment at Fermilab no evidence was found, with sensitivity for the pion branching ratio  $B(\pi \rightarrow \mu Q^0) \cdot B(Q^0 \rightarrow \text{visible})$  as low as  $10^{-13}$ .

40 ASSAMAGAN 98 obtain a limit on heavy neutrino admixture from  $\pi^+$  decay essentially at rest, by measuring with good resolution the momentum distribution of the muons. However, the search uses an ad hoc shape correction. The authors report upper limit for  $|U_{\mu x}|^2$  of 0.22 for  $m_\nu = 0.53$  MeV, 0.029 for  $m_\nu = 0.75$  MeV, and 0.016 for  $m_\nu = 1.0$  MeV at 90% CL.

41 BRYMAN 96 search for massive unconventional neutrinos of mass  $m_{\nu_x}$  in  $\pi^+$  decay.

42 ARMBRUSTER 95 study the reactions  $^{12}\text{C}(\nu_e, e^-)^{12}\text{N}$  and  $^{12}\text{C}(\nu, \nu')^{12}\text{C}^*$  induced by neutrinos from  $\pi^+$  and  $\mu^+$  decay at the ISIS neutron spallation source at the Rutherford-Appleton laboratory. An anomaly in the time distribution can be interpreted as the decay  $\pi^+ \rightarrow \mu^+ \nu_x$ , where  $\nu_x$  is a neutral weakly interacting particle with mass  $\approx 33.9$  MeV and spin 1/2. The lower limit to the branching ratio is a function of the lifetime of the new massive neutral particle, and reaches a minimum of a few  $\times 10^{-16}$  for  $\tau_X \sim 5$  s.

43 From experiments of  $\pi^+$  and  $\pi^-$  decay in flight at PSI, to check the claim of the KARMEN Collaboration quoted above (ARMBRUSTER 95).

44  $\pi^+ \rightarrow \mu^+ \nu_\mu$  peak search experiment.

45  $K^+ \rightarrow \mu^+ \nu_\mu$  peak search experiment.

<sup>52</sup>VAITAITIS 99 search for  $L^0_\mu \rightarrow \mu X$ . See paper for rather complicated limit as function of  $m_{\nu_x}$ .

<sup>53</sup>ABREU 97i long-lived  $\nu_x$  analysis. Short-lived analysis extends limit to lower masses with decreasing sensitivity except at 3.5 GeV, where the limit is the same as at 6 GeV.

<sup>54</sup>VILAIN 95c is a search for the decays of heavy isosinglet neutrinos produced by neutral current neutrino interactions. Limits were quoted for masses in the range from 0.3 to 24 GeV. The best limit is listed above.

<sup>55</sup>BURCHAT 90 includes the analyses reported in JUNG 90, ABRAMS 89c, and WENDT 87.

<sup>56</sup>See also limits on  $|U_{3\tau}|^2$  from WENDT 87.

<sup>57</sup>COOPER-SARKAR 85 also give limits based on model-dependent assumptions for  $\nu_\tau$  flux. We do not list these. Note that for this bound to be nontrivial,  $x$  is not equal to 3, i.e.  $\nu_x$  cannot be the dominant mass eigenstate in  $\nu_\tau$  since  $m_{\nu_3} < 70$  MeV

(ALBRECHT 85i). Also, of course,  $x$  is not equal to 1 or 2, so a fourth generation would be required for this bound to be nontrivial.

## QUARK MASSES

Updated Jan 2014 by A.V. Manohar (University of California, San Diego) and C.T. Sachrajda (University of Southampton)

### A. Introduction

This note discusses some of the theoretical issues relevant for the determination of quark masses, which are fundamental parameters of the Standard Model of particle physics. Unlike the leptons, quarks are confined inside hadrons and are not observed as physical particles. Quark masses therefore cannot be measured directly, but must be determined indirectly through their influence on hadronic properties. Although one often speaks loosely of quark masses as one would of the mass of the electron or muon, any quantitative statement about the value of a quark mass must make careful reference to the particular theoretical framework that is used to define it. It is important to keep this *scheme dependence* in mind when using the quark mass values tabulated in the data listings.

Historically, the first determinations of quark masses were performed using quark models. The resulting masses only make sense in the limited context of a particular quark model, and cannot be related to the quark mass parameters of the Standard Model. In order to discuss quark masses at a fundamental level, definitions based on quantum field theory be used, and the purpose of this note is to discuss these definitions and the corresponding determinations of the values of the masses.

### B. Mass parameters and the QCD Lagrangian

The QCD [1] Lagrangian for  $N_F$  quark flavors is

$$\mathcal{L} = \sum_{k=1}^{N_F} \bar{q}_k (i\mathcal{D} - m_k) q_k - \frac{1}{4} G_{\mu\nu} G^{\mu\nu}, \quad (1)$$

where  $\mathcal{D} = (\partial_\mu - igA_\mu) \gamma^\mu$  is the gauge covariant derivative,  $A_\mu$  is the gluon field,  $G_{\mu\nu}$  is the gluon field strength,  $m_k$  is the mass parameter of the  $k^{\text{th}}$  quark, and  $q_k$  is the quark Dirac field. After renormalization, the QCD Lagrangian Eq. (1) gives finite values for physical quantities, such as scattering amplitudes. Renormalization is a procedure that invokes a subtraction scheme to render the amplitudes finite, and requires the introduction of a dimensionful scale parameter  $\mu$ . The mass parameters in the QCD Lagrangian Eq. (1) depend on the renormalization scheme used to define the theory, and also on the scale parameter  $\mu$ . The most commonly used renormalization scheme for QCD perturbation theory is the  $\overline{\text{MS}}$  scheme.

The QCD Lagrangian has a chiral symmetry in the limit that the quark masses vanish. This symmetry is spontaneously broken by dynamical chiral symmetry breaking, and explicitly broken by the quark masses. The nonperturbative scale of dynamical chiral symmetry breaking,  $\Lambda_\chi$ , is around 1 GeV [2]. It is conventional to call quarks heavy if  $m > \Lambda_\chi$ , so that explicit

chiral symmetry breaking dominates ( $c$ ,  $b$ , and  $t$  quarks are heavy), and light if  $m < \Lambda_\chi$ , so that spontaneous chiral symmetry breaking dominates ( $u$ ,  $d$  and  $s$  quarks are light). The determination of light- and heavy-quark masses is considered separately in sections D and E below.

At high energies or short distances, nonperturbative effects, such as chiral symmetry breaking, become small and one can, in principle, determine quark masses by analyzing mass-dependent effects using QCD perturbation theory. Such computations are conventionally performed using the  $\overline{\text{MS}}$  scheme at a scale  $\mu \gg \Lambda_\chi$ , and give the  $\overline{\text{MS}}$  “running” mass  $\overline{m}(\mu)$ . We use the  $\overline{\text{MS}}$  scheme when reporting quark masses; one can readily convert these values into other schemes using perturbation theory.

The  $\mu$  dependence of  $\overline{m}(\mu)$  at short distances can be calculated using the renormalization group equation,

$$\mu^2 \frac{d\overline{m}(\mu)}{d\mu^2} = -\gamma(\overline{\alpha}_s(\mu)) \overline{m}(\mu), \quad (2)$$

where  $\gamma$  is the anomalous dimension which is now known to four-loop order in perturbation theory [3,4].  $\overline{\alpha}_s$  is the coupling constant in the  $\overline{\text{MS}}$  scheme. Defining the expansion coefficients  $\gamma_r$  by

$$\gamma(\overline{\alpha}_s) \equiv \sum_{r=1}^{\infty} \gamma_r \left( \frac{\overline{\alpha}_s}{4\pi} \right)^r,$$

the first four coefficients are given by

$$\begin{aligned} \gamma_1 &= 4, \\ \gamma_2 &= \frac{202}{3} - \frac{20N_L}{9}, \\ \gamma_3 &= 1249 + \left( -\frac{2216}{27} - \frac{160}{3}\zeta(3) \right) N_L - \frac{140}{81} N_L^2, \\ \gamma_4 &= \frac{4603055}{162} + \frac{135680}{27}\zeta(3) - 8800\zeta(5) \\ &\quad + \left( -\frac{91723}{27} - \frac{34192}{9}\zeta(3) + 880\zeta(4) + \frac{18400}{9}\zeta(5) \right) N_L \\ &\quad + \left( \frac{5242}{243} + \frac{800}{9}\zeta(3) - \frac{160}{3}\zeta(4) \right) N_L^2 \\ &\quad + \left( -\frac{332}{243} + \frac{64}{27}\zeta(3) \right) N_L^3, \end{aligned}$$

where  $N_L$  is the number of active light quark flavors at the scale  $\mu$ , i.e. flavors with masses  $< \mu$ , and  $\zeta$  is the Riemann zeta function ( $\zeta(3) \simeq 1.2020569$ ,  $\zeta(4) \simeq 1.0823232$ , and  $\zeta(5) \simeq 1.0369278$ ). In addition, as the renormalization scale crosses quark mass thresholds one needs to match the scale dependence of  $m$  below and above the threshold. There are finite threshold corrections; the necessary formulae can be found in Ref. [5].

The quark masses for light quarks discussed so far are often referred to as current quark masses. Nonrelativistic quark models use constituent quark masses, which are of order 350 MeV for the  $u$  and  $d$  quarks. Constituent quark masses

# Quark Particle Listings

## Quarks

model the effects of dynamical chiral symmetry breaking, and are not related to the quark mass parameters  $m_k$  of the QCD Lagrangian Eq. (1). Constituent masses are only defined in the context of a particular hadronic model.

### C. Lattice Gauge Theory

The use of the lattice simulations for *ab initio* determinations of the fundamental parameters of QCD, including the coupling constant and quark masses (except for the top-quark mass) is a very active area of research (see the review on Lattice Quantum Chromodynamics in this *Review*). Here we only briefly recall those features which are required for the determination of quark masses. In order to determine the lattice spacing ( $a$ , i.e. the distance between neighboring points of the lattice) and quark masses, one computes a convenient and appropriate set of physical quantities (frequently chosen to be a set of hadronic masses) for a variety of input values of the quark masses. The true (physical) values of the quark masses are those which correctly reproduce the set of physical quantities being used for the calibration.

The values of the quark masses obtained directly in lattice simulations are bare quark masses, corresponding to a particular discretization of QCD and with the lattice spacing as the ultraviolet cut-off. In order for these results to be useful in phenomenological applications, it is necessary to relate them to renormalized masses defined in some standard renormalization scheme such as  $\overline{\text{MS}}$ . Provided that both the ultraviolet cut-off  $a^{-1}$  and the renormalization scale are much greater than  $\Lambda_{\text{QCD}}$ , the bare and renormalized masses can be related in perturbation theory. However, in order to avoid uncertainties due to the unknown higher-order coefficients in lattice perturbation theory, most results obtained recently use *non-perturbative renormalization* to relate the bare masses to those defined in renormalization schemes which can be simulated directly in lattice QCD (e.g. those obtained from quark and gluon Green functions at specified momenta in the Landau gauge [51] or those defined using finite-volume techniques and the Schrödinger functional [52]). The conversion to the  $\overline{\text{MS}}$  scheme (which cannot be simulated) is then performed using continuum perturbation theory.

The determination of quark masses using lattice simulations is well established and the current emphasis is on the reduction and control of the systematic uncertainties. With improved algorithms and access to more powerful computing resources, the precision of the results has improved immensely in recent years. Particularly pleasing is the observation that results obtained using different formulations of lattice QCD, with different systematic uncertainties, give results which are largely consistent with each other. This gives us broad confidence in the estimates of the systematic errors. As the precision of the results approaches the percent level, more attention will now have to be given to sources of systematic uncertainty which have only been studied in a limited way up to now. In particular most current simulations are performed with degenerate  $u$

and  $d$  quarks and without including electromagnetic effects. Vacuum polarisation effects are included with  $N_f = 2 + 1$  or  $N_f = 2$  flavors of sea quarks, although simulations with charm sea quarks are now beginning. In earlier *reviews*, results were presented from simulations in which vacuum polarization effects were completely neglected (this is the so-called *quenched* approximation), leading to systematic uncertainties which could not be estimated reliably. It is no longer necessary to include quenched results in compilations of quark masses.

### D. Light quarks

In this section we review the determination of the masses of the light quarks  $u$ ,  $d$  and  $s$  from lattice simulations and then discuss the consequences of the approximate chiral symmetry.

**Lattice Gauge Theory:** The most reliable determinations of the strange quark mass  $m_s$  and of the average of the up and down quark masses  $m_{ud} = (m_u + m_d)/2$  are obtained from lattice simulations. As explained in section C above, the simulations are performed with degenerate up and down quarks ( $m_u = m_d$ ) and so it is the average which is obtained directly from the computations. Below we discuss attempts to derive  $m_u$  and  $m_d$  separately using lattice results in combination with other techniques, but here we briefly present our estimate of the current status of the latest lattice results. Based largely on references [19–26], which have among the most reliable estimates of the systematic errors, our summary is

$$\overline{m}_s = (93.5 \pm 2.5) \text{ MeV}, \quad \overline{m}_{ud} = (3.40 \pm 0.25) \text{ MeV} \quad (3)$$

and

$$\frac{\overline{m}_s}{\overline{m}_{ud}} = 27.5 \pm 0.3. \quad (4)$$

The masses are given in the  $\overline{\text{MS}}$  scheme at a renormalization scale of 2 GeV. Because the errors are dominated by systematics, these results are not simply the combinations of all the results in quadrature, but include a judgement of the remaining uncertainties. Since the different collaborations use different formulations of lattice QCD, the (relatively small) variations of the results between the groups provides important information about the reliability of the estimates.

Current lattice simulations are performed in the isospin symmetry limit, i.e. with the masses of the up and down quarks equal,  $m_u = m_d \equiv m_{ud}$  and, apart from Refs. [31,32], electromagnetic effects are not included in the simulation. It is the average of the physical up and down quark masses which is determined directly. In order to estimate  $m_u$  and  $m_d$  separately, further experimental and theoretical inputs have to be included. Recent studies which combine lattice data with studies of isospin breaking effects using chiral perturbation theory and phenomenology include those by the MILC [20,27] and BMW [22,23] collaborations and by the Flavianet Lattice Averaging Group [32]. Based on these results we summarise the current status as

$$\frac{\overline{m}_u}{\overline{m}_d} = 0.46(5), \quad \overline{m}_u = 2.15(15) \text{ MeV}, \quad \overline{m}_d = 4.70(20) \text{ MeV}. \quad (5)$$

Again the masses are given in the  $\overline{\text{MS}}$  scheme at a renormalization scale of 2 GeV. Of particular importance is the fact that  $m_u \neq 0$  since there would have been no strong  $CP$  problem had  $m_u$  been equal to zero.

The quark mass ranges for the light quarks given in the listings combine the lattice and continuum values and use the PDG method for determining errors given in the introductory notes.

**Chiral Perturbation Theory:** For light quarks, one can use the techniques of chiral perturbation theory [6–8] to extract quark mass ratios. The mass term for light quarks in the QCD Lagrangian is

$$\overline{\Psi}M\Psi = \overline{\Psi}_L M \Psi_R + \overline{\Psi}_R M^\dagger \Psi_L, \quad (6)$$

where  $M$  is the light quark mass matrix,

$$M = \begin{pmatrix} m_u & 0 & 0 \\ 0 & m_d & 0 \\ 0 & 0 & m_s \end{pmatrix}, \quad (7)$$

$\Psi = (u, d, s)$ , and  $L$  and  $R$  are the left- and right-chiral components of  $\Psi$  given by  $\Psi_{L,R} = P_{L,R}\Psi$ ,  $P_L = (1 - \gamma_5)/2$ ,  $P_R = (1 + \gamma_5)/2$ . The mass term is the only term in the QCD Lagrangian that mixes left- and right-handed quarks. In the limit  $M \rightarrow 0$ , there is an independent  $SU(3) \times U(1)$  flavor symmetry for the left- and right-handed quarks. The vector  $U(1)$  symmetry is baryon number; the axial  $U(1)$  symmetry of the classical theory is broken in the quantum theory due to the anomaly. The remaining  $G_\chi = SU(3)_L \times SU(3)_R$  chiral symmetry of the QCD Lagrangian is spontaneously broken to  $SU(3)_V$ , which, in the limit  $M \rightarrow 0$ , leads to eight massless Goldstone bosons, the  $\pi$ 's,  $K$ 's, and  $\eta$ .

The symmetry  $G_\chi$  is only an approximate symmetry, since it is explicitly broken by the quark mass matrix  $M$ . The Goldstone bosons acquire masses which can be computed in a systematic expansion in  $M$ , in terms of low-energy constants, which are unknown nonperturbative parameters of the effective theory, and are not fixed by the symmetries. One treats the quark mass matrix  $M$  as an external field that transforms under  $G_\chi$  as  $M \rightarrow LMR^\dagger$ , where  $\Psi_L \rightarrow L\Psi_L$  and  $\Psi_R \rightarrow R\Psi_R$  are the  $SU(3)_L$  and  $SU(3)_R$  transformations, and writes down the most general Lagrangian invariant under  $G_\chi$ . Then one sets  $M$  to its given constant value Eq. (7), which implements the symmetry breaking. To first order in  $M$  one finds that [9]

$$\begin{aligned} m_{\pi^0}^2 &= B(m_u + m_d), \\ m_{\pi^\pm}^2 &= B(m_u + m_d) + \Delta_{\text{em}}, \\ m_{K^0}^2 &= m_{\overline{K}^0}^2 = B(m_d + m_s), \\ m_{K^\pm}^2 &= B(m_u + m_s) + \Delta_{\text{em}}, \\ m_\eta^2 &= \frac{1}{3}B(m_u + m_d + 4m_s), \end{aligned} \quad (8)$$

with two unknown constants  $B$  and  $\Delta_{\text{em}}$ , the electromagnetic mass difference. From Eq. (8), one can determine the quark mass ratios [9]

$$\begin{aligned} \frac{m_u}{m_d} &= \frac{2m_{\pi^0}^2 - m_{\pi^\pm}^2 + m_{K^+}^2 - m_{K^0}^2}{m_{K^0}^2 - m_{K^+}^2 + m_{\pi^+}^2} = 0.56, \\ \frac{m_s}{m_d} &= \frac{m_{K^0}^2 + m_{K^+}^2 - m_{\pi^+}^2}{m_{K^0}^2 + m_{\pi^+}^2 - m_{K^+}^2} = 20.2, \end{aligned} \quad (9)$$

to lowest order in chiral perturbation theory, with an error which will be estimated below. Since the mass ratios extracted using chiral perturbation theory use the symmetry transformation property of  $M$  under the chiral symmetry  $G_\chi$ , it is important to use a renormalization scheme for QCD that does not change this transformation law. Any mass independent subtraction scheme such as  $\overline{\text{MS}}$  is suitable. The ratios of quark masses are scale independent in such a scheme, and Eq. (9) can be taken to be the ratio of  $\overline{\text{MS}}$  masses. Chiral perturbation theory cannot determine the overall scale of the quark masses, since it uses only the symmetry properties of  $M$ , and any multiple of  $M$  has the same  $G_\chi$  transformation law as  $M$ .

Chiral perturbation theory is a systematic expansion in powers of the light quark masses. The typical expansion parameter is  $m_K^2/\Lambda_\chi^2 \sim 0.25$  if one uses  $SU(3)$  chiral symmetry, and  $m_\pi^2/\Lambda_\chi^2 \sim 0.02$  if instead one uses  $SU(2)$  chiral symmetry. Electromagnetic effects at the few percent level also break  $SU(2)$  and  $SU(3)$  symmetry. The mass formulæ Eq. (8) were derived using  $SU(3)$  chiral symmetry, and are expected to have approximately a 25% uncertainty due to second order corrections. This estimate of the uncertainty is consistent with the lattice results found in Eq. (3) and Eq. (4).

There is a subtlety which arises when one tries to determine quark mass ratios at second order in chiral perturbation theory. The second order quark mass term [10]

$$\left(M^\dagger\right)^{-1} \det M^\dagger \quad (10)$$

(which can be generated by instantons) transforms in the same way under  $G_\chi$  as  $M$ . Chiral perturbation theory cannot distinguish between  $M$  and  $\left(M^\dagger\right)^{-1} \det M^\dagger$ ; one can make the replacement  $M \rightarrow M(\lambda) = M + \lambda M \left(M^\dagger M\right)^{-1} \det M^\dagger$  in the chiral Lagrangian,

$$\begin{aligned} M(\lambda) &= \text{diag}(m_u(\lambda), m_d(\lambda), m_s(\lambda)) \\ &= \text{diag}(m_u + \lambda m_d m_s, m_d + \lambda m_u m_s, m_s + \lambda m_u m_d), \end{aligned} \quad (11)$$

and leave all observables unchanged.

The combination

$$\left(\frac{m_u}{m_d}\right)^2 + \frac{1}{Q^2} \left(\frac{m_s}{m_d}\right)^2 = 1 \quad (12)$$

where

$$Q^2 = \frac{m_s^2 - \hat{m}^2}{m_d^2 - m_u^2}, \quad \hat{m} = \frac{1}{2}(m_u + m_d),$$

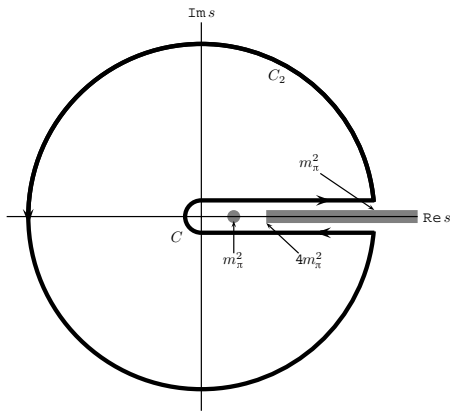

# Quark Particle Listings

## Quarks

is insensitive to the transformation in Eq. (11). Eq. (12) gives an ellipse in the  $m_u/m_d - m_s/m_d$  plane. The ellipse is well-determined by chiral perturbation theory, but the exact location on the ellipse, and the absolute normalization of the quark masses, has larger uncertainties.  $Q$  is determined to be in the range 21–25 from  $\eta \rightarrow 3\pi$  decay and the electromagnetic contribution to the  $K^+ - K^0$  and  $\pi^+ - \pi^0$  mass differences [11].

The absolute normalization of the quark masses cannot be determined using chiral perturbation theory. Other methods, such as lattice simulations discussed above or spectral function sum rules [12,13] for hadronic correlation functions, which we review next are necessary.

**Sum Rules:** Sum rule methods have been used extensively to determine quark masses and for illustration we briefly discuss here their application to hadronic  $\tau$  decays [14]. Other applications involve very similar techniques.

**Figure 1:** The analytic structure of  $\Pi(s)$  in the complex  $s$ -plane. The contours  $C_1$  and  $C_2$  are the integration contours discussed in the text.

The experimentally measured quantity is  $R_\tau$ ,

$$\frac{dR_\tau}{ds} = \frac{d\Gamma/ds(\tau^- \rightarrow \text{hadrons} + \nu_\tau(\gamma))}{\Gamma(\tau^- \rightarrow e^- \bar{\nu}_e \nu_\tau(\gamma))} \quad (13)$$

the hadronic invariant mass spectrum in semihadronic  $\tau$  decay, normalized to the leptonic  $\tau$  decay rate. It is useful to define  $q$  as the total momentum of the hadronic final state, so  $s = q^2$  is the hadronic invariant mass. The total hadronic  $\tau$  decay rate  $R_\tau$  is then given by integrating  $dR_\tau/ds$  over the kinematically allowed range  $0 \leq s \leq M_\tau^2$ .

$R_\tau$  can be written as

$$R_\tau = 12\pi \int_0^{M_\tau^2} \frac{ds}{M_\tau^2} \left(1 - \frac{s}{M_\tau^2}\right)^2 \times \left[ \left(1 + 2\frac{s}{M_\tau^2}\right) \text{Im} \Pi^T(s) + \text{Im} \Pi^L(s) \right] \quad (14)$$

where  $s = q^2$ , and the hadronic spectral functions  $\Pi^{L,T}$  are defined from the time-ordered correlation function of two weak

currents is the time-ordered correlator of the weak interaction current ( $j^\mu(x)$  and  $j^\nu(0)$ ) by

$$\Pi^{\mu\nu}(q) = i \int d^4x e^{iq \cdot x} \langle 0 | T(j^\mu(x) j^\nu(0)^\dagger) | 0 \rangle, \quad (15)$$

$$\Pi^{\mu\nu}(q) = (-g^{\mu\nu} + q^\mu q^\nu) \Pi^T(s) + q^\mu q^\nu \Pi^L(s), \quad (16)$$

and the decomposition Eq. (16) is the most general possible structure consistent with Lorentz invariance.

By the optical theorem, the imaginary part of  $\Pi^{\mu\nu}$  is proportional to the total cross-section for the current to produce all possible states. A detailed analysis including the phase space factors leads to Eq. (14). The spectral functions  $\Pi^{L,T}(s)$  are analytic in the complex  $s$  plane, with singularities along the real axis. There is an isolated pole at  $s = m_\pi^2$ , and single- and multi-particle singularities for  $s \geq 4m_\pi^2$ , the two-particle threshold. The discontinuity along the real axis is  $\Pi^{L,T}(s + i0^+) - \Pi^{L,T}(s - i0^+) = 2i \text{Im} \Pi^{L,T}(s)$ . As a result, Eq. (14) can be rewritten with the replacement  $\text{Im} \Pi^{L,T}(s) \rightarrow -i\Pi^{L,T}(s)/2$ , and the integration being over the contour  $C_1$ . Finally, the contour  $C_1$  can be deformed to  $C_2$  without crossing any singularities, and so leaving the integral unchanged. One can derive a series of sum rules analogous to Eq. (14) by weighting the differential  $\tau$  hadronic decay rate by different powers of the hadronic invariant mass,

$$R_\tau^{kl} = \int_0^{M_\tau^2} ds \left(1 - \frac{s}{M_\tau^2}\right)^k \left(\frac{s}{M_\tau^2}\right)^l \frac{dR_\tau}{ds} \quad (17)$$

where  $dR_\tau/ds$  is the hadronic invariant mass distribution in  $\tau$  decay normalized to the leptonic decay rate. This leads to the final form of the sum rule(s),

$$R_\tau^{kl} = -6\pi i \int_{C_2} \frac{ds}{M_\tau^2} \left(1 - \frac{s}{M_\tau^2}\right)^{2+k} \left(\frac{s}{M_\tau^2}\right)^l \times \left[ \left(1 + 2\frac{s}{M_\tau^2}\right) \Pi^T(s) + \Pi^L(s) \right]. \quad (18)$$

The manipulations so far are completely rigorous and exact, relying only on the general analytic structure of quantum field theory. The left-hand side of the sum rule Eq. (18) is obtained from experiment. The right hand-side can be computed for  $s$  far away from any physical cuts using the operator product expansion (OPE) for the time-ordered product of currents in Eq. (15), and QCD perturbation theory. The OPE is an expansion for the time-ordered product Eq. (15) in a series of local operators, and is an expansion about the  $q \rightarrow \infty$  limit. It gives  $\Pi(s)$  as an expansion in powers of  $\alpha_s(s)$  and  $\Lambda_{\text{QCD}}^2/s$ , and is valid when  $s$  is far (in units of  $\Lambda_{\text{QCD}}^2$ ) from any singularities in the complex  $s$ -plane.

The OPE gives  $\Pi(s)$  as a series in  $\alpha_s$ , quark masses, and various non-perturbative vacuum matrix element. By computing  $\Pi(s)$  theoretically, and comparing with the experimental values of  $R_\tau^{kl}$ , one determines various parameters such as  $\alpha_s$  and the quark masses. The theoretical uncertainties in using Eq. (18) arise from neglected higher order corrections (both

perturbative and non-perturbative), and because the OPE is no longer valid near the real axis, where  $\Pi$  has singularities. The contribution of neglected higher order corrections can be estimated as for any other perturbative computation. The error due to the failure of the OPE is more difficult to estimate. In Eq. (18), the OPE fails on the endpoints of  $C_2$  that touch the real axis at  $s = M_\tau^2$ . The weight factor  $(1 - s/M_\tau^2)$  in Eq. (18) vanishes at this point, so the importance of the endpoint can be reduced by choosing larger values of  $k$ .

### E. Heavy quarks

For heavy-quark physics one can exploit the fact that  $m_Q \gg \Lambda_{\text{QCD}}$  to construct effective theories ( $m_Q$  is the mass of the heavy quark  $Q$ ). The masses and decay rates of hadrons containing a single heavy quark, such as the  $B$  and  $D$  mesons can be determined using the heavy quark effective theory (HQET) [34]. The theoretical calculations involve radiative corrections computed in perturbation theory with an expansion in  $\alpha_s(m_Q)$  and non-perturbative corrections with an expansion in powers of  $\Lambda_{\text{QCD}}/m_Q$ . Due to the asymptotic nature of the QCD perturbation series, the two kinds of corrections are intimately related; an example of this are renormalon effects in the perturbative expansion which are associated with non-perturbative corrections.

Systems containing two heavy quarks such as the  $\Upsilon$  or  $J/\Psi$  are treated using non-relativistic QCD (NRQCD) [35]. The typical momentum and energy transfers in these systems are  $\alpha_s m_Q$ , and  $\alpha_s^2 m_Q$ , respectively, so these bound states are sensitive to scales much smaller than  $m_Q$ . However, smeared observables, such as the cross-section for  $e^+e^- \rightarrow \bar{b}b$  averaged over some range of  $s$  that includes several bound state energy levels, are better behaved and only sensitive to scales near  $m_Q$ . For this reason, most determinations of the  $c, b$  quark masses using perturbative calculations compare smeared observables with experiment [36–38].

There are many continuum extractions of the  $c$  and  $b$  quark masses, some with quoted errors of 10 MeV or smaller. There are systematic effects of comparable size, which are typically not included in these error estimates. Reference [30], for example, shows that even though the error estimate of  $m_c$  using the rapid convergence of the  $\alpha_s$  perturbation series is only a few MeV, the central value of  $m_c$  can differ by a much larger amount depending on which algorithm (all of which are formally equally good) is used to determine  $m_c$  from the data. This leads to a systematic error from perturbation theory of around 20 MeV for the  $c$  quark and 25 MeV for the  $b$  quark. Electromagnetic effects, which also are important at this precision, are often not included. For this reason, we inflate the errors on the continuum extractions of  $m_c$  and  $m_b$ . The average values of  $m_c$  and  $m_b$  from continuum determinations are (see Sec. G for the 1S scheme)

$$\overline{m}_c(\overline{m}_c) = (1.275 \pm 0.025) \text{ GeV}$$

$$\overline{m}_b(\overline{m}_b) = (4.18 \pm 0.03) \text{ GeV}, \quad m_b^{1S} = (4.65 \pm 0.03) \text{ GeV}.$$

Lattice simulations of QCD lead to discretization errors which are powers of  $m_Q a$  (modulated by logarithms); the power depends on the formulation of lattice QCD being used and in most cases is quadratic. Clearly these errors can be reduced by performing simulations at smaller lattice spacings, but also by using *improved* discretizations of the theory. Recently, with more powerful computing resources, better algorithms and techniques, it has become possible to perform simulations in the charm quark region and beyond, also decreasing the extrapolation which has to be performed to reach the  $b$ -quark. A novel approach proposed in [53] has been to compare the lattice results for moments of correlation functions of  $c\bar{c}$  quark-bilinear operators to perturbative calculations of the same quantities at 4-loop order. In this way both the strong coupling constant and the charm quark mass can be determined with remarkably small errors; in particular  $\overline{m}_c(\overline{m}_c) = 1.273(6) \text{ GeV}$  [26]. This lattice determination also uses the perturbative expression for the current-current correlator, and so has the perturbation theory systematic error discussed above.

Traditionally, the main approach to controlling the discretization errors in lattice studies of heavy quark physics is to perform simulations of the effective theories such as HQET and NRQCD. This remains an important technique, both in its own right and in providing additional information for extrapolations from lower masses to the bottom region. Using effective theories,  $m_b$  is obtained from what is essentially a computation of the difference of  $M_{H_b} - m_b$ , where  $M_{H_b}$  is the mass of a hadron  $H_b$  containing a  $b$ -quark. The relative error on  $m_b$  is therefore much smaller than that for  $M_{H_b} - m_b$ , and this is the reason for the small errors quoted in section G. The principal systematic errors are the matching of the effective theories to QCD and the presence of power divergences in  $a^{-1}$  in the  $1/m_b$  corrections which have to be subtracted numerically. The use of HQET or NRQCD is less precise for the charm quark, but in this case, as mentioned above, direct QCD simulations have recently become possible.

### F. Pole Mass

For an observable particle such as the electron, the position of the pole in the propagator is the definition of its mass. In QCD this definition of the quark mass is known as the pole mass. It is known that the on-shell quark propagator has no infrared divergences in perturbation theory [41,42], so this provides a perturbative definition of the quark mass. The pole mass cannot be used to arbitrarily high accuracy because of nonperturbative infrared effects in QCD. The full quark propagator has no pole because the quarks are confined, so that the pole mass cannot be defined outside of perturbation theory. The relation between the pole mass  $m_Q$  and the  $\overline{\text{MS}}$  mass  $\overline{m}_Q$  is known to three loops [43,44,45,46]

$$m_Q = \overline{m}_Q(\overline{m}_Q) \left\{ 1 + \frac{4\overline{\alpha}_s(\overline{m}_Q)}{3\pi} + \left[ -1.0414 \sum_k \left( 1 - \frac{4\overline{m}_{Qk}}{3\overline{m}_Q} \right) + 13.4434 \right] \left[ \frac{\overline{\alpha}_s(\overline{m}_Q)}{\pi} \right]^2 \right.$$

# Quark Particle Listings

## Quarks

$$+ [0.6527N_L^2 - 26.655N_L + 190.595] \left[ \frac{\bar{\alpha}_s(\bar{m}_Q)}{\pi} \right]^3 \}, \quad (19)$$

where  $\bar{\alpha}_s(\mu)$  is the strong interaction coupling constants in the  $\overline{\text{MS}}$  scheme, and the sum over  $k$  extends over the  $N_L$  flavors  $Q_k$  lighter than  $Q$ . The complete mass dependence of the  $\alpha_s^2$  term can be found in [43]; the mass dependence of the  $\alpha_s^3$  term is not known. For the  $b$ -quark, Eq. (19) reads

$$m_b = \bar{m}_b(\bar{m}_b) [1 + 0.09 + 0.05 + 0.03], \quad (20)$$

where the contributions from the different orders in  $\alpha_s$  are shown explicitly. The two and three loop corrections are comparable in size and have the same sign as the one loop term. This is a signal of the asymptotic nature of the perturbation series [there is a renormalon in the pole mass]. Such a badly behaved perturbation expansion can be avoided by directly extracting the  $\overline{\text{MS}}$  mass from data without extracting the pole mass as an intermediate step.

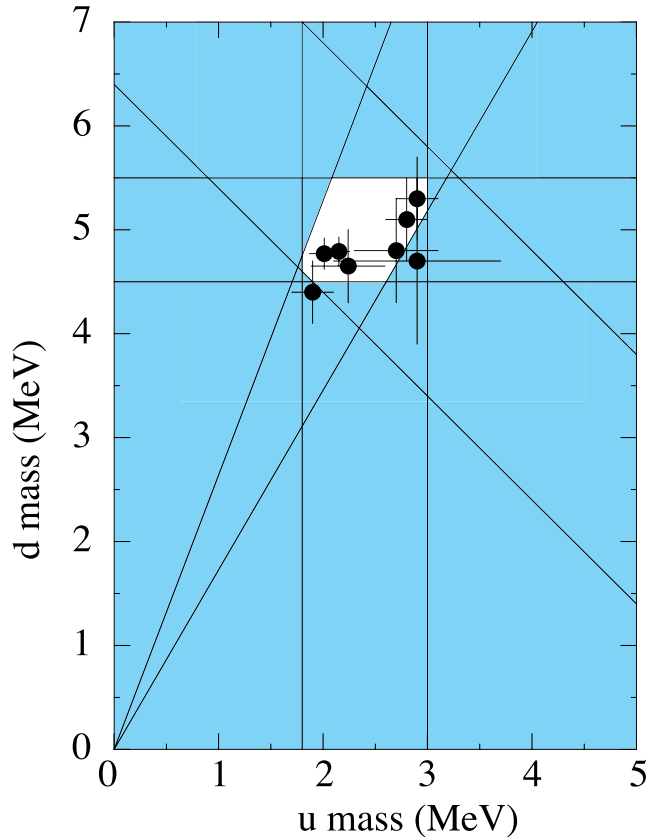

### G. Numerical values and caveats

The quark masses in the particle data listings have been obtained by using a wide variety of methods. Each method involves its own set of approximations and uncertainties. In most cases, the errors are an estimate of the size of neglected higher-order corrections or other uncertainties. The expansion parameters for some of the approximations are not very small (for example, they are  $m_K^2/\Lambda_\chi^2 \sim 0.25$  for the chiral expansion and  $\Lambda_{\text{QCD}}/m_b \sim 0.1$  for the heavy-quark expansion), so an unexpectedly large coefficient in a neglected higher-order term could significantly alter the results. It is also important to note that the quark mass values can be significantly different in the different schemes.

The heavy quark masses obtained using HQET, QCD sum rules, or lattice gauge theory are consistent with each other if they are all converted into the same scheme and scale. We have specified all masses in the  $\overline{\text{MS}}$  scheme. For light quarks, the renormalization scale has been chosen to be  $\mu = 2 \text{ GeV}$ . The light quark masses at 1 GeV are significantly different from those at 2 GeV,  $\bar{m}(1 \text{ GeV})/\bar{m}(2 \text{ GeV}) \sim 1.35$ . It is conventional to choose the renormalization scale equal to the quark mass for a heavy quark, so we have quoted  $\bar{m}_Q(\mu)$  at  $\mu = \bar{m}_Q$  for the  $c$  and  $b$  quarks. Recent analyses of inclusive  $B$  meson decays have shown that recently proposed mass definitions lead to a better behaved perturbation series than for the  $\overline{\text{MS}}$  mass, and hence to more accurate mass values. We have chosen to also give values for one of these, the  $b$  quark mass in the 1S-scheme [47,48]. Other schemes that have been proposed are the PS-scheme [49] and the kinetic scheme [50].

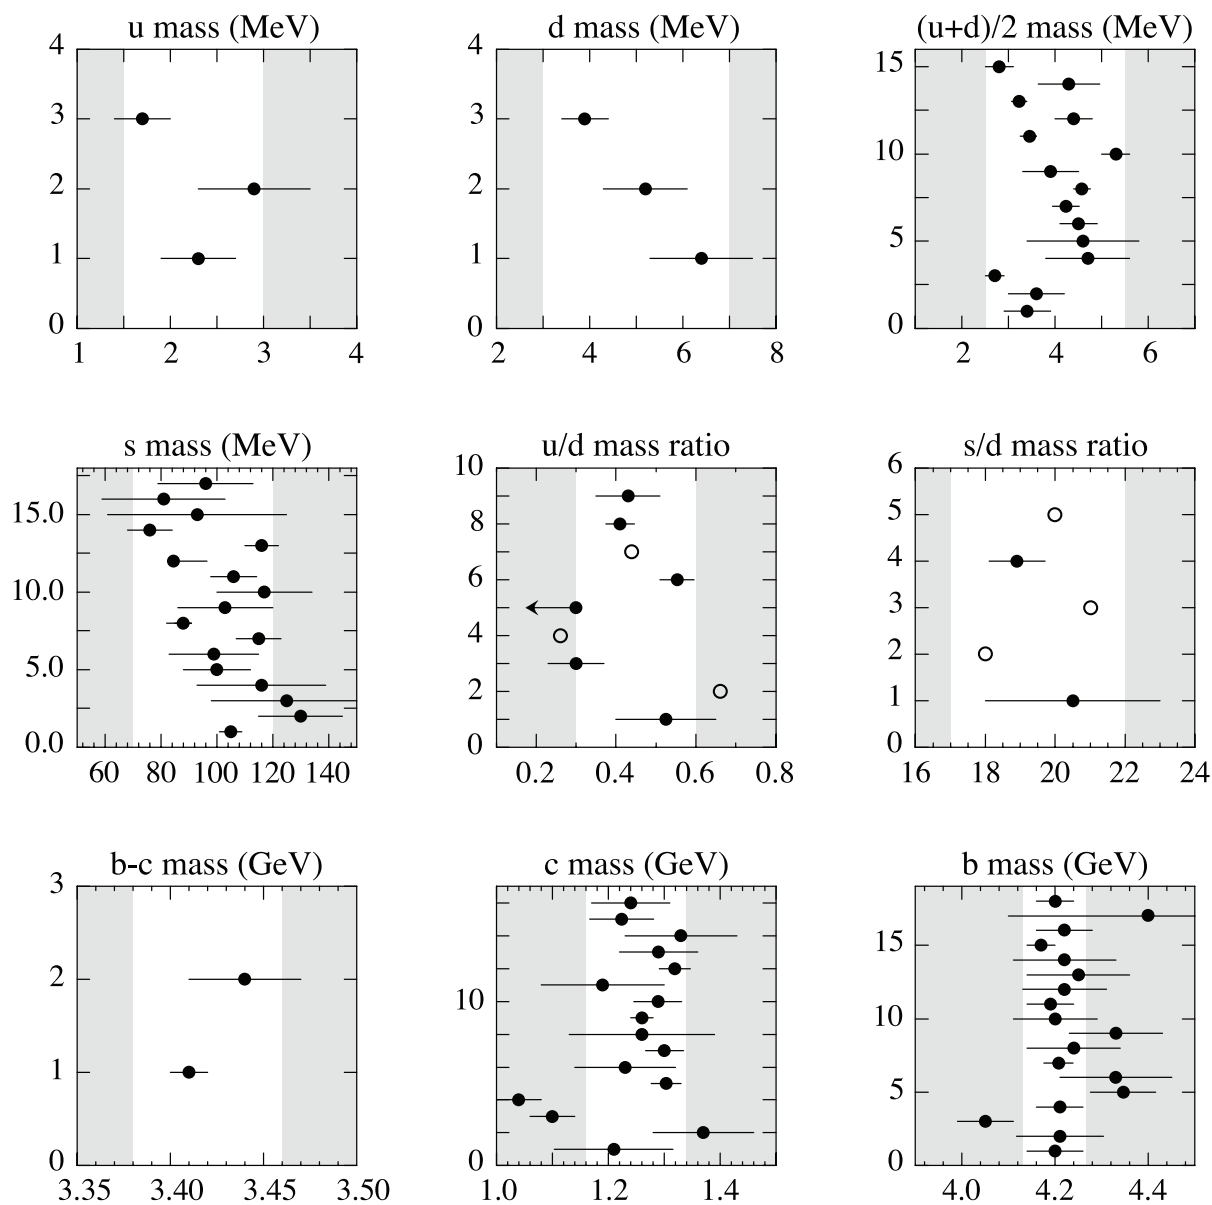

If necessary, we have converted values in the original papers to our chosen scheme using two-loop formulæ. It is important to realized that our conversions introduce significant additional errors. In converting to the  $\overline{\text{MS}}$   $b$ -quark mass, for example, the three-loop conversions from the 1S and pole masses give values about 40 MeV and 135 MeV lower than the two-loop

conversions. The uncertainty in  $\alpha_s(M_Z) = 0.1187(20)$  gives an uncertainty of  $\pm 20 \text{ MeV}$  and  $\pm 35 \text{ MeV}$  respectively in the same conversions. We have not added these additional errors when we do our conversions. The  $\alpha_s$  value in the conversion is correlated with the  $\alpha_s$  value used in determining the quark mass, so the conversion error is not a simple additional error on the quark mass.

**Figure 2:** The allowed region (shown in white) for up quark and down quark masses. This region was determined in part from papers reporting values for  $m_u$  and  $m_d$  (data points shown) and in part from analysis of the allowed ranges of other mass parameters (see Fig. 3). The parameter  $(m_u + m_d)/2$  yields the two downward-sloping lines, while  $m_u/m_d$  yields the two rising lines originating at  $(0,0)$ .

See key on page 547

**Figure 3.** The values of each quark mass parameter taken from the Data Listings. The points are in chronological order with the more recent measurements at the top. Points from papers reporting no error bars are colored grey. The shaded regions indicate values excluded by our evaluations; some regions were determined in part through examination of Fig. 2.

$$m_u/m_d = 0.38\text{--}0.58$$

**d**

$$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$$

$$\text{Mass } m = 4.8^{+0.5}_{-0.3} \text{ MeV} \quad \text{Charge} = -\frac{1}{3} e \quad I_z = -\frac{1}{2}$$

$$m_s/m_d = 17\text{--}22$$

$$\bar{m} = (m_u + m_d)/2 = 3.5^{+0.7}_{-0.2} \text{ MeV}$$

**s**

$$I(J^P) = 0(\frac{1}{2}^+)$$

$$\text{Mass } m = 95 \pm 5 \text{ MeV} \quad \text{Charge} = -\frac{1}{3} e \quad \text{Strangeness} = -1$$

$$(m_s - (m_u + m_d)/2)/(m_d - m_u) = 27.5 \pm 1.0$$

## LIGHT QUARKS ( $u$ , $d$ , $s$ )

OMITTED FROM SUMMARY TABLE

### u-QUARK MASS

The  $u$ -,  $d$ -, and  $s$ -quark masses are estimates of so-called "current-quark masses," in a mass-independent subtraction scheme such as  $\overline{\text{MS}}$ . The ratios  $m_u/m_d$  and  $m_s/m_d$  are extracted from pion and kaon masses using chiral symmetry. The estimates of  $d$  and  $u$  masses are not without controversy and remain under active investigation. Within the literature there are even suggestions that the  $u$  quark could be essentially massless. The  $s$ -quark mass is estimated from SU(3) splittings in hadron masses.

We have normalized the  $\overline{\text{MS}}$  masses at a renormalization scale of  $\mu = 2$  GeV. Results quoted in the literature at  $\mu = 1$  GeV have been rescaled by dividing by 1.35. The values of "Our Evaluation" were determined in part via Figures 1 and 2.

## Light Quarks ( $u, d, s$ )

••• We do not use the following data for averages, fits, limits, etc. •••

2.01 ± 0.14	3 DAVIES	10	LATT	$\overline{MS}$ scheme
2.9 ± 0.8	8 DEANDREA	08	THEO	$\overline{MS}$ scheme
3.02 ± 0.33	9 BLUM	07	LATT	$\overline{MS}$ scheme
1.7 ± 0.3	10 AUBIN	04A	LATT	$\overline{MS}$ scheme

1 DURR 11 determine quark mass from a lattice computation of the meson spectrum using  $N_f = 2 + 1$  dynamical flavors. The lattice simulations were done at the physical quark mass, so that extrapolation in the quark mass was not needed. The individual  $m_u, m_d$  values are obtained using the lattice determination of the average mass  $m_{ud}$  and of the ratio  $m_s/m_{ud}$  and the value of  $Q = (m_s^2 - m_{ud}^2) / (m_d^2 - m_u^2)$  as determined from  $\eta \rightarrow 3\pi$  decays.

2 BLUM 10 determines light quark masses using a QCD plus QED lattice computation of the electromagnetic mass splittings of the low-lying hadrons. The lattice simulations use 2+1 dynamical quark flavors.

3 DAVIES 10 and MCNEILE 10 determine  $\overline{m}_c(\mu)/\overline{m}_s(\mu) = 11.85 \pm 0.16$  using a lattice computation with  $N_f = 2 + 1$  dynamical fermions of the pseudoscalar meson masses. Mass  $m_s$  is obtained from this using the value of  $m_c$  from ALLISON 08 or MCNEILE 10 and the BAZAVOV 10 values for the light quark mass ratios,  $m_s/\overline{m}$  and  $m_u/m_d$ .

4 DOMINGUEZ 09 use QCD finite energy sum rules for the two-point function of the divergence of the axial vector current computed to order  $\alpha_s^4$ .

5 JAMIN 06 determine  $m_u(2 \text{ GeV})$  by combining the value of  $m_s$  obtained from the spectral function for the scalar  $K\pi$  form factor with other determinations of the quark mass ratios.

6 MASON 06 extract light quark masses from a lattice simulation using staggered fermions with an improved action, and three dynamical light quark flavors with degenerate  $u$  and  $d$  quarks. Perturbative corrections were included at NNLO order. The quark masses  $m_u$  and  $m_d$  were determined from their  $(m_u + m_d)/2$  measurement and AUBIN 04A  $m_u/m_d$  value.

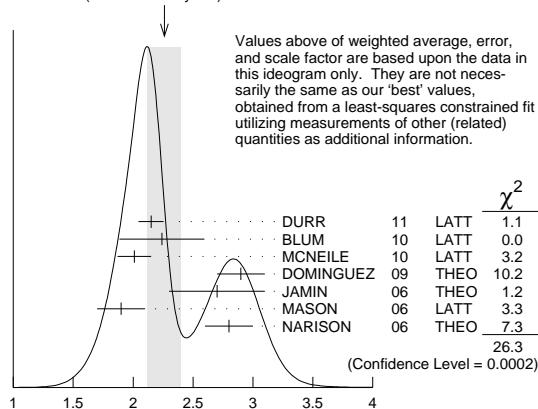

7 NARISON 06 uses sum rules for  $e^+e^- \rightarrow$  hadrons to order  $\alpha_s^3$  to determine  $m_s$  combined with other determinations of the quark mass ratios.

8 DEANDREA 08 determine  $m_u - m_d$  from  $\eta \rightarrow 3\pi^0$ , and combine with the PDG 06 lattice average value of  $m_u + m_d = 7.6 \pm 1.6$  to determine  $m_u$  and  $m_d$ .

9 BLUM 07 determine quark masses from the pseudoscalar meson masses using a QED plus QCD lattice computation with two dynamical quark flavors.

10 AUBIN 04A employ a partially quenched lattice calculation of the pseudoscalar meson masses.

- 1 AOKI 11A determine quark masses from a lattice computation of the hadron spectrum using  $N_f = 2 + 1$  dynamical flavors of domain wall fermions.
- 2 DURR 11 determine quark mass from a lattice computation of the meson spectrum using  $N_f = 2 + 1$  dynamical flavors. The lattice simulations were done at the physical quark mass, so that extrapolation in the quark mass was not needed.
- 3 BLOSSIER 10 determines quark masses from a computation of the hadron spectrum using  $N_f=2$  dynamical twisted-mass Wilson fermions.
- 4 DAVIES 10 and MCNEILE 10 determine  $\overline{m}_c(\mu)/\overline{m}_s(\mu) = 11.85 \pm 0.16$  using a lattice computation with  $N_f = 2 + 1$  dynamical fermions of the pseudoscalar meson masses. Mass  $\overline{m}$  is obtained from this using the value of  $m_c$  from ALLISON 08 or MCNEILE 10 and the BAZAVOV 10 values for the light quark mass ratio,  $m_s/\overline{m}$ .
- 5 DOMINGUEZ 09 use QCD finite energy sum rules for the two-point function of the divergence of the axial vector current computed to order  $\alpha_s^4$ .
- 6 ALLTON 08 use a lattice computation of the  $\pi, K$ , and  $\Omega$  masses with 2+1 dynamical flavors of domain wall quarks, and non-perturbative renormalization.
- 7 ISHIKAWA 08 use a lattice computation of the light meson spectrum with 2+1 dynamical flavors of  $\mathcal{O}(a)$  improved Wilson quarks, and one-loop perturbative renormalization.
- 8 BLUM 07 determine quark masses from the pseudoscalar meson masses using a QED plus QCD lattice computation with two dynamical quark flavors.
- 9 GOCKELER 06 use an unquenched lattice computation of the axial Ward Identity with  $N_f = 2$  dynamical light quark flavors, and non-perturbative renormalization, to obtain  $\overline{m}(2 \text{ GeV}) = 4.08 \pm 0.25 \pm 0.19 \pm 0.23 \text{ MeV}$ , where the first error is statistical, the second and third are systematic due to the fit range and force scale uncertainties, respectively. We have combined the systematic errors linearly.
- 10 GOCKELER 06A use an unquenched lattice computation of the pseudoscalar meson masses with  $N_f = 2$  dynamical light quark flavors, and non-perturbative renormalization.
- 11 MASON 06 extract light quark masses from a lattice simulation using staggered fermions with an improved action, and three dynamical light quark flavors with degenerate  $u$  and  $d$  quarks. Perturbative corrections were included at NNLO order.
- 12 NARISON 06 uses sum rules for  $e^+e^- \rightarrow$  hadrons to order  $\alpha_s^3$  to determine  $m_s$  combined with other determinations of the quark mass ratios.
- 13 BLOSSIER 08 use a lattice computation of pseudoscalar meson masses and decay constants with 2 dynamical flavors and non-perturbative renormalization.
- 14 DOMINGUEZ-CLARIMON 08B obtain an inequality from sum rules for the scalar two-point correlator.
- 15 NAKAMURA 08 do a lattice computation using quenched domain wall fermions and non-perturbative renormalization.
- 16 AUBIN 04 perform three flavor dynamical lattice calculation of pseudoscalar meson masses, with one-loop perturbative renormalization constant.
- 17 AOKI 03 uses quenched lattice simulation of the meson and baryon masses with degenerate light quarks. The extrapolations are done using quenched chiral perturbation theory.
- 18 The errors given in AOKI 03B were  $\pm 0.046$ . We changed them to  $\pm 0.3$  for calculating the overall best values. AOKI 03B uses lattice simulation of the meson and baryon masses with two dynamical light quarks. Simulations are performed using the  $\mathcal{O}(a)$  improved Wilson action.
- 19 BECIREVIC 03 perform quenched lattice computation using the vector and axial Ward identities. Uses  $\mathcal{O}(a)$  improved Wilson action and nonperturbative renormalization.
- 20 CHIU 03 determines quark masses from the pion and kaon masses using a lattice simulation with a chiral fermion action in quenched approximation.

0.553 ± 0.043	4 LEUTWYLER	96	THEO Compilation

- 1 BLUM 07 determine quark masses from the pseudoscalar meson masses using a QED plus QCD lattice computation with two dynamical quark flavors.
- 2 AUBIN 04A perform three flavor dynamical lattice calculation of pseudoscalar meson masses, with continuum estimate of electromagnetic effects in the kaon masses.
- 3 NELSON 03 computes coefficients in the order  $p^4$  chiral Lagrangian using a lattice calculation with three dynamical flavors. The ratio  $m_u/m_d$  is obtained by combining this with the chiral perturbation theory computation of the meson masses to order  $p^4$ .
- 4 LEUTWYLER 96 uses a combined fit to  $\eta \rightarrow 3\pi$  and  $\psi' \rightarrow J/\psi(\pi, \eta)$  decay rates, and the electromagnetic mass differences of the  $\pi$  and  $K$ .

WEIGHTED AVERAGE  
0.50±0.04 (Error scaled by 1.9)

Values above of weighted average, error, and scale factor are based upon the data in this ideogram only. They are not necessarily the same as our 'best' values, obtained from a least-squares constrained fit utilizing measurements of other (related) quantities as additional information.

### s-QUARK MASS

See the comment for the  $u$  quark above.

We have normalized the  $\overline{MS}$  masses at a renormalization scale of  $\mu = 2 \text{ GeV}$ . Results quoted in the literature at  $\mu = 1 \text{ GeV}$  have been rescaled by dividing by 1.35.

# Quark Particle Listings

## Light Quarks ( $u, d, s$ )

- 1 BODENSTEIN 13 determines  $m_s$  from QCD finite energy sum rules, and the perturbative computation of the pseudoscalar correlator to five-loop order.
- 2 FRITZSCH 12 determine  $m_s$  using a lattice computation with  $N_f = 2$  dynamical flavors.
- 3 AOKI 11A determine quark masses from a lattice computation of the hadron spectrum using  $N_f = 2 + 1$  dynamical flavors of domain wall fermions.
- 4 DURR 11 determine quark mass from a lattice computation of the meson spectrum using  $N_f = 2 + 1$  dynamical flavors. The lattice simulations were done at the physical quark mass, so that extrapolation in the quark mass was not needed.
- 5 BLOSSIER 10 determines quark masses from a computation of the hadron spectrum using  $N_f=2$  dynamical twisted-mass Wilson fermions.
- 6 BLUM 10 determines light quark masses using a QCD plus QED lattice computation of the electromagnetic mass splittings of the low-lying hadrons. The lattice simulations use 2+1 dynamical quark flavors.
- 7 DAVIES 10 and MCNEILE 10 determine  $\overline{m}_C(\mu)/\overline{m}_S(\mu) = 11.85 \pm 0.16$  using a lattice computation with  $N_f = 2 + 1$  dynamical fermions of the pseudoscalar meson masses. Mass  $m_s$  is obtained from this using the value of  $m_C$  from ALLISON 08 or MCNEILE 10.
- 8 ALLTON 08 use a lattice computation of the  $\pi, K$ , and  $\Omega$  masses with 2+1 dynamical flavors of domain wall quarks, and non-perturbative renormalization.
- 9 DOMINGUEZ 08A make determination from QCD finite energy sum rules for the pseudoscalar two-point function computed to order  $\alpha_s^4$ .
- 10 ISHIKAWA 08 use a lattice computation of the light meson spectrum with 2+1 dynamical flavors of  $\mathcal{O}(a)$  improved Wilson quarks, and one-loop perturbative renormalization.
- 11 CHETYSRKIN 06 use QCD sum rules in the pseudoscalar channel to order  $\alpha_s^4$ .
- 12 GOCKELER 06 use an unquenched lattice computation of the axial Ward Identity with  $N_f = 2$  dynamical light quark flavors, and non-perturbative renormalization, to obtain  $\overline{m}_S(2 \text{ GeV}) = 111 \pm 6 \pm 4 \pm 6 \text{ MeV}$ , where the first error is statistical, the second and third are systematic due to the fit range and force scale uncertainties, respectively. We have combined the systematic errors linearly.
- 13 GOCKELER 06A use an unquenched lattice computation of the pseudoscalar meson masses with  $N_f = 2$  dynamical light quark flavors, and non-perturbative renormalization.
- 14 JAMIN 06 determine  $\overline{m}_S(2 \text{ GeV})$  from the spectral function for the scalar  $K\pi$  form factor.
- 15 MASON 06 extract light quark masses from a lattice simulation using staggered fermions with an improved action, and three dynamical light quark flavors with degenerate  $u$  and  $d$  quarks. Perturbative corrections were included at NNLO order.
- 16 NARISON 06 uses sum rules for  $e^+e^- \rightarrow \text{hadrons}$  to order  $\alpha_s^3$ .
- 17 BLOSSIER 08 use a lattice computation of pseudoscalar meson masses and decay constants with 2 dynamical flavors and non-perturbative renormalization.
- 18 NAKAMURA 08 do a lattice computation using quenched domain wall fermions and non-perturbative renormalization.
- 19 BLUM 07 determine quark masses from the pseudoscalar meson masses using a QED plus QCD lattice computation with two dynamical quark flavors.
- 20 NARISON 06 obtains the quoted range from positivity of the spectral functions.
- 21 BAIKOV 05 determines  $\overline{m}_S(M_\tau) = 100 \frac{+5}{-3} \frac{+17}{-19}$  from sum rules using the strange spectral function in  $\tau$  decay. The computations were done to order  $\alpha_s^3$ , with an estimate of the  $\alpha_s^4$  terms. We have converted the result to  $\mu = 2 \text{ GeV}$ .
- 22 GAMIZ 05 determines  $\overline{m}_S(2 \text{ GeV})$  from sum rules using the strange spectral function in  $\tau$  decay. The computations were done to order  $\alpha_s^2$ , with an estimate of the  $\alpha_s^3$  terms.
- 23 GORBUNOV 05 use hadronic tau decays to  $N^3\text{LO}$ , including power corrections.
- 24 NARISON 05 determines  $\overline{m}_S(2 \text{ GeV})$  from sum rules using the strange spectral function in  $\tau$  decay. The computations were done to order  $\alpha_s^3$ .
- 25 AUBIN 04 perform three flavor dynamical lattice calculation of pseudoscalar meson masses, with one-loop perturbative renormalization constant.
- 26 AOKI 03 uses quenched lattice simulation of the meson and baryon masses with degenerate light quarks. The extrapolations are done using quenched chiral perturbation theory. Determines  $m_s = 113.8 \pm 2.3 \pm 5.8$  using  $K$  mass as input and  $m_s = 142.3 \pm 5.8 \pm 2.0$  using  $\phi$  mass as input. We have performed a weighted average of these values.
- 27 AOKI 03B uses lattice simulation of the meson and baryon masses with two dynamical light quarks. Simulations are performed using the  $\mathcal{O}(a)$  improved Wilson action.
- 28 BEGREVIC 03 perform quenched lattice computation using the vector and axial Ward identities. Uses  $\mathcal{O}(a)$  improved Wilson action and nonperturbative renormalization. They also quote  $\overline{m}/m_s = 24.3 \pm 0.2 \pm 0.6$ .
- 29 CHIU 03 determines quark masses from the pion and kaon masses using a lattice simulation with a chiral fermion action in quenched approximation.
- 30 GAMIZ 03 determines  $m_s$  from SU(3) breaking in the  $\tau$  hadronic width. The value of  $V_{us}$  is chosen to satisfy CKM unitarity.
- 31 GAMIZ 03 determines  $m_s$  from SU(3) breaking in the  $\tau$  hadronic width. The value of  $V_{us}$  is taken from the PDG.

18 to 23	5 LEUTWYLER 90B	THEO	

- 1 GAO 97 uses electromagnetic mass splittings of light mesons.
- 2 LEUTWYLER 96 uses a combined fit to  $\eta \rightarrow 3\pi$  and  $\psi' \rightarrow J/\psi(\pi, \eta)$  decay rates, and the electromagnetic mass differences of the  $\pi$  and  $K$ .
- 3 DONOGHUE 92 result is from a combined analysis of meson masses,  $\eta \rightarrow 3\pi$  using second-order chiral perturbation theory including nonanalytic terms, and  $(\psi(2S) \rightarrow J/\psi(1S)\pi)/(\psi(2S) \rightarrow J/\psi(1S)\eta)$ .
- 4 GERARD 90 uses large  $N$  and  $\eta$ - $\eta'$  mixing.
- 5 LEUTWYLER 90B determines quark mass ratios using second-order chiral perturbation theory for the meson and baryon masses, including nonanalytic corrections. Also uses Weinberg sum rules to determine  $L_7$ .

### c-QUARK MASS

The  $c$ -quark mass corresponds to the "running" mass  $m_c(\mu = m_c)$  in the  $\overline{\text{MS}}$  scheme. We have converted masses in other schemes to the  $\overline{\text{MS}}$  scheme using two-loop QCD perturbation theory with  $\alpha_s(\mu = m_c) = 0.38 \pm 0.03$ . The value  $1.275 \pm 0.025$  GeV for the  $\overline{\text{MS}}$  mass corresponds to  $1.67 \pm 0.07$  GeV for the pole mass (see the "Note on Quark Masses").

- 1 ABRAMOWICZ 13c determines  $m_c$  from charm production in deep inelastic  $ep$  scattering, using the QCD prediction at NLO order. The uncertainties from model and parameterization assumptions, and the value of  $\alpha_s$  of  $\pm 0.03$ ,  $\pm 0.02$ , and  $\pm 0.02$  respectively, have been combined in quadrature.
- 2 ALEKHIN 13 determines  $m_c$  from charm production in deep inelastic scattering at HERA using approximate NNLO QCD.
- 3 DEHNADI 13 determines  $m_c$  using QCD sum rules for the charmonium spectrum and charm continuum to order  $\alpha_s^3$  (N3LO). The statistical and systematic experimental errors of  $\pm 0.006$  and  $\pm 0.009$  have been combined in quadrature. The theoretical uncertainties  $\pm 0.019$  from truncation of the perturbation series,  $\pm 0.010$  from  $\alpha_s$ , and  $\pm 0.002$  from the gluon condensate have been combined in quadrature.
- 4 NARISON 13 determines  $m_c$  using QCD spectral sum rules to order  $\alpha_s^2$  (NNLO) and including condensates up to dimension 6.
- 5 SAMOYLOV 13 determines  $m_c$  from a study of charm dimuon production in neutrino-iron scattering using the NLO QCD result for the charm quark vector current cross section.
- 6 ALEKHIN 12 determines  $m_c$  from heavy quark production in deep inelastic scattering at HERA using approximate NNLO QCD.
- 7 NARISON 12A determines  $m_c$  using sum rules for the vector current correlator to order  $\alpha_s^3$ , including the effect of gluon condensates up to dimension eight.
- 8 BODENSTEIN 11 determine  $\overline{m}_c(3 \text{ GeV}) = 0.987 \pm 0.009$  GeV and  $\overline{m}_c(\overline{m}_c) = 1.278 \pm 0.009$  GeV using QCD sum rules for the charm quark vector current correlator.
- 9 LASCHKA 11 determine the  $c$  mass from the charmonium spectrum. The theoretical computation uses the heavy  $Q\overline{Q}$  potential to order  $1/m_Q$  obtained by matching the short-distance perturbative result onto lattice QCD result at larger scales.
- 10 AUBERT 10A determine the  $b$ - and  $c$ -quark masses from a fit to the inclusive decay spectra in semileptonic  $B$  decays in the kinetic scheme (and convert it to the  $\overline{\text{MS}}$  scheme).
- 11 BLOSSIER 10 determines quark masses from a computation of the hadron spectrum using  $N_f=2$  dynamical twisted-mass Wilson fermions.
- 12 MCNEILE 10 determines  $m_c$  by comparing the order  $\alpha_s^3$  perturbative results for the pseudo-scalar current to lattice simulations with  $N_f = 2+1$  sea-quarks by the HPQCD collaboration.
- 13 CHETYRKIN 09 determine  $m_c$  and  $m_b$  from the  $e^+ e^- \rightarrow Q\overline{Q}$  cross-section and sum rules, using an order  $\alpha_s^3$  computation of the heavy quark vacuum polarization. They also determine  $m_c(3 \text{ GeV}) = 0.986 \pm 0.013$  GeV.
- 14 SIGNER 09 determines the  $c$ -quark mass using non-relativistic sum rules to analyze the  $e^+ e^- \rightarrow c\overline{c}$  cross-section near threshold. Also determine the PS mass  $m_{PS}(\mu_F = 0.7 \text{ GeV}) = 1.50 \pm 0.04$  GeV.
- 15 BOUGHEZAL 06 result comes from the first moment of the hadronic production cross-section to order  $\alpha_s^3$ .
- 16 BUCHMULLER 06 determine  $m_b$  and  $m_c$  by a global fit to inclusive  $B$  decay spectra.
- 17 HOANG 06 determines  $\overline{m}_c(\overline{m}_c)$  from a global fit to inclusive  $B$  decay data. The  $B$  decay distributions were computed to order  $\alpha_s^3/\beta_0$ , and the conversion between different  $m_c$  mass schemes to order  $\alpha_s^3$ .

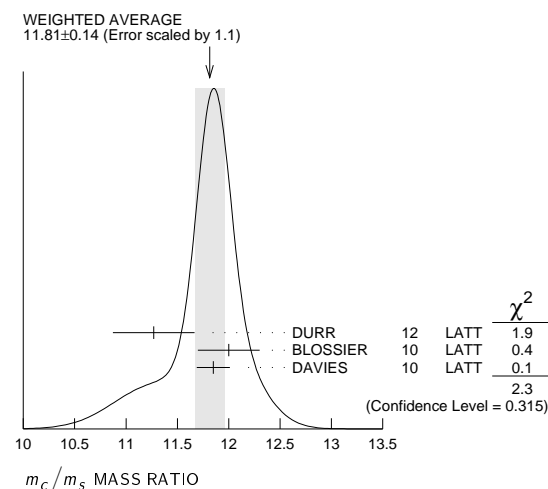

See key on page 547

- <sup>18</sup> ALEKHIN 11 determines  $m_c$  from heavy quark production in deep inelastic scattering using fixed target and HERA data, and approximate NNLO QCD.
- <sup>19</sup> BODENSTEIN 10 determines  $\overline{m}_c(3 \text{ GeV}) = 1.008 \pm 0.026 \text{ GeV}$  using finite energy sum rules for the vector current correlator. The authors have converted this to  $\overline{m}_c(\overline{m}_c)$  using  $\alpha_s(M_Z) = 0.1189 \pm 0.0020$ .
- <sup>20</sup> NARISON 10 determines  $m_c$  from ratios of moments of vector current correlators computed to order  $\alpha_s^3$  and including the dimension-six gluon condensate.
- <sup>21</sup> ALLISON 08 determine  $m_c$  by comparing four-loop perturbative results for the pseudoscalar current correlator to lattice simulations by the HPQCD collaboration. The result has been updated in MCNEILE 10.
- <sup>22</sup> KUHN 07 determine  $\overline{m}_c(\mu = 3 \text{ GeV}) = 0.986 \pm 0.013 \text{ GeV}$  and  $\overline{m}_c(\overline{m}_c)$  from a four-loop sum-rule computation of the cross-section for  $e^+e^- \rightarrow$  hadrons in the charm threshold region.
- <sup>23</sup> AUBERT 04x obtain  $m_c$  from a fit to the hadron mass and lepton energy distributions in semileptonic  $B$  decay. The paper quotes values in the kinetic scheme. The  $\overline{M_S}$  value has been provided by the BABAR collaboration.
- <sup>24</sup> HOANG 04 determines  $\overline{m}_c(\overline{m}_c)$  from moments at order  $\alpha_s^2$  of the charm production cross-section in  $e^+e^-$  annihilation.
- <sup>25</sup> DEDIVITIS 03 use a quenched lattice computation of heavy-heavy and heavy-light meson masses.
- <sup>26</sup> EIDEMULLER 03 determines  $m_b$  and  $m_c$  using QCD sum rules.
- <sup>27</sup> ERLER 03 determines  $m_b$  and  $m_c$  using QCD sum rules. Includes recent BES data.
- <sup>28</sup> ZYABLYUK 03 determines  $m_c$  by using QCD sum rules in the pseudoscalar channel and comparing with the  $\eta_c$  mass.

 **$m_c/m_s$  MASS RATIO**

VALUE	DOCUMENT ID	TECN
<b>11.81±0.14 OUR AVERAGE</b>	Error includes scale factor of 1.1. See the ideogram below.

$$J(P) = 0(\frac{1}{2}^+)$$

Charge =  $-\frac{1}{3} e$  Bottom =  $-1$

**b-QUARK MASS**

The first value is the "running mass"  $\overline{m}_b(\mu = \overline{m}_b)$  in the  $\overline{M_S}$  scheme, and the second value is the  $1S$  mass, which is half the mass of the  $T(1S)$  in perturbation theory. For a review of different quark mass definitions and their properties, see EL-KHADRA 02. The  $1S$  mass is better suited for use in analyzing  $B$  decays than the  $\overline{M_S}$  mass because it gives a stable perturbative expansion. We have converted masses in other schemes to the  $\overline{M_S}$  mass and  $1S$  mass using two-loop QCD perturbation theory with  $\alpha_s(\mu = \overline{m}_b) = 0.223 \pm 0.008$ . The values  $4.18 \pm 0.03 \text{ GeV}$  for the  $\overline{M_S}$  mass and  $4.66 \pm 0.03 \text{ GeV}$  for the  $1S$  mass correspond to  $4.78 \pm 0.06 \text{ GeV}$  for the pole mass, using the two-loop conversion formula. A discussion of masses in different schemes can be found in the "Note on Quark Masses."

- 1 LEE 130 determines  $m_b$  using lattice calculations of the  $\Upsilon$  and  $B_s$  binding energies in NRQCD, including three light dynamical quark flavors. The quark mass shift in NRQCD is determined to order  $\alpha_s^2$ , with partial  $\alpha_s^3$  contributions.
- 2 LUCHA 13 determines  $m_b$  from QCD sum rules for heavy-light currents using the lattice value for  $f_B$  of  $191.5 \pm 7.3$  GeV.
- 3 NARISON 13 determines  $m_b$  using QCD spectral sum rules to order  $\alpha_s^2$  (NNLO) and including condensates up to dimension 6. We have converted the  $\overline{MS}$  value to the 1S scheme.
- 4 NARISON 13A determines  $m_b$  using HQET sum rules to order  $\alpha_s^2$  (NNLO) and the  $B$  meson mass and decay constant.
- 5 BODENSTEIN 12 determine  $m_b$  using sum rules for the vector current correlator and the  $e^+e^- \rightarrow Q\bar{Q}$  total cross-section. We have converted  $\overline{m}_b(\overline{m}_b)$  to the 1S scheme.
- 6 DIMOPOULOS 12 determine quark masses from a lattice computation using  $N_f = 2$  dynamical flavors of twisted mass fermions. We have converted  $\overline{m}_b(\overline{m}_b)$  to the 1S scheme.
- 7 HOANG 12 determine  $m_b$  using non-relativistic sum rules for the  $\Upsilon$  system at order  $\alpha_s^2$  (NNLO) with renormalization group improvement.
- 8 Determines  $m_b$  to order  $\alpha_s^3$  (N3LO), including the effect of gluon condensates up to dimension eight combining the methods of NARISON 12 and NARISON 12A. We have converted  $\overline{m}_b(\overline{m}_b)$  to the 1S scheme.
- 9 LASCHKA 11 determine the  $b$  mass from the charmonium spectrum. The theoretical computation uses the heavy  $Q\bar{Q}$  potential to order  $1/m_Q$  obtained by matching the short-distance perturbative result onto lattice QCD result at larger scales. We have converted  $\overline{m}_b(\overline{m}_b)$  to the 1S scheme.
- 10 AUBERT 10A determine the  $b$ - and  $c$ -quark masses from a fit to the inclusive decay spectra in semileptonic  $B$  decays in the kinetic scheme (and convert it to the  $\overline{MS}$  scheme). We have converted this to the 1S scheme.
- 11 MCNEILE 10 determines  $m_b$  by comparing order  $\alpha_s^3$  (N3LO) perturbative results for the pseudo-scalar current to lattice simulations with  $N_f = 2+1$  sea-quarks by the HPQCD collaboration. We have converted  $\overline{m}_b(\overline{m}_b)$  to the 1S scheme.
- 12 CHETYRKIN 09 determine  $m_c$  and  $m_b$  from the  $e^+e^- \rightarrow Q\bar{Q}$  cross-section and sum rules, using an order  $\alpha_s^3$  (N3LO) computation of the heavy quark vacuum polarization. We have converted their  $m_b$  to the 1S scheme.
- 13 ABDALLAH 08D determine  $\overline{m}_b(M_Z) = 3.76 \pm 1.0$  GeV from a leading order study of four-jet rates at LEP. We have converted this to  $\overline{m}_b(\overline{m}_b)$  and  $m_b^{1S}$ .
- 14 SCHWANDA 08 measure moments of the inclusive photon spectrum in  $B \rightarrow X_s \gamma$  decay to determine  $m_b^{1S}$ . We have converted this to  $\overline{MS}$  scheme.
- 15 ABDALLAH 06D determine  $m_b(M_Z) = 2.85 \pm 0.32$  GeV from Z-decay three-jet events containing a  $b$ -quark. We have converted this to  $\overline{m}_b(\overline{m}_b)$  and  $m_b^{1S}$ .
- 16 BOUGHEZAL 06  $\overline{MS}$  scheme result comes from the first moment of the hadronic production cross-section to order  $\alpha_s^3$ . We have converted it to the 1S scheme.
- 17 BUCHMULLER 06 determine  $m_b$  and  $m_c$  by a global fit to inclusive  $B$  decay spectra. We have converted this to the 1S scheme.
- 18 PINEDA 06  $\overline{MS}$  scheme result comes from a partial NNLL evaluation (complete at order  $\alpha_s^2$  (NNLO)) of sum rules of the bottom production cross-section in  $e^+e^-$  annihilation. We have converted it to the 1S scheme.
- 19 BAUER 04 determine  $m_b$ ,  $m_c$  and  $m_b - m_c$  by a global fit to inclusive  $B$  decay spectra. We have converted  $m_b$  to the 1S scheme.
- 20 HOANG 04 determines  $\overline{m}_b(\overline{m}_b)$  from moments at order  $\alpha_s^2$  of the bottom production cross-section in  $e^+e^-$  annihilation.
- 22 BORDES 03 determines  $m_b$  using QCD finite energy sum rules to order  $\alpha_s^2$ .
- 23 CORCELLA 03 determines  $\overline{m}_b$  using sum rules computed to order  $\alpha_s^2$ . Includes charm quark mass effects.
- 24 EIDEMULLER 03 determines  $\overline{m}_b$  and  $\overline{m}_c$  using QCD sum rules.
- 25 ERLER 03 determines  $\overline{m}_b$  and  $\overline{m}_c$  using QCD sum rules. Includes recent BES data.
- 26 MAHMOOD 03 determines  $m_b^{1S}$  by a fit to the lepton energy moments in  $B \rightarrow X_c \ell \nu_\ell$  decay. The theoretical expressions used are of order  $1/m^3$  and  $\alpha_s^2 \beta_0$ . We have converted their result to the  $\overline{MS}$  scheme.
- 27 BRAMBILLA 02 determine  $\overline{m}_b(\overline{m}_b)$  from a computation of the  $\Upsilon(1S)$  mass to order  $\alpha_s^4$ , including finite  $m_c$  corrections. We have converted this to the 1S scheme.
- 28 PENIN 02 determines  $\overline{m}_b$  from the spectrum of the  $\Upsilon$  system.
- 29 NARISON 12 determines  $m_b$  using exponential sum rules for the vector current correlator to order  $\alpha_s^2$ , including the effect of gluon condensates up to dimension eight. We have converted  $\overline{m}_b(\overline{m}_b)$  to the 1S scheme.
- 30 NARISON 12A determines  $m_b$  using sum rules for the vector current correlator to order  $\alpha_s^3$ , including the effect of gluon condensates up to dimension eight. We have converted  $\overline{m}_b(\overline{m}_b)$  to the 1S scheme.

- 31 NARISON 10 determines  $m_b$  from ratios of moments of vector current correlators computed to order  $\alpha_s^3$  and including the dimension-six gluon condensate. These values are taken from the erratum to that reference.
- 32 GUZZINI 08 determine  $\overline{m}_b(\overline{m}_b)$  from a quenched lattice simulation of heavy meson masses. The  $\pm 0.08$  is an estimate of the quenching error. We have converted these values to the 1S scheme.
- 33 DELLA-MORTE 07 determine  $\overline{m}_b(\overline{m}_b)$  from a computation of the spin-averaged  $B$  meson mass using quenched lattice HQET at order  $1/m$ . The  $\pm 0.08$  is an estimate of the quenching error.
- 34 KUHN 07 determine  $\overline{m}_b(\mu = 10 \text{ GeV}) = 3.609 \pm 0.025$  GeV and  $\overline{m}_b(\overline{m}_b)$  from a four-loop sum-rule computation of the cross-section for  $e^+e^- \rightarrow$  hadrons in the bottom threshold region. We have converted this to the 1S scheme.
- 35 GRAY 05 determines  $\overline{m}_b(\overline{m}_b)$  from a lattice computation of the  $\Upsilon$  spectrum. The simulations have  $2+1$  dynamical light flavors. The  $b$  quark is implemented using NRQCD.
- 36 AUBERT 04X obtain  $m_b$  from a fit to the hadron mass and lepton energy distributions in semileptonic  $B$  decay. The paper quotes values in the kinetic scheme. The  $\overline{MS}$  value has been provided by the BABAR collaboration, and we have converted this to the 1S scheme.
- 37 MCNEILE 04 use lattice QCD with dynamical light quarks and a static heavy quark to compute the masses of heavy-light mesons.
- 38 BAUER 03 determine the  $b$  quark mass by a global fit to  $B$  decay observables. The experimental data includes lepton energy and hadron invariant mass moments in semileptonic  $B \rightarrow X_c \ell \nu_\ell$  decay, and the inclusive photon spectrum in  $B \rightarrow X_s \gamma$  decay. The theoretical expressions used are of order  $1/m^3$ , and  $\alpha_s^2 \beta_0$ .
- 39 DEDIVITIIS 03 use a quenched lattice computation of heavy-heavy and heavy-light meson masses.

**THE TOP QUARK**

Updated September 2013 by T.M. Liss (Univ. Illinois), F. Maltoni (Univ. Catholique de Louvain), and A. Quadt (Univ. Göttingen).

**A. Introduction**

The top quark is the  $Q = 2/3$ ,  $T_3 = +1/2$  member of the weak-isospin doublet containing the bottom quark (see the review on the “Electroweak Model and Constraints on New Physics” for more information). Its phenomenology is driven by its large mass. Being heavier than a  $W$  boson, it is the only quark that decays semi-weakly, i.e., into a real  $W$  boson and a  $b$  quark, before hadronization can occur. In addition, it is the only quark whose Yukawa coupling to the Higgs boson is order of unity. For these reasons the top quark plays a special role in the Standard Model (SM) and in many extensions thereof. An accurate knowledge of its properties (mass, couplings, production cross section, decay branching ratios, *etc.*) can bring key information on fundamental interactions at the electroweak breaking scale and beyond. This review provides a concise discussion of the experimental and theoretical issues involved in the determination the top-quark properties.

**B. Top-quark production at the Tevatron and LHC**

In hadron collisions, top quarks are produced dominantly in pairs through the processes  $q\bar{q} \rightarrow t\bar{t}$  and  $gg \rightarrow t\bar{t}$ , at leading order in QCD. Approximately 85% of the production cross section at the Tevatron is from  $q\bar{q}$  annihilation, with the remainder from gluon-gluon fusion, while at LHC energies about 90% of the production is from the latter process at  $\sqrt{s} = 14$  TeV ( $\approx 80\%$  at  $\sqrt{s} = 7$  TeV).

Predictions for the total cross sections are now available at next-to-next-to leading order (NNLO) with next-to-next-to-leading-log (NNLL) soft gluon resummation [1]. These results supersede previous approximated ones [2]. Assuming a top-quark mass of  $173.3$  GeV/ $c^2$ , close to the world average [3] (LHC results not yet included), the resulting theoretical prediction of the top-quark pair cross-section at NNLO+NNLL accuracy at the Tevatron at  $\sqrt{s} = 1.96$  TeV is  $\sigma_{t\bar{t}} = 7.164^{+0.11+0.17}_{-0.20-0.12}$  pb where the first uncertainty is from scale dependence and the second from parton distribution functions, while at the LHC at  $\sqrt{s} = 7$  TeV (8 TeV) is  $\sigma_{t\bar{t}} = 172.0^{+4.4+4.7}_{-5.8-4.8}$  pb ( $\sigma_{t\bar{t}} = 245.8^{+6.2+6.2}_{-8.4-6.4}$  pb).

Electroweak single top-quark production mechanisms, namely from  $q\bar{q}' \rightarrow t\bar{b}$  [4],  $qb \rightarrow q't$  [5], mediated by virtual  $s$ -channel and  $t$ -channel  $W$ -bosons, and  $Wt$ -associated production, through  $bg \rightarrow W^-t$ , lead to somewhat smaller cross sections. For example,  $t$ -channel production, while suppressed by the weak coupling with respect to the strong pair production,

is kinematically enhanced, resulting in a sizable cross section both at Tevatron and LHC energies. At the Tevatron, the  $t$ - and  $s$ -channel cross sections of top and antitop are identical, while at the LHC they are not. Approximate NNLO cross sections for  $t$ -channel single top-quark production ( $t + \bar{t}$ ) are calculated for  $m_t = 173.3$  GeV/ $c^2$  to be  $2.06^{+0.13}_{-0.13}$  pb in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV (scale and parton distribution functions uncertainties are combined in quadrature) and  $65.7^{+1.9}_{-1.9}$  ( $87.1^{+0.24}_{-0.24}$ ) pb in  $pp$  collisions at  $\sqrt{s} = 7$  (8) TeV, where 65% and 35% are the relative proportions of  $t$  and  $\bar{t}$  [6]. For the  $s$ -channel, these calculations yield  $1.03^{+0.05}_{-0.05}$  pb for the Tevatron, and  $4.5^{+0.2}_{-0.2}$  ( $5.5^{+0.2}_{-0.2}$ ) pb for  $\sqrt{s} = 7$  (8) TeV at the LHC, with 69% (31%) of top (anti-top) quarks [7]. While negligible at the Tevatron, at LHC energies the  $Wt$ -associated production becomes relevant. At  $\sqrt{s} = 7$  (8) TeV, an approximate NNLO calculation using the MSTW2008 PDF gives  $15.5^{+1.2}_{-1.2}$  ( $22.1^{+1.5}_{-1.5}$ ) pb ( $t + \bar{t}$ ), with an equal proportion of top and anti-top quarks [8].

Assuming  $|V_{tb}| \gg |V_{td}|, |V_{ts}|$  (see the review “The CKM Quark-Mixing Matrix” for more information), the cross sections for single top production are proportional to  $|V_{tb}|^2$ , and no extra hypothesis is needed on the number of quark families or on the unitarity of the CKM matrix in extracting  $|V_{tb}|$ . Separate measurements of the  $s$ - and  $t$ -channel processes provide sensitivity to physics beyond the Standard Model [9].

With a mass above the  $Wb$  threshold, and  $|V_{tb}| \gg |V_{td}|, |V_{ts}|$ , the decay width of the top quark is expected to be dominated by the two-body channel  $t \rightarrow Wb$ . Neglecting terms of order  $m_b^2/m_t^2$ ,  $\alpha_s^2$ , and  $(\alpha_s/\pi)M_W^2/m_t^2$ , the width predicted in the SM at NLO is [10]:

$$\Gamma_t = \frac{G_F m_t^3}{8\pi\sqrt{2}} \left(1 - \frac{M_W^2}{m_t^2}\right)^2 \left(1 + 2\frac{M_W^2}{m_t^2}\right) \left[1 - \frac{2\alpha_s}{3\pi} \left(\frac{2\pi^2}{3} - \frac{5}{2}\right)\right], \quad (1)$$

where  $m_t$  refers to the top-quark pole mass. The width for a value of  $m_t = 173.3$  GeV/ $c^2$  is  $1.35$  GeV/ $c^2$  (we use  $\alpha_s(M_Z) = 0.118$ ) and increases with mass. With its correspondingly short lifetime of  $\approx 0.5 \times 10^{-24}$  s, the top quark is expected to decay before top-flavored hadrons or  $t\bar{t}$ -quarkonium-bound states can form [11]. In fact, since the decay time is close to the would-be-resonance binding time, a peak will be visible in  $e^+e^-$  scattering at the  $t\bar{t}$  threshold [12] and it is in principle present (yet very difficult to measure) in hadron collisions, too [13]. The order  $\alpha_s^2$  QCD corrections to  $\Gamma_t$  are also available [14], thereby improving the overall theoretical accuracy to better than 1%.

The final states for the leading pair-production process can be divided into three classes:

- $t\bar{t} \rightarrow W^+ b W^- \bar{b} \rightarrow q\bar{q}' b q'' \bar{q}'' \bar{b}$ , (45.7%)
- $t\bar{t} \rightarrow W^+ b W^- \bar{b} \rightarrow q\bar{q}' b \ell^- \bar{\nu}_\ell \bar{b} + \ell^+ \nu_\ell b q'' \bar{q}'' \bar{b}$ , (43.8%)
- $t\bar{t} \rightarrow W^+ b W^- \bar{b} \rightarrow \bar{\ell} \nu_\ell b \ell' \bar{\nu}_{\ell'}$ . (10.5%)

The quarks in the final state evolve into jets of hadrons. A, B, and C are referred to as the all-jets, lepton+jets ( $\ell$ +jets), and dilepton ( $\ell\ell$ ) channels, respectively. Their relative contributions, including hadronic corrections, are given in parentheses assuming lepton universality. While  $\ell$  in the above processes

# Quark Particle Listings

*t*

refers to  $e$ ,  $\mu$ , or  $\tau$ , most of the analyses distinguish the  $e$  and  $\mu$  from the  $\tau$  channel, which is more difficult to reconstruct. Therefore, in what follows, we will use  $\ell$  to refer to  $e$  or  $\mu$ , unless otherwise noted. Here, typically leptonic decays of  $\tau$  are included. In addition to the quarks resulting from the top-quark decays, extra QCD radiation (quarks and gluons) from the colored particles in the event can lead to extra jets.

The number of jets reconstructed in the detectors depends on the decay kinematics, as well as on the algorithm for reconstructing jets used by the analysis. Information on the transverse momenta of neutrinos is obtained from the imbalance in transverse momentum measured in each event (missing  $p_T$ , which is here also called missing  $E_T$ ).

The identification of top quarks in the electroweak single top channel is much more difficult than in the QCD  $t\bar{t}$  channel, due to a less distinctive signature and significantly larger backgrounds, mostly due to  $t\bar{t}$  and  $W$ +jets production.

Fully exclusive predictions via Monte Carlo generators for the  $t\bar{t}$  and single top production processes at NLO accuracy in QCD, including top-quark decays, are available [15,16] through the MC@NLO [17] and POWHEG [18] methods.

Besides fully inclusive QCD or EW top-quark production, more exclusive final states can be accessed at hadron colliders, whose cross sections are typically much smaller, yet can provide key information on the properties of the top quark. For all relevant final states (*e.g.*,  $t\bar{t}\gamma$ ,  $t\bar{t}Z$ ,  $t\bar{t}W$ ,  $t\bar{t}H$ ,  $t\bar{t}$ +jets,  $t\bar{t}b\bar{b}$ ,  $t\bar{t}t\bar{t}$ ) automatic or semi-automatic predictions at NLO accuracy in QCD also in the form of event generators, *i.e.*, interfaced to parton-shower programs, are available (see the review “Monte Carlo event generators” for more information).

## C. Top-quark measurements

Since the discovery of the top quark, direct measurements of  $t\bar{t}$  production have been made at four center-of-mass energies, providing stringent tests of QCD. The first measurements were made in Run I at the Tevatron at  $\sqrt{s} = 1.8$  TeV. In Run II at the Tevatron relatively precise measurements were made at  $\sqrt{s} = 1.96$  TeV. Finally, beginning in 2010, measurements have been made at the LHC at  $\sqrt{s} = 7$  TeV and  $\sqrt{s} = 8$  TeV.

Production of single top quarks through electroweak interactions has now been measured with good precision at the Tevatron at  $\sqrt{s} = 1.96$  TeV, and at the LHC at both  $\sqrt{s} = 7$  TeV and  $\sqrt{s} = 8$  TeV. Recent measurements at the Tevatron are beginning to separate the  $s$ - and  $t$ -channel production cross sections, and at the LHC, the  $Wt$  mechanism as well, though the  $t$ -channel is measured with best precision to date. The measurements allow an extraction of the CKM matrix element  $V_{tb}$ .

The top-quark mass is now measured at the 0.5% level, by far the most precisely measured quark mass. Together with the  $W$ -boson mass measurement and the newly discovered Higgs boson, this provides a stringent test of the Standard Model.

With almost 9 fb<sup>-1</sup> of Tevatron data analyzed as of this writing, and almost 20 fb<sup>-1</sup> of LHC data, many properties of

the top quark are now being measured with precision. These include properties related to the production mechanism, such as  $t\bar{t}$  spin correlations, forward-backward or charge asymmetries, and differential production cross sections, as well as properties related to the  $t - W - b$  decay vertex, such as the helicity of the  $W$ -bosons from the top-quark decay. In addition, many searches for physics beyond the Standard Model are being performed with increasing reach in both production and decay channels.

In the following sections we review the current status of measurements of the characteristics of the top quark.

## C.1 Top-quark production

**C.1.1  $t\bar{t}$  production:** Fig. 1 summarizes the  $t\bar{t}$  production cross-section measurements from both the Tevatron and LHC. The most recent measurement from DØ [19], combining the measurements from the dilepton and lepton plus jets final states in 5.4 fb<sup>-1</sup>, is  $7.56^{+0.63}_{-0.56}$  pb. From CDF the most precise measurement made recently [20] is in 4.6 fb<sup>-1</sup> and is a combination of dilepton, lepton plus jets, and all-hadronic final-state measurements, yielding  $7.50 \pm 0.48$  pb. Both of these measurements assume a top-quark mass of 172.5 GeV/ $c^2$ . The dependence of the cross section measurements on the value chosen for the mass is less than that of the theory calculations because it only affects the determination of the acceptance. In some analyses also the shape of topological variables might be modified. Very recently, CDF updated some of their measurements with the full Run-II dataset up to 8.8 fb<sup>-1</sup>. The resulting combined  $t\bar{t}$  cross-section is  $\sigma_{t\bar{t}} = 7.63 \pm 0.50$  pb (7.1%) for CDF,  $\sigma_{t\bar{t}} = 7.56 \pm 0.59$  pb (9.3%) for DØ and  $\sigma_{t\bar{t}} = 7.60 \pm 0.41$  pb (5.4%) for the Tevatron combination [21] in good agreement with the SM expectation of  $7.16^{+0.20}_{-0.23}$  pb at NNLO+NNLL in perturbative QCD. The contributions to the uncertainty are 0.20 pb from statistical sources, 0.29 pb from systematic sources, and 0.21 pb from the uncertainty on the integrated luminosity.

CDF also performs measurements of the  $t\bar{t}$  production cross section normalized to the  $Z$  production cross section in order to reduce the impact of the luminosity uncertainty.

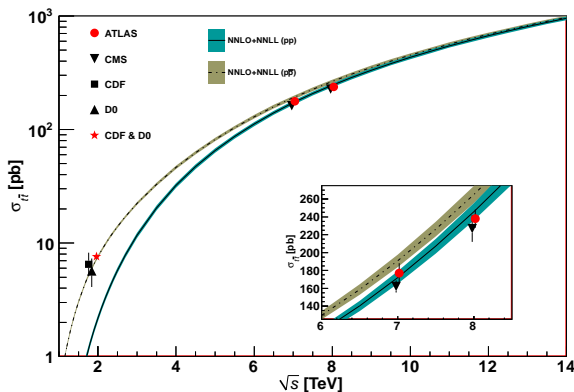

The LHC experiments ATLAS and CMS use similar techniques to measure the  $t\bar{t}$  cross-section in  $pp$  collisions. At  $\sqrt{s} = 7$  TeV, ATLAS performs measurements in 0.7 fb<sup>-1</sup> in the lepton+jets channel [22], in the dilepton channel [23], and in 1.02 fb<sup>-1</sup> in the all-hadronic channel [24], which together yield a combined value of  $\sigma_{t\bar{t}} = 177 \pm 3(\text{stat.}) \pm 8(\text{syst.}) \pm 7(\text{lumi.})$  pb (6.2%) assuming  $m_t = 172.5$  GeV/ $c^2$  [25]. Further analyses in the hadronic tau plus jets channel in 1.67 fb<sup>-1</sup> [26], the hadronic tau + lepton channel in 2.05 fb<sup>-1</sup> [27], and the all-hadronic channel in 4.7 fb<sup>-1</sup> [28] yield consistent albeit less precise results. CMS performs  $t\bar{t}$  cross-section measurements with 2.3 fb<sup>-1</sup> in the  $e/\mu$ +jets channel [29] and in the dilepton channel [30], with 3.5 fb<sup>-1</sup> in the all-hadronic channel [31], with 2.2 fb<sup>-1</sup> in the lepton+ $\tau$  channel [32], and with 3.9 fb<sup>-1</sup> in the  $\tau$ +jets channel [33]. The most precise result is obtained in the dilepton channel, where they obtain

See key on page 547

$\sigma_{t\bar{t}} = 162 \pm 2(\text{stat.}) \pm 5(\text{syst.}) \pm 4(\text{lumi.})$  pb, which corresponds to a 4.2% precision [30].

At  $\sqrt{s} = 8$  TeV, ATLAS and CMS perform cross-section analyses as well, although only a few channels have been considered so far due to the large number of systematic uncertainties being dominant. ATLAS measures the  $t\bar{t}$  cross-section in the lepton+jets channel with  $5.8 \text{ fb}^{-1}$  [34], and in the  $e\mu$  dilepton channel using  $20.3 \text{ fb}^{-1}$  [35]. In the latter, they select an extremely clean sample and determine the  $t\bar{t}$  cross-section simultaneously with the efficiency to reconstruct and  $b$ -tag jets, yielding  $\sigma_{t\bar{t}} = 237.7 \pm 1.7(\text{stat.}) \pm 7.4(\text{syst.}) \pm 7.4(\text{lumi.}) \pm 4.0(\text{beam energy})$  pb assuming  $m_t = 172.5 \text{ GeV}/c^2$ , which corresponds to a 4.7% precision. CMS performs a template fit to the  $M_{lb}$  mass distribution using  $2.7 \text{ fb}^{-1}$  in the lepton+jets channel [36] and a cut-and-count analysis in  $2.4 \text{ fb}^{-1}$  in the dilepton channel [37]. In combination, they achieve  $\sigma_{t\bar{t}} = 227 \pm 3(\text{stat.}) \pm 11(\text{syst.}) \pm 10(\text{lumi.})$  pb for  $m_t = 172.5 \text{ GeV}/c^2$  [37], which corresponds to a 6.7% precision.

These experimental results should be compared to the theoretical calculations that yield  $7.16^{+0.20}_{-0.23}$  pb for top-quark mass of  $173.3 \text{ GeV}/c^2$  [1] at  $\sqrt{s} = 1.96$  TeV,  $\sigma_{t\bar{t}} = 172.0^{+6.4}_{-7.5}$  pb at  $\sqrt{s} = 7$  TeV, and  $\sigma_{t\bar{t}} = 245.8^{+8.8}_{-10.6}$  pb at  $\sqrt{s} = 8$  TeV, at the LHC [1] (see Section B).

**Figure 1:** Measured and predicted  $t\bar{t}$  production cross sections from Tevatron energies in  $p\bar{p}$  collisions to LHC energies in  $pp$  collisions. Tevatron data points at  $\sqrt{s} = 1.8$  TeV are from Refs. [41,42]. Those at  $\sqrt{s} = 1.96$  TeV are from Refs. [19–21]. The ATLAS and CMS data points are from Refs. [25,35] and [30,36,37], respectively. Theory curves are generated using [1] for  $m_t = 173.3 \text{ GeV}/c^2$ . Figure adapted from Ref. [40].

In Fig. 1, one sees the importance of  $p\bar{p}$  at Tevatron energies where the valence antiquarks in the antiprotons contribute to the dominant  $q\bar{q}$  production mechanism. At LHC energies, the dominant production mode is gluon-gluon fusion and the  $pp$ - $p\bar{p}$  difference nearly disappears. The excellent agreement of these measurements with the theory calculations is a strong validation of QCD and the soft-gluon resummation techniques employed in the calculations. The measurements reach high precision and

provide stringent tests of pQCD calculations at NNLO+NNLL level including their respective PDF uncertainties.

Most of these measurements assume a  $t \rightarrow Wb$  branching ratio of 100%. CDF and DØ have made direct measurements of the  $t \rightarrow Wb$  branching ratio [38]. Comparing the number of events with 0, 1 and 2 tagged  $b$  jets in the lepton+jets channel, and also in the dilepton channel, using the known  $b$ -tagging efficiency, the ratio  $R = B(t \rightarrow Wb) / \sum_{q=d,s,b} B(t \rightarrow Wq)$  can be extracted. In  $5.4 \text{ fb}^{-1}$  of data, DØ measures  $R = 0.90 \pm 0.04$ ,  $2.5\sigma$  from unity. A similar measurement was made by CMS in  $16.7 \text{ fb}^{-1}$  at  $\sqrt{s} = 8$  TeV. They find  $R = 1.023^{+0.036}_{-0.034}$  and  $R > 0.945$  at 95% C.L. [39]. A significant deviation of  $R$  from unity would imply either non-SM top-quark decay (for example a flavor-changing neutral-current decay), or a fourth generation of quarks.

Thanks to the large available event samples, the Tevatron and the LHC experiments performed first differential cross-section measurements in  $t\bar{t}$  production. Such measurements are crucial, as they allow even more stringent tests of perturbative QCD as description of the production mechanism, allow the extraction or the use of PDF fits, and enhance the sensitivity to possible new physics contributions. Furthermore, such measurements reduce the uncertainty in the description of  $t\bar{t}$  production as background in Higgs physics and searches for rare processes or beyond Standard Model physics. Differential cross-sections are typically measured by a selection of candidate events, their kinematic reconstruction and subsequent unfolding of the obtained event counts in bins of kinematic distributions in order to correct for detector resolution effects, acceptance and migration effects. In some cases a bin-by-bin unfolding is used, other analyses use a more sophisticated technique, taking into account the known migrations effects and correlations or employing some regularization.

Using  $2.7 \text{ fb}^{-1}$ , CDF measured the differential cross-section with respect to the  $t\bar{t}$  invariant mass,  $d\sigma/dM_{t\bar{t}}$ , in the lepton+jets channel providing sensitivity to a variety of exotic particles decaying into  $t\bar{t}$  pairs [43]. In  $9.7 \text{ fb}^{-1}$  of lepton+jets data, DØ measured the differential  $t\bar{t}$  production cross-section with respect to the transverse momentum and absolute rapidity of the top quarks as well as of the invariant mass of the  $t\bar{t}$  pair [44], which are all found to be in good agreement with the SM predictions. Also ATLAS measured the differential  $t\bar{t}$  production cross-section with respect to the top-quark transverse momentum, and of the mass, transverse momentum and rapidity of the  $t\bar{t}$  system in  $4.6 \text{ fb}^{-1}$  at  $\sqrt{s} = 7$  TeV in the lepton+jets channel [45]. The measured spectra are fully corrected for detector efficiency and resolution effects and are compared to several Monte Carlo simulations as well as selected theoretical calculations. The results show sensitivity to these predictions and to different sets of parton distribution functions. It is found that data is softer than all predictions in the tail of the top-quark  $p_T$  spectrum beginning at 200 GeV, particularly in the case of the **Alpgen+Herwig** generator. The  $m_{t\bar{t}}$  spectrum is not well described by NLO+NNLL calculations

# Quark Particle Listings

*t*

and there are also disagreements between the measured  $y_{t\bar{t}}$  spectrum and the MC@NLO+Herwig and POWHEG+Herwig generators, both evaluated with the CT10 PDF set. All distributions show a preference for HERAPDF1.5 when used for the NLO QCD predictions. In  $5.0 \text{ fb}^{-1}$  of  $\sqrt{s} = 7 \text{ TeV}$  data in the lepton+jets and the dilepton channels, CMS measured normalised differential  $t\bar{t}$  cross-sections with respect to kinematic properties of the final-state charged leptons and jets associated to  $b$ -quarks, as well as those of the top quarks and the  $t\bar{t}$  system. The data are compared with several predictions from perturbative QCD calculations and found to be consistent [46]. Recently, in  $12 \text{ fb}^{-1}$  at  $\sqrt{s} = 8 \text{ TeV}$ , CMS repeated those measurements in the lepton+jets [47] and in the dilepton channels [48]. While the overall precision is improved, no significant deviations from the Standard Model are observed. Very recently, they also performed a normalized differential cross-section measurement in  $20 \text{ fb}^{-1}$  of lepton+jets data with respect to a number of event-level observables, including missing transverse energy, jet transverse momentum scalar sum, total event transverse momentum scalar sum, leptonic  $W$  transverse momentum, and leptonic  $W$  transverse mass. The results are consistent with the Standard Model expectations [49].

Further cross-section measurements are performed for  $t\bar{t}$ +heavy flavour and  $t\bar{t}$ +jets production [50,51].

**C.1.2 Single-top production:** Single-top quark production was first observed in 2009 by DØ [52] and CDF [53,54] at the Tevatron. The production cross section at the Tevatron is roughly half that of the  $t\bar{t}$  cross section, but the final state with a single  $W$ -boson and typically two jets is less distinct than that for  $t\bar{t}$  and much more difficult to distinguish from the background of  $W$ +jets and other sources. A recent review of the first observation and the techniques used to extract the signal from the backgrounds can be found in [55].

The dominant production at the Tevatron is through  $s$ -channel and  $t$ -channel  $W$ -boson exchange. Associated production with a  $W$ -boson ( $Wt$  production) has a cross section that is too small to observe at the Tevatron. The  $t$ -channel process is  $qb \rightarrow q't$ , while the  $s$ -channel process is  $q\bar{q}' \rightarrow t\bar{b}$ . The  $s$ - and  $t$ -channel productions can be separated kinematically. This is of particular interest because potential physics beyond the Standard Model, such as fourth-generation quarks, heavy  $W$  and  $Z$  bosons, flavor-changing-neutral-currents [9], or a charged Higgs boson, would affect the  $s$ - and  $t$ -channels differently. However, the separation is difficult and initial observations and measurements at the Tevatron by both experiments were of combined  $s + t$ -channel production. The two experiments combined their measurements for maximum precision with a resulting  $s + t$  channel production cross section of  $2.76_{-0.47}^{+0.58} \text{ pb}$  [56]. The measured value assumes a top-quark mass of  $170 \text{ GeV}/c^2$ . The mass dependence of the result comes both from the acceptance dependence and from the  $t\bar{t}$  background evaluation. Also the shape of discriminating topological variables is sensitive to  $m_t$ . It is therefore not necessarily a simple linear dependence but

amounts to only a few tenths of picobarns over the range  $170 - 175 \text{ GeV}/c^2$ . The measured value agrees well with the theoretical calculation at  $m_t = 173 \text{ GeV}/c^2$  of  $\sigma_{s+t} = 3.12 \text{ pb}$  (including both top and anti-top production) [6,7].

Recently, CDF has updated the  $s + t$ -channel measurement with  $7.5 \text{ fb}^{-1}$  to  $\sigma_{s+t} = 3.04_{-0.53}^{+0.57} \text{ pb}$  assuming a Standard Model ratio of  $s$ - to  $t$ -channel, resulting in a lower limit of  $|V_{tb}| > 0.78$  at 95% C.L. [57]. They also analyzed the full Run-II data set of  $9.1 \text{ fb}^{-1}$  in  $W$ +jets events where no electron or muon has been identified, and where the tau lepton in the  $t \rightarrow Wb \rightarrow \tau\nu b$  channel is reconstructed as a jet in the calorimeters. Multivariate analysis discriminants and a profile likelihood technique are used to obtain a cross section of  $\sigma_{s+t} = 3.0_{-1.4}^{+1.5} \text{ pb}$  [58]. DØ has measured the combined cross section to  $\sigma_{s+t} = 3.43_{-0.74}^{+0.73} \text{ pb}$  for  $m_t = 172.5/c^2 \text{ GeV}$  [59].

Both experiments have done separate measurements of the  $s$ - and  $t$ -channel cross sections by reoptimizing the analysis for one or both of the channels separately. In a simultaneous measurement of  $s$ - and  $t$ -channel cross sections, CDF measures  $\sigma_s = 1.81_{-0.58}^{+0.63} \text{ pb}$  and  $\sigma_t = 1.49_{-0.42}^{+0.47} \text{ pb}$ , respectively, in  $7.5 \text{ fb}^{-1}$  of data [57]. Using  $9.4 \text{ fb}^{-1}$ , they performed an analysis in the missing  $E_T$  plus  $b\bar{b}$  channel yielding  $\sigma_s = 1.10_{-0.66}^{+0.65} \text{ pb}$  [58,60] and in the  $\nu b\bar{b}$  channel resulting in  $\sigma_s = 1.43_{-0.42}^{+0.44} \text{ pb}$  [61]. The latter also corresponds to a 3.7 standard deviations evidence. In this analysis, CDF assumes the  $t$ -channel cross-section to take the SM value. DØ performs a sophisticated multivariate analysis combining a matrix-element technique, a Bayesian neural network and boosted decision trees to form one output variable using another boosted decision tree. In  $9.7 \text{ fb}^{-1}$  of integrated luminosity, they measure  $\sigma_s = 1.10_{-0.31}^{+0.33} \text{ pb}$  [62], which corresponds to 3.7 standard deviations and is the first evidence for  $s$ -channel single-top production at the Tevatron. In this measurement, they also obtain  $\sigma_t = 3.07_{-0.49}^{+0.53} \text{ pb}$ , which corresponds to 7.7 standard deviations. In combination, the result is  $\sigma_{s+t} = 4.11_{-0.55}^{+0.60} \text{ pb}$  [62]. In this measurement, they do not make any assumption about the  $t$ -channel. They also set a limit on  $|V_{tb}| > 0.92$  at 95% C.L. In a slightly different analysis, using  $5.4 \text{ fb}^{-1}$ , they measure the  $t$ -channel production cross section in a dedicated analysis [59,63] with a significance of 5.5 standard deviations using a variety of advanced analysis techniques similar to those described in [55]. These take advantage of kinematic differences in such things as the leading  $b$ -tagged jet  $p_T$ , centrality of jets, lepton charge times  $\eta$  of the jets, and the scalar sum of the energy of the final state objects. The  $p\bar{p} \rightarrow tq + X$  cross section is measured to be  $2.90 \pm 0.59 \text{ pb}$ , assuming a top-quark mass of  $172.5 \text{ GeV}/c^2$ . This is in good agreement with the theoretical value at this mass of  $2.08 \pm 0.13 \text{ pb}$  [6]. It should be noted that the theory citations here list cross sections for  $t$  or  $\bar{t}$  alone, whereas the experiments measure the sum. At the Tevatron, these cross sections are equal. The theory values quoted here already include this factor of two.

The Tevatron experiments are working on an  $s$ -channel combination, which is expected to come out very soon.

At the LHC, the  $t$ -channel cross section is expected to be more than three times as large as  $s$ -channel and  $Wt$  production, combined. Both ATLAS and CMS have measured single top production cross sections at  $\sqrt{s} = 7$  TeV in  $pp$  collisions (assuming  $m_t = 172.5$  GeV/ $c^2$  unless noted otherwise), where they recently observed  $t$ -channel production [64,65]. ATLAS analyses  $1.04 \text{ fb}^{-1}$  of 7 TeV data in the lepton plus 2 or 3 jets channel with one  $b$ -tag by fitting the distribution of a multivariate discriminant constructed with a neural network, yielding  $\sigma_t = 83 \pm 4(\text{stat.})_{-19}^{+20}(\text{syst.})$  pb (this value refers to the sum of top and antitop cross-section) as well as  $|V_{tb}| = 1.13_{-0.13}^{+0.14}$  and  $|V_{tb}| > 0.75$  at 95% C.L. [64]. In an update with  $4.7 \text{ fb}^{-1}$  using a binned maximum likelihood fit to the output distribution of neural networks, they find  $\sigma_t = 53.2 \pm 10.8$  pb and  $\sigma_{\bar{t}} = 29.5_{-7.5}^{+7.4}$  pb with a cross-section charge ratio  $R_t = 1.81_{-0.22}^{+0.23}$  [66] that is sensitive to the ratio of the up-quark and down-quark parton distribution functions in the proton. CMS follows two approaches in  $1.6 \text{ fb}^{-1}$  of lepton plus jets events. The first approach exploits the distributions of the pseudorapidity of the recoil jet and reconstructed top-quark mass using background estimates determined from control samples in data. The second approach is based on multivariate analysis techniques that probe the compatibility of the candidate events with the signal. They find  $\sigma_t = 67.2 \pm 6.1$  pb, and  $|V_{tb}| = 1.020 \pm 0.046(\text{meas.}) \pm 0.017(\text{theor.})$  [65].

At  $\sqrt{s} = 8$  TeV, both experiments repeat and refine their measurements. ATLAS uses  $5.8 \text{ fb}^{-1}$  by performing a combined binned maximum likelihood fit to the neural network output distribution. The measured  $t$ -channel cross-section is  $\sigma_t = 95.1 \pm 2.4(\text{stat.}) \pm 18.0(\text{syst.})$  pb with  $|V_{tb}| = 1.04_{-0.11}^{+0.1}$  and  $|V_{tb}| > 0.80$  at 95% C.L. [67]. CMS uses  $5.0 \text{ fb}^{-1}$  in the muon plus jets channel, exploiting the pseudorapidity distribution of the recoil jet. They find  $\sigma_t = 80.1 \pm 5.7(\text{stat.}) \pm 11.0(\text{syst.}) \pm 4.0(\text{lumi.})$  pb [68] assuming  $m_t = 173$  GeV/ $c^2$ . A combination of the two measurements yields  $\sigma_t = 85 \pm 4(\text{stat.}) \pm 11(\text{syst.}) \pm 3(\text{lumi.})$  pb [69]. Very recently, CMS has updated their measurement with the complete Run-I dataset of  $20 \text{ fb}^{-1}$  and furthermore measured the top-quark polarization in  $t$ -channel single top production to be  $P_t = 0.82 \pm 0.12(\text{stat.}) \pm 0.32(\text{syst.})$ , which is consistent with the SM expectation [70]. Based on  $12.2 \text{ fb}^{-1}$ , CMS updated their results to find  $\sigma_t = 49.9 \pm 9.1$  pb and  $\sigma_{\bar{t}} = 28.3 \pm 5.5$  pb, which yields a cross-section charge ratio of  $R_t = 1.76 \pm 0.27$  for  $m_t = 173$  GeV/ $c^2$  in agreement with the Standard Model [71].

The  $s$ -channel production cross section is expected to be only  $4.6 \pm 0.3$  pb for  $m_t = 173$  GeV/ $c^2$  at  $\sqrt{s} = 7$  TeV [7], and has not yet been observed at LHC. The  $Wt$  process has a theoretical cross section of  $15.6 \pm 1.2$  pb [8]. This is of interest because it probes the  $W - t - b$  vertex in a different kinematic region than  $s$ - and  $t$ -channel production, and because of its similarity to the associated production of a charged-Higgs boson and a top quark. The signal is difficult to extract because of its similarity to the  $t\bar{t}$  signature. Furthermore, it is difficult to uniquely define because at NLO a subset of diagrams have

the same final state as  $t\bar{t}$  and the two interfere [72]. The cross section is calculated using the *diagram removal* technique [73] to define the signal process. In the diagram removal technique the interfering diagrams are removed, at the amplitude level, from the signal definition (an alternate technique, *diagram subtraction* removes these diagrams at the cross-section level and yields similar results). These techniques work provided the selection cuts are defined such that the interference effects are small, which is usually the case.

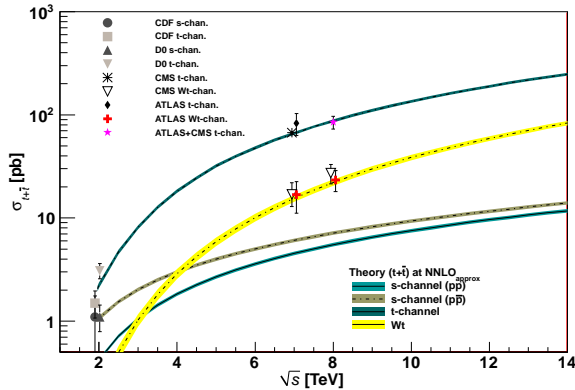

Both, ATLAS and CMS, also provide evidence for the associate  $Wt$  production at  $\sqrt{s} = 7$  TeV [74,75]. ATLAS uses  $2.05 \text{ fb}^{-1}$  in the dilepton plus missing  $E_T$  plus jets channel, where a template fit to the final classifier distributions resulting from boosted decision trees as signal to background separation is performed. The result is incompatible with the background-only hypothesis at the  $3.3\sigma$  ( $3.4\sigma$  expected) level, yielding  $\sigma_{Wt} = 16.8 \pm 2.9(\text{stat.}) \pm 4.9(\text{syst.})$  pb and  $|V_{tb}| = 1.03_{-0.19}^{+0.16}$  [74]. CMS uses  $4.9 \text{ fb}^{-1}$  in the dilepton plus jets channel with at least one  $b$ -tag. A multivariate analysis based on kinematic properties is utilized to separate the  $t\bar{t}$  background from the signal. The observed signal has a significance of  $4.0\sigma$  and corresponds to a cross section of  $\sigma_{Wt} = 16_{-4}^{+5}$  pb [75]. Both experiments repeated their analyses at  $\sqrt{s} = 8$  TeV. ATLAS uses  $20.3 \text{ fb}^{-1}$  to select events with one electron and one oppositely-charged muon, significant missing transverse momentum and at least one  $b$ -tagged central jet. They perform a template fit to a boosted decision tree classifier distribution and obtain  $\sigma_{Wt} = 27.2 \pm 5.8$  pb and  $|V_{tb}| = 1.10 \pm 0.12(\text{exp.}) \pm 0.03(\text{theory})$  [76], which corresponds to a  $4.2\sigma$  significance. Assuming  $|V_{tb}| \gg |V_{ts}|, |V_{td}|$  they derive  $|V_{tb}| > 0.72$  at 95% C.L. CMS uses  $12.2 \text{ fb}^{-1}$  in events with two leptons and a jet originated from a  $b$ -quark. A multivariate analysis based on kinematic properties is utilized to separate the signal and background. The  $Wt$  associate production signal is observed at the level of  $6.0\sigma$ , yielding  $\sigma_{Wt} = 23.4_{-5.4}^{+5.5}$  pb and  $|V_{tb}| = 1.03 \pm 0.12(\text{exp.}) \pm 0.04(\text{theory})$  [77].

At ATLAS, a search for  $s$ -channel single top quark production is performed in  $0.7 \text{ fb}^{-1}$  using events containing one lepton, missing transverse energy and two  $b$ -jets. Using a cut-based analysis, an observed (expected) upper limit at 95% C.L. on the  $s$ -channel cross-section of  $\sigma_s < 26.5(20.5)$  pb is obtained [78].

Fig. 2 provides a summary of all single top cross-section measurements at the Tevatron and the LHC as a function of the center-of-mass energy. All cross-section measurements are very well described by the theory calculation within their uncertainty.

**C.1.3 Top-Quark Forward-Backward & Charge Asymmetry:** A forward-backward asymmetry in  $t\bar{t}$  production arises from an interference between the Born and box production diagrams and between diagrams with initial- and final-state gluon radiation. The asymmetry,  $A_{FB}$ , is defined by

$$A_{FB} = \frac{N(\Delta y > 0) - N(\Delta y < 0)}{N(\Delta y > 0) + N(\Delta y < 0)} \quad (2)$$

**Figure 2:** Measured and predicted single top production cross sections from Tevatron energies in  $p\bar{p}$  collisions to LHC energies in  $pp$  collisions. Tevatron data points at  $\sqrt{s} = 1.96$  TeV are from Refs. [57,60] and [62]. The ATLAS and CMS data points at  $\sqrt{s} = 7$  TeV are from Refs. [64,66,74,78] and [79,65,75], respectively. The ones at  $\sqrt{s} = 8$  TeV are from Refs. [67,69,76] and [68,69,77]. Theory curves are generated using [6,7,8].

where  $\Delta y = y_t - y_{\bar{t}}$  is the rapidity difference between the top- and the anti-top quark. NLO calculations predict a small  $A_{FB}$  at the Tevatron. The most recent calculations at NLO, including electromagnetic and electroweak corrections, yield a predicted asymmetry of  $(\approx 8.8 \pm 0.6)\%$  [80,81].

Both, CDF and DØ, have measured asymmetry values in excess of the SM prediction, fueling speculation about exotic production mechanisms (see, for example, [82] and references therein). The first measurement of this asymmetry by DØ in  $0.9 \text{ fb}^{-1}$  [83] found an asymmetry at the detector level of  $(12 \pm 8)\%$ . The first CDF measurement in  $1.9 \text{ fb}^{-1}$  [84] yielded  $(24 \pm 14)\%$  at parton level. Both values were higher, though statistically consistent with the SM expectation. With the addition of more data, the uncertainties have been reduced, but the measured asymmetries remain in excess of the SM expectation. The most recent measurement from DØ in  $5.4 \text{ fb}^{-1}$  finds an asymmetry, corrected for detector acceptance and resolution, of  $(19.6 \pm 6.5)\%$  [85]. From CDF, the most recent measurement uses  $9.4 \text{ fb}^{-1}$ , and finds  $(16.4 \pm 4.7)\%$  [86]. With additional data they report further evidence for an  $M_{t\bar{t}}$ -dependent asymmetry first reported in [87], with a larger asymmetry at large  $M_{t\bar{t}}$  and an approximately linear dependence with  $M_{t\bar{t}}$ . DØ does not see any significant increase at large mass [85]. The new CDF measurement also includes a differential measurement of  $A_{FB}$  in bins of  $|\Delta y|$  which also shows an approximately linear dependence with a positive slope. The SM prediction is also for an approximately linear dependence with a positive slope, but these studies show that the excess above the SM prediction occurs primarily at large values of these parameters. A further study of the dependence of  $A_{FB}$  on the  $p_T$  of the  $t\bar{t}$  system indicates that the asymmetry is independent of the transverse momentum of the  $t\bar{t}$  system.

At the LHC, where the dominant  $t\bar{t}$  production mechanism is the charge-symmetric gluon-gluon fusion, the measurement is more difficult. For the sub-dominant  $q\bar{q}$  production mechanism, the symmetric  $pp$  collision does not define a forward and backward direction. Instead, the charge asymmetry,  $A_C$ , is defined in terms of a positive versus a negative  $t - \bar{t}$  rapidity difference

$$A_C = \frac{N(\Delta|y| > 0) - N(\Delta|y| < 0)}{N(\Delta|y| > 0) + N(\Delta|y| < 0)} \quad (3)$$

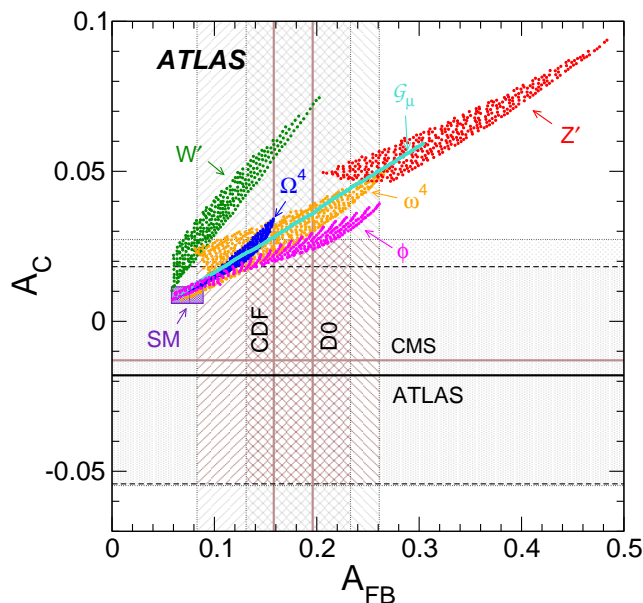

Both CMS and ATLAS have measured  $A_C$  in the LHC dataset. Using lepton+jets events in  $4.7 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 7$  TeV, ATLAS measures  $A_C = (0.6 \pm 1.0)\%$  [88]. CMS, in  $5.0(19.7) \text{ fb}^{-1}$  of  $\sqrt{s} = 7(8)$  TeV data uses lepton+jets events to measure  $A_C = (0.4 \pm 1.5)\%$  ( $A_C = (0.005 \pm 0.007(\text{stat.}) \pm 0.006(\text{syst.}))$ ) [89,90]. Both measurements are consistent with the SM expectation of  $A_C = 1.23 \pm 0.05\%$  [81], although the uncertainties are still too large for a precision test. In their 7 and 8 TeV analyses, both, ATLAS and CMS, also provide differential measurements as a function of the  $t\bar{t}$  mass, the transverse momentum  $p_T$  and the rapidity  $y$ .

Another avenue for measuring the forward-backward and charge asymmetries that has recently been exploited by the experiments is given by the measurement of the pseudorapidity distributions of the charged leptons resulting from  $t\bar{t}$  decay. Although the expected asymmetry is smaller, this technique does not require the reconstruction of the top-quark direction. Single-lepton asymmetries are defined by  $q \times \eta$ , and dilepton asymmetries by the sign of  $\Delta\eta$ , where  $q$  and  $\eta$  are the charge and pseudorapidity of the lepton and  $\Delta\eta = \eta_{\ell^+} - \eta_{\ell^-}$ . DØ has recently measured the single-lepton asymmetry in  $9.7 \text{ fb}^{-1}$  of lepton+jets events, and finds a value of  $(4.7 \pm 2.3^{+1.1}_{-1.4})\%$  [91], consistent with an expectation of  $(3.8 \pm 0.6)\%$  [81]. A measurement by DØ using dilepton events in the same dataset [92] yields a dilepton asymmetry of  $(12.3 \pm 5.4 \pm 1.5)$ , less than two standard deviations away from the expectation of  $(4.0 \pm 0.4)\%$  [81]. CDF, in  $9.4 \text{ fb}^{-1}$  of Tevatron data measures [93]  $(9.4^{+3.2}_{-2.9})\%$ . As in the DØ case, this is larger than the SM expectation, but less than two standard deviations away.

At the LHC, both ATLAS and CMS have now measured leptonic asymmetries. ATLAS, in  $4.7 \text{ fb}^{-1}$  of  $\sqrt{s} = 7$  TeV data, has measured an asymmetry in dilepton events of  $(2.3 \pm 1.2 \pm 0.8)\%$  [94]. CMS, in  $5.0 \text{ fb}^{-1}$  of  $\sqrt{s} = 7$  TeV data, uses dilepton events to measure an asymmetry of  $(1.0 \pm 1.5 \pm 0.6)\%$  [95]. Both of these are consistent, within their large uncertainties, with the SM expectation, derived by the experiments from the MC@NLO and POWHEG generators, respectively, of about 0.4%.

A model-independent comparison of the Tevatron and LHC results is made difficult by the differing  $t\bar{t}$  production mechanisms at work at the two accelerators and by the symmetric nature of the  $pp$  collisions at the LHC. Given a particular model of BSM physics, a comparison can be obtained through the resulting asymmetry predicted by the model at the two machines, see Fig. 3.

**Figure 3:** Measured inclusive FB asymmetries from the Tevatron and charge asymmetries from the LHC, compared to predictions from the SM as well as predictions incorporating various potential new physics contributions. The horizontal (vertical) bands and lines correspond to the ATLAS and CMS (CDF and D0) measurements [96].

## C.2 Top-Quark Properties

**C.2.1 Top-Quark Mass Measurements:** The most precisely studied property of the top quark is its mass. The top-quark mass has been measured in the lepton+jets, the dilepton, and the all-jets channel by all four Tevatron and LHC experiments. The latest and/or most precise results are summarized in Table 1. The lepton+jets channel still yields the most precise single measurements because of good signal to background (in particular after  $b$ -tagging) and the presence of only a single neutrino in the final state. The momentum of a single neutrino can be reconstructed (up to a quadratic ambiguity) via the missing  $E_T$  measurement and the constraint that the lepton and neutrino momenta reconstruct to the known  $W$  boson mass. In the large data samples available at the LHC, measurements in the dilepton channel are only slightly less precise.

A large number of techniques have now been applied to measuring the top-quark mass. The original ‘template method’ [97], in which Monte Carlo templates of reconstructed mass distributions are fit to data, has evolved into a precision tool in the lepton+jets channel, where the systematic uncertainty due to the jet energy scale (JES) uncertainty is controlled by a simultaneous, *in situ*, fit to the  $W \rightarrow jj$  hypothesis [98]. All the latest measurements in the lepton+jets and the all-jets channels use this technique one way or the other. In  $4.7 \text{ fb}^{-1}$  of data in the lepton+jets channel, ATLAS and CMS achieve a total uncertainty of 0.9% and 0.6%, with a statistical component of 0.44% [99] and 0.25% [100], respectively. The ATLAS measurement is in fact based on a 3-dimensional template fit,

determining the top-quark mass, the global jet energy scale and a  $b$ -to-light jet energy scale factor. The measurement from CDF with  $8.7 \text{ fb}^{-1}$  [101] achieves a precision of 0.6% in the lepton+jets channel, while D0 achieves 0.9% in  $3.6 \text{ fb}^{-1}$  [102].

The template method is complemented by the ‘matrix element’ method. This method was first applied by the D0 Collaboration [103], and is similar to a technique originally suggested by Kondo *et al.* [104] and Dalitz and Goldstein [105]. In the matrix element method a probability for each event is calculated as a function of the top-quark mass, using a LO matrix element for the production and decay of  $t\bar{t}$  pairs. The *in situ* calibration of dijet pairs to the  $W \rightarrow jj$  hypothesis is now also used with the matrix element technique to constrain the jet energy scale uncertainty. The latest measurement with this technique is from D0 in the lepton+jets channel with  $3.6 \text{ fb}^{-1}$  yielding an uncertainty of about 0.9% [102].

CMS has measured the top-quark mass at LHC using an ‘ideogram’ method, first used by D0 [106], in which a constrained fit is performed and an event-by-event likelihood for signal or background is calculated taking into account all jet-parton assignments. In the lepton+jets channel at CMS, with an *in situ* fit of the JES using  $W \rightarrow jj$ , the measurement has a precision of 1.07 GeV (0.6%) in  $5 \text{ fb}^{-1}$  [100], which is the most precise top-quark mass measurement to date.

In the dilepton channel, the signal to background is typically very good, but reconstruction of the mass is non-trivial because there are two neutrinos in the final state, yielding a kinematically unconstrained system. A variety of techniques has been developed to handle this. An analytic solution to the problem has been proposed [107], but this has not yet been used in the mass measurement. One of the two most precise measurements in the dilepton channel currently comes from using the invariant mass of the charged lepton and  $b$ -quark system ( $M_{\ell b}$ ), which is sensitive to the top-quark mass and avoids the kinematic difficulties of the two-neutrino final state. In  $4.7 \text{ fb}^{-1}$  of data, ATLAS has measured the top-quark mass in the dilepton channel to a precision of 0.9% using a template fit to the  $M_{\ell b}$  distribution [108]. The other dilepton-channel measurement of similar precision comes from  $5.0 \text{ fb}^{-1}$  of CMS data [109] using a so-called analytical matrix weighting technique (AMWT) in which each event is fit many times to a range of top-quark masses and each fit is assigned a weight, from the PDFs, given by the inferred kinematics of the initial state partons, and from the probability of the observed charged lepton energies for the top-quark mass in question.

Several other techniques can also yield precise measurements in the dilepton channel. In the neutrino weighting technique, similar to AMWT above, a weight is assigned by assuming a top-quark mass value and applying energy-momentum conservation to the top-quark decay, resulting in up to four possible pairs of solutions for the neutrino and anti-neutrino momenta. The missing  $E_T$  calculated in this way is then compared to the

# Quark Particle Listings

*t*

observed missing  $E_T$  to assign a weight [110]. Another measurement in the dilepton channel uses the Dalitz and Goldstein technique [111–113].

In the all-jets channel there is no ambiguity due to neutrino momenta, but the signal to background is significantly poorer due to the severe QCD multijets background. The emphasis therefore has been on background modeling, and reduction through event selection. The most recent measurement in the all-jets channel, by CMS in  $3.54 \text{ fb}^{-1}$  [114], uses an ideogram method to extract the top-quark mass and achieves a precision of 0.8%. Here, the 1-dimensional fit for the top-mass with fixed jet energy scale is expected to be more precise than the 2-dimensional simultaneous fit for  $m_t$  and the jet energy scale. A recent measurement from ATLAS [115] uses the template method in the all-hadronic channel, also with an *in situ*, fit to the  $W \rightarrow jj$  hypothesis, yielding a measurement with 2% precision in only  $2.0 \text{ fb}^{-1}$  of data. A measurement from CDF in  $5.7 \text{ fb}^{-1}$  uses a neural net to select events with a missing  $E_T$  plus jets signature [116]. A modified template method is used to extract the top-quark mass, including an *in situ*  $W \rightarrow jj$  fit. A precision of 1% is achieved.

A dominant systematic uncertainty in these methods is the understanding of the jet energy scale, and so several techniques have been developed that have little sensitivity to the jet energy scale uncertainty. These include the measurement of the top-quark mass using the following techniques: Fitting of the lepton  $p_T$  spectrum of candidate events [117]; fitting of the transverse decay length of the  $b$ -jet ( $L_{xy}$ ) [118]; fitting the invariant mass of a lepton from the  $W$ -decay and a muon from the semileptonic  $b$  decay [119].

Several measurements have now been made in which the top-quark mass is extracted from the measured cross section using the theoretical relationship between the mass and the production cross section, which allows the direct extraction of the  $\overline{\text{MS}}$  mass section [120].

Combined measurements from the Tevatron experiments and from the LHC experiments take into account the correlations between different measurements from a single experiment and between measurements from different experiments. The Tevatron average [3], using up to  $8.7 \text{ fb}^{-1}$  of data, now has a precision of 0.5%. The LHC combination, using up to  $4.9 \text{ fb}^{-1}$  of data, has a precision of just over 0.5% [121], where more work on systematic uncertainties is required. A Tevatron-LHC combination is not yet available.

The direct measurements of the top-quark mass, such as those shown in Table 1, are generally assumed to be measurements of the pole mass. Strictly speaking, the mass measured in these direct measurements is the mass used in the Monte Carlo generators. The relation between the Monte Carlo generator mass and the pole mass is uncertain at the level of 1 GeV [123], which is now comparable to the measurement uncertainty. A review of top-quark mass measurements can be found in reference [124].

**Table 1:** Measurements of top-quark mass from Tevatron and LHC.  $\int \mathcal{L} dt$  is given in  $\text{fb}^{-1}$ . The results shown are mostly preliminary (not yet submitted for publication as of September 2013); for a complete set of published results see the Listings. Statistical uncertainties are listed first, followed by systematic uncertainties.

$m_t$ (GeV/ $c^2$ )	Source	$\int \mathcal{L} dt$	Ref.	Channel
$174.94 \pm 1.14 \pm 0.96$	DØ Run II	3.6	[102]	$\ell$ +jets
$172.85 \pm 0.71 \pm 0.85$	CDF Run II	8.7	[101]	$\ell$ +jets
$173.93 \pm 1.64 \pm 0.87$	CDF Run II	8.7	[116]	Missing $E_T$ +jets

\*The Tevatron average is a combination of published Run I and preliminary or pub. Run-II meas., yielding a  $\chi^2$  of 8.5 for 11 deg. of freedom. The LHC average includes both published and preliminary results, yielding a  $\chi^2$  of 1.8 for 4 deg. of freedom.

With the discovery of a Higgs boson at the LHC with a mass of about 126 GeV [125,126], the precision measurement of the top-quark mass takes a central role in the question of the stability of the electroweak vacuum because top-quark radiative corrections tend to drive the Higgs quartic coupling,  $\lambda$ , negative, potentially leading to an unstable vacuum. A recent calculation at NNLO [127] leads to the conclusion of vacuum stability for a Higgs mass satisfying  $M_H \geq 129.4 \pm 5.6 \text{ GeV}$  [128]. Given the uncertainty, a Higgs mass of 126 GeV satisfies the limit, but the central value of the Higgs and top-quark masses put the electroweak vacuum squarely in the metastable region. The uncertainty is dominated by the precision of the top-quark mass measurement and its interpretation as the pole mass. For more details, see the Higgs boson review in this volume.

As a test of the CPT-symmetry, the mass difference of top- and antitop-quarks  $\Delta m_t = m_t - m_{\bar{t}}$ , which is expected to be zero, can be measured. CDF measures the mass difference in  $8.7 \text{ fb}^{-1}$  of 1.96 TeV data in the lepton+jets channel using a template method to find  $\Delta m_t = -1.95 \pm 1.11(\text{stat.}) \pm 0.59(\text{syst.}) \text{ GeV}/c^2$  [129] while DØ uses  $3.6 \text{ fb}^{-1}$  of lepton+jets events and the matrix element method with at least one  $b$ -tag. They find  $\Delta m_t = 0.8 \pm 1.8(\text{stat.}) \pm 0.5(\text{syst.}) \text{ GeV}/c^2$  [130]. In  $4.7 \text{ fb}^{-1}$  of 7 TeV data, ATLAS measures the mass difference in lepton+jets events with a double  $b$ -tag requirement and hence very low background to find  $\Delta m_t = 0.67 \pm 0.61(\text{stat.}) \pm$

See key on page 547

0.41(*syst.*) GeV/ $c^2$  [131]. CMS measures the top-quark mass difference in 5 fb $^{-1}$  of 7 TeV data in the lepton+jets channel and finds  $\Delta m_t = -0.44 \pm 0.46(\text{stat.}) \pm 0.27(\text{syst.})$  GeV/ $c^2$  [132]. They repeat this measurement with 18.9 fb $^{-1}$  of 8 TeV data to find  $\Delta m_t = -0.27 \pm 0.20(\text{stat.}) \pm 0.12(\text{syst.})$  GeV/ $c^2$  [133]. All measurements are consistent with the SM expectation.

**C.2.2 Top-Quark Spin Correlations and Width:** One of the unique features of the top quark is that it decays before its spin can be flipped by the strong interaction. Thus the top-quark polarization is directly observable via the angular distribution of its decay products. Hence, it is possible to define and measure observables sensitive to the top-quark spin and its production mechanism. Although the top- and antitop-quarks produced by strong interactions in hadron collisions are essentially unpolarized, the spins of  $t$  and  $\bar{t}$  are correlated. For QCD production at threshold, the  $t\bar{t}$  system is produced in a  $^3S_1$  state with parallel spins for  $q\bar{q}$  annihilation or in a  $^1S_0$  state with antiparallel spins for gluon-gluon fusion. Hence, the situations at the Tevatron and at the LHC are complementary. The direction of the top-quark spin is 100% correlated to the angular distributions of the down-type fermion (charged leptons or  $d$ -type quarks) in the decay. The joint angular distribution [134–136]

$$\frac{1}{\sigma} \frac{d^2\sigma}{d(\cos\theta_+)d(\cos\theta_-)} = \frac{1 + \kappa \cdot \cos\theta_+ \cdot \cos\theta_-}{4}, \quad (4)$$

where  $\theta_+$  and  $\theta_-$  are the angles of the daughters in the top-quark rest frame with respect to a particular spin quantization axis, is a very sensitive observable. The maximum value for  $\kappa$ , 0.782 at NLO at the Tevatron [137], is found in the off-diagonal basis [134], while at the LHC the value at NLO is 0.326 in the helicity basis [137]. The spin correlation could be modified by a new  $t\bar{t}$  production mechanism such as through a  $Z'$  boson, Kaluza-Klein gluons, or a Higgs boson.

CDF used 5.1 fb $^{-1}$  in the dilepton channel to measure the correlation coefficient in the beam axis [138]. The measurement was made using the expected distributions of  $(\cos\theta_+, \cos\theta_-)$  and  $(\cos\theta_b, \cos\theta_{\bar{b}})$  of the charged leptons or the  $b$ -quarks in the  $t\bar{t}$  signal and background templates to calculate a likelihood of observed reconstructed distributions as a function of assumed  $\kappa$ . They determined the 68% confidence interval for the correlation coefficient  $\kappa$  as  $-0.52 < \kappa < 0.61$  or  $\kappa = 0.04 \pm 0.56$  assuming  $m_t = 172.5$  GeV/ $c^2$ .

CDF also analyzed lepton+jets events in 5.3 fb $^{-1}$  [139] assuming  $m_t = 172.5$  GeV/ $c^2$ . They form three separate templates - the same-spin template, the opposite-spin template, and the background template for the 2-dimensional distributions in  $\cos(\theta_l)\cos(\theta_d)$  vs.  $\cos(\theta_l)\cos(\theta_b)$ . The fit to the data in the helicity basis returns an opposite helicity fraction of  $F_{OH} = 0.74 \pm 0.24(\text{stat}) \pm 0.11(\text{syst})$ . Converting this to the spin correlation coefficient yields  $\kappa_{\text{helicity}} = 0.48 \pm 0.48(\text{stat}) \pm 0.22(\text{syst})$ . In the beamline basis, they find an opposite spin fraction of  $F_{OS} = 0.86 \pm 0.32(\text{stat}) \pm 0.13(\text{syst})$  which can be converted into a correlation coefficient of  $\kappa_{\text{beam}} = 0.72 \pm 0.64(\text{stat}) \pm 0.26(\text{syst})$ .

DØ performed a measurement of the ratio  $f$  of events with correlated  $t$  and  $\bar{t}$  spins to the total number of  $t\bar{t}$  events in 5.3 fb $^{-1}$  in the lepton+jets channel using a matrix element technique [140]. From 729 events, they obtain  $f_{\text{meas}} = 1.15_{-0.43}^{+0.42}$  (stat + syst) and can exclude values of  $f < 0.420$  at the 95% C.L. In the dilepton channel [141], they also use a matrix element method and can exclude at the 97.7% C.L. the hypothesis that the spins of the  $t$  and  $\bar{t}$  are uncorrelated. The combination [140] yields  $f_{\text{meas}} = 0.85 \pm 0.29$  (stat + syst) and a  $t\bar{t}$  production cross section which is in good agreement with the SM prediction and previous measurements. For an expected fraction of  $f = 1$ , they can exclude  $f < 0.481$  at the 95% C.L. For the observed value of  $f_{\text{meas}} = 0.85$ , they can exclude  $f < 0.344(0.052)$  at the 95(99.7)% C.L. The observed fraction  $f_{\text{meas}}$  translates to a measured asymmetry value of  $A_{\text{meas}} = 0.66 \pm 0.23$  (stat + syst), where the spin correlation coefficient,  $A$ , is defined as

$$A = \frac{N(\uparrow\uparrow) + N(\downarrow\downarrow) - N(\uparrow\downarrow) - N(\downarrow\uparrow)}{N(\uparrow\uparrow) + N(\downarrow\downarrow) + N(\uparrow\downarrow) + N(\downarrow\uparrow)}, \quad (5)$$

where the first arrow represents the direction of the top-quark spin along a chosen quantization axis, and the second arrow represents the same for the antitop-quark. They therefore obtain first evidence of SM spin correlation at 3.1 standard deviations.

Using 5.4 fb $^{-1}$  of data, DØ measures the correlation in the dilepton channel also from the angles of the two leptons in the  $t$  and  $\bar{t}$  rest frames, yielding a correlation strength  $C = 0.10 \pm 0.45$  [142] ( $C$  is equivalent to the opposite of  $\kappa$  in Eq. 4, in agreement with the NLO QCD prediction, but also in agreement with the no correlation hypothesis).

Spin correlations have now been conclusively measured at the LHC by both the ATLAS and CMS collaborations. In the dominant gluon fusion production mode for  $t\bar{t}$  pairs at the LHC, the angular distribution between the two leptons in  $t\bar{t}$  decays to dileptons is sensitive to the degree of spin correlation [143].

The ATLAS collaboration has performed a study of spin correlations in  $t\bar{t}$  production at  $\sqrt{s} = 7$  TeV using 2.1 fb $^{-1}$  of data. Candidate events are selected in the dilepton topology with large missing transverse energy and at least two jets. The difference in azimuthal angle between the two charged leptons is compared to the expected distributions in the Standard Model, and to the case where the top quarks are produced with uncorrelated spin. Using the helicity basis as the quantization axis, the strength of the spin correlation between the top- and antitop-quark is measured to be  $A_{\text{helicity}} = 0.40_{-0.08}^{+0.09}$  [144], which is in agreement with the NLO prediction of about 0.31 [145]. The hypothesis of no spin correlations is excluded at 5.1 standard deviations. An update of this analysis with 4.6 fb $^{-1}$  yields results for four different variables, which have sensitivity to different properties of the production mechanism. The results can be translated to  $A_{\text{helicity}} = 0.37 \pm 0.06(\text{stat.} + \text{syst.})$  [146].

*t*

A similar analysis at CMS using dilepton events in  $5.0 \text{ fb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$ . The angular distribution between the two leptons is fit to extract  $A_{\text{helicity}} = 0.24 \pm 0.02 \pm 0.08$  [147].

Observation of top-quark spin correlations requires a top-quark lifetime less than the spin decorrelation timescale [148]. The top-quark width, inversely proportional to its lifetime, is expected to be of order  $1 \text{ GeV}/c^2$  (Eq. 1). The sensitivity of current experiments does not approach this level in direct measurements. Nevertheless, several measurements have been made.

CDF presents a direct measurement of the top-quark width in the lepton+jets decay channel of  $t\bar{t}$  events from a data sample corresponding to  $8.7 \text{ fb}^{-1}$  of integrated luminosity. The top-quark mass and the mass of the hadronically decaying  $W$  boson that comes from the top-quark decay are reconstructed for each event and compared with templates of different top-quark widths ( $\Gamma_t$ ) and deviations from nominal jet energy scale ( $\Delta JES$ ) to perform a simultaneous fit for both parameters, where  $\Delta JES$  is used for the *in situ* calibration of the jet energy scale. By applying a Feldman-Cousins approach, they establish an upper limit at 95% C.L. of  $\Gamma_t < 6.38 \text{ GeV}$  and a two-sided 68% C.L. interval of  $1.10 \text{ GeV} < \Gamma_t < 4.05 \text{ GeV}$ , corresponding to a lifetime interval of  $1.6 \times 10^{-15} < \tau_{\text{top}} < 6.0 \times 10^{-25}$  [149], consistent with the SM prediction. For comparison, a typical hadronization timescale is an order of magnitude larger than these limits.

$D\bar{O}$  extracts the total width of the top-quark from the partial decay width  $\Gamma(t \rightarrow Wb)$  and the branching fraction  $B(t \rightarrow Wb)$ .  $\Gamma(t \rightarrow Wb)$  is obtained from the measured  $t$ -channel cross section for single top-quark production in  $5.4 \text{ fb}^{-1}$ , and  $B(t \rightarrow Wb)$  is extracted from a measurement of the ratio  $R = B(t \rightarrow Wb)/B(t \rightarrow Wq)$  in  $t\bar{t}$  events in lepton+jets channels with 0, 1 and 2 b-tags. Assuming  $B(t \rightarrow Wq) = 1$ , where  $q$  includes any kinematically accessible quark, the result is:  $\Gamma_t = 2.00_{-0.43}^{+0.47} \text{ GeV}$  which translates to a top-quark lifetime of  $\tau_t = (3.29_{-0.63}^{+0.90}) \times 10^{-25} \text{ s}$ . Assuming a high mass fourth generation  $b'$  quark and unitarity of the four-generation quark-mixing matrix, they set the first upper limit on  $|V_{tb'}| < 0.59$  at 95% C.L. [150].

**C.2.3  $W$ -Boson Helicity in Top-Quark Decay:** The Standard Model dictates that the top quark has the same vector-minus-axial-vector ( $V - A$ ) charged-current weak interactions  $\left(-i \frac{g}{\sqrt{2}} V_{tb} \gamma^\mu \frac{1}{2} (1 - \gamma_5)\right)$  as all the other fermions. In the SM, the fraction of top-quark decays to longitudinally polarized  $W$  bosons is similar to its Yukawa coupling and hence enhanced with respect to the weak coupling. It is expected to be [151]  $\mathcal{F}_0^{\text{SM}} \approx x/(1+x)$ ,  $x = m_t^2/2M_W^2$  ( $\mathcal{F}_0^{\text{SM}} \sim 70\%$  for  $m_t = 175 \text{ GeV}/c^2$ ). Fractions of left-handed, right-handed, or longitudinal  $W$  bosons are denoted as  $\mathcal{F}_-$ ,  $\mathcal{F}_+$ , and  $\mathcal{F}_0$  respectively. In the SM,  $\mathcal{F}_-$  is expected to be  $\approx 30\%$  and  $\mathcal{F}_+ \approx 0\%$ . Predictions for the  $W$  polarization fractions at NNLO in QCD are available [152].

The Tevatron and the LHC experiments use various techniques to measure the helicity of the  $W$  boson in top-quark decays, in both the lepton+jets and in dilepton channels in  $t\bar{t}$  production.

The first method uses a kinematic fit, similar to that used in the lepton+jets mass analyses, but with the top-quark mass constrained to a fixed value, to improve the reconstruction of final-state observables, and render the under-constrained dilepton channel solvable. Alternatively, in the dilepton channel  $\theta^*$  can also be obtained through an algebraic solution of the kinematics. The distribution of the helicity angle ( $\cos \theta^*$ ) between the lepton and the  $b$  quark in the  $W$  rest frame provides the most direct measure of the  $W$  helicity. In a simplified version of this approach, the  $\cos \theta^*$  distribution is reduced to a forward-backward asymmetry.

The second method ( $p_T^\ell$ ) uses the different lepton  $p_T$  spectra from longitudinally or transversely polarized  $W$ -decays to determine the relative contributions.

A third method uses the invariant mass of the lepton and the  $b$ -quark in top-quark decays ( $M_{b\ell}^2$ ) as an observable, which is directly related to  $\cos \theta^*$ .

At the LHC, top-quark pairs in the dilepton channels are reconstructed by solving a set of six independent kinematic equations on the missing transverse energy in  $x$ - and in  $y$ -direction, two  $W$ -masses, and the two top/antitop-quark masses. In addition, the two jets with the largest  $p_T$  in the event are interpreted as  $b$ -jets. The pairing of the jets to the charged leptons is based on the minimization of the sum of invariant masses  $m_{\text{min}}$ . Simulations show that this criterion gives the correct pairing in 68% of the events.

Finally, the Matrix Element method (ME) has also been used, in which a likelihood is formed from a product of event probabilities calculated from the ME for a given set of measured kinematic variables and assumed  $W$ -helicity fractions. The results of recent CDF,  $D\bar{O}$ , ATLAS, and CMS analyses are summarized in Table 2.

The datasets are now large enough to allow for a simultaneous fit of  $\mathcal{F}_0$ ,  $\mathcal{F}_-$  and  $\mathcal{F}_+$ , which we denote by ‘3-param’ or  $\mathcal{F}_0$  and  $\mathcal{F}_+$ , which we denote by ‘2-param’ in the table. Results with either  $\mathcal{F}_0$  or  $\mathcal{F}_+$  fixed at its SM value are denoted ‘1-param’. For the simultaneous fits, the correlation coefficient between the two values is about  $-0.8$ . A complete set of published results can be found in the Listings. All results are in agreement with the SM expectation.

CDF and  $D\bar{O}$  combined their results based on  $2.7 - 5.4 \text{ fb}^{-1}$  using the BLUE method [153] for a top-quark mass of  $172.5 \text{ GeV}/c^2$ . ATLAS presents results from  $1.04 \text{ fb}^{-1}$  of  $\sqrt{s} = 7 \text{ TeV}$  data using a template method for the  $\cos \theta^*$  distribution and angular asymmetries from the unfolded  $\cos \theta^*$  distribution in the lepton+jets and the dilepton channel [155]. CMS performs a similar measurement based on template fits to the  $\cos \theta^*$  distribution with  $5.0 \text{ fb}^{-1}$  of  $7 \text{ TeV}$  data in the lepton+jets final state [156]. As the polarization of the  $W$  bosons in top-quark decays is sensitive to the  $W - t - b$  vertex

Lorentz structure and anomalous couplings, both experiments also derive limits on anomalous contributions to the  $W - t - b$  couplings. Recently, both experiments also combined their results from 7 TeV data to obtain values on the helicity fractions as well as limits on anomalous couplings [157]. Very recently, CMS came out with a measurement of the  $W$ -helicity fractions in  $19.6 \text{ fb}^{-1}$  of muon+jets events recorded at 8 TeV [158]. Also, a first measurement of the  $W$ -boson helicity in top-quark decays was made in electroweak single top production [159], yielding consistent results.

**Table 2:** Measurement and 95% C.L. upper limits of the  $W$  helicity in top-quark decays. The table includes both preliminary, as of September 2013, and published results. A full set of published results is given in the Listings.

$W$ Helicity	Source	$\int \mathcal{L} dt$ ( $\text{fb}^{-1}$ )	Ref.	Method

**C.2.4 Top-Quark Electric Charge:** The top quark is the only quark whose electric charge has not been measured through production at threshold in  $e^+e^-$  collisions. Furthermore, it is the only quark whose electromagnetic coupling has not been observed and studied until recently. Since the CDF and DØ analyses on top-quark production did not associate the  $b$ ,  $\bar{b}$ , and  $W^\pm$  uniquely to the top or antitop, decays such as  $t \rightarrow W^+ \bar{b}$ ,  $\bar{t} \rightarrow W^- b$  were not excluded. A charge  $4/3$  quark of this kind is consistent with current electroweak precision data. The  $Z \rightarrow \ell^+ \ell^-$  and  $Z \rightarrow b \bar{b}$  data, in particular the discrepancy between  $A_{LR}$  from SLC at SLAC and  $A_{FB}^{0,b}$  of  $b$ -quarks and  $A_{FB}^{0,\ell}$  of leptons from LEP at CERN, can be fitted with a top quark of mass  $m_t = 270 \text{ GeV}/c^2$ , provided that the right-handed  $b$  quark mixes with the isospin  $+1/2$  component of an exotic doublet of charge  $-1/3$  and  $-4/3$  quarks,  $(Q_1, Q_4)_R$  [160,161].

DØ studies the top-quark charge in double-tagged lepton+jets events, CDF does it in single tagged lepton+jets and dilepton events. Assuming the top- and antitop-quarks have equal but opposite electric charge, then reconstructing the

charge of the  $b$ -quark through jet charge discrimination techniques, the  $|Q_{top}| = 4/3$  and  $|Q_{top}| = 2/3$  scenarios can be differentiated. For the exotic model of Chang *et al.* [161] with a top-quark charge  $|Q_{top}| = 4/3$ , DØ excludes the exotic model at 91.2% C.L.% [162] using  $370 \text{ pb}^{-1}$ , while CDF excludes the model at 99% C.L. [163] in  $5.6 \text{ fb}^{-1}$ . Both results indicate that the observed particle is indeed consistent with being a SM  $|Q_{top}| = 2/3$  quark.

In  $2.05 \text{ fb}^{-1}$  at  $\sqrt{s} = 7 \text{ TeV}$ , ATLAS performed a similar analysis, reconstructing the  $b$ -quark charge either via a jet-charge technique or via the lepton charge in soft muon decays in combination with a kinematic likelihood fit. They measure the top-quark charge to be  $0.64 \pm 0.02(\text{stat.}) \pm 0.08(\text{syst.})e$  from the charges of the top-quark decay products in single lepton  $t\bar{t}$  events, and hence exclude the exotic scenario with charge  $-4/3$  at more than  $8\sigma$  [164].

In  $4.6 \text{ fb}^{-1}$  at  $\sqrt{s} = 7 \text{ TeV}$ , CMS discriminates between the Standard Model and the exotic top-quark charge scenario in the muon+jets final states in  $t\bar{t}$  events. They exploit the charge correlation between high- $p_t$  muons from  $W$ -boson decays and soft muons from  $B$ -hadron decays in  $b$ -jets. Using an asymmetry technique, where  $A = -1$  represent the exotic  $q = -4/3$  scenario and  $A = +1$  the Standard Model  $q = +2/3$  scenario, they find  $A_{meas} = 0.97 \pm 0.12(\text{stat.}) \pm 0.31(\text{syst.})$ , which agrees with the Standard Model expectation and excludes the exotics scenario at 99.9% C.L. [165].

The electromagnetic or the weak coupling of the top quark can be probed directly by investigating  $t\bar{t}$  events with an additional gauge boson, like  $t\bar{t}\gamma$  and  $t\bar{t}Z$  events.

CDF performs a search for events containing a lepton, a photon, significant missing transverse momentum, and a jet identified as containing a  $b$ -quark and at least three jets and large total transverse energy in  $6.0 \text{ fb}^{-1}$ . They reported evidence for the observation of  $t\bar{t}\gamma$  production with a cross section  $\sigma_{t\bar{t}\gamma} = 0.18 \pm 0.08 \text{ pb}$  and a ratio of  $\sigma_{t\bar{t}\gamma}/\sigma_{t\bar{t}} = 0.024 \pm 0.009$  [166].

ATLAS performed a first measurement of the  $t\bar{t}\gamma$  cross section in pp collisions at  $\sqrt{s} = 7 \text{ TeV}$  using  $1.04 \text{ fb}^{-1}$  of data. Events are selected that contain a large transverse momentum electron or muon and a large transverse momentum photon, yielding 52 and 70 events in the electron and muon samples, respectively. The resulting cross section times branching ratio into the single lepton and dilepton channels for  $t\bar{t}\gamma$  production with a photon with transverse momentum above 8 GeV is  $\sigma(t\bar{t}\gamma) = 2.0 \pm 0.5(\text{stat.}) \pm 0.7(\text{syst.}) \pm 0.1(\text{lumi.}) \text{ pb}$  [167], which is consistent with theoretical calculations. A real test, however, of the vector and axial vector couplings in  $t\bar{t}\gamma$  events or searches for possible tensor couplings of top-quarks to photons will only be feasible with an integrated luminosity of several hundred  $\text{fb}^{-1}$  in the future.

CMS also performed measurements of the  $t\bar{t}W$  and  $t\bar{t}Z$  production cross section at  $\sqrt{s} = 7 \text{ TeV}$  with  $5 \text{ fb}^{-1}$ , yielding results at about 3 standard deviations significance [168]. ATLAS performed a similar analysis with  $4.7 \text{ fb}^{-1}$  in the three-lepton

channel and set an upper limit of 0.71 pb at 95% C.L. [169]. Also here, more data is expected to yield an observation.

### C.3 Searches for Beyond the Standard Model Physics

The top quark plays a special role in the SM. Being the only quark with a coupling to the Higgs boson of order one, it provides the most important contributions to the quadratic radiative corrections to the Higgs mass raising the question of the naturalness of the SM. It is therefore very common for models where the naturalness problem is addressed to have new physics associated with the top quark. In SUSY, for instance, naturalness predicts the scalar top partners to be the lightest among the squarks and to be accessible at the LHC energies (see the review "Supersymmetry: Theory"). In models where the Higgs is a pseudo-Goldstone boson, such as Little Higgs models, naturalness predicts the existence of partners of the top quarks with the same spin and color, but with different electroweak couplings, the so-called vectorial  $t'$ . Stops and  $t'$ 's are expected to have sizable branching ratios to top quarks. Another intriguing prediction of SUSY models with universal couplings at the unification scale is that for a top-quark mass close to the measured value, the running of the Yukawa coupling down to 1 TeV naturally leads to the radiative breaking of the electroweak symmetry [170]. In fact, the top quark plays a role in the dynamics of electroweak symmetry breaking in many models. One example is topcolor [171], where a large top-quark mass can be generated through the formation of a dynamic  $t\bar{t}$  condensate,  $X$ , which is formed by a new strong gauge force coupling preferentially to the third generation. Another example is topcolor-assisted technicolor [172], predicting the existence of a heavy  $Z'$  boson that couples preferentially to the third generation of quarks. If light enough such a state might be directly accessible at the present hadron collider energies, or if too heavy, lead to four-top interactions possibly visible in the production cross section for  $t\bar{t}\bar{t}\bar{t}$ .

Current strategies to search for new physics in top-quark events at hadron colliders are either tailored to the discovery of specific models or model independent. They can be broadly divided in two classes. In the first class new resonant states are looked for through decay processes involving the top quarks. Current searches for bosonic resonances in  $t\bar{t}$  final states, or for direct stop and  $t'$  production, or for a charged Higgs in  $H^+ \rightarrow t\bar{b}$  fall in the category. On the other hand, if new states are too heavy to be directly produced, they might still give rise to deviations from the SM predictions for the strength and Lorentz form of the top-quark couplings to other SM particles. Accurate predictions and measurements are therefore needed and the results be efficiently systematized in the framework of an effective field theory [173,174]. The on-going efforts to constrain the  $W - t - b$  coupling and to search for flavor-changing neutral currents involving the top quark fall in this second category.

**C.3.1 New Physics in Top-Quark Production:** Theoretical [175–177] and experimental efforts have been devoted to the searches for new physics in  $t\bar{t}$  resonances.

At the Tevatron, both the CDF and DØ collaborations have searched for resonant production of  $t\bar{t}$  pairs in the lepton+jets channel [182,183]. In both analyses, the data indicate no evidence of resonant production of  $t\bar{t}$  pairs. They place upper limits on the production cross section times branching fraction to  $t\bar{t}$  in comparison to the prediction for a narrow ( $\Gamma_{Z'} = 0.012M_{Z'}$ ) leptophobic topcolor  $Z'$  boson. Within this model, they exclude  $Z'$  bosons with masses below 915 (CDF-full data set) and 835 (DØ,  $5 \text{ fb}^{-1}$ )  $\text{GeV}/c^2$  at the 95% C.L. These limits turn out to be independent of couplings of the  $t\bar{t}$  resonance (pure vector, pure axial-vector, or SM-like  $Z'$ ). A similar analysis has been performed by CDF in the all-jets channel using  $2.8 \text{ fb}^{-1}$  of data [184].

At the LHC, both the CMS and ATLAS collaborations have searched for resonant production of  $t\bar{t}$  pairs, employing different techniques and final-state signatures (all-jets, lepton+jets, dilepton) at  $\sqrt{s} = 7$  and 8 TeV. In the low mass range, from the  $t\bar{t}$  threshold to about one TeV, standard techniques based on the reconstruction of each of the decay objects (lepton, jets and  $b$ -jets, missing  $E_T$ ) are used to identify the top quarks, while at higher invariant mass, the top quarks are boosted and the decay products more collimated and can appear as large-radius jets with substructure. Dedicated reconstruction techniques have been developed in recent years for boosted top quarks [185] that are currently employed at the LHC. Most of the analyses are model-independent (i.e., no assumption on the quantum numbers of the resonance is made) yet they assume a small width and no signal-background interference.

Using dilepton and lepton+jets signatures in a data set corresponding to an integrated luminosity of  $5.0 \text{ fb}^{-1}$ , the CMS collaboration finds no significant deviations from the SM background. In the dilepton analysis, upper limits are presented for the production cross section times branching fraction of top quark-antiquark resonances for masses from 750 to 3000  $\text{GeV}/c^2$ . In particular, the existence of a leptophobic topcolor particle  $Z'$  is excluded at the 95% confidence level for resonance masses  $M_{Z'} < 1.3$  (1.9)  $\text{TeV}/c^2$  for  $\Gamma_{Z'} = 0.012(0.1)M_{Z'}$  [186]. Using a lepton+jets sample, results are obtained from the combination of two dedicated searches optimized for boosted production and production at threshold. In this case, topcolor  $Z'$  bosons with narrow (wide) width are excluded at 95% confidence level for masses below 1.49 (2.04)  $\text{TeV}/c^2$  and an upper limit of 0.3 (1.3) pb or lower is set on the production cross section times branching fraction for resonance masses above 1  $\text{TeV}/c^2$ . Kaluza-Klein excitations of a gluon with masses below 1.82  $\text{TeV}/c^2$  (at 95% confidence level) in the Randall-Sundrum model are also excluded, and an upper limit of 0.7 pb or lower is set on the production cross section times branching fraction for resonance masses above 1  $\text{TeV}/c^2$  [187]. In  $19.7 \text{ fb}^{-1}$  of 8 TeV data, CMS recently updated their measurement in the lepton+jets and the all-jets channel to obtain an

exclusion of  $M_{Z'} < 2.1(2.7)$  TeV/ $c^2$  for  $\Gamma_{Z'} = 0.013(0.1)M_{Z'}$  and gluon masses below 2.5 TeV/ $c^2$  in Randall-Sundrum models at 95% C.L. [188].

The ATLAS collaboration has performed a search for resonant  $t\bar{t}$  production in the lepton+jets channel using  $4.7 \text{ fb}^{-1}$  ( $14 \text{ fb}^{-1}$ ) of proton-proton (pp) collision data collected at a center-of-mass energy  $\sqrt{s} = 7(8)$  TeV [189,190]. The  $t\bar{t}$  system is reconstructed using both small-radius and large-radius jets, the latter being supplemented by a jet substructure analysis. A search for local excesses in the number of data events compared to the Standard Model expectation in the  $t\bar{t}$  invariant mass spectrum is performed. No evidence for a  $t\bar{t}$  resonance is found and 95% confidence-level limits on the production rate are determined for massive states predicted in two benchmark models. The most stringent limits come from the sample collected at 8 TeV. The upper limits on the cross section times branching ratio of a narrow  $Z'$  boson decaying to top-quark pairs range from 5.3 pb for a resonance mass of 0.5 TeV/ $c^2$  to 0.08 pb for a mass of 3 TeV/ $c^2$ . A narrow leptophobic topcolor  $Z'$  boson with a mass below 1.8 TeV/ $c^2$  is excluded. Upper limits are set on the cross section times branching ratio for a broad color-octet resonance with  $\Gamma/m = 15.3\%$  decaying to  $t\bar{t}$ . These range from 9.6 pb for a mass of 0.5 TeV/ $c^2$  to 0.152 pb for a mass of 2.5 TeV/ $c^2$ . A Kaluza-Klein excitation of the gluon in a Randall-Sundrum model (a slightly different model is used compared to CMS) is excluded for masses below 2.0 TeV/ $c^2$ .

ATLAS has also conducted a search in the all-jet final state at 7 TeV corresponding to an integrated luminosity of  $4.7 \text{ fb}^{-1}$  [191]. The  $t\bar{t}$  events are reconstructed by selecting two top quarks in their fully hadronic decay modes which are reconstructed using the Cambridge/Aachen jet finder algorithm with a radius parameter of 1.5. The substructure of the jets is analysed using the HEPTopTagger algorithm [192] to separate top-quark jets from those originating from gluons and lighter quark jets. The invariant mass spectrum of the data is compared to the SM prediction, and no evidence for resonant production of top-quark pairs is found. The data are used to set upper limits on the cross section times branching ratio for resonant  $t\bar{t}$  production in two models at 95% confidence level. Leptophobic  $Z'$  bosons with masses between 700 and 1000 GeV/ $c^2$  as well as 1280 – 1320 GeV/ $c^2$  and Kaluza-Klein-Gluons with masses between 700 and 1620 GeV/ $c^2$  are excluded at the 95% confidence level.

Heavy charged bosons, such as  $W'$  or  $H^+$ , can also be searched for in  $t\bar{b}$  final states (for more information see the review "W'-boson searches" and "Higgs Bosons: theory and searches"). Other resonances are searched for in final states such as  $tZ, t_j, tH, tW, bW$ .

For instance, ATLAS has performed a search for  $t$ -jet resonances in the lepton+jets channel of  $t\bar{t}$ + jets events in  $4.7 \text{ fb}^{-1}$  at  $\sqrt{s} = 7$  TeV [193]. A heavy new particle, assumed to be produced singly in association with a  $t(\bar{t})$  quark, decays to a  $t(\bar{t})$  quark and a light flavor quark, leading to a color singlet (triplet) resonance in the  $t(\bar{t})$ +jet system. The full 2011 ATLAS

$pp$  collision dataset from the LHC ( $4.7 \text{ fb}^{-1}$ ) is used to select  $t\bar{t}$  events. The data are consistent with the SM expectation and a new particle with mass below 350 (430) GeV/ $c^2$  for  $W$  (color triplet) models is excluded with a 95% confidence level, assuming unit right-handed coupling. ATLAS has conducted a search for the pair production of a new charge +2/3 quark ( $T$ ) decaying via  $T \rightarrow Zt$  in a dataset corresponding to  $14.3 \text{ fb}^{-1}$  luminosity at  $\sqrt{s} = 8$  TeV [194]. Selected events contain a high transverse momentum  $Z$ -boson candidate reconstructed from a pair of oppositely charged electrons or muons. Additionally, the presence of at least two jets possessing properties consistent with the decay of a  $b$ -hadron is required, as well as large total transverse momentum of all central jets in the event. No significant excess of events above the SM expectation is observed, and upper limits are derived for vector-like quarks of various masses in a two-dimensional plane of branching ratios. Under branching ratio assumptions corresponding to a weak-isospin singlet scenario, a  $T$  quark with mass lower than 585 GeV/ $c^2$  is excluded at the 95% confidence level. Under branching ratio assumptions corresponding to a particular weak-isospin doublet scenario, a  $T$  quark with mass lower than 680 GeV/ $c^2$  is excluded at the 95% confidence level.

A complementary search [195] in the lepton+jets final state of the same dataset, characterized by an isolated electron or muon with moderately high transverse momentum, significant missing transverse momentum, and at least six jets is performed to look for  $T \rightarrow Wb, Ht$  decays. The search exploits the high total transverse momenta of all final state objects and the high multiplicity of  $b$ -jets characteristic of signal events with at least one Higgs boson decaying into  $b\bar{b}$ , to discriminate against the dominant background from top-quark pair production. No significant excess of events above the SM expectation is observed, and upper limits are derived for vector-like quarks of various masses in the two-dimensional plane of  $B(T \rightarrow Wb)$  versus  $B(T \rightarrow Ht)$ , where  $H$  is the Standard Model Higgs boson, assumed to have a mass of 125 GeV/ $c^2$ . Under the branching ratio assumptions corresponding to a weak-isospin doublet (singlet) scenario, a  $T$  quark with mass lower than 790 (640) GeV/ $c^2$  is excluded at the 95% C.L.

Finally, a more general search is performed in the same data set [196], looking for exotic processes that result in final states containing jets including at least one  $b$ -jet, sizable missing transverse momentum, and a pair of leptons with the same electric charge. In addition to the new physics signal discussed above, this study provides limits on four top-quark production and production of two positively-charged top quarks. No significant excess of events over the background expectation is observed. This observation is interpreted as constraining the signal hypotheses, and it is found at 95% C.L. level that: the lower bound on the fourth generation  $B$  quark mass, assuming 100% branching fraction to  $Wt$ , is 0.72 TeV/ $c^2$ ; the mass of a vector-like  $B$  ( $T$ ) quark, assuming branching ratios to  $W, Z$ , and  $H$  decay modes consistent with the  $B$  or  $T$  being a singlet, is larger than 0.59 (0.54) TeV/ $c^2$ ; the four top production cross

# Quark Particle Listings

*t*

section must be less than 85 fb in the SM and less than 59 fb for production via a contact interaction; the mass of a sgluon must be greater than 0.80 TeV/ $c^2$ ; in the context of models with two universal extra dimensions the inverse size of the extra dimensions must be larger 0.90 TeV/ $c^2$ ; and the cross section for production of two positively-charged top quarks must be smaller than 210 fb.

In many models top-quark partners preferably decay to top quarks and weakly interacting neutral stable particles that are not detected. An observable especially sensitive to new physics effects in  $t\bar{t}$  production is therefore the missing momentum. CMS has presented a differential cross section measurement of top-quark pair production with missing transverse energy using 5.1 fb $^{-1}$  of data collected at 7 TeV [197]. The analysis selects events in the lepton+jets final state and the differential cross section is measured in bins of missing transverse energy. Recently, CMS has updated their analysis with 20 fb $^{-1}$  at 8 TeV [49]. The results are consistent with the predictions of the SM. An analogous search, but more targeted to discover new physics in  $t\bar{t}$  events with large missing transverse momentum in proton-proton collisions at a center-of-mass energy of 7 TeV in 1.04 fb $^{-1}$  of data has been performed by ATLAS [198]. The search is carried out in the lepton+jets channel. The results are interpreted in terms of a model where new top-quark partners are pair-produced and each decay to an on-shell top (or antitop) quark and a long-lived undetected neutral particle. The data are found to be consistent with SM expectations. A limit at 95% C.L. is set excluding a cross-section times branching ratio of 1.1 pb for a top-partner mass of 420 GeV/ $c^2$  and a neutral particle mass less than 10 GeV/ $c^2$ . In a model of exotic fourth generation quarks, top-partner masses are excluded up to 420 GeV/ $c^2$  and neutral particle masses up to 140 GeV/ $c^2$ .

Flavor-changing-neutral-currents (FCNC) are hugely suppressed in the SM, and non zero only due to the large mass hierarchy between the top quark and the other quarks. Several observables are accessible at colliders to test and constrain such couplings.

CMS has performed a study of top-quark couplings through the search for a single top quark produced in association with a  $Z$  boson in 5 fb $^{-1}$  integrated luminosity at 7 TeV [199]. The event selection requires the presence of three isolated leptons, electrons or muons, and of at least one jet. The upper limits on effective coupling strength can be translated to the 95% upper limits on the corresponding branching ratios  $B(t \rightarrow gu) \leq 0.56\%$ ,  $B(t \rightarrow gc) \leq 7.1\%$ ,  $B(t \rightarrow Zu) \leq 0.51\%$ ,  $B(t \rightarrow Zc) \leq 11\%$ .

ATLAS has presented results on the search for single top-quark production via FCNC's in strong interactions using data collected at  $\sqrt{s}=8$  TeV and corresponding to an integrated luminosity of 14.2 fb $^{-1}$ . Flavor-changing-neutral-current events are searched for in which a light quark ( $u$  or  $c$ ) interacts with a gluon to produce a single top quark, either with or without the associated production of another light quark or gluon. Candidate events of top quarks decaying into leptons

and jets are selected and classified into signal- and background-like events using a neural network. The observed 95% C.L.  $B(t \rightarrow ug) < 3.1 \cdot 10^{-5}$  and  $B(t \rightarrow cg) < 1.6 \cdot 10^{-4}$  [200]. This result supersedes the corresponding 7 TeV analysis in 2 fb $^{-1}$  [201].

Constraints on FCNC couplings of the top quark can also be obtained from searches for anomalous single top-quark production in  $e^+e^-$  collisions, via the process  $e^+e^- \rightarrow \gamma, Z^* \rightarrow t\bar{q}$  and its charge-conjugate ( $q = u, c$ ), or in  $e^\pm p$  collisions, via the process  $e^\pm u \rightarrow e^\pm t$ . For a leptonic  $W$  decay, the topology is at least a high- $p_T$  lepton, a high- $p_T$  jet and missing  $E_T$ , while for a hadronic  $W$ -decay, the topology is three high- $p_T$  jets. Limits on the cross section for this reaction have been obtained by the LEP collaborations [202] in  $e^+e^-$  collisions, and by H1 [203] and ZEUS [204] in  $e^\pm p$  collisions. When interpreted in terms of branching ratios in top decay [205,206], the LEP limits lead to typical 95% C.L. upper bounds of  $B(t \rightarrow qZ) < 0.137$ . Assuming no coupling to the  $Z$  boson, the 95% C.L. limits on the anomalous FCNC coupling  $\kappa_\gamma < 0.13$  and  $< 0.27$  by ZEUS and H1, respectively, are stronger than the CDF limit of  $\kappa_\gamma < 0.42$ , and improve over LEP sensitivity in that domain. The H1 limit is slightly weaker than the ZEUS limit due to an observed excess of five-candidate events over an expected background of  $3.2 \pm 0.4$ . If this excess is attributed to FCNC top-quark production, this leads to a total cross section of  $\sigma(ep \rightarrow e + t + X, \sqrt{s} = 319 \text{ GeV}) < 0.25 \text{ pb}$  [203,207].

**C.3.2 New Physics in Top-Quark decays:** The large sample of top quarks produced at the Tevatron and the LHC allows to measure or set stringent limits on the branching ratios of rare top-quark decays. For example, the existence of a light  $H^+$  can be constrained by looking for  $t \rightarrow H^+ b$  decay, in particular with tau-leptons in the final state (for more information see the review "Higgs Bosons: theory and searches").

A first class of searches for new physics focuses on the structure of the  $W - t - b$  vertex. Using up to 2.7 fb $^{-1}$  of data, DØ has measured the  $Wtb$  coupling form factors by combining information from the  $W$ -boson helicity in top-quark decays in  $t\bar{t}$  events and single top-quark production, allowing to place limits on the left-handed and right-handed vector and tensor couplings [225–227].

More recently, ATLAS has published the results of a search for  $CP$  violation in the decay of single top quarks produced in the  $t$ -channel where the top quarks are predicted to be highly polarized, using the lepton+jets final state [228]. The data analyzed are from  $pp$  collisions at  $\sqrt{s} = 7$  TeV and correspond to an integrated luminosity of 4.7 fb $^{-1}$ . In the Standard Model, the couplings at the  $Wtb$  vertex are left-handed, right-handed couplings being absent. A forward-backward asymmetry with respect to the normal to the plane defined by the  $W$ -momentum and the top-quark polarization has been used to probe the complex phase of a possibly non-zero value of the right-handed coupling, signaling a source of  $CP$ -violation

beyond the SM. The measured value of the asymmetry is  $0.031 \pm 0.065(\text{stat.})_{-0.031}^{+0.029}(\text{syst.})$  in good agreement with the Standard Model.

A second class of searches focuses on FCNC's in the top-quark decays.

Both, CDF and DØ, have provided the first limits for FCNC's in Run I and II. The most recent results from CDF give  $B(t \rightarrow qZ) < 3.7\%$  and  $B(t \rightarrow q\gamma) < 3.2\%$  at the 95% C.L. [229] while DØ [230,231] sets  $B(t \rightarrow qZ)(q = u, c \text{ quarks}) < 3.2\%$  at 95% C.L.,  $B(t \rightarrow gu) < 2.0 \cdot 10^{-4}$ , and  $B(t \rightarrow gc) < 3.9 \cdot 10^{-3}$  at the 95% C.L.

At the LHC, CMS has used a sample at a center-of-mass energy of 8 TeV corresponding to  $19.7 \text{ fb}^{-1}$  of integrated luminosity to perform a search for flavor changing neutral current top-quark decay  $t \rightarrow Zq$ . Events with a topology compatible with the decay chain  $t\bar{t} \rightarrow Wb + Zq \rightarrow \ell\nu b + \ell\ell q$  are searched for. There is no excess seen in the observed number of events relative to the SM prediction; thus no evidence for flavor changing neutral current in top-quark decays is found. A combination with a previous search at 7 TeV excludes a  $t \rightarrow Zq$  branching fraction greater than 0.05% at the 95% confidence level [232].

The ATLAS collaboration has also searched for FCNC processes in  $2.1 \text{ fb}^{-1}$  of  $t\bar{t}$  events with one top quark decaying through FCNC ( $t \rightarrow qZ$ ) and the other through the SM dominant mode ( $t \rightarrow bW$ ). Only the decays of the  $Z$  boson to charged leptons and leptonic  $W$  boson decays were considered as signal, leading to a final state topology characterized by the presence of three isolated leptons, at least two jets and missing transverse energy from the undetected neutrino. No evidence for an FCNC signal was found. An upper limit on the  $t \rightarrow qZ$  branching ratio of  $B(t \rightarrow qZ) < 0.73\%$  is set at the 95% confidence level [233]. Another analysis looks for FCNCs in  $t \rightarrow cH$  with  $H \rightarrow \gamma\gamma$  in  $20 \text{ fb}^{-1}$  of  $t\bar{t}$  events at  $\sqrt{s} = 9 \text{ TeV}$ , yielding a 95% C.L. limit of the  $tcH$  coupling of 0.17 (0.14 expected) [234].

#### D. Outlook

Top-quark physics at hadron colliders has developed into precision physics. Various properties of the top quark have been measured with high precision, where the LHC is about to or has already reached the precision of the Tevatron. Several  $\sqrt{s}$ -dependent physics quantities, such as the production cross-section, have been measured at several energies at the Tevatron and the LHC. Up to now, all measurements are consistent with the SM predictions and allow stringent tests of the underlying production mechanisms by strong and weak interactions. Given the very large event samples available at the LHC, top-quark properties will be further determined in  $t\bar{t}$  as well as in electroweak single top-quark production. At the Tevatron, the  $t$ - and  $s$ -channels for electroweak single top-quark production have been measured separately. At the LHC, significant progress has been achieved and all the three relevant channels are expected to be independently accessible in the near future. Furthermore,  $t\bar{t}\gamma$ ,  $t\bar{t}Z$  and  $t\bar{t}W$  associated production

will provide further information on the top-quark electroweak couplings. At the same time various models of physics beyond the SM involving top-quark production are being constrained. With the upcoming LHC Run-II with twice the center-of-mass energy and much higher luminosity, top-quark physics has the potential to shed light on new aspects of and open questions in physics at the TeV scale.

## t-QUARK MASS

We first list the direct measurements of the top quark mass which employ the event kinematics and then list the measurements which extract a top quark mass from the measured  $t\bar{t}$  cross-section using theory calculations. A discussion of the definition of the top quark mass in these measurements can be found in the review "The Top Quark."

OUR EVALUATION OF  $173.21 \pm 0.51 \pm 0.71$  GeV is an average of published top mass measurements from Tevatron Runs. The first combination of the top-quark mass measurements, including some unpublished data, has been performed by the CDF and D0 experiments at the Tevatron and ATLAS and CMS experiments at the LHC. The resulting combined top-quark mass is  $173.34 \pm 0.27 \pm 0.71$  GeV, consistent with Tevatron average. The Tevatron average was provided by the Tevatron Electroweak Working Group (TEVEWWG). It takes correlated uncertainties into account and has a  $\chi^2$  of 8.5 for 11 degrees of freedom.

For earlier search limits see PDG 96, Physical Review **D54** 1 (1996). We no longer include a compilation of indirect top mass determinations from Standard Model Electroweak fits in the Listings (our last compilation can be found in the Listings of the 2007 partial update). For a discussion of current results see the reviews "The Top Quark" and "Electroweak Model and Constraints on New Physics."

## t-Quark Mass (Direct Measurements)

The following measurements extract a  $t$ -quark mass from the kinematics of  $t\bar{t}$  events. They are sensitive to the top quark mass used in the MC generator that is usually interpreted as the pole mass, but the theoretical uncertainty in this interpretation is hard to quantify. See the review "The Top Quark" and references therein for more information.

t-Quark  $\overline{MS}$  Mass from Cross-Section Measurements

The top quark  $\overline{MS}$  or pole mass can be extracted from a measurement of  $\sigma(t\bar{t})$  by using theory calculations. We quote below the  $\overline{MS}$  mass. See the review "The Top Quark" and references therein for more information.

## t-Quark Pole Mass from Cross-Section Measurements

VALUE (GeV)	DOCUMENT ID	TECN	COMMENT
<b>176.7 ± 3.8 ± 3.4</b>	<sup>66</sup> CHATRCHYAN14	CMS	$\sigma(t\bar{t})$ + theory

<sup>1</sup> Based on 8.7 fb<sup>-1</sup> in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV. Events with an identified charged lepton or small  $\cancel{E}_T$  are rejected from the event sample, so that the measurement is statistically independent from those in the  $\ell$  + jets and all hadronic channels while being sensitive to those events with a  $\tau$  lepton in the final state.

<sup>2</sup> Based on 5.0 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 7$  TeV. CHATRCHYAN 13s studied events with di-lepton +  $\cancel{E}_T + \geq 2$  b-jets, and looked for kinematical endpoints of MT2, MT2T and subsystem variables.

<sup>3</sup> Based on 1.04 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 7$  TeV. Uses 2d-template analysis (MT) with  $m_t$  and jet energy scale factor (JSF) from  $m_W$  mass fit.

<sup>4</sup> Based on 8.7 fb<sup>-1</sup> of data in  $p\bar{p}$  collisions at 1.96 TeV. The JES is calibrated by using the dijet mass from the  $W$  boson decay.

<sup>5</sup> Use the ME method based on 2.2 fb<sup>-1</sup> of data in  $p\bar{p}$  collisions at 1.96 TeV.

<sup>6</sup> Based on 5.8 fb<sup>-1</sup> of data in  $p\bar{p}$  collisions at 1.96 TeV. The quoted systematic error is the sum of JES( $\pm 1.0$ ) and systematic( $\pm 1.1$ ) uncertainties. The measurement is performed with a likelihood fit technique which simultaneously determines  $m_t$  and JES.

<sup>7</sup> Combination with the result in 1 fb<sup>-1</sup> of preceding data reported in ABAZOV 09AH as well as the MWT result of ABAZOV 11R with a statistical correlation of 60%.

<sup>8</sup> Based on 5.0 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 7$  TeV. Uses an analytical matrix weighting technique (AMWT) and full kinematic analysis (KIN).

<sup>9</sup> Based on 5.0 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 7$  TeV. The first error is statistical and JES combined, and the second is systematic. Ideogram method is used to obtain 2D likelihood for the kinematical fit with two parameters  $m_{top}$  and JES.

<sup>10</sup> Based on 5.6 fb<sup>-1</sup> in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV. Employs a multi-dimensional template likelihood technique where the lepton plus jets (one or two b-tags) channel gives  $172.2 \pm 1.2 \pm 0.9$  GeV while the dilepton channel yields  $170.3 \pm 2.0 \pm 3.1$  GeV. The results are combined. OUR EVALUATION includes the measurement in the dilepton channel only.

<sup>11</sup> Based on 3.6 fb<sup>-1</sup> in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV. ABAZOV 11P reports  $174.94 \pm 0.83 \pm 0.78 \pm 0.96$  GeV, where the first uncertainty is from statistics, the second from JES, and the last from other systematic uncertainties. We combine the JES and systematic uncertainties. A matrix-element method is used where the JES uncertainty is constrained by the  $W$  mass. ABAZOV 11P describes a measurement based on 2.6 fb<sup>-1</sup> that is combined with ABAZOV 08AH, which employs an independent 1 fb<sup>-1</sup> of data.

<sup>12</sup> Based on 5.6 fb<sup>-1</sup> in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV. The likelihood calculated using a matrix element method gives  $m_t = 173.0 \pm 0.7(\text{stat}) \pm 0.6(\text{JES}) \pm 0.9(\text{syst})$  GeV, for a total uncertainty of 1.2 GeV.

# Quark Particle Listings

*t*

- 13 Based on  $1.9 \text{ fb}^{-1}$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$ . The result is from the measurement using the transverse decay length of  $b$ -hadrons and that using the transverse momentum of the  $W$  decay muons, which are both insensitive to the JES (jet energy scale) uncertainty. OUR EVALUATION uses only the measurement exploiting the decay length significance which yields  $166.9^{+9.5}_{-8.5}(\text{stat}) \pm 2.9(\text{syst}) \text{ GeV}$ . The measurement that uses the lepton transverse momentum is excluded from the average because of a statistical correlation with other samples.
- 14 Obtained by re-analysis of the lepton + jets candidate events that led to ABBOTT 98F. It is based upon the maximum likelihood method which makes use of the leading order matrix elements.
- 15 Based on  $125 \pm 7 \text{ pb}^{-1}$  of data at  $\sqrt{s} = 1.8 \text{ TeV}$ .
- 16 Based on  $\sim 106 \text{ pb}^{-1}$  of data at  $\sqrt{s} = 1.8 \text{ TeV}$ .
- 17 Based on  $109 \pm 7 \text{ pb}^{-1}$  of data at  $\sqrt{s} = 1.8 \text{ TeV}$ .
- 18 See AFFOLDER 01 for details of systematic error re-evaluation.
- 19 Based on the first observation of all hadronic decays of  $t\bar{t}$  pairs. Single  $b$ -quark tagging with jet-shape variable constraints was used to select signal enriched multi-jet events. The updated systematic error is listed. See AFFOLDER 01, appendix C.
- 20 Combination based on up to  $5.8 \text{ fb}^{-1}$  of data in  $p\bar{p}$  collisions at  $1.96 \text{ TeV}$ .
- 21 Based on  $4.3 \text{ fb}^{-1}$  of data in  $p$ - $\bar{p}$ bar collisions at  $1.96 \text{ TeV}$ . The measurement reduces the JES uncertainty by using the single lepton channel study of ABAZOV 11P.
- 22 Based on  $3.2 \text{ fb}^{-1}$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$ . The first error is from statistics and JES combined, and the latter is from the other systematic uncertainties. The result is obtained using an unbinned maximum likelihood method where the top quark mass and the JES are measured simultaneously, with  $\Delta_{JES} = 0.3 \pm 0.3(\text{stat})$ .
- 23 Based on  $5.7 \text{ fb}^{-1}$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$ . Events with an identified charged lepton or small  $E_T$  are rejected from the event sample, so that the measurement is statistically independent from those in the  $\ell + \text{jets}$  and all hadronic channels while being sensitive to those events with a  $\tau$  lepton in the final state. Supersedes AALTONEN 07B.
- 24 Uses a likelihood fit of the lepton  $p_T$  distribution based on  $2.7 \text{ fb}^{-1}$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$ .
- 25 Based on a matrix-element method which employs  $5.4 \text{ fb}^{-1}$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$ . Superseded by ABAZOV 12AB.
- 26 Based on  $36 \text{ pb}^{-1}$  of  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$ . A Kinematic Method using  $b$ -tagging and an analytical Matrix Weighting Technique give consistent results and are combined. Superseded by CHATRCHYAN 12BA.
- 27 Based on  $3.4 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$ . The result is obtained by combining the MT2 variable method and the NWA (Neutrino Weighting Algorithm). The MT2 method alone gives  $m_t = 168.0^{+4.8}_{-4.0}(\text{stat}) \pm 2.9(\text{syst}) \text{ GeV}$  with smaller systematic error due to small JES uncertainty.
- 28 Based on  $2.9 \text{ fb}^{-1}$  of  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$ . The first error is from statistics and JES uncertainty, and the latter is from the other systematics. Neural-network-based kinematical selection of 6 highest  $E_T$  jets with a vtx  $b$ -tag is used to distinguish signal from background. Superseded by AALTONEN 12G.
- 29 Based on  $2 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . The top mass is obtained from the measurement of the invariant mass of the lepton ( $e$  or  $\mu$ ) from  $W$  decays and the soft  $\mu$  in  $b$ -jet. The result is insensitive to jet energy scaling.
- 30 Based on  $1.9 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . The first error is from statistics and jet energy scale uncertainty, and the latter is from the other systematics. Matrix element method with effective propagators.
- 31 Based on  $943 \text{ pb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . The first error is from statistical and jet-energy-scale uncertainties, and the latter is from other systematics. AALTONEN 09k selected 6 jet events with one or more vertex  $b$ -tags and used the tree-level matrix element to construct template models of signal and background.
- 32 Based on  $1.9 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . The first error is from statistical and jet-energy-scale (JES) uncertainties, and the second is from other systematics. Events with lepton + jets and those with dilepton + jets were simultaneously fit to constrain  $m_t$  and JES. Lepton + jets data only give  $m_t = 171.2^{+5.3}_{-5.1} \text{ GeV}$ .
- 33 Based on  $2 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . Matrix Element method. Optimal selection criteria for candidate events with two high  $p_T$  leptons, high  $E_T$ , and two or more jets with and without  $b$ -tag are obtained by neural network with neuroevolution technique to minimize the statistical error of  $m_t$ .
- 34 Based on  $2.9 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . Mass  $m_t$  is estimated from the likelihood for the eight-fold kinematical solutions in the plane of the azimuthal angles of the two neutrino momenta.
- 35 Based on  $1 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . Events with two identified leptons, and those with one lepton plus one isolated track and a  $b$ -tag were used to constrain  $m_t$ . The result is a combination of the  $\nu$ WT ( $\nu$  Weighting Technique) result of  $176.2 \pm 4.8 \pm 2.1 \text{ GeV}$  and the MWT (Matrix-element Weighting Technique) result of  $173.2 \pm 4.9 \pm 2.0 \text{ GeV}$ .
- 36 Reports measurement of  $170.7^{+4.2}_{-3.9} \pm 2.6 \pm 2.4 \text{ GeV}$  based on  $1.2 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . The last error is due to the theoretical uncertainty on  $\sigma_{t\bar{t}}$ . Without the cross-section constraint a top mass of  $169.7^{+5.2}_{-4.9} \pm 3.1 \text{ GeV}$  is obtained.
- 37 Template method.
- 38 Result is based on  $1 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . The first error is from statistics and jet energy scale uncertainty, and the latter is from the other systematics.
- 39 Based on  $310 \text{ pb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ .
- 40 Ideogram method.
- 41 Based on  $311 \text{ pb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . Events with 4 or more jets with  $E_T > 15 \text{ GeV}$ , significant missing  $E_T$ , and secondary vertex  $b$ -tag are used in the fit. About 44% of the signal acceptance is from  $\tau\nu + 4 \text{ jets}$ . Events with identified  $e$  or  $\mu$  are vetoed to provide a statistically independent measurement.
- 42 Based on  $1.02 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . Superseded by AALTONEN 12G.
- 43 Based on  $955 \text{ pb}^{-1}$  of data  $\sqrt{s} = 1.96 \text{ TeV}$ .  $m_t$  and JES (Jet Energy Scale) are fitted simultaneously, and the first error contains the JES contribution of  $1.5 \text{ GeV}$ .
- 44 Matrix element method.
- 45 Based on  $425 \text{ pb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . The first error is a combination of statistics and JES (Jet Energy Scale) uncertainty, which has been measured simultaneously to give  $JES = 0.989 \pm 0.029(\text{stat})$ .
- 46 Based on  $370 \text{ pb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . Combined result of MWT (Matrix-element Weighting Technique) and  $\nu$ WT ( $\nu$  Weighting Technique) analyses is  $178.1 \pm 6.7 \pm 4.8 \text{ GeV}$ .
- 47 Based on  $1.0 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . ABULENCIA 07D improves the matrix element description by including the effects of initial-state radiation.
- 48 Based on  $695 \text{ pb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . The transverse decay length of the  $b$  hadron is used to determine  $m_t$ , and the result is free from the JES (jet energy scale) uncertainty.
- 49 Based on  $\sim 400 \text{ pb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . The first error includes statistical and systematic jet energy scale uncertainties, the second error is from the other systematics. The result is obtained with the  $b$ -tagging information. The result without  $b$ -tagging is  $169.2^{+5.0+1.5}_{-7.4-1.4} \text{ GeV}$ . Superseded by ABAZOV 08AH.
- 50 Based on  $318 \text{ pb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ .
- 51 Dynamical likelihood method.
- 52 Based on  $340 \text{ pb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ .
- 53 Based on  $360 \text{ pb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ .
- 54 Based on  $110.2 \pm 5.8 \text{ pb}^{-1}$  at  $\sqrt{s} = 1.8 \text{ TeV}$ .
- 55 Based on the all hadronic decays of  $t\bar{t}$  pairs. Single  $b$ -quark tagging via the decay chain  $b \rightarrow c \rightarrow \mu$  was used to select signal enriched multijet events. The result was obtained by the maximum likelihood method after bias correction.
- 56 Obtained by combining the measurements in the lepton + jets [AFFOLDER 01], all-jets [ABE 97R, ABE 99B], and dilepton [ABE 99B] decay topologies.
- 57 Obtained by combining the D0 result  $m_t(\text{GeV}) = 168.4 \pm 12.3 \pm 3.6$  from 6 di-lepton events (see also ABBOTT 98D) and  $m_t(\text{GeV}) = 173.3 \pm 5.6 \pm 5.5$  from lepton+jet events (ABBOTT 98F).
- 58 Obtained by combining the CDF results of  $m_t(\text{GeV}) = 167.4 \pm 10.3 \pm 4.8$  from 8 dilepton events,  $m_t(\text{GeV}) = 175.9 \pm 4.8 \pm 5.3$  from lepton+jet events (ABE 98E), and  $m_t(\text{GeV}) = 186.0 \pm 10.0 \pm 5.7$  from all-jet events (ABE 97R). The systematic errors in the latter two measurements are changed in this paper.
- 59 See ABAZOV 04G.
- 60 The updated systematic error is listed. See AFFOLDER 01, appendix C.
- 61 Obtained by combining the D0 results of  $m_t(\text{GeV}) = 168.4 \pm 12.3 \pm 3.6$  from 6 dilepton events and  $m_t(\text{GeV}) = 173.3 \pm 5.6 \pm 5.5$  from 77 lepton+jet events.
- 62 Obtained by combining the D0 results from dilepton and lepton+jet events, and the CDF results (ABE 99B) from dilepton, lepton+jet events, and all-jet events.
- 63 Based on  $5.3 \text{ fb}^{-1}$  in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$ . ABAZOV 11S uses the measured  $t\bar{t}$  production cross section of  $8.13^{+1.02}_{-0.90} \text{ pb}$  [ABAZOV 11E] in the lepton plus jets channel to obtain the top quark  $\overline{MS}$  mass by using an approximate NNLO computation (MOCH 08, LANGENFELD 09). The corresponding top quark pole mass is  $167.5^{+5.4}_{-4.9} \text{ GeV}$ . A different theory calculation (AHRENS 10, AHRENS 10A) is also used and yields  $m_t^{\overline{MS}} = 154.5^{+5.0}_{-4.3} \text{ GeV}$ .
- 64 Based on  $1 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . Uses the  $\ell + \text{jets}$ ,  $\ell\ell$ , and  $\ell\tau + \text{jets}$  channels. ABAZOV 09AG extract the pole mass of the top quark using two different calculations that yield  $169.1^{+5.9}_{-5.2} \text{ GeV}$  (MOCH 08, LANGENFELD 09) and  $168.2^{+5.9}_{-5.4} \text{ GeV}$  (KIDONAKIS 08).
- 65 Based on  $1 \text{ fb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ . Uses the  $\ell\ell$  and  $\ell\tau + \text{jets}$  channels. ABAZOV 09R extract the pole mass of the top quark using two different calculations that yield  $173.3^{+9.8}_{-8.6} \text{ GeV}$  (MOCH 08, LANGENFELD 09) and  $171.5^{+9.9}_{-8.8} \text{ GeV}$  (CACCIARI 08).
- 66 Used  $\sigma(t\bar{t})$  from  $pp$  collisions at  $\sqrt{s} = 7 \text{ TeV}$  measured in CHATRCHYAN 12AX to obtain  $m_t(\text{pole})$  for  $\alpha_s(m_Z) = 0.1184 \pm 0.0007$ .

## $m_t - m_{\bar{t}}$

Test of  $CPT$  conservation. OUR AVERAGE assumes that the systematic uncertainties are uncorrelated.

## $t$ -quark DECAY WIDTH

VALUE (GeV)	CL%	DOCUMENT ID	TECN	COMMENT
<b><math>2.00^{+0.47}_{-0.43}</math></b>		<sup>1</sup> ABAZOV	12T D0	$\Gamma(t \rightarrow bW)/\Gamma(t \rightarrow bW)$
• • • We do not use the following data for averages, fits, limits, etc. • • •				
$< 6.38$	95	<sup>2</sup> AALTONEN	13Z CDF	$\ell + E_T + \geq 4 \text{ jets}$ ( $\geq 0$ $b$ -tag), direct
$1.99^{+0.69}_{-0.55}$		<sup>3</sup> ABAZOV	11B D0	Repl. by ABAZOV 12T
$> 1.21$	95	<sup>3</sup> ABAZOV	11B D0	$\Gamma(t \rightarrow Wb)$
$< 7.6$	95	<sup>4</sup> AALTONEN	10AC CDF	$\ell + \text{jets}$ , direct
$< 13.1$	95	<sup>5</sup> AALTONEN	09M CDF	$m_t(\text{rec})$ distribution

<sup>1</sup> Based on 5.4 fb<sup>-1</sup> of data in pp collisions at 1.96 TeV.  $\Gamma(t \rightarrow bW) = 1.87^{+0.44}_{-0.40}$  GeV is obtained from the observed t-channel single top quark production cross section, whereas  $B(t \rightarrow bW) = 0.90 \pm 0.04$  is used assuming  $\sum_q B(t \rightarrow qW) = 1$ . The result is valid for  $m_t = 172.5$  GeV, where as those for  $m_t = 170$  and 175 GeV are given.

<sup>2</sup> Based on 8.7 fb<sup>-1</sup> of data. The two sided 68% CL interval is 1.10 GeV <  $\Gamma_t$  < 4.05 GeV for  $m_t = 172.5$  GeV.

<sup>3</sup> Based on 2.3 fb<sup>-1</sup> in p $\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV. ABAZOV 11B extracted  $\Gamma_t$  from the partial width  $\Gamma(t \rightarrow Wb) = 1.92^{+0.58}_{-0.51}$  GeV measured using the t-channel single top production cross section, and the branching fraction  $\text{br}t \rightarrow Wb = 0.962 + 0.068(\text{stat}) + 0.064(\text{sys})$ . The  $\Gamma(t \rightarrow Wb)$  measurement gives the 95% CL lowerbound of  $\Gamma(t \rightarrow Wb)$  and hence that of  $\Gamma_t$ .

<sup>4</sup> Results are based on 4.3 fb<sup>-1</sup> of data in p $\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV. The top quark mass and the hadronically decaying W boson mass are reconstructed for each candidate events and compared with templates of different top quark width. The two sided 68% CL interval is 0.3 GeV <  $\Gamma_t$  < 4.4 GeV for  $m_t = 172.5$  GeV.

<sup>5</sup> Based on 955 pb<sup>-1</sup> of p $\bar{p}$  collision data at  $\sqrt{s} = 1.96$  TeV. AALTONEN 09M selected t $\bar{t}$  candidate events for the  $\ell + \cancel{E}_T + \text{jets}$  channel with one or two b-tags, and examine the decay width dependence of the reconstructed  $m_t$  distribution. The result is for  $m_t = 175$  GeV, whereas the upper limit is lower for smaller  $m_t$ .

### t DECAY MODES

Mode	Fraction ( $\Gamma_i/\Gamma$ )	Confidence level
$\Gamma_1$ W q (q = b, s, d)		
$\Gamma_2$ Wb		
$\Gamma_3$ $\ell\nu_\ell$ anything	[a,b] (9.4 ± 2.4) %	
$\Gamma_4$ $\tau\nu_\tau b$		
$\Gamma_5$ $\gamma q$ (q = u, c)	[c] < 5.9 × 10 <sup>-3</sup>	95%
<b><math>\Delta T = 1</math> weak neutral current (TI) modes</b>		
$\Gamma_6$ Z q (q = u, c)	TI [d] < 2.1 × 10 <sup>-3</sup>	95%

[a]  $\ell$  means e or  $\mu$  decay mode, not the sum over them.

[b] Assumes lepton universality and W-decay acceptance.

[c] This limit is for  $\Gamma(t \rightarrow \gamma q)/\Gamma(t \rightarrow Wb)$ .

[d] This limit is for  $\Gamma(t \rightarrow Zq)/\Gamma(t \rightarrow Wb)$ .

<sup>1</sup> Based on 8.7 fb<sup>-1</sup> of p $\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV. Measure the fraction of  $t \rightarrow Wb$  decays simultaneously with the t $\bar{t}$  cross section. The correlation coefficient between those two measurements is -0.434. Assume unitarity of the 3x3 CKM matrix and set  $|V_{tb}| > 0.89$  at 95% CL.

<sup>2</sup> Based on 5.4 fb<sup>-1</sup> of data. The error is statistical and systematic combined. The result is a combination of 0.95 ± 0.07 from  $\ell + \text{jets}$  channel and 0.86 ± 0.05 from  $\ell\ell$  channel.  $|V_{tb}| = 0.95 \pm 0.02$  follows from the result by assuming unitarity of the 3x3 CKM matrix.

<sup>3</sup> Result is based on 0.9 fb<sup>-1</sup> of data. The 95% CL lower bound  $R > 0.79$  gives  $|V_{tb}| > 0.89$  (95% CL).

<sup>4</sup> ABAZOV 06k result is from the analysis of  $t\bar{t} \rightarrow \ell\nu + \geq 3$  jets with 230 pb<sup>-1</sup> of data at  $\sqrt{s} = 1.96$  TeV. It gives  $R > 0.61$  and  $|V_{tb}| > 0.78$  at 95% CL. Superseded by ABAZOV 08M.

<sup>5</sup> ACOSTA 05A result is from the analysis of lepton + jets and di-lepton + jets final states of t $\bar{t}$  candidate events with  $\sim 162$  pb<sup>-1</sup> of data at  $\sqrt{s} = 1.96$  TeV. The first error is statistical and the second systematic. It gives  $R > 0.61$ , or  $|V_{tb}| > 0.78$  at 95% CL.

<sup>6</sup> AFFOLDER 01c measures the top-quark decay width ratio  $R = \Gamma(Wb)/\Gamma(Wq)$ , where q is a d, s, or b quark, by using the number of events with multiple b-tags. The first error is statistical and the second systematic. A numerical integration of the likelihood function gives  $R > 0.61$  (0.56) at 90% (95%) CL. By assuming three generation unitarity,  $|V_{tb}| = 0.97^{+0.16}_{-0.12}$  or  $|V_{tb}| > 0.78$  (0.75) at 90% (95%) CL is obtained. The result is based on 109 pb<sup>-1</sup> of data at  $\sqrt{s} = 1.8$  TeV.

< 0.032	95	<sup>6</sup> ABE 98G	CDF	t $\bar{t}$ → (Wb) ( $\gamma c$ or $\gamma u$ )

<sup>1</sup> CHEKANOV 03 looked for single top production via FCNC in the reaction  $e^\pm p \rightarrow e^\pm (t \text{ or } \bar{t}) X$  in 130.1 pb<sup>-1</sup> of data at  $\sqrt{s} = 300\text{--}318$  GeV. No evidence for top production and its decay into bW was found. The result is obtained for  $m_t = 175$  GeV when  $B(\gamma c) = B(\gamma u) = 0$ , where q is a u or c quark. Bounds on the effective t-u- $\gamma$  and t-u-Z couplings are found in their Fig. 4. The conversion to the constraint listed is from private communication, E. Gallo, January 2004.

<sup>2</sup> AARON 09A looked for single top production via FCNC in  $e^\pm p$  collisions at HERA with 474 pb<sup>-1</sup>. The upper bound of the cross section gives the bound on the FCNC coupling  $\kappa_{t u \gamma} / \Lambda < 1.03$  TeV<sup>-1</sup>, which corresponds to the result for  $m_t = 175$  GeV.

<sup>3</sup> ABDALLAH 04c looked for single top production via FCNC in the reaction  $e^+ e^- \rightarrow \bar{t} c$  or  $\bar{t} u$  in 541 pb<sup>-1</sup> of data at  $\sqrt{s} = 189\text{--}208$  GeV. No deviation from the SM is found, which leads to the bound on  $B(t \rightarrow \gamma q)$ , where q is a u or c quark, for  $m_t = 175$  GeV when  $B(t \rightarrow Zq) = 0$  is assumed. The conversion to the listed bound is from private communication, O. Yushchenko, April 2005. The bounds on the effective t-q- $\gamma$  and t-q-Z couplings are given in their Fig. 7 and Table 4, for  $m_t = 170\text{--}180$  GeV, where most conservative bounds are found by choosing the chiral couplings to maximize the negative interference between the virtual  $\gamma$  and Z exchange amplitudes.

<sup>4</sup> AKTAS 04 looked for single top production via FCNC in  $e^\pm$  collisions at HERA with 118.3 pb<sup>-1</sup>, and found 5 events in the e or  $\mu$  channels. By assuming that they are due to statistical fluctuation, the upper bound on the  $t u \gamma$  coupling  $\kappa_{t u \gamma} < 0.27$  (95% CL) is obtained. The conversion to the partial width limit, when  $B(\gamma c) = B(Zu) = B(Zc) = 0$ , is from private communication, E. Perez, May 2005.

<sup>5</sup> ACHARD 02j looked for single top production via FCNC in the reaction  $e^+ e^- \rightarrow \bar{t} c$  or  $\bar{t} u$  in 634 pb<sup>-1</sup> of data at  $\sqrt{s} = 189\text{--}209$  GeV. No deviation from the SM is found, which leads to a bound on the top-quark decay branching fraction  $B(\gamma q)$ , where q is a u or c quark. The bound assumes  $B(Zq) = 0$  and is for  $m_t = 175$  GeV; bounds for  $m_t = 170$  GeV and 180 GeV and  $B(Zq) \neq 0$  are given in Fig. 5 and Table 7.

<sup>6</sup> ABE 98g looked for t $\bar{t}$  events where one t decays into  $\gamma q$  while the other decays into bW. The quoted bound is for  $\Gamma(\gamma q)/\Gamma(Wb)$ .

$\Gamma(Zq(q = u, c))/\Gamma_{\text{total}}$   $\Gamma_6/\Gamma$

Test for  $\Delta T = 1$  weak neutral current. Allowed by higher-order electroweak interaction.

<sup>1</sup> Based on 5.0 fb<sup>-1</sup> of pp data at  $\sqrt{s} = 7$  TeV. Search for FCNC decays of the top quark in  $t\bar{t} \rightarrow \ell^+ \ell^- \ell'^{\pm} \nu + \text{jets}$  ( $\ell, \ell' = e, \mu$ ) final states found no excess of signal events.

<sup>2</sup> Based on 2.1 fb<sup>-1</sup> of pp data at  $\sqrt{s} = 7$  TeV.

<sup>3</sup> Based on 4.1 fb<sup>-1</sup> of data. ABAZOV 11M searched for FCNC decays of the top quark in  $t\bar{t} \rightarrow \ell^+ \ell^- \ell'^{\pm} \nu + \text{jets}$  ( $\ell, \ell' = e, \mu$ ) final states, and absence of the signal gives the bound.

<sup>4</sup> Based on p $\bar{p}$  data of 1.52 fb<sup>-1</sup>. AALTONEN 09AL compared  $t\bar{t} \rightarrow WbWb \rightarrow \ell\nu b j j b$  and  $t\bar{t} \rightarrow ZcWb \rightarrow \ell\ell c j j b$  decay chains, and absence of the latter signal gives the bound. The result is for 100% longitudinally polarized Z boson and the theoretical t $\bar{t}$  production cross section. The results for different Z polarizations and those without the cross section assumption are given in their Table XI.

<sup>5</sup> Result is based on 1.9 fb<sup>-1</sup> of data at  $\sqrt{s} = 1.96$  TeV. t $\bar{t}$  → WbZq or ZqZq processes have been looked for in Z +  $\geq 4$  jet events with and without b-tag. No signal leads to the bound  $B(t \rightarrow Zq) < 0.037$  (0.041) for  $m_t = 175$  (170) GeV.

<sup>6</sup> ABDALLAH 04c looked for single top production via FCNC in the reaction  $e^+ e^- \rightarrow \bar{t} c$  or  $\bar{t} u$  in 541 pb<sup>-1</sup> of data at  $\sqrt{s} = 189\text{--}208$  GeV. No deviation from the SM is found, which leads to the bound on  $B(t \rightarrow Zq)$ , where q is a u or c quark, for  $m_t = 175$  GeV when  $B(t \rightarrow \gamma q) = 0$  is assumed. The conversion to the listed bound is from private communication, O. Yushchenko, April 2005. The bounds on the effective t-q- $\gamma$  and t-q-Z couplings are given in their Fig. 7 and Table 4, for  $m_t = 170\text{--}180$  GeV, where

## Quark Particle Listings

t

most conservative bounds are found by choosing the chiral couplings to maximize the negative interference between the virtual  $\gamma$  and Z exchange amplitudes.

- <sup>7</sup>ACHARD 02J looked for single top production via FCNC in the reaction  $e^+e^- \rightarrow \bar{t}c$  or  $\bar{t}u$  in 634 pb<sup>-1</sup> of data at  $\sqrt{s}=189-209$  GeV. No deviation from the SM is found, which leads to a bound on the top-quark decay branching fraction  $B(Zq)$ , where  $q$  is a  $u$  or  $c$  quark. The bound assumes  $B(\gamma q)=0$  and is for  $m_t=175$  GeV; bounds for  $m_t=170$  GeV and 180 GeV and  $B(\gamma q) \neq 0$  are given in Fig. 5 and Table 7. Table 6 gives constraints on  $t$ - $c$ - $e$ - $e$  four-fermi contact interactions.
- <sup>8</sup>HEISTER 02Q looked for single top production via FCNC in the reaction  $e^+e^- \rightarrow \bar{t}c$  or  $\bar{t}u$  in 214 pb<sup>-1</sup> of data at  $\sqrt{s}=204-209$  GeV. No deviation from the SM is found, which leads to a bound on the branching fraction  $B(Zq)$ , where  $q$  is a  $u$  or  $c$  quark. The bound assumes  $B(\gamma q)=0$  and is for  $m_t=174$  GeV. Bounds on the effective  $t$ -( $c$  or  $u$ )- $\gamma$  and  $t$ -( $c$  or  $u$ )-Z couplings are given in their Fig. 2.
- <sup>9</sup>ABBIENDI 01T looked for single top production via FCNC in the reaction  $e^+e^- \rightarrow \bar{t}c$  or  $\bar{t}u$  in 600 pb<sup>-1</sup> of data at  $\sqrt{s}=189-209$  GeV. No deviation from the SM is found, which leads to bounds on the branching fractions  $B(Zq)$  and  $B(\gamma q)$ , where  $q$  is a  $u$  or  $c$  quark. The result is obtained for  $m_t=174$  GeV. The upper bound becomes 9.7% (20.6%) for  $m_t=169$  (179) GeV. Bounds on the effective  $t$ -( $c$  or  $u$ )- $\gamma$  and  $t$ -( $c$  or  $u$ )-Z couplings are given in their Fig. 4.
- <sup>10</sup>BARATE 00s looked for single top production via FCNC in the reaction  $e^+e^- \rightarrow \bar{t}c$  or  $\bar{t}u$  in 411 pb<sup>-1</sup> of data at c.m. energies between 189 and 202 GeV. No deviation from the SM is found, which leads to a bound on the branching fraction. The bound assumes  $B(\gamma q)=0$ . Bounds on the effective  $t$ -( $c$  or  $u$ )- $\gamma$  and  $t$ -( $c$  or  $u$ )-Z couplings are given in their Fig. 4.
- <sup>11</sup>ABE 98g looked for  $t\bar{t}$  events where one  $t$  decays into three jets and the other decays into  $qZ$  with  $Z \rightarrow \ell\ell$ . The quoted bound is for  $\Gamma(Zq)/\Gamma(Wb)$ .

## t-quark EW Couplings

$W$  helicity fractions in top decays.  $F_0$  is the fraction of longitudinal and  $F_+$  the fraction of right-handed  $W$  bosons.  $F_{V+A}$  is the fraction of  $V+A$  current in top decays. The effective Lagrangian (cited by ABAZOV 08A1) has terms  $f_L^T$  and  $f_R^T$  for  $V-A$  and  $V+A$  couplings,  $f_2^T$  and  $f_3^T$  for tensor couplings with  $b_R$  and  $b_L$  respectively.

- <sup>1</sup>Based on 8.7 fb<sup>-1</sup> of data in  $p\bar{p}$  collisions at  $\sqrt{s}=1.96$  TeV using  $t\bar{t}$  events with  $\ell + \cancel{E}_T + \geq 4$  jets ( $\geq 1 b$ ), and under the constraint  $F_0 + F_+ + F_- = 1$ . The statistical errors of  $F_0$  and  $F_+$  are correlated with correlation coefficient  $\rho(F_0, F_+) = -0.69$ .
- <sup>2</sup>Based on 5.0 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s}=7$  TeV. CHATRCHYAN 13BH studied  $tt$  events with large  $\cancel{E}_T$  and  $\ell + \geq 4$  jets using a constrained kinematic fit.
- <sup>3</sup>Based on 1.04 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s}=7$  TeV. AAD 12BG studied  $tt$  events with large  $\cancel{E}_T$  and either  $\ell + \geq 4j$  or  $\ell\ell + \geq 2j$ . The uncertainties are not independent,  $\rho(F_0, F_-) = -0.96$ .
- <sup>4</sup>Based on 2.7 and 5.1 fb<sup>-1</sup> of CDF data in  $\ell +$  jets and dilepton channels, and 5.4 fb<sup>-1</sup> of D0 data in  $\ell +$  jets and dilepton channels.  $F_0 = 0.682 \pm 0.035 \pm 0.046$  if  $F_+ = 0.0017(1)$ , while  $F_+ = -0.015 \pm 0.018 \pm 0.030$  if  $F_0 = 0.688(4)$ , where the assumed fixed values are the SM prediction for  $m_t = 173.3 \pm 1.1$  GeV and  $m_W = 80.399 \pm 0.023$  GeV.
- <sup>5</sup>Results are based on 5.4 fb<sup>-1</sup> of data in  $p\bar{p}$  collisions at 1.96 TeV, including those of ABAZOV 08B. Under the SM constraint of  $f_0 = 0.698$  (for  $m_t = 173.3$  GeV,  $m_W = 80.399$  GeV),  $f_+ = 0.010 \pm 0.022 \pm 0.030$  is obtained.
- <sup>6</sup>AFFOLDER 00B studied the angular distribution of leptonic decays of  $W$  bosons in  $t \rightarrow Wb$  events. The ratio  $F_0$  is the fraction of the helicity zero (longitudinal)  $W$  bosons in the decaying top quark rest frame.  $B(t \rightarrow W_+ b)$  is the fraction of positive helicity (right-handed) positive charge  $W$  bosons in the top quark decays. It is obtained by assuming the Standard Model value of  $F_0$ .
- <sup>7</sup>Results are based on 2.7 fb<sup>-1</sup> of data in  $p\bar{p}$  collisions at  $\sqrt{s}=1.96$  TeV.  $F_0$  result is obtained by assuming  $F_+ = 0$ , while  $F_+$  result is obtained for  $F_0 = 0.70$ , the SM value. Model independent fits for the two fractions give  $F_0 = 0.88 \pm 0.11 \pm 0.06$  and  $F_+ = -0.15 \pm 0.07 \pm 0.06$  with correlation coefficient of  $-0.59$ . The results are for  $m_t = 175$  GeV.
- <sup>8</sup>Results are based on 1.9 fb<sup>-1</sup> of data in  $p\bar{p}$  collisions at  $\sqrt{s}=1.96$  TeV.  $F_0$  result is obtained assuming  $F_+ = 0$ , while  $F_+$  result is obtained for  $F_0 = 0.70$ , the SM values. Model independent fits for the two fractions give  $F_0 = 0.66 \pm 0.16 \pm 0.05$  and  $F_+ = -0.03 \pm 0.06 \pm 0.03$ .
- <sup>9</sup>Based on 1 fb<sup>-1</sup> at  $\sqrt{s}=1.96$  TeV.
- <sup>10</sup>Based on 318 pb<sup>-1</sup> of data at  $\sqrt{s}=1.96$  TeV.
- <sup>11</sup>Based on 200 pb<sup>-1</sup> of data at  $\sqrt{s}=1.96$  TeV.  $t \rightarrow Wb \rightarrow \ell\nu b$  ( $\ell = e$  or  $\mu$ ). The errors are stat + syst.
- <sup>12</sup>ABAZOV 05G studied the angular distribution of leptonic decays of  $W$  bosons in  $t\bar{t}$  candidate events with lepton + jets final states, and obtained the fraction of longitudinally polarized  $W$  under the constraint of no right-handed current,  $F_+ = 0$ . Based on 125 pb<sup>-1</sup> of data at  $\sqrt{s}=1.8$  TeV.

<sup>1</sup>Based on 8.7 fb<sup>-1</sup> of data in  $p\bar{p}$  collisions at  $\sqrt{s}=1.96$  TeV using  $t\bar{t}$  events with  $\ell + \cancel{E}_T + \geq 4$  jets ( $\geq 1 b$ ), and under the constraint  $F_0 + F_+ + F_- = 1$ . The statistical errors of  $F_0$  and  $F_+$  are correlated with correlation coefficient  $\rho(F_0, F_+) = -0.69$ .

<sup>2</sup>Based on 5.0 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s}=7$  TeV. CHATRCHYAN 13BH studied  $tt$  events with large  $\cancel{E}_T$  and  $\ell + \geq 4$  jets using a constrained kinematic fit.

<sup>3</sup>Based on 1.04 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s}=7$  TeV. AAD 12BG studied  $tt$  events with large  $\cancel{E}_T$  and either  $\ell + \geq 4j$  or  $\ell\ell + \geq 2j$ .

<sup>4</sup>Results are based on 5.4 fb<sup>-1</sup> of data in  $p\bar{p}$  collisions at 1.96 TeV, including those of ABAZOV 08B. Under the SM constraint of  $f_0 = 0.698$  (for  $m_t = 173.3$  GeV,  $m_W = 80.399$  GeV),  $f_+ = 0.010 \pm 0.022 \pm 0.030$  is obtained.

<sup>5</sup>AFFOLDER 00B studied the angular distribution of leptonic decays of  $W$  bosons in  $t \rightarrow Wb$  events. The ratio  $F_0$  is the fraction of the helicity zero (longitudinal)  $W$  bosons in the decaying top quark rest frame.  $B(t \rightarrow W_+ b)$  is the fraction of positive helicity (right-handed) positive charge  $W$  bosons in the top quark decays. It is obtained by assuming the Standard Model value of  $F_0$ .

<sup>6</sup>Based on 2.7 and 5.1 fb<sup>-1</sup> of CDF data in  $\ell +$  jets and dilepton channels, and 5.4 fb<sup>-1</sup> of D0 data in  $\ell +$  jets and dilepton channels.  $F_0 = 0.682 \pm 0.035 \pm 0.046$  if  $F_+ = 0.0017(1)$ , while  $F_+ = -0.015 \pm 0.018 \pm 0.030$  if  $F_0 = 0.688(4)$ , where the assumed fixed values are the SM prediction for  $m_t = 173.3 \pm 1.1$  GeV and  $m_W = 80.399 \pm 0.023$  GeV.

<sup>7</sup>Results are based on 2.7 fb<sup>-1</sup> of data in  $p\bar{p}$  collisions at  $\sqrt{s}=1.96$  TeV.  $F_0$  result is obtained by assuming  $F_+ = 0$ , while  $F_+$  result is obtained for  $F_0 = 0.70$ , the SM value. Model independent fits for the two fractions give  $F_0 = 0.88 \pm 0.11 \pm 0.06$  and  $F_+ = -0.15 \pm 0.07 \pm 0.06$  with correlation coefficient of  $-0.59$ . The results are for  $m_t = 175$  GeV.

<sup>8</sup>Results are based on 1.9 fb<sup>-1</sup> of data in  $p\bar{p}$  collisions at  $\sqrt{s}=1.96$  TeV.  $F_0$  result is obtained assuming  $F_+ = 0$ , while  $F_+$  result is obtained for  $F_0 = 0.70$ , the SM values. Model independent fits for the two fractions give  $F_0 = 0.66 \pm 0.16 \pm 0.05$  and  $F_+ = -0.03 \pm 0.06 \pm 0.03$ .

<sup>9</sup>Based on 1 fb<sup>-1</sup> at  $\sqrt{s}=1.96$  TeV.

<sup>10</sup>Based on 370 pb<sup>-1</sup> of data at  $\sqrt{s}=1.96$  TeV, using the  $\ell +$  jets and dilepton decay channels. The result assumes  $F_0 = 0.70$ , and it gives  $F_+ < 0.23$  at 95% CL.

<sup>11</sup>Based on 318 pb<sup>-1</sup> of data at  $\sqrt{s}=1.96$  TeV.

<sup>12</sup>Based on 200 pb<sup>-1</sup> of data at  $\sqrt{s}=1.96$  TeV.  $t \rightarrow Wb \rightarrow \ell\nu b$  ( $\ell = e$  or  $\mu$ ). The errors are stat + syst.

<sup>13</sup>ABAZOV 05L studied the angular distribution of leptonic decays of  $W$  bosons in  $t\bar{t}$  events, where one of the  $W$ 's from  $t$  or  $\bar{t}$  decays into  $e$  or  $\mu$  and the other decays hadronically. The fraction of the "+" helicity  $W$  boson is obtained by assuming  $F_0 = 0.7$ , which is the generic prediction for any linear combination of V and A currents. Based on 230 ± 15 pb<sup>-1</sup> of data at  $\sqrt{s}=1.96$  TeV.

<sup>14</sup>ACOSTA 05D measures the  $m_{\ell\nu}^2 + b$  distribution in  $t\bar{t}$  production events where one or both  $W$ 's decay leptonically to  $\ell = e$  or  $\mu$ , and finds a bound on the  $V+A$  coupling of the  $tW$  vertex. By assuming the SM value of the longitudinal  $W$  fraction  $F_0 = B(t \rightarrow W_0 b) = 0.70$ , the bound on  $F_+$  is obtained. If the results are combined with those of AFFOLDER 00B, the bounds become  $F_{V+A} < 0.61$  (95% CL) and  $F_+ < 0.18$  (95% CL), respectively. Based on 109 ± 7 pb<sup>-1</sup> of data at  $\sqrt{s}=1.8$  TeV (run I).

 $F_{V+A}$

	$ f_2^R ^2 < 0.3$	95	5 ABAZOV	08AI D0	$ f_1^L ^2 = 1.4^{+0.9}_{-0.8}$

<sup>1</sup> Based on 1.04 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 7$  TeV. AAD 12BG studied  $tt$  events with large  $E_T$  and either  $\ell + \geq 4j$  or  $\ell\ell + \geq 2j$ .

<sup>2</sup> Based on 5.4 fb<sup>-1</sup> of data. For each value of the form factor quoted the other two are assumed to have their SM value. Their Fig. 4 shows two-dimensional posterior probability density distributions for the anomalous couplings.

<sup>3</sup> Based on 5.4 fb<sup>-1</sup> of data in  $p\bar{p}$  collisions at 1.96 TeV. Results are obtained by combining the limits from the  $W$  helicity measurements and those from the single top quark production.

<sup>4</sup> Based on 1 fb<sup>-1</sup> of data at  $p\bar{p}$  collisions  $\sqrt{s} = 1.96$  TeV. Combined result of the  $W$  helicity measurement in  $t\bar{t}$  events (ABAZOV 08B) and the search for anomalous  $tbW$  couplings in the single top production (ABAZOV 08AI). Constraints when  $f_1^L$  and one of the anomalous couplings are simultaneously allowed to vary are given in their Fig. 1 and Table 1.

<sup>5</sup> Result is based on 0.9 fb<sup>-1</sup> of data at  $\sqrt{s} = 1.96$  TeV. Single top quark production events are used to measure the Lorentz structure of the  $tbW$  coupling. The upper bounds on the non-standard couplings are obtained when only one non-standard coupling is allowed to be present together with the SM one,  $f_1^L = V_{tb}^*$ .

### Spin Correlation in $t\bar{t}$ Production

$C$  is the correlation strength parameter,  $f$  is the ratio of events with correlated  $t$  and  $\bar{t}$  spins (SM prediction:  $f = 1$ ), and  $\kappa$  is the spin correlation coefficient. See "The Top Quark" review for more information.

VALUE	DOCUMENT ID	TECN	COMMENT
• • •	We do not use the following data for averages, fits, limits, etc. • • •		
$0.85 \pm 0.29$	1 ABAZOV	12B D0	$f(\ell\ell + \geq 2 \text{ jets}, \ell + \geq 4 \text{ jets})$
$1.15^{+0.42}_{-0.43}$	2 ABAZOV	12B D0	$f(\ell + \cancel{E}_T + \geq 4 \text{ jets})$
$0.60^{+0.50}_{-0.16}$	3 AALTONEN	11AR CDF	$\kappa(\ell + \cancel{E}_T + \geq 4 \text{ jets})$

$< 0.037$	95	4 ABAZOV	07V D0	$\kappa^{utg}/\Lambda$
$< 0.15$	95	4 ABAZOV	07V D0	$\kappa^{ctg}/\Lambda$

<sup>1</sup> Based on 2.05 fb<sup>-1</sup> of  $pp$  data at  $\sqrt{s} = 7$  TeV. The results are obtained from the 95% CL upper limit on the single top-quark production  $\sigma(q\bar{q} \rightarrow t)\text{B}(t \rightarrow bW) < 3.9$  pb, for  $q=u$  or  $q=c$ ,  $\text{B}(t \rightarrow ug) < 5.7 \times 10^{-5}$  and  $\text{B}(t \rightarrow ug) < 2.7 \times 10^{-4}$ .

<sup>2</sup> Based on 2.3 fb<sup>-1</sup> of data in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV. Upper limit of single top quark production cross section 0.20 pb and 0.27 pb via FCNC  $t$ - $u$ - $g$  and  $t$ - $c$ - $g$  couplings, respectively, lead to the bounds without assuming the absence of the other coupling.  $\text{B}(t \rightarrow u+g) < 2.0 \times 10^{-4}$  and  $\text{B}(t \rightarrow c+g) < 3.9 \times 10^{-3}$  follow.

<sup>3</sup> Based on 2.2 fb<sup>-1</sup> of data in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV. Upper limit of single top quark production cross section  $\sigma(u(c) + g \rightarrow t) < 1.8$  pb (95% CL) via FCNC  $t$ - $u$ - $g$  and  $t$ - $c$ - $g$  couplings lead to the bounds.  $\text{B}(t \rightarrow u+g) < 3.9 \times 10^{-4}$  and  $\text{B}(t \rightarrow c+g) < 5.7 \times 10^{-3}$  follow.

<sup>4</sup> Result is based on 230 pb<sup>-1</sup> of data at  $\sqrt{s} = 1.96$  TeV. Absence of single top quark production events via FCNC  $t$ - $u$ - $g$  and  $t$ - $c$ - $g$  couplings lead to the upper bounds on the dimensioned couplings,  $\kappa^{utg}/\Lambda$  and  $\kappa^{ctg}/\Lambda$ , respectively.

### Single $t$ -Quark Production Cross Section in $p\bar{p}$ Collisions at $\sqrt{s} = 1.8$ TeV

Direct probe of the  $tbW$  coupling and possible new physics at  $\sqrt{s} = 1.8$  TeV.

<sup>1</sup> Based on  $9.7 \text{ fb}^{-1}$  of data. Events with  $\ell + \cancel{E}_T + 2$  or 3 jets (1 or 2  $b$ -tag) are analysed, assuming  $m_t = 172.5 \text{ GeV}$ . The combined s- + t-channel cross section gives  $|V_{tb}|^2 f_1^L = 1.12^{+0.09}_{-0.08}$ , or  $|V_{tb}| > 0.92$  at 95% CL for  $f_1^L = 1$  and a flat prior within  $0 \leq |V_{tb}|^2 \leq 1$ .

<sup>2</sup> Based on  $5.4 \text{ fb}^{-1}$  of data. The error is statistical + systematic combined. The results are for  $m_t = 172.5 \text{ GeV}$ . Results for other  $m_t$  values are given in Table 2 of ABAZOV 11AA.

<sup>3</sup> Based on  $5.4 \text{ fb}^{-1}$  of data and for  $m_t = 172.5 \text{ GeV}$ . The error is statistical + systematic combined. Results for other  $m_t$  values are given in Table III of ABAZOV 11AD. The result is obtained by assuming the SM ratio between  $t\bar{b}$  (s-channel) and  $tqb$  (t-channel) productions, and gives  $|V_{tb}|^2 f_1^L = 1.02^{+0.10}_{-0.11}$ , or  $|V_{tb}| > 0.79$  at 95% CL for a flat prior within  $0 < |V_{tb}|^2 < 1$ .

<sup>4</sup> Based on  $3.2 \text{ fb}^{-1}$  of data. For combined s- + t-channel result see AALTONEN 09AT.

<sup>5</sup> Result is based on  $2.1 \text{ fb}^{-1}$  of data. Events with large missing  $E_T$  and jets with at least one  $b$ -jet without identified electron or muon are selected. Result is obtained when observed  $2.1 \sigma$  excess over the background originates from the signal for  $m_t = 175 \text{ GeV}$ , giving  $|V_{tb}| = 1.24^{+0.34}_{-0.29} \pm 0.07(\text{theory})$ .

<sup>6</sup> Result is based on  $2.3 \text{ fb}^{-1}$  of data. Events with isolated  $\ell + \cancel{E}_T + 2, 3, 4$  jets with one or two  $b$ -tags are selected. The analysis assumes  $m_t = 170 \text{ GeV}$ .

<sup>7</sup> Result is based on  $4.8 \text{ fb}^{-1}$  of data. Events with an isolated reconstructed tau lepton, missing  $E_T + 2, 3$  jets with one or two  $b$ -tags are selected. When combined with ABAZOV 09Z result for  $e + \mu$  channels, the s- and t-channels combined cross section is  $3.84^{+0.89}_{-0.83} \text{ pb}$ .

<sup>8</sup> Based on  $3.2 \text{ fb}^{-1}$  of data. Events with isolated  $\ell + \cancel{E}_T +$  jets with at least one  $b$ -tag are analyzed and s- and t-channel single top events are selected by using the likelihood function, matrix element, neural-network, boosted decision tree, likelihood function optimized for s-channel process, and neural-networked based analysis of events with  $\cancel{E}_T$  that has sensitivity for  $W \rightarrow \tau\nu$  decays. The result is for  $m_t = 175 \text{ GeV}$ , and the mean value decreases by  $0.02 \text{ pb/GeV}$  for smaller  $m_t$ . The signal has 5.0 sigma significance. The result gives  $|V_{tb}| = 0.91 \pm 0.11 (\text{stat+syst}) \pm 0.07 (\text{theory})$ , or  $|V_{tb}| > 0.71$  at 95% CL.

<sup>9</sup> Based on  $2.3 \text{ fb}^{-1}$  of data. Events with isolated  $\ell + \cancel{E}_T + \geq 2$  jets with 1 or 2  $b$ -tags are analyzed and s- and t-channel single top events are selected by using boosted decision tree, Bayesian neural networks and the matrix element method. The signal has 5.0 sigma significance. The result gives  $|V_{tb}| = 1.07 \pm 0.12$ , or  $|V_{tb}| > 0.78$  at 95% CL. The analysis assumes  $m_t = 170 \text{ GeV}$ .

<sup>10</sup> Result is based on  $2.2 \text{ fb}^{-1}$  of data. Events with isolated  $\ell + \cancel{E}_T + 2, 3$  jets with at least one  $b$ -tag are selected, and s- and t-channel single top events are selected by using likelihood, matrix element, and neural network discriminants. The result can be interpreted as  $|V_{tb}| = 0.88^{+0.13}_{-0.12} (\text{stat} + \text{syst}) \pm 0.07(\text{theory})$ , and  $|V_{tb}| > 0.66$  (95% CL) under the  $|V_{tb}| < 1$  constraint.

<sup>11</sup> Result is based on  $0.9 \text{ fb}^{-1}$  of data. Events with isolated  $\ell + \cancel{E}_T + 2, 3, 4$  jets with one or two  $b$ -vertex-tag are selected, and contributions from  $W$  + jets,  $t\bar{t}$ , s- and t-channel single top events are identified by using boosted decision trees, Bayesian neural networks, and matrix element analysis. The result can be interpreted as the measurement of the CKM matrix element  $|V_{tb}| = 1.31^{+0.25}_{-0.21}$ , or  $|V_{tb}| > 0.68$  (95% CL) under the  $|V_{tb}| < 1$  constraint.

<sup>12</sup> Result is based on  $0.9 \text{ fb}^{-1}$  of data. This result constrains  $V_{tb}$  to  $0.68 < |V_{tb}| \leq 1$  at 95% CL.

<sup>13</sup> ABAZOV 05P bounds single top-quark production from either the s-channel  $W$ -exchange process,  $q'\bar{q} \rightarrow t\bar{b}$ , or the t-channel  $W$ -exchange process,  $q'\bar{q} \rightarrow qt\bar{b}$ , based on  $\sim 230 \text{ pb}^{-1}$  of data.

<sup>14</sup> ACOSTA 05N bounds single top-quark production from the t-channel  $W$ -exchange process ( $q'\bar{q} \rightarrow qt\bar{b}$ ), the s-channel  $W$ -exchange process ( $q'\bar{q} \rightarrow t\bar{b}$ ), and from the combined cross section of t- and s-channel. Based on  $\sim 162 \text{ pb}^{-1}$  of data.

Single  $t$ -Quark Production Cross Section in  $pp$  Collisions at  $\sqrt{s} = 7 \text{ TeV}$ 

Direct probe of the  $tbW$  coupling and possible new physics at  $\sqrt{s} = 7 \text{ TeV}$ .

VALUE (pb)	DOCUMENT ID	TECN	COMMENT

$83.6 \pm 29.8 \pm 3.3$	3	CHATRCHYAN11R CMS	t-channel

<sup>1</sup> Based on  $1.04 \text{ fb}^{-1}$  of data. The result gives  $|V_{tb}| = 1.13^{+0.14}_{-0.13}$  from the ratio  $\sigma(\text{exp})/\sigma(\text{th})$ , where  $\sigma(\text{th})$  is the SM prediction for  $|V_{tb}| = 1$ . The 95% CL lower bound of  $|V_{tb}| > 0.75$  is found if  $|V_{tb}| < 1$  is assumed.  $\sigma(t) = 59^{+18}_{-16} \text{ pb}$  and  $\sigma(\bar{t}) = 33^{+13}_{-12} \text{ pb}$  are found for the separate single  $t$  and  $\bar{t}$  production cross sections, respectively. The results assume  $m_t = 172.5 \text{ GeV}$  for the acceptance.

<sup>2</sup> Based on  $1.17 \text{ fb}^{-1}$  of data for  $\ell = \mu$ ,  $1.56 \text{ fb}^{-1}$  of data for  $\ell = e$  at 7 TeV collected during 2011. The result gives  $|V_{tb}| = 1.020 \pm 0.046(\text{meas}) \pm 0.017(\text{th})$ . The 95% CL lower bound of  $|V_{tb}| > 0.92$  is found if  $|V_{tb}| < 1$  is assumed. The results assume  $m_t = 172.5 \text{ GeV}$  for the acceptance.

<sup>3</sup> Based on  $36 \text{ pb}^{-1}$  of data. The first error is statistical + systematic combined, the second is luminosity. The result gives  $|V_{tb}| = 1.114 \pm 0.22(\text{exp}) \pm 0.02(\text{th})$  from the ratio  $\sigma(\text{exp})/\sigma(\text{th})$ , where  $\sigma(\text{th})$  is the SM prediction for  $|V_{tb}| = 1$ . The 95% CL lower bound of  $|V_{tb}| > 0.62$  (0.68) is found from the 2D (BDT) analysis under the constraint  $0 < |V_{tb}|^2 < 1$ .

- 1 Based on 8.8 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV.
- 2 Based on 8.7 fb<sup>-1</sup> of  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV. Measure the  $t\bar{t}$  cross section simultaneously with the fraction of  $t \rightarrow Wb$  decays. The correlation coefficient between those two measurements is  $-0.434$ . Assume unitarity of the  $3 \times 3$  CKM matrix and set  $|V_{tb}| > 0.89$  at 95% CL.
- 3 Based on 2.2 fb<sup>-1</sup> of data in  $p\bar{p}$  collisions at 1.96 TeV. The result assumes the acceptance for  $m_t = 172.5$  GeV.
- 4 Based on 1.12 fb<sup>-1</sup> and assumes  $m_t = 175$  GeV, where the cross section changes by  $\pm 0.1$  pb for every  $\mp 1$  GeV shift in  $m_t$ . AALTONEN 11b fits simultaneously the  $t\bar{t}$  production cross section and the  $b$ -tagging efficiency and find improvements in both measurements.
- 5 Based on 2.7 fb<sup>-1</sup>. The first error is from statistics and systematics, the second is from luminosity. The result is for  $m_t = 175$  GeV. AALTONEN 11w fits simultaneously a jet flavor discriminator between  $b$ -,  $c$ -, and light-quarks, and find significant reduction in the systematic error.
- 6 Based on 2.2 fb<sup>-1</sup>. The result is for  $m_t = 172.5$  GeV. AALTONEN 11y selects multi-jet events with large  $E_T$ , and vetoes identified electrons and muons.
- 7 Based on 5.3 fb<sup>-1</sup>. The error is statistical + systematic + luminosity combined. The result is for  $m_t = 172.5$  GeV. The results for other  $m_t$  values are given in Table XII and eq.(10) of ABAZOV 11E.
- 8 Combination of a dilepton measurement presented in ABAZOV 11z (based on 5.4 fb<sup>-1</sup>), which yields  $7.36^{+0.90}_{-0.79}$  (stat+syst) pb, and the lepton + jets measurement of ABAZOV 11E. The result is for  $m_t = 172.5$  GeV. The results for other  $m_t$  values is given by eq.(5) of ABAZOV 11A.
- 9 Based on 2.8 fb<sup>-1</sup>. The result is for  $m_t = 175$  GeV.
- 10 Based on 2.9 fb<sup>-1</sup>. Result is obtained from the fraction of signal events in the top quark mass measurement in the all hadronic decay channel.
- 11 Based on 1.7 fb<sup>-1</sup>. The result is for  $m_t = 175$  GeV. AALTONEN 10v uses soft electrons from  $b$ -hadron decays to suppress  $W$ +jets background events.
- 12 Based on 4.6 fb<sup>-1</sup>. The result is for  $m_t = 172.5$  GeV. The ratio  $\sigma(t\bar{t} \rightarrow \ell + \text{jets}) / \sigma(Z/\gamma^* \rightarrow \ell\ell)$  is measured and then multiplied by the theoretical  $Z/\gamma^* \rightarrow \ell\ell$  cross section of  $\sigma(Z/\gamma^* \rightarrow \ell\ell) = 251.3 \pm 5.0$  pb, which is free from the luminosity error.
- 13 Based on 1 fb<sup>-1</sup>. The result is for  $m_t = 175$  GeV.  $7.9 \pm 2.3$  pb is found for  $m_t = 170$  GeV. ABAZOV 10i uses a likelihood discriminant to separate signal from background, where the background model was created from lower jet-multiplicity data.
- 14 Based on 1 fb<sup>-1</sup>. The result is for  $m_t = 170$  GeV. For  $m_t = 175$  GeV, the result is  $6.3^{+1.2}_{-1.1}$ (stat)  $\pm 0.7$ (syst)  $\pm 0.4$ (lumi) pb. Cross section of  $t\bar{t}$  production has been measured in the  $t\bar{t} \rightarrow \tau_h + \text{jets}$  topology, where  $\tau_h$  denotes hadronically decaying  $\tau$  leptons. The result for the cross section times the branching ratio is  $\sigma(t\bar{t}) \cdot B(t\bar{t} \rightarrow \tau_h + \text{jets}) = 0.60^{+0.23+0.15}_{-0.22-0.14} \pm 0.04$  pb for  $m_t = 170$  GeV.
- 15 Based on 1.1 fb<sup>-1</sup>. The result is for  $B(W \rightarrow \ell\nu) = 10.8\%$  and  $m_t = 175$  GeV; the mean value is 9.8 for  $m_t = 172.5$  GeV and 10.1 for  $m_t = 170$  GeV. AALTONEN 09AD used high  $p_T$   $e$  or  $\mu$  with an isolated track to select  $t\bar{t}$  decays into dileptons including  $\ell = \tau$ . The result is based on the candidate event samples with and without vertex  $b$ -tag.
- 16 Based on 2 fb<sup>-1</sup>. The result is for  $m_t = 175$  GeV; the mean value is 3% higher for  $m_t = 170$  GeV and 4% lower for  $m_t = 180$  GeV.
- 17 Result is based on 1 fb<sup>-1</sup> of data. The result is for  $m_t = 170$  GeV, and the mean value decreases with increasing  $m_t$ ; see their Fig. 2. The result is obtained after combining  $\ell + \text{jets}$ ,  $\ell\ell$ , and  $\ell\tau$  final states, and the ratios of the extracted cross sections are  $R^{\ell\ell/\ell j} = 0.86^{+0.19}_{-0.17}$  and  $R^{\ell\tau/\ell\ell-\ell j} = 0.97^{+0.32}_{-0.29}$ , consistent with the SM expectation of  $R = 1$ . This leads to the upper bound of  $B(t \rightarrow bH^+)$  as a function of  $m_{H^+}$ . Results are shown in their Fig. 1 for  $B(H^+ \rightarrow \tau\nu) = 1$  and  $B(H^+ \rightarrow c\bar{s}) = 1$  cases. Comparison of the  $m_t$  dependence of the extracted cross section and a partial NNLO prediction gives  $m_t = 169.1^{+5.9}_{-5.2}$  GeV.
- 18 Result is based on 1 fb<sup>-1</sup> of data. The result is for  $m_t = 170$  GeV, and the mean value changes by  $-0.07$  [ $m_t(\text{GeV}) - 170$ ] pb near the reference  $m_t$  value. Comparison of the  $m_t$  dependence of the extracted cross section and a partial NNLO QCD prediction gives  $m_t = 171.5^{+9.9}_{-8.8}$  GeV. The  $\ell\tau$  channel alone gives  $7.6^{+4.9+3.5+1.4}_{-4.3-3.4-0.9}$  pb and the  $\ell\ell$  channel gives  $7.5^{+1.2+0.7+0.7}_{-1.1-0.6-0.5}$  pb.
- 19 Result is based on 0.9 fb<sup>-1</sup> of data. The first error is from stat + syst, while the latter error is from luminosity. The result is for  $m_t = 175$  GeV, and the mean value changes by  $-0.09$  pb [ $m_t(\text{GeV}) - 175$ ].
- 20 Result is based on 0.9 fb<sup>-1</sup> of data. The cross section is obtained from the  $\ell + \geq 3$  jet event rates with 1 or 2  $b$ -tag, and also from the kinematical likelihood analysis of the  $\ell + 3, 4$  jet events. The result is for  $m_t = 172.6$  GeV, and its  $m_t$  dependence shown in Fig. 3 leads to the constraint  $m_t = 170 \pm 7$  GeV when compared to the SM prediction.

- 21 Result is based on 360 pb<sup>-1</sup> of data. Events with high  $p_T$  oppositely charged dileptons  $\ell^+\ell^-$  ( $\ell = e, \mu$ ) are used to obtain cross sections for  $t\bar{t}$ ,  $W^+W^-$ , and  $Z \rightarrow \tau^+\tau^-$  production processes simultaneously. The other cross sections are given in Table IV.
- 22 Based on 1.02 fb<sup>-1</sup> of data. Result is for  $m_t = 175$  GeV. Secondary vertex  $b$ -tag and neural network selections are used to achieve a signal-to-background ratio of about 1/2.
- 23 Based on 425 pb<sup>-1</sup> of data. Result is for  $m_t = 175$  GeV. For  $m_t = 170.9$  GeV,  $7.8 \pm 1.8$ (stat + syst) pb is obtained.
- 24 Based on 405 ± 25 pb<sup>-1</sup> of data. Result is for  $m_t = 175$  GeV. The last error is for luminosity. Secondary vertex  $b$ -tag and neural network are used to separate the signal events from the background.
- 25 Based on 425 pb<sup>-1</sup> of data. Assumes  $m_t = 175$  GeV.
- 26 Based on  $\sim 425$  pb<sup>-1</sup>. Assuming  $m_t = 175$  GeV. The first error is combined statistical and systematic, the second one is luminosity.
- 27 Based on  $\sim 318$  pb<sup>-1</sup>. Assuming  $m_t = 178$  GeV. The cross section changes by  $\pm 0.08$  pb for each  $\mp 1$  GeV change in the assumed  $m_t$ . Result is for at least one  $b$ -tag. For at least two  $b$ -tagged jets,  $t\bar{t}$  signal of significance greater than  $5\sigma$  is found, and the cross section is  $10.1^{+1.6+2.0}_{-1.4-1.3}$  pb for  $m_t = 178$  GeV.
- 28 Based on  $\sim 311$  pb<sup>-1</sup>. Assuming  $m_t = 178$  GeV. For  $m_t = 175$  GeV, the result is  $6.0 \pm 1.2^{+0.9}_{-0.7}$ . This is the first CDF measurement without lepton identification, and hence it has sensitivity to the  $W \rightarrow \tau\nu$  mode.
- 29 ABULENCIA,A 06E measures the  $t\bar{t}$  production cross section in the all hadronic decay mode by selecting events with 6 to 8 jets and at least one  $b$ -jet.  $S/B = 1/5$  has been achieved. Based on 311 pb<sup>-1</sup>. Assuming  $m_t = 178$  GeV.
- 30 Based on  $\sim 318$  pb<sup>-1</sup>. Assuming  $m_t = 178$  GeV. Result is for at least one  $b$ -tag. For at least two  $b$ -tagged jets, the cross section is  $11.1^{+2.3+2.5}_{-1.9-1.9}$  pb.
- 31 ABAZOV 05Q measures the top-quark pair production cross section with  $\sim 230$  pb<sup>-1</sup> of data, based on the analysis of  $W$  plus  $n$ -jet events where  $W$  decays into  $e$  or  $\mu$  plus neutrino, and at least one of the jets is  $b$ -jet like. The first error is statistical and systematic, and the second accounts for the luminosity uncertainty. The result assumes  $m_t = 175$  GeV; the mean value changes by  $(175 - m_t(\text{GeV})) \times 0.06$  pb in the mass range 160 to 190 GeV.
- 32 ABAZOV 05R measures the top-quark pair production cross section with 224–243 pb<sup>-1</sup> of data, based on the analysis of events with two charged leptons in the final state. The result assumes  $m_t = 175$  GeV; the mean value changes by  $(175 - m_t(\text{GeV})) \times 0.08$  pb in the mass range 160 to 190 GeV.
- 33 Based on 230 pb<sup>-1</sup>. Assuming  $m_t = 175$  GeV.
- 34 Based on 194 pb<sup>-1</sup>. Assuming  $m_t = 175$  GeV.
- 35 Based on 194 ± 11 pb<sup>-1</sup>. Assuming  $m_t = 175$  GeV.
- 36 Based on 162 ± 10 pb<sup>-1</sup>. Assuming  $m_t = 175$  GeV.
- 37 ACOSTA 05V measures the top-quark pair production cross section with  $\sim 162$  pb<sup>-1</sup> data, based on the analysis of  $W$  plus  $n$ -jet events where  $W$  decays into  $e$  or  $\mu$  plus neutrino, and at least one of the jets is  $b$ -jet like. Assumes  $m_t = 175$  GeV.
- 38 ACOSTA 04I measures the top-quark pair production cross section with 197 ± 12 pb<sup>-1</sup> data, based on the analysis of events with two charged leptons in the final state. Assumes  $m_t = 175$  GeV.

### Ratio of the Production Cross Sections of $t\bar{t}\gamma$ to $t\bar{t}$ at $\sqrt{s} = 1.96$ TeV

VALUE	DOCUMENT ID	TECN	COMMENT
•••	We do not use the following data for averages, fits, limits, etc. •••		
0.024 ± 0.009	1	AALTONEN 11z	CDF $E_T(\gamma) > 10$ GeV, $ \eta(\gamma)  < 1.0$
1	Based on 6.0 fb <sup>-1</sup> of data. The error is statistical and systematic combined. Events with lepton + $E_T + \geq 3$ jets ( $\geq 1b$ ) with and without central, high $E_T$ photon are measured. The result is consistent with the SM prediction of $0.024 \pm 0.005$ . The absolute production cross section is measured to be $0.18 \pm 0.08$ fb. The statistical significance is 3.0 standard deviations.		

### $t\bar{t}$ Production Cross Section in $p\bar{p}$ Collisions at $\sqrt{s} = 7$ TeV

Unless otherwise noted the first quoted error is from statistics, the second from systematic uncertainties, and the third from luminosity. If only two errors are quoted the luminosity is included in the systematic uncertainties.

*t*

- <sup>1</sup> Based on  $1.67 \text{ fb}^{-1}$  of data. The result uses the acceptance for  $m_t = 172.5 \text{ GeV}$ .
- <sup>2</sup> Based on  $3.54 \text{ fb}^{-1}$  of data.
- <sup>3</sup> Based on  $2.3 \text{ fb}^{-1}$  of data.
- <sup>4</sup> Based on  $3.9 \text{ fb}^{-1}$  of data.
- <sup>5</sup> Based on  $35 \text{ pb}^{-1}$  of data for an assumed top quark mass of  $m_t = 172.5 \text{ GeV}$ .
- <sup>6</sup> Based on  $0.70 \text{ fb}^{-1}$  of data. The 3 errors are from statistics, systematics, and luminosity. The result uses the acceptance for  $m_t = 172.5 \text{ GeV}$ .
- <sup>7</sup> Based on  $35 \text{ pb}^{-1}$  of data. The 3 errors are from statistics, systematics, and luminosity. The result uses the acceptance for  $m_t = 172.5 \text{ GeV}$  and  $173 \pm 17^{+18}_{-16} \pm 6 \text{ pb}$  is found without the *b*-tag.
- <sup>8</sup> Based on  $2.05 \text{ fb}^{-1}$  of data. The hadronic  $\tau$  candidates are selected using a BDT technique. The 3 errors are from statistics, systematics, and luminosity. The result uses the acceptance for  $m_t = 172.5 \text{ GeV}$ .
- <sup>9</sup> Based on  $2.0 \text{ fb}^{-1}$  and  $2.2 \text{ fb}^{-1}$  of data for  $\ell = e$  and  $\ell = \mu$ , respectively. The 3 errors are from statistics, systematics, and luminosity. The result uses the acceptance for  $m_t = 172.5 \text{ GeV}$ .
- <sup>10</sup> Based on  $2.3 \text{ fb}^{-1}$  of data. The 3 errors are from statistics, systematics, and luminosity. The result uses the profile likelihood-ratio (PLB) method and an assumed  $m_t$  of  $172.5 \text{ GeV}$ .
- <sup>11</sup> Based on  $2.9 \text{ pb}^{-1}$  of data. The result for single lepton channels is  $142 \pm 34^{+50}_{-31} \text{ pb}$ , while for the dilepton channels is  $151^{+78+37}_{-62-24} \text{ pb}$ .
- <sup>12</sup> Result is based on  $36 \text{ pb}^{-1}$  of data. The first uncertainty corresponds to the statistical and systematic uncertainties, and the second corresponds to the luminosity.
- <sup>13</sup> Based on  $36 \text{ pb}^{-1}$  of data. The ratio of  $t\bar{t}$  and  $Z/\gamma^*$  cross sections is measured as  $\sigma(pp \rightarrow t\bar{t})/\sigma(pp \rightarrow Z/\gamma^* \rightarrow e^+e^-/\mu^+\mu^-) = 0.175 \pm 0.018(\text{stat}) \pm 0.015(\text{syst})$  for  $60 < m_{\ell\ell} < 120 \text{ GeV}$ , for which they use an NNLO prediction for the denominator cross section of  $972 \pm 42 \text{ pb}$ .
- <sup>14</sup> Result is based on  $36 \text{ pb}^{-1}$  of data. The first error is from statistical and systematic uncertainties, and the second from luminosity. This is a combination of a measurement in the dilepton channel (CHATRCHYAN 11F) and the measurement in the  $\ell + \text{jets}$  channel (CHATRCHYAN 11Z) which yields  $150 \pm 9 \pm 17 \pm 6 \text{ pb}$ .
- <sup>15</sup> Result is based on  $3.1 \pm 0.3 \text{ pb}^{-1}$  of data.

$95.2^{+0.5}_{-0.6} \pm 0.4$	1 AAD	12BL ATLS	$Q_0 = 150 \text{ GeV}$ ( $ \eta  < 2.1$ )

- <sup>1</sup> Based on  $2.05 \text{ fb}^{-1}$  of data. The  $t\bar{t}$  events are selected in the dilepton decay channel with two identified *b*-jets.

## $t\bar{t}$ Charge Asymmetry ( $A_C$ ) in *pp* Collisions at $\sqrt{s} = 7 \text{ TeV}$

$A_C = (N(\Delta|y| > 0) - N(\Delta|y| < 0)) / (N(\Delta|y| > 0) + N(\Delta|y| < 0))$  where  $\Delta|y| = |y_t| - |y_{\bar{t}}|$  is the difference between the absolute values of the top and antitop rapidities and *N* is the number of events with  $\Delta|y|$  positive or negative.

VALUE (%)	DOCUMENT ID	TECN	COMMENT
$-1.9 \pm 2.8 \pm 2.4$	1 AAD	12BK ATLS	$\ell + \cancel{E}_T + \geq 4j$ ( $\geq 1b$ )
$0.4 \pm 1.0 \pm 1.1$	2 CHATRCHYAN12BB	CMS	$\ell + \cancel{E}_T + \geq 4j$ ( $\geq 1b$ )
$-1.3 \pm 2.8^{+2.9}_{-3.1}$	3 CHATRCHYAN12Bs	CMS	$\ell + \cancel{E}_T + \geq 4j$ ( $\geq 1b$ )

- <sup>1</sup> Based on  $1.04 \text{ fb}^{-1}$  of data. The result is consistent with  $A_C = 0.006 \pm 0.002$  (MC at NLO). No significant dependence of  $A_C$  on  $m_{t\bar{t}}$  is observed.

<sup>2</sup> Based on  $5.0 \text{ fb}^{-1}$  of data at  $7 \text{ TeV}$ .

<sup>3</sup> Based on  $1.09 \text{ fb}^{-1}$  of data. The result is consistent with the SM predictions.

## *t*-quark Polarization in $t\bar{t}$ Events in *pp* Collisions at $\sqrt{s} = 7 \text{ TeV}$

The double differential distribution in polar angles,  $\theta_1$  ( $\theta_2$ ) of the decay particle of the top (anti-top) decay products, is parametrized as  $(1/\sigma)d\sigma/(d\cos\theta_1 d\cos\theta_2) = (1/4) (1 + A_t \cos\theta_1 + A_{\bar{t}} \cos\theta_2 - C \cos\theta_1 \cos\theta_2)$ . The charged lepton is used to tag *t* or  $\bar{t}$ .

The coefficient  $A_t$  and  $A_{\bar{t}}$  measure the average helicity of *t* and  $\bar{t}$ , respectively.  $A_{CP}$  assumes *CP* conservation, whereas  $A_{CPV}$  corresponds to maximal *CP* violation.

VALUE	DOCUMENT ID	TECN	COMMENT
$-0.035 \pm 0.014 \pm 0.037$	1 AAD	13BE ATLS	$A_{CP} = A_t = A_{\bar{t}}$
$0.020 \pm 0.016^{+0.013}_{-0.017}$	1 AAD	13BE ATLS	$A_{CPV} = A_t = -A_{\bar{t}}$

- <sup>1</sup> Based on  $4.7 \text{ fb}^{-1}$  of data using the final states containing one or two isolated electrons or muons and jets with at least one *b*-tag.

## $gg \rightarrow t\bar{t}$ Fraction in *p* $\bar{p}$ Collisions at $\sqrt{s} = 1.96 \text{ TeV}$

VALUE	CL%	DOCUMENT ID	TECN	COMMENT
$<0.33$	68	1 AALTONEN	09F CDF	$t\bar{t}$ correlations
$0.07 \pm 0.14 \pm 0.07$		2 AALTONEN	08AG CDF	low $p_T$ number of tracks

- <sup>1</sup> Based on  $955 \text{ pb}^{-1}$ . AALTONEN 09F used differences in the  $t\bar{t}$  production angular distribution and polarization correlation to discriminate between  $gg \rightarrow t\bar{t}$  and  $q\bar{q} \rightarrow t\bar{t}$  subprocesses. The combination with the result of AALTONEN 08AG gives  $0.07^{+0.15}_{-0.07}$ .

- <sup>2</sup> Result is based on  $0.96 \text{ fb}^{-1}$  of data. The contribution of the subprocesses  $gg \rightarrow t\bar{t}$  and  $q\bar{q} \rightarrow t\bar{t}$  is distinguished by using the difference between quark and gluon initiated jets in the number of small  $p_T$  ( $0.3 \text{ GeV} < p_T < 3 \text{ GeV}$ ) charged particles in the central region ( $|\eta| < 1.1$ ).

$12 \pm 8 \pm 1$	8 ABAZOV	08L D0	$\ell + \cancel{E}_T + \geq 4$ jets

- <sup>1</sup> Based on  $9.4 \text{ fb}^{-1}$  of data. Reported  $A_{FB}$  values come from the determination of  $a_j$  coefficients of  $d\sigma/d(\cos\theta_t) = \sum_i a_i P_i(\cos\theta_t)$  measurement. The result of  $a_1/a_0 = (40 \pm 12)\%$  seems higher than the NLO SM prediction of  $(15^{+7}_{-3})\%$ .

- <sup>2</sup> Based on  $9.4 \text{ fb}^{-1}$  of data. The quoted result is the asymmetry at the parton level.

- <sup>3</sup> Based on  $9.4 \text{ fb}^{-1}$  of data. The observed asymmetry is to be compared with the SM prediction of  $A_{FB}^t = 0.038 \pm 0.003$ .

- <sup>4</sup> Based on  $5.4 \text{ fb}^{-1}$  of data. ABAZOV 13A studied the dilepton channel of the  $t\bar{t}$  events and measured the leptonic forward-backward asymmetry to be  $A_{FB}^t = 5.8 \pm 5.1 \pm 1.3\%$ , which is consistent with the SM (QCD+EW) prediction of  $4.7 \pm 0.1\%$ . The result is obtained after combining the measurement ( $15.2 \pm 4.0\%$ ) in the  $\ell + \text{jets}$  channel ABAZOV 11AH. The top quark helicity is measured by using the neutrino weighting method to be consistent with zero in both dilepton and  $\ell + \text{jets}$  channels.

- <sup>5</sup> Based on  $5.3 \text{ fb}^{-1}$  of data. The error is statistical and systematic combined. Events with lepton +  $\cancel{E}_T + \geq 4\text{jets}(\geq 1b)$  are used. AALTONEN 11F also measures the asymmetry as a function of the rapidity difference  $|y_t - y_{\bar{t}}|$ . The NLO QCD predictions [MCFM] are  $(4.0 \pm 0.6)\%$  and  $(8.8 \pm 1.3)\%$  for  $m_{t\bar{t}} < 450$  and  $> 450 \text{ GeV}$ , respectively.

- <sup>6</sup> Based on  $5.4 \text{ fb}^{-1}$  of data. The error is statistical and systematic combined. The quoted asymmetry is obtained after unfolding to be compared with the MC@NLO prediction of  $(5.0 \pm 0.1)\%$ . No significant difference between the  $m_{t\bar{t}} < 450$  and  $> 450 \text{ GeV}$  data samples is found. A corrected asymmetry based on the lepton from a top quark decay of  $(15.2 \pm 4.0)\%$  is measured to be compared to the MC@NLO prediction of  $(2.1 \pm 0.1)\%$ .

- <sup>7</sup> Result is based on  $1.9 \text{ fb}^{-1}$  of data. The *FB* asymmetry in the  $t\bar{t}$  events has been measured in the  $\ell + \text{jets}$  mode, where the lepton charge is used as the flavor tag. The asymmetry in the  $p\bar{p}$  frame is defined in terms of  $\cos(\theta)$  of hadronically decaying *t*-quark momentum, whereas that in the  $t\bar{t}$  frame is defined in terms of the *t* and  $\bar{t}$  rapidity difference. The results are consistent ( $\leq 2\sigma$ ) with the SM predictions.

- <sup>8</sup> Result is based on  $0.9 \text{ fb}^{-1}$  of data. The asymmetry in the number of  $t\bar{t}$  events with  $y_t > y_{\bar{t}}$  and those with  $y_t < y_{\bar{t}}$  has been measured in the lepton + jets final state. The observed value is consistent with the SM prediction of  $0.8\%$  by MC@NLO, and an upper bound on the  $Z' \rightarrow t\bar{t}$  contribution for the SM *Z*-like couplings is given in Fig. 2 for  $350 \text{ GeV} < m_{Z'} < 1 \text{ TeV}$ .

## *t*-Quark Electric Charge

2 AALTONEN 13J CDF  $p\bar{p}$  at 1.96 TeV

3 AALTONEN 10s CDF Repl. by AALTONEN 13J

4 ABAZOV 07c D0 fraction of  $|q| = 4e/3$  pair

- <sup>1</sup> Based on  $2.05 \text{ fb}^{-1}$  of *pp* data at  $\sqrt{s} = 7 \text{ TeV}$ , the result is obtained by reconstructing  $t\bar{t}$  events in the lepton + jets final state, where *b*-jet charges are tagged by the jet-charge algorithm. This measurement excludes the charge  $-4/3$  assignment to the top quark at more than 8 standard deviations.

- <sup>2</sup> AALTONEN 13J excludes the charge  $-4/3$  assignment to the top quark at 99% CL, using  $5.6 \text{ fb}^{-1}$  of data in *p* $\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$ . Result is obtained by reconstructing  $t\bar{t}$  events in the lepton + jets final state, where *b*-jet charges are tagged by the jet-charge algorithm.

- <sup>3</sup> AALTONEN 10s excludes the charge  $-4/3$  assignment for the top quark [CHANG 99] at 95% CL, using  $2.7 \text{ fb}^{-1}$  of data in *p* $\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$ . Result is obtained by reconstructing  $t\bar{t}$  events in the lepton + jets final state, where *b*-jet charges are tagged by the SLT (soft lepton tag) algorithm.

- <sup>4</sup> ABAZOV 07c reports an upper limit  $\rho < 0.80$  (90% CL) on the fraction  $\rho$  of exotic quark pairs  $Q\bar{Q}$  with electric charge  $|q| = 4e/3$  in  $t\bar{t}$  candidate events with high  $p_T$  lepton, missing  $E_T$  and  $\geq 4$  jets. The result is obtained by measuring the fraction of events in which the quark pair decays into  $W^- + b$  and  $W^+ + \bar{b}$ , where *b* and  $\bar{b}$  jets are discriminated by using the charge and momenta of tracks within the jet cones. The maximum CL at which the model of CHANG 99 can be excluded is 92%. Based on  $370 \text{ pb}^{-1}$  of data at  $\sqrt{s} = 1.96 \text{ TeV}$ .

1 Based on  $5.0 \text{ fb}^{-1}$  of  $pp$  data at  $\sqrt{s} = 7 \text{ TeV}$ . CHATRCHYAN 13I looked for events with one isolated electron or muon, large  $E_{T\gamma}$ , and at least four jets with large transverse momenta, where one jet is likely to originate from the decay of a bottom quark.

2 Based on  $2.0 \text{ fb}^{-1}$  of  $pp$  data at  $\sqrt{s} = 7 \text{ TeV}$ . No  $b' \rightarrow Zb$  invariant mass peak is found in the search of heavy quark pair production that decay into  $Z$  and a  $b$  quark in events with  $Z \rightarrow e^+e^-$  and at least one  $b$ -jet. The lower mass limit is  $358 \text{ GeV}$  for a vector-like singlet  $b'$  mixing solely with the third SM generation.

3 Based on  $1.04 \text{ fb}^{-1}$  of  $pp$  data at  $\sqrt{s} = 7 \text{ TeV}$ . No signal is found for the search of heavy quark pair production that decay into  $W$  and a quark in the events with dileptons, large  $E_{T\gamma}$ , and  $\geq 2$  jets.

4 Based on  $5 \text{ fb}^{-1}$  of  $pp$  data at  $\sqrt{s} = 7 \text{ TeV}$ . CHATRCHYAN 12BH searched for QCD and EW production of single and pair of degenerate  $4^{th}$  generation quarks that decay to  $bW$  or  $tW$ . Absence of signal in events with one lepton, same-sign dileptons or tripletons gives the bound. With a mass difference of  $25 \text{ GeV}/c^2$  between  $m_{t'}$  and  $m_{b'}$ , the corresponding limit shifts by about  $\pm 20 \text{ GeV}/c^2$ .

5 Result is based on  $1.1 \text{ fb}^{-1}$  of data. No signal is found for the search of long-lived particles which decay into final states with two electrons or photons, and upper bound on the cross section times branching fraction is obtained for  $2 < c\tau < 7000 \text{ mm}$ ; see Fig. 3. 95% CL excluded region of  $b'$  lifetime and mass is shown in Fig. 4.

6 ACOSTA 03 looked for long-lived fourth generation quarks in the data sample of  $90 \text{ pb}^{-1}$  of  $\sqrt{s}=1.8 \text{ TeV}$   $p\bar{p}$  collisions by using the muon-like penetration and anomalously high ionization energy loss signature. The corresponding lower mass bound for the charge  $(2/3)e$  quark ( $t'$ ) is  $220 \text{ GeV}$ . The  $t'$  bound is higher than the  $b'$  bound because  $t'$  is more likely to produce charged hadrons than  $b'$ . The 95% CL upper bounds for the production cross sections are given in their Fig. 3.

7 Based on  $1.04 \text{ fb}^{-1}$  of  $pp$  data at  $\sqrt{s} = 7 \text{ TeV}$ . No signal is found for the search of heavy quark pair production that decay into  $W$  and a  $t$  quark in the events with a high  $p_T$  isolated lepton, large  $E_{T\gamma}$ , and at least 6 jets in which one, two or more dijets are from  $W$ .

8 Based on  $1.04 \text{ fb}^{-1}$  of  $pp$  data at  $\sqrt{s} = 7 \text{ TeV}$ . AAD 12BE looked for events with two isolated like-sign leptons and at least 2 jets, large  $E_{T\gamma}$  and  $H_{T\gamma} > 350 \text{ GeV}$ .

9 Based on  $4.9 \text{ fb}^{-1}$  of  $pp$  data at  $\sqrt{s} = 7 \text{ TeV}$ . CHATRCHYAN 12X looked for events with tripletons or same-sign dileptons and at least one  $b$  jet.

10 Based on  $4.8 \text{ fb}^{-1}$  of data in  $p\bar{p}$  collisions at  $1.96 \text{ TeV}$ . AALTONEN 11J looked for events with  $\ell + E_{T\gamma} + \geq 5j$  ( $\geq 1 b$  or  $c$ ). No signal is observed and the bound  $\sigma(b'\bar{b}') < 30 \text{ fb}$  for  $m_{b'} > 375 \text{ GeV}$  is found for  $B(b' \rightarrow Wt) = 1$ .

11 Based on  $34 \text{ pb}^{-1}$  of data in  $pp$  collisions at  $7 \text{ TeV}$ . CHATRCHYAN 11L looked for multi-jet events with tripletons or same-sign dileptons. No excess above the SM background excludes  $m_{b'}$  between  $255$  and  $361 \text{ GeV}$  at 95% CL for  $B(b' \rightarrow Wt) = 1$ .

12 Based on  $2.7 \text{ fb}^{-1}$  of data in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96 \text{ TeV}$ . AALTONEN 10H looked for pair production of heavy quarks which decay into  $tW^-$  or  $tW^+$ , in events with same sign dileptons ( $e$  or  $\mu$ ), several jets and large missing  $E_T$ . The result is obtained for  $b'$  which decays into  $tW^-$ . For the charge  $5/3$  quark ( $T_{5/3}$ ) which decays into  $tW^+$ ,  $m_{T_{5/3}} > 365 \text{ GeV}$  (95% CL) is found when it has the charge  $-1/3$  partner  $B$  of the same mass.

13 FLACCO 10 result is obtained from AALTONEN 10H result of  $m_{b'} > 338 \text{ GeV}$ , by relaxing the condition  $B(b' \rightarrow Wt) = 100\%$  when  $m_{b'} > m_{t'}$ .

14 Result is based on  $1.06 \text{ fb}^{-1}$  of data. No excess from the SM  $Z$ +jet events is found when  $Z$  decays into  $e$  or  $\mu\mu$ . The  $m_{b'}$  bound is found by comparing the resulting upper bound on  $\sigma(b'\bar{b}') [1 - (1 - B(b' \rightarrow Zb))^2]$  and the LO estimate of the  $b'$  pair production cross section shown in Fig. 38 of the article.

15 HUANG 08 reexamined the  $b'$  mass lower bound of  $268 \text{ GeV}$  obtained in AALTONEN 07C that assumes  $B(b' \rightarrow Zb) = 1$ , which does not hold for  $m_{b'} > 255 \text{ GeV}$ . The lower mass bound is given in the plane of  $\sin^2(\theta_{tb'})$  and  $m_{b'}$ .

16 AFFOLDER 00 looked for  $b'$  that decays in to  $b+Z$ . The signal searched for is  $bbZ$  events where one  $Z$  decays into  $e^+e^-$  or  $\mu^+\mu^-$  and the other  $Z$  decays hadronically. The bound assumes  $B(b' \rightarrow Zb) = 100\%$ . Between  $100 \text{ GeV}$  and  $199 \text{ GeV}$ , the 95%CL upper bound on  $\sigma(b' \rightarrow \bar{b}') \times B^2(b' \rightarrow Zb)$  is also given (see their Fig. 2).

17 ABE 98N looked for  $Z \rightarrow e^+e^-$  decays with displaced vertices. Quoted limit assumes  $B(b' \rightarrow Zb) = 1$  and  $c\tau_{b'} = 1 \text{ cm}$ . The limit is lower than  $m_Z + m_b$  ( $\sim 96 \text{ GeV}$ ) if  $c\tau > 22 \text{ cm}$  or  $c\tau < 0.009 \text{ cm}$ . See their Fig. 4.

18 ABACHI 97D searched for  $b'$  that decays mainly via FCNC. They obtained 95%CL upper bounds on  $B(b'\bar{b}') \rightarrow \gamma + 3 \text{ jets}$  and  $B(b'\bar{b}') \rightarrow 2\gamma + 2 \text{ jets}$ , which can be interpreted as the lower mass bound  $m_{b'} > m_Z + m_b$ .

19 ABACHI 95F bound on the top-quark also applies to  $b'$  and  $t'$  quarks that decay predominantly into  $W$ . See FROGGATT 97.

20 MUKHOPADHYAYA 93 analyze CDF dilepton data of ABE 92G in terms of a new quark decaying via flavor-changing neutral current. The above limit assumes  $B(b' \rightarrow b\ell^+\ell^-) = 1\%$ . For an exotic quark decaying only via virtual  $Z$  [ $B(b\ell^+\ell^-) = 3\%$ ], the limit is  $85 \text{ GeV}$ .

21 ABE 92 dilepton analysis limit of  $>85 \text{ GeV}$  at CL=95% also applies to  $b'$  quarks, as discussed in ABE 90b.

22 ABE 90b exclude the region 28-72 GeV.

23 AKESSON 90 searched for events having an electron with  $p_T > 12 \text{ GeV}$ , missing momentum  $> 15 \text{ GeV}$ , and a jet with  $E_T > 10 \text{ GeV}$ ,  $|\eta| < 2.2$ , and excluded  $m_{b'}$  between  $30$  and  $69 \text{ GeV}$ .

24 For the reduction of the limit due to non-charged-current decay modes, see Fig. 19 of ALBAJAR 90b.

25 ALBAJAR 88 study events at  $E_{cm} = 546$  and  $630 \text{ GeV}$  with a muon or isolated electron, accompanied by one or more jets and find agreement with Monte Carlo predictions for the production of charm and bottom, without the need for a new quark. The lower mass limit is obtained by using a conservative estimate for the  $b'\bar{b}'$  production cross section and by assuming that it cannot be produced in  $W$  decays. The value quoted here is revised using the full  $O(\alpha_s^3)$  cross section of ALTARELLI 88.

#### $b'$ mass limits from single production in $p\bar{p}$ and $pp$ collisions

VALUE (GeV)	CL%	DOCUMENT ID	TECN	COMMENT
>693	95	26 ABAZOV 11F	D0	$qu \rightarrow q'b' \rightarrow q'(Wu)$ $\bar{\kappa}_{ub'}=1, B(b' \rightarrow Wu)=1$
>430	95	26 ABAZOV 11F	D0	$qd \rightarrow qb' \rightarrow q(Zd)$ $\bar{\kappa}_{db'}=\sqrt{2}, B(b' \rightarrow Zd)=1$

26 Based on  $5.4 \text{ fb}^{-1}$  of data in  $p\bar{p}$  collisions at  $1.96 \text{ TeV}$ . ABAZOV 11F looked for single production of  $b'$  via the  $W$  or  $Z$  coupling to the first generation up or down quarks, respectively. Model independent cross section limits for the single production processes  $p\bar{p} \rightarrow b'q \rightarrow Wuq$ , and  $p\bar{p} \rightarrow b'q \rightarrow Zdq$  are given in Figs. 3 and 4, respectively, and the mass limits are obtained for the model of ATRE 09 with degenerate bi-doublets of vector-like quarks.

#### MASS LIMITS for $b'$ ( $4^{th}$ Generation) Quark or Hadron in $e^+e^-$ Collisions

Search for hadrons containing a fourth-generation  $-1/3$  quark denoted  $b'$ .

The last column specifies the assumption for the decay mode (CC denotes the conventional charged-current decay) and the event signature which is looked for.

$b'$  (Fourth Generation) Quark,  $t'$  (Fourth Generation) Quark $t'$  (4<sup>th</sup> Generation) Quark, Searches for

- 27 DECAMP 90F looked for isolated charged particles, for isolated photons, and for four-jet final states. The modes  $b' \rightarrow b\gamma$  for  $B(b' \rightarrow b\gamma) > 65\%$   $b' \rightarrow b\gamma$  for  $B(b' \rightarrow b\gamma) > 5\%$  are excluded. Charged Higgs decay were not discussed.
- 28 ABDALLAH 07 searched for  $b'$  pair production at  $E_{cm}=196-209$  GeV, with  $420\text{ pb}^{-1}$ . No signal leads to the 95% CL upper limits on  $B(b' \rightarrow bZ)$  and  $B(b' \rightarrow cW)$  for  $m_{b'}$  = 96 to 103 GeV.
- 29 ADRIANI 93G search for vector quarkonium states near Z and give limit on quarkonium-Z mixing parameter  $\delta m^2 < (10-30)\text{ GeV}^2$  (95%CL) for the mass 88-94.5 GeV. Using Richardson potential, a  $1S(b'\bar{b}')$  state is excluded for the mass range 87.7-94.7 GeV. This range depends on the potential choice.
- 30 ABREU 90D assumed  $m_{H^\pm} < m_{b'} - 3\text{ GeV}$ .
- 31 Superseded by ABREU 91F.
- 32 AKRAWY 90B search was restricted to data near the Z peak at  $E_{cm} = 91.26$  GeV at LEP. The excluded region is between 23.6 and 41.4 GeV if no  $H^\pm$  decays exist. For charged Higgs decays the excluded regions are between  $(m_{H^\pm} + 1.5\text{ GeV})$  and 45.5 GeV.
- 33 AKRAWY 90J search for isolated photons in hadronic Z decay and derive  $B(Z \rightarrow b'\bar{b}')B(b' \rightarrow \gamma X)/B(Z \rightarrow \text{hadrons}) < 2.2 \times 10^{-3}$ . Mass limit assumes  $B(b' \rightarrow \gamma X) > 10\%$ .
- 34 ABE 89E search at  $E_{cm} = 56-57$  GeV at TRISTAN for multihadron events with a spherical shape (using thrust and acoplanarity) or containing isolated leptons.
- 35 ABE 89G search was at  $E_{cm} = 55-60.8$  GeV at TRISTAN.
- 36 If the photonic decay mode is large ( $B(b' \rightarrow b\gamma) > 25\%$ ), the ABRAMS 89c limit is 45.4 GeV. The limit for Higgs decay ( $b' \rightarrow cH^\pm, H^\pm \rightarrow \tau s$ ) is 45.2 GeV.
- 37 ADACHI 89c search was at  $E_{cm} = 56.5-60.8$  GeV at TRISTAN using multi-hadron events accompanying muons.
- 38 ADACHI 89c also gives limits for any mixture of  $CC$  and  $b\gamma$  decays.
- 39 ENO 89 search at  $E_{cm} = 50-60.8$  at TRISTAN.
- 40 ENO 89 considers arbitrary mixture of the charged current,  $b\gamma$ , and  $b\gamma$  decays.
- 41 IGARASHI 88 searches for leptons in low-thrust events and gives  $\Delta R(b') < 0.26$  (95% CL) assuming charged current decay, which translates to  $m_{b'} > 24.4$  GeV.
- 42 SAGAWA 88 set limit  $\sigma(\text{top}) < 6.1\text{ pb}$  at  $CL=95\%$  for top-flavored hadron production from event shape analyses at  $E_{cm} = 52$  GeV. By using the quark parton model cross-section formula near threshold, the above limit leads to lower mass bounds of 23.8 GeV for charge  $-1/3$  quarks.
- 43 ADEVA 86 give 95%CL upper bound on an excess of the normalized cross section,  $\Delta R$ , as a function of the minimum c.m. energy (see their figure 3). Production of a pair of  $1/3$  charge quarks is excluded up to  $E_{cm} = 45.4$  GeV.
- 44 ALTHOFF 84c narrow state search sets limit  $\Gamma(e^+e^-)B(\text{hadrons}) < 2.4\text{ keV}$  CL = 95% and heavy charge  $1/3$  quark pair production  $m > 21$  GeV, CL = 95%.
- 45 ALTHOFF 84i exclude heavy quark pair production for  $7 < m < 19$  GeV ( $1/3$  charge) using aplanarity distributions (CL = 95%).

1 Based on  $19.5\text{ fb}^{-1}$  of  $p\bar{p}$  data at  $\sqrt{s} = 8\text{ TeV}$ . The  $t'$  quark is pair produced and is assumed to decay into three different final states of  $bW$ ,  $tZ$ , and  $th$ . The search is carried out using events with at least one isolated lepton.

2 Based on  $1.04\text{ fb}^{-1}$  of  $p\bar{p}$  data at  $\sqrt{s} = 7\text{ TeV}$ . No signal is found for the search of heavy quark pair production that decay into  $W$  and a quark in the events with dileptons, large  $E_T$ , and  $\geq 2$  jets.

3 Based on  $1.04\text{ fb}^{-1}$  of data in  $p\bar{p}$  collisions at  $7\text{ TeV}$ . AAD 12c looked for  $t'\bar{t}'$  production followed by  $t'$  decaying into a top quark and  $X$ , an invisible particle, in a final state with an isolated high- $P_T$  lepton, four or more jets, and a large missing transverse energy. No excess over the SM  $t\bar{t}$  production gives the upper limit on  $t'\bar{t}'$  production cross section as a function of  $m_{t'}$  and  $m_X$ . The result is obtained for  $B(t' \rightarrow Wt) = 1$ .

4 Based on  $5\text{ fb}^{-1}$  of  $p\bar{p}$  data at  $\sqrt{s} = 7\text{ TeV}$ . CHATRCHYAN 12BH searched for QCD and EW production of single and pair of degenerate 4<sup>th</sup> generation quarks that decay to  $Wb$  or  $Wt$ . Absence of signal in events with one lepton, same-sign dileptons or tri-leptons gives the bound. With a mass difference of  $25\text{ GeV}/c^2$  between  $m_{t'}$  and  $m_{b'}$ , the corresponding limit shifts by about  $\pm 20\text{ GeV}/c^2$ .

5 Based on  $5.0\text{ fb}^{-1}$  of  $p\bar{p}$  data at  $\sqrt{s} = 7\text{ TeV}$ . CHATRCHYAN 12P looked for  $t'\bar{t}'$  production events with two isolated high- $p_T$  leptons, large  $E_T$ , and 2 high  $p_T$  jets with  $b$ -tag. The absence of signal above the SM background gives the limit for  $B(t' \rightarrow Wb) = 1$ .

6 Based on  $4.7\text{ fb}^{-1}$  of  $p\bar{p}$  data at  $\sqrt{s} = 7\text{ TeV}$ . No signal is found for the search of heavy quark pair production that decay into  $W$  and a  $b$  quark in the events with a high  $p_T$  isolated lepton, large  $E_T$ , and at least 3 jets ( $\geq 1$   $b$ -tag). Vector-like quark of charge  $2/3$  with  $400 < m_{t'} < 550\text{ GeV}$  and  $B(t' \rightarrow Wb) > 0.63$  is excluded at 95% CL.

7 Based on  $5.0\text{ fb}^{-1}$  of  $p\bar{p}$  data at  $\sqrt{s} = 7\text{ TeV}$ . CHATRCHYAN 13I looked for events with one isolated electron or muon, large  $E_T$ , and at least four jets with large transverse momenta, where one jet is likely to originate from the decay of a bottom quark.

8 Based on  $1.04\text{ fb}^{-1}$  of  $p\bar{p}$  data at  $\sqrt{s} = 7\text{ TeV}$ . No signal is found in the search for pair produced heavy quarks that decay into  $W$  boson and a  $b$  quark in the events with a high  $p_T$  isolated lepton, large  $E_T$ , and at least 3 jets ( $\geq 1$   $b$ -tag).

9 Based on  $5.0\text{ fb}^{-1}$  of  $p\bar{p}$  data at  $\sqrt{s} = 7\text{ TeV}$ . CHATRCHYAN 12BC looked for  $t'\bar{t}'$  production events with a single isolated high  $p_T$  lepton, large  $E_T$ , and at least 4 high  $p_T$  jets with a  $b$ -tag. The absence of signal above the SM background gives the limit for  $B(t' \rightarrow Wb) = 1$ .

10 Based on  $5.7\text{ fb}^{-1}$  of data in  $p\bar{p}$  collisions at  $1.96\text{ TeV}$ . AALTONEN 11AH looked for  $t'\bar{t}'$  production followed by  $t'$  decaying into a top quark and  $X$ , an invisible particle, in the all hadronic decay mode of  $t\bar{t}$ . No excess over the SM  $t\bar{t}$  production gives the upper limit on  $t'\bar{t}'$  production cross section as a function of  $m_{t'}$  and  $m_X$ . The result is obtained for  $B(t' \rightarrow Xt) = 1$ .

11 Based on  $5.6\text{ fb}^{-1}$  of data in  $p\bar{p}$  collisions at  $1.96\text{ TeV}$ . AALTONEN 11AL looked for  $\ell + \geq 4$  jets events and set upper limits on  $\sigma(t'\bar{t}')$  as functions of  $m_{t'}$ .

12 Based on  $4.8\text{ fb}^{-1}$  of data in  $p\bar{p}$  collisions at  $1.96\text{ TeV}$ . AALTONEN 11O looked for  $t'\bar{t}'$  production signal when  $t'$  decays into a top quark and  $X$ , an invisible particle, in  $\ell + E_T + \text{jets}$  channel. No excess over the SM  $t\bar{t}$  production gives the upper limit on  $t'\bar{t}'$  production cross section as a function of  $m_{t'}$  and  $m_X$ . The result is obtained for  $B(t' \rightarrow Xt) = 1$ .

13 Based on  $5.3\text{ fb}^{-1}$  of data in  $p\bar{p}$  collisions at  $1.96\text{ TeV}$ . ABAZOV 11Q looked for  $\ell + E_T + \geq 4$  jets events and set upper limits on  $\sigma(t'\bar{t}')$  as functions of  $m_{t'}$ .

14 Searches for pair production of a new heavy top-like quark  $t'$  decaying to a  $W$  boson and another quark by fitting the observed spectrum of total transverse energy and reconstructed  $t'$  mass in the lepton + jets events.

15 HUANG 08 reexamined the  $t'$  mass lower bound of 256 GeV obtained in AALTONEN 08H that assumes  $B(b' \rightarrow qZ) = 1$  for  $q = u, c$  which does not hold when  $m_{b'} < m_{t'} - m_W$  or the mixing  $\sin^2(\theta_{bt'})$  is so tiny that the decay occurs outside of the vertex detector.

Fig. 1 gives that lower bound on  $m_{t'}$  in the plane of  $\sin^2(\theta_{bt'})$  and  $m_{b'}$ .

## $t'$ (Fourth Generation) Quark, Free Quark Searches

### $t'$ mass limits from single production in $p\bar{p}$ and $pp$ collisions

VALUE (GeV)	CL%	DOCUMENT ID	TECN	COMMENT
>403	95	16 ABAZOV	11F D0	$q d \rightarrow q' t' \rightarrow q'(Wd)$ $\tilde{\kappa}_{dt'}=1, B(t' \rightarrow Wd)=1$
>551	95	16 ABAZOV	11F D0	$qu \rightarrow q t' \rightarrow q(Zu)$ $\tilde{\kappa}_{ut'}=\sqrt{2}, B(t' \rightarrow Zu)=1$

<sup>16</sup>Based on 5.4 fb<sup>-1</sup> of data in ppbar collisions at 1.96 TeV. ABAZOV 11F looked for single production of  $t'$  via the Z or E coupling to the first generation up or down quarks, respectively. Model independent cross section limits for the single production processes  $p\bar{p} \rightarrow t' q \rightarrow (Wd)q$ , and  $p\bar{p} \rightarrow t' q \rightarrow (Zd)q$  are given in Figs. 3 and 4, respectively, and the mass limits are obtained for the model of ATRE 09 with degenerate bi-doublets of vector-like quarks.

## Free Quark Searches

### FREE QUARK SEARCHES

The basis for much of the theory of particle scattering and hadron spectroscopy is the construction of the hadrons from a set of fractionally charged constituents (quarks). A central but unproven hypothesis of this theory, Quantum Chromodynamics, is that quarks cannot be observed as free particles but are confined to mesons and baryons.

Experiments show that it is at best difficult to “unglue” quarks. Accelerator searches at increasing energies have produced no evidence for free quarks, while only a few cosmic-ray and matter searches have produced uncorroborated events.

This compilation is only a guide to the literature, since the quoted experimental limits are often only indicative. Reviews can be found in Refs. 1–4.

<sup>1</sup> CHATRCHYAN 13AR limits assume pair-produced long-lived spin-1/2 particles neutral under SU(3)<sub>C</sub> and SU(2)<sub>L</sub>.

<sup>2</sup> ABE 92J flux limits decrease as the mass increases from 50 to 500 GeV.

<sup>3</sup> HE 91 limits are for charges of the form  $N\pm 1/3$  from 23/3 to 38/3.

<sup>4</sup> Hadronic or leptonic quarks.

<sup>5</sup> Cross section cm<sup>2</sup>/GeV<sup>2</sup>.

<sup>6</sup>  $3 \times 10^{-5}$  <lifetime <  $1 \times 10^{-3}$  s.

<sup>7</sup> Includes BOTT 72 results.

<sup>8</sup> Assumes isotropic cm production.

<sup>9</sup> Cross section inferred from flux.

### Quark Flux — Accelerator Searches

The definition of FLUX depends on the experiment

- (a) is the ratio of measured free quarks to predicted free quarks if there is no “confinement.”
- (b) is the probability of fractional charge on nuclear fragments. Energy is in GeV/nucleon.
- (c) is the 90%CL upper limit on fractionally-charged particles produced per interaction.
- (d) is quarks per collision.
- (e) is inclusive quark-production cross-section ratio to  $\sigma(e^+e^- \rightarrow \mu^+\mu^-)$ .
- (f) is quark flux per charged particle.
- (g) is the flux per  $\nu$ -event.
- (h) is quark yield per  $\pi^-$  yield.
- (i) is 2-body exclusive quark-production cross-section ratio to  $\sigma(e^+e^- \rightarrow \mu^+\mu^-)$ .

<sup>11</sup> HUENTRUP 96 quote 95% CL limits for production of fragments with charge differing by as much as  $\pm 1/3$  (in units of  $e$ ) for charge  $6 \leq Z \leq 10$ .

<sup>12</sup> BUSKULIC 93c limits for inclusive quark production are more conservative if the ALEPH hadronic fragmentation function is assumed.

<sup>13</sup> CECCHINI 93 limit at 90%CL for  $23/3 \leq Z \leq 40/3$ , for 16A GeV O, 14.5A Si, and 200A S incident on Cu target. Other limits are  $2.3 \times 10^{-4}$  for  $17/3 \leq Z \leq 20/3$  and  $1.2 \times 10^{-4}$  for  $20/3 \leq Z \leq 23/3$ .

<sup>14</sup> GHOSH 92 reports measurement of spallation fragment charge based on ionization in emulsion. Out of 650 measured tracks, 2 were consistent with charge  $5e/3$ , and 4 with  $7e/3$ .

<sup>15</sup> Hadronic quark.

<sup>16</sup> Leptonic quark.

<sup>17</sup> HE 91 limits are for charges of the form  $N \pm 1/3$  from  $23/3$  to  $38/3$ , and correspond to cross-section limits of  $380 \mu\text{b}$  (Pb) and  $320 \mu\text{b}$  (Cu).

<sup>18</sup> The limits apply to projectile fragment charges of 17, 19, 20, 22, 23 in units of  $e/3$ .

<sup>19</sup> The limits apply to projectile fragment charges of 16, 17, 19, 20, 22, 23 in units of  $e/3$ .

<sup>20</sup> Flux limits and mass range depend on charge.

<sup>21</sup> Bound to nuclei.

<sup>22</sup> Quark lifetimes  $> 1 \times 10^{-8}$  s.

<sup>23</sup> One candidate  $m < 0.17$  GeV.

### Quark Flux — Cosmic Ray Searches

Shielding values followed with an asterisk indicate altitude in km. Shielding values not followed with an asterisk indicate sea level in  $\text{kg}/\text{cm}^2$ .

<sup>33</sup> 95% CL limit for fractional charge particles with  $0.18e \leq |Q_{residual}| \leq 0.82e$  in total of 70.1 mg of silicone oil.

<sup>34</sup> 95% CL limit for particles with fractional charge  $|Q_{residual}| > 0.16e$  in total of 17.4 mg of silicone oil.

<sup>35</sup> Also set limits for  $Q = \pm e/6$ .

<sup>36</sup> Note that in PHILLIPS 88 these authors report a subtle magnetic effect which could account for the apparent fractional charges.

<sup>37</sup> Limit inferred by JONES 77b.

$\pi^\pm$

$$I^G(J^P) = 1^-(0^-)$$

We have omitted some results that have been superseded by later experiments. The omitted results may be found in our 1988 edition Physics Letters **B204** 1 (1988).

**$\pi^\pm$  MASS**

The most accurate charged pion mass measurements are based upon x-ray wavelength measurements for transitions in  $\pi^-$ -mesonic atoms. The observed line is the blend of three components, corresponding to different K-shell occupancies. JECKELMANN 94 revisits the occupancy question, with the conclusion that two sets of occupancy ratios, resulting in two different pion masses (Solutions A and B), are equally probable. We choose the higher Solution B since only this solution is consistent with a positive mass-squared for the muon neutrino, given the precise muon momentum measurements now available (DAUM 91, ASSAMAGAN 94, and ASSAMAGAN 96) for the decay of pions at rest. Earlier mass determinations with  $\pi$ -mesonic atoms may have used incorrect K-shell screening corrections.

Measurements with an error of  $> 0.005$  MeV have been omitted from this Listing.

139.5686 ± 0.0020	CARTER	76	CNTR	—	Mesonic atoms
139.5660 ± 0.0024	<sup>7,8</sup> MARUSHEN..	76	CNTR	—	Mesonic atoms

<sup>1</sup> LENZ 98 result does not suffer K-electron configuration uncertainties as does JECKELMANN 94.  
<sup>2</sup> JECKELMANN 94 Solution B (dominant 2-electron K-shell occupancy), chosen for consistency with positive  $m_{\nu_\mu}^2$ .  
<sup>3</sup> ASSAMAGAN 96 measures the  $\mu^+$  momentum  $p_\mu$  in  $\pi^+ \rightarrow \mu^+ \nu_\mu$  decay at rest to be  $29.79200 \pm 0.00011$  MeV/c. Combined with the  $\mu^+$  mass and the assumption  $m_{\nu_\mu} = 0$ , this gives the  $\pi^+$  mass above; if  $m_{\nu_\mu} > 0$ ,  $m_{\pi^+}$  given above is a lower limit. Combined instead with  $m_\mu$  and (assuming *CPT*) the  $\pi^-$  mass of JECKELMANN 94,  $p_\mu$  gives an upper limit on  $m_{\nu_\mu}$  (see the  $\nu_\mu$ ).  
<sup>4</sup> JECKELMANN 94 Solution A (small 2-electron K-shell occupancy) in combination with either the DAUM 91 or ASSAMAGAN 94 pion decay muon momentum measurement yields a significantly negative  $m_{\nu_\mu}^2$ . It is accordingly not used in our fits.  
<sup>5</sup> The DAUM 91 value includes the ABELA 84 result. The value is based on a measurement of the  $\mu^+$  momentum for  $\pi^+$  decay at rest,  $p_\mu = 29.79179 \pm 0.00053$  MeV, uses  $m_\mu = 105.658389 \pm 0.000034$  MeV, and assumes that  $m_{\nu_\mu} = 0$ . The last assumption means that in fact the value is a lower limit.  
<sup>6</sup> JECKELMANN 86b gives  $m_\pi/m_e = 273.12677(71)$ . We use  $m_e = 0.51099906(15)$  MeV from COHEN 87. The authors note that two solutions for the probability distribution of K-shell occupancy fit equally well, and use other data to choose the lower of the two possible  $\pi^\pm$  masses.  
<sup>7</sup> These values are scaled with a new wavelength-energy conversion factor  $\nu\lambda = 1.23984244(37) \times 10^{-6}$  eV m from COHEN 87. The LU 80 screening correction relies upon a theoretical calculation of inner-shell refilling rates.  
<sup>8</sup> This MARUSHENKO 76 value used at the authors' request to use the accepted set of calibration  $\gamma$  energies. Error increased from 0.0017 MeV to include QED calculation error of 0.0017 MeV (12 ppm).

$$m_{\pi^+} - m_{\mu^+}$$

Measurements with an error  $> 0.05$  MeV have been omitted from this Listing.

**$\pi^+$  DECAY MODES**

$\pi^-$  modes are charge conjugates of the modes below.

For decay limits to particles which are not established, see the section on Searches for Axions and Other Very Light Bosons.

Mode	Fraction ( $\Gamma_i/\Gamma$ )	Confidence level
$\Gamma_1$ $\mu^+ \nu_\mu$	[a] (99.98770 ± 0.00004) %	
$\Gamma_2$ $\mu^+ \nu_\mu \gamma$	[b] ( 2.00 ± 0.25 ) × 10 <sup>-4</sup>	
$\Gamma_3$ $e^+ \nu_e$	[a] ( 1.230 ± 0.004 ) × 10 <sup>-4</sup>	
$\Gamma_4$ $e^+ \nu_e \pi^0 \gamma$	[b] ( 7.39 ± 0.05 ) × 10 <sup>-7</sup>	
$\Gamma_5$ $e^+ \nu_e \pi^0$	( 1.036 ± 0.006 ) × 10 <sup>-8</sup>	
$\Gamma_6$ $e^+ \nu_e e^+ e^-$	( 3.2 ± 0.5 ) × 10 <sup>-9</sup>	
$\Gamma_7$ $e^+ \nu_e \nu \bar{\nu}$	< 5	× 10 <sup>-6</sup> 90%

**Lepton Family number (LF) or Lepton number (L) violating modes**

$\Gamma_8$ $\mu^+ \bar{\nu}_e$	L	[c] < 1.5	× 10 <sup>-3</sup> 90%
$\Gamma_9$ $\mu^+ \nu_e$	LF	[c] < 8.0	× 10 <sup>-3</sup> 90%
$\Gamma_{10}$ $\mu^- e^+ e^+ \nu$	LF	< 1.6	× 10 <sup>-6</sup> 90%

[a] Measurements of  $\Gamma(e^+ \nu_e)/\Gamma(\mu^+ \nu_\mu)$  always include decays with  $\gamma$ 's, and measurements of  $\Gamma(e^+ \nu_e \gamma)$  and  $\Gamma(\mu^+ \nu_\mu \gamma)$  never include low-energy  $\gamma$ 's. Therefore, since no clean separation is possible, we consider the modes with  $\gamma$ 's to be subreactions of the modes without them, and let  $[\Gamma(e^+ \nu_e) + \Gamma(\mu^+ \nu_\mu)]/\Gamma_{\text{total}} = 100\%$ .

[b] See the Particle Listings below for the energy limits used in this measurement; low-energy  $\gamma$ 's are not included.

[c] Derived from an analysis of neutrino-oscillation experiments.

**$\pi^+$  BRANCHING RATIOS**

$$\Gamma(e^+ \nu_e) / \Gamma_{\text{total}} \qquad \Gamma_3 / \Gamma$$

See note [a] in the list of  $\pi^+$  decay modes just above, and see also the next block of data. See also the note on "Decay Constants of Charged Pseudoscalar Mesons" in the  $D_s^\pm$  Listings.

## FORM FACTORS FOR RADIATIVE PION AND KAON DECAYS

Updated September 2013 by M. Bychkov (University of Virginia) and G. D'Ambrosio (INFN Sezione di Napoli)

The radiative decays,  $\pi^\pm \rightarrow l^\pm \nu \gamma$  and  $K^\pm \rightarrow l^\pm \nu \gamma$ , with  $l$  standing for an  $e$  or a  $\mu$ , and  $\gamma$  for a real or virtual photon ( $e^+e^-$  pair), provide a powerful tool to investigate the hadronic structure of pions and kaons. The structure-dependent part  $SD_i$  of the amplitude describes the emission of photons from virtual hadronic states, and is parametrized in terms of form factors  $V, A$ , (vector, axial vector), in the standard description [1,2,3,4]. Exotic, non-standard contributions like  $i = T, S$  (tensor, scalar) have also been considered. Apart from the SD terms, there is also the Inner Bremsstrahlung amplitude, IB, corresponding to photon radiation from external charged particles and described by Low theorem in terms of the physical decay  $\pi^\pm(K^\pm) \rightarrow l^\pm \nu$ . Experiments try to optimize their kinematics so as to minimize the IB part of the amplitude.

The SD amplitude in its standard form is given as

$$M(SD_V) = \frac{-eG_F U_{qq'}}{\sqrt{2}m_P} \epsilon^\mu l^\nu V^P \epsilon_{\mu\nu\sigma\tau} k^\sigma q^\tau \quad (1)$$

$$M(SD_A) = \frac{-ieG_F U_{qq'}}{\sqrt{2}m_P} \epsilon^\mu l^\nu \{ A^P [(qk - k^2)g_{\mu\nu} - q_\mu k_\nu] + R^P k^2 g_{\mu\nu} \}, \quad (2)$$

which contains an additional axial form factor  $R^P$  which only can be accessed if the photon remains virtual.  $U_{qq'}$  is the Cabibbo-Kobayashi-Maskawa mixing-matrix element;  $\epsilon^\mu$  is the polarization vector of the photon (or the effective vertex,  $\epsilon^\mu = (e/k^2)\bar{u}(p_-)\gamma^\mu v(p_+)$ , of the  $e^+e^-$  pair);  $l^\nu = \bar{u}(p_\nu)\gamma^\nu(1 - \gamma_5)v(p_l)$  is the lepton-neutrino current;  $q$  and  $k$  are the meson

and photon four-momenta ( $k = p_+ + p_-$  for virtual photons); and  $P$  stands for  $\pi$  or  $K$ .

The pion vector form factor,  $V^\pi$ , is related via CVC (Conserved Vector Current) to the  $\pi^0 \rightarrow \gamma\gamma$  decay width. The constant term is given by  $|V^\pi(0)| = (1/\alpha)\sqrt{2\Gamma_{\pi^0 \rightarrow \gamma\gamma}/\pi m_{\pi^0}}$  [3]. The resulting value,  $V^\pi(0) = 0.0259(9)$ , has been confirmed by calculations based on chiral perturbation theory ( $\chi PT$ ) [4], and by two experiments given in the Listings below. A recent experiment by the PIBETA collaboration [5] obtained a  $V^\pi(0)$  that is in excellent agreement with the CVC hypothesis. It also measured the slope parameter  $a$  in  $V^\pi(s) = V^\pi(0)(1 + a \cdot s)$ , where  $s = (1 - 2E_\gamma/m_\pi)$ , and  $E_\gamma$  is the gamma energy in the pion rest frame:  $a = 0.095 \pm 0.058$ . A functional dependence on  $s$  is expected for all form factors. It becomes non-negligible in the case of  $V^\pi(s)$  when a wide range of photon momenta is recorded; proper treatment in the analysis of  $K$  decays is mandatory.

The form factor,  $R^P$ , can be related to the electromagnetic radius,  $r_P$ , of the meson [2]:  $R^P = \frac{1}{3}m_P f_P \langle r_P^2 \rangle$  using PCAC (Partial Conserved Axial vector Current;  $f_P$  is the meson decay constant). In lowest order  $\chi PT$ , the ratio  $A^\pi/V^\pi$  is related to the pion electric polarizability  $\alpha_E = [\alpha/(8\pi^2 m_\pi f_\pi^2)] \times A^\pi/V^\pi$  [6]. The first non-trivial  $\chi PT$  contributions to  $A^K$  and  $V^K$  appear at  $\mathcal{O}(p^4)$  [4], respectively from Gasser-Leutwyler coefficients,  $L_i$ 's, and the anomalous lagrangian:

$$A^K = \frac{4\sqrt{2}M_K}{F_\pi}(L_9^r + L_{10}^r) = 0.042, \quad V^K = \frac{\sqrt{2}M_K}{8\pi^2 F_\pi} = 0.096. \quad (3)$$

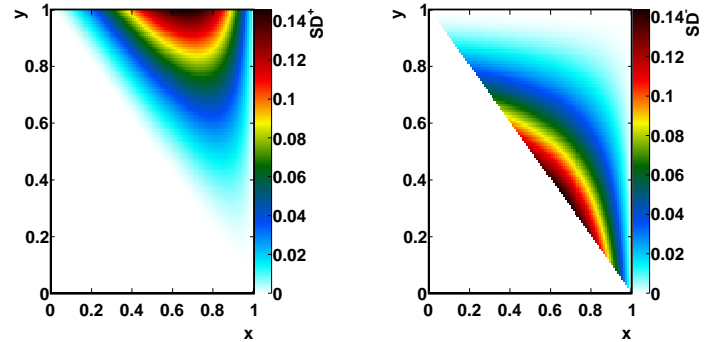

$\mathcal{O}(p^6)$  contributions to  $A^K$  can be predicted accurately: they are flat in the momentum dependence and shift the  $\mathcal{O}(p^4)$  value to 0.034.  $\mathcal{O}(p^6)$  contributions to  $V^K$  are model dependent and can be approximated by a form factor linearly dependent on momentum. For example, when looking at the spread of results obtained within two different models, the constant piece of this linear form factor is shifted to  $0.078 \pm 0.005$  [1,2,4].

For decay processes where the photon is real, the partial decay width can be written in analytical form as a sum of IB, SD, and IB/SD interference terms INT [1,4]:

$$\begin{aligned} \frac{d^2\Gamma_{P \rightarrow \ell\nu\gamma}}{dx dy} &= \frac{d^2(\Gamma_{IB} + \Gamma_{SD} + \Gamma_{INT})}{dx dy} \\ &= \frac{\alpha}{2\pi}\Gamma_{P \rightarrow \ell\nu} \frac{1}{(1-r)^2} \left\{ \text{IB}(x, y) \right. \\ &+ \frac{1}{r} \left( \frac{m_P}{2f_P} \right)^2 \left[ (V+A)^2 \text{SD}^+(x, y) + (V-A)^2 \text{SD}^-(x, y) \right] \\ &\left. + \frac{m_P}{f_P} \left[ (V+A) \text{S}_{INT}^+(x, y) + (V-A) \text{S}_{INT}^-(x, y) \right] \right\}. \quad (4) \end{aligned}$$

Here

$$\begin{aligned} \text{IB}(x, y) &= \left[ \frac{1-y+r}{x^2(x+y-1-r)} \right] \\ &\left[ x^2 + 2(1-x)(1-r) - \frac{2xr(1-r)}{x+y-1-r} \right] \end{aligned}$$

**Figure 1:** Components of the structure dependent terms of the decay width. Left:  $SD^+$ , right:  $SD^-$

$$\text{SD}^+(x, y) = (x + y - 1 - r) \left[ (x + y - 1)(1 - x) - r \right]$$

$$\text{SD}^-(x, y) = (1 - y + r) \left[ (1 - x)(1 - y) + r \right]$$

$$\text{S}_{INT}^+(x, y) = \left[ \frac{1 - y + r}{x(x + y - 1 - r)} \right] \left[ (1 - x)(1 - x - y) + r \right]$$

$$\text{S}_{INT}^-(x, y) = \left[ \frac{1 - y + r}{x(x + y - 1 - r)} \right] \left[ x^2 - (1 - x)(1 - x - y) - r \right] \quad (5)$$

where  $x = 2E_\gamma/m_P$ ,  $y = 2E_\ell/m_P$ , and  $r = (m_\ell/m_P)^2$ . The structure dependent terms  $SD^+$  and  $SD^-$  are shown in Fig. 1. The  $SD^-$  term is maximized in the same kinematic region where overwhelming  $IB$  term dominates (along  $x + y = 1$  diagonal). Thus experimental yields with less background are dominated by  $SD^+$  contribution and proportional to  $A^P + V^P$  making simultaneous precise determination of the form factors difficult.

Recently, formulas (4) and (5) have been extended to describe polarized distributions in radiative meson and muon decays [7].

The ‘‘helicity’’ factor  $r$  is responsible for the enhancement of the SD over the IB amplitude in the decays  $\pi^\pm \rightarrow e^\pm\nu\gamma$ , while  $\pi^\pm \rightarrow \mu^\pm\nu\gamma$  is dominated by IB. Interference terms are important for the decay  $K^\pm \rightarrow \mu^\pm\nu\gamma$  [8], but contribute only a few percent correction to pion decays. However, they provide the basis for determining the signs of  $V$  and  $A$ . Radiative corrections to the decay  $\pi^+ \rightarrow e^+\nu\gamma$  have to be taken into account in the analysis of the precision experiments. They make up to 4% corrections in the total decay rate [9]. In  $\pi^\pm \rightarrow e^\pm\nu e^+e^-$  and  $K^\pm \rightarrow \ell^\pm\nu e^+e^-$  decays, all three form factors,  $V^P$ ,  $A^P$ , and  $R^P$ , can be determined [10,11].

We give the experimental  $\pi^\pm$  form factors  $V^\pi$ ,  $A^\pi$ , and  $R^\pi$  in the Listings below. In the  $K^\pm$  Listings, we give the extracted sum  $A^K + V^K$  and difference  $A^K - V^K$ , as well as  $V^K$ ,  $A^K$  and  $R^K$ . In particular KLOE has measured for the constant piece

## Meson Particle Listings

 $\pi^\pm$ 

of the form factor  $A^K + V^K = 0.125 \pm 0.007 \pm 0.001$  [13] while Istra+,  $V^K - A^K = 0.21 \pm 0.04 \pm 0.04$  [14].

Several searches for the exotic form factors  $F_T^\pi$ ,  $F_T^K$  (tensor), and  $F_S^K$  (scalar) have been pursued in the past. In particular,  $F_T^\pi$  has been brought into focus by experimental as well as theoretical work [12]. New high-statistics data from the PIBETA collaboration have been re-analyzed together with an additional data set optimized for low backgrounds in the radiative pion decay. In particular, lower beam rates have been used in order to reduce the accidental background, thereby making the treatment of systematic uncertainties easier and more reliable. The PIBETA analysis now restricts  $F_T^\pi$  to the range  $-5.2 \times 10^{-4} < F_T^\pi < 4.0 \times 10^{-4}$  at a 90% confidence limit [5]. This result is in excellent agreement with the most recent theoretical work [4].

Precision measurements of radiative pion and kaon decays are effective tools to study QCD in the non-perturbative region and are of interest beyond the scope of radiative decays. Meanwhile other processes such as  $\pi^+ \rightarrow e^+ \nu$  that seem to be better suited to search for new physics at the precision frontier are currently studied. The advantages of such process are the very accurate and reliable theoretical predictions and the more straightforward experimental analysis.

 $\pi^0$ 

$$I^G(J^{PC}) = 1^-(0^{-+})$$

We have omitted some results that have been superseded by later experiments. The omitted results may be found in our 1988 edition Physics Letters **B204** 1 (1988).

 $\pi^0$  MASS

The value is calculated from  $m_{\pi^\pm}$  and  $(m_{\pi^\pm} - m_{\pi^0})$ . See also the notes under the  $\pi^\pm$  Mass Listings.

VALUE (MeV)	DOCUMENT ID
<b>134.9766±0.0006 OUR FIT</b>	Error includes scale factor of 1.1.

 $m_{\pi^\pm} - m_{\pi^0}$ 

Measurements with an error > 0.01 MeV have been omitted.

 $\pi^0$  MEAN LIFE

Most experiments measure the  $\pi^0$  width which we convert to a lifetime. ATHERTON 85 is the only direct measurement of the  $\pi^0$  lifetime. Our average based only on indirect measurement yields  $(8.30 \pm 0.19) \times 10^{-17}$  s. The two Primakoff measurements from 1970 have been excluded from our average because they suffered model-related systematics unknown at the time. More information on the  $\pi^0$  lifetime can be found in BERNSTEIN 13.

VALUE ( $10^{-17}$ s)	EVTs	DOCUMENT ID	TECN	COMMENT
<b>8.52±0.18 OUR AVERAGE</b>				Error includes scale factor of 1.2.

9 ± 0.68		KRYSHKIN 70	CNTR	Primakoff effect
7.3 ± 1.1		BELLETTINI 65B	CNTR	Primakoff effect

- <sup>1</sup>LARIN 11 reported  $\Gamma(\pi^0 \rightarrow \gamma\gamma) = 7.82 \pm 0.14 \pm 0.17$  eV which we converted to mean life  $\tau = \hbar/\Gamma$  (total).
- <sup>2</sup>BYCHKOV 09 obtains this using the conserved-vector-current relation between the vector form factor  $F_V$  and the  $\pi^0$  lifetime.
- <sup>3</sup>WILLIAMS 88 gives  $\Gamma(\gamma\gamma) = 7.7 \pm 0.5 \pm 0.5$  eV. We give here  $\tau = \hbar/\Gamma$  (total).
- <sup>4</sup>BROWMAN 74 gives a  $\pi^0$  width  $\Gamma = 8.02 \pm 0.42$  eV. The mean life is  $\hbar/\Gamma$ .

 $\pi^0$  DECAY MODES

For decay limits to particles which are not established, see the appropriate Search sections ( $A^0$  (axion) and Other Light Boson ( $X^0$ ) Searches, etc.).

[a] Astrophysical and cosmological arguments give limits of order  $10^{-13}$ ; see the Particle Listings below.

### CONSTRAINED FIT INFORMATION

An overall fit to 2 branching ratios uses 6 measurements and one constraint to determine 3 parameters. The overall fit has a  $\chi^2 = 4.6$  for 4 degrees of freedom.

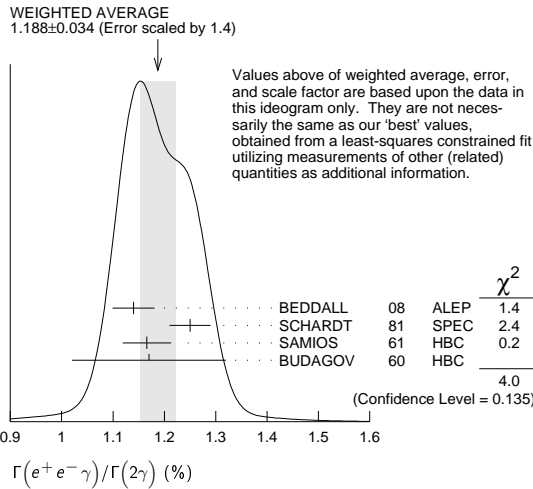

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

$x_2$	-100	
$x_4$	0	-1

3.18 ± 0.30	146	<sup>8</sup> SAMIOS	62B HBC		

<sup>7</sup> This ABOUZAID 08D value includes all radiative final states. The error includes both statistical and systematic errors. The correlation between the Dalitz-pair planes gives a direct measurement of the  $\pi^0$  parity. The  $\pi^0 2\gamma^*$  form factor is measured and limits are placed on a scalar contribution to the decay.  
<sup>8</sup> SAMIOS 62B value uses a Panofsky ratio = 1.62.

$\Gamma(e^+ e^-) / \Gamma_{\text{total}}$   $\Gamma_5 / \Gamma$   
 Experimental results are listed; branching ratios corrected for radiative effects are given in the footnotes. BERMAN 60 found  $B(\pi^0 \rightarrow e^+ e^-) \geq 4.69 \times 10^{-8}$  via an exact QED calculation.

 $\pi^0$  ELECTROMAGNETIC FORM FACTOR

The amplitude for the process  $\pi^0 \rightarrow e^+e^-\gamma$  contains a form factor  $F(x)$  at the  $\pi^0\gamma\gamma$  vertex, where  $x = [m_{e^+e^-}/m_{\pi^0}]^2$ . The parameter  $a$  in the linear expansion  $F(x) = 1 + ax$  is listed below.

All the measurements except that of BEHREND 91 are in the time-like region of momentum transfer.

LINEAR COEFFICIENT OF  $\pi^0$  ELECTROMAGNETIC FORM FACTOR

<sup>20</sup>BEHREND 91 estimates that their systematic error is of the same order of magnitude as their statistical error, and so we have included a systematic error of this magnitude. The value of  $a$  is obtained by extrapolation from the region of large space-like momentum transfer assuming vector dominance.

<sup>21</sup>TUPPER 83 is a theoretical analysis of FISCHER 78 including 2-photon exchange in the corrections.

<sup>22</sup>The FISCHER 78 error is statistical only. The result without radiation corrections is  $+0.05 \pm 0.03$ .

 $\eta$ 

$$I^G(J^{PC}) = 0^+(0^+)$$

We have omitted some results that have been superseded by later experiments. The omitted results may be found in our 1988 edition Physics Letters **B204** (1988).

 $\eta$  MASS

Recent measurements resolve the obvious inconsistency in previous  $\eta$  mass measurements in favor of the higher value first reported by NA48 (LA1 02). We use only precise measurements consistent with this higher mass value for our  $\eta$  mass average.

[a] C parity forbids this to occur as a single-photon process.

**CONSTRAINED FIT INFORMATION**

An overall fit to a decay rate and 19 branching ratios uses 49 measurements and one constraint to determine 9 parameters. The overall fit has a  $\chi^2 = 43.7$  for 41 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

0.324 $\pm$ 0.046		BROWMAN	74B	CNTR Primakoff effect
1.00 $\pm$ 0.22		<sup>3</sup> BEMPORAD	67	CNTR Primakoff effect
<sup>2</sup> RODRIGUES 08 uses a more sophisticated calculation for the inelastic background due to incoherent photoproduction to reanalyze the $\eta$ photoproduction data on Be and Cu at 9 GeV from BROWMAN 74B. This brings the value of $\Gamma(\eta \rightarrow 2\gamma)$ in line with direct measurements of the width. The error here is only statistical.				
<sup>3</sup> BEMPORAD 67 gives $\Gamma(2\gamma) = 1.21 \pm 0.26$ keV assuming $\Gamma(2\gamma)/\Gamma(\text{total}) = 0.314$ . Bemporad private communication gives $\Gamma(2\gamma)^2/\Gamma(\text{total}) = 0.380 \pm 0.083$ . We evaluate this using $\Gamma(2\gamma)/\Gamma(\text{total}) = 0.38 \pm 0.01$ . Not included in average because the uncertainty resulting from the separation of the coulomb and nuclear amplitudes has apparently been underestimated.

<30		90	0 DAVYDOV 81	GAM2	$\pi^- p \rightarrow \eta n$
<sup>8</sup> PRAKHOV 08 is a reanalysis of the data of PRAKHOV 05, using for the first time the invariant-mass spectrum of the two photons.					
<sup>9</sup> Normalized using $\Gamma(\eta \rightarrow 2\gamma)/\Gamma = 0.3943 \pm 0.0026$ .					
<sup>10</sup> This measurement and the independent analysis of the same data by KNECHT 04 both imply a lower value of $\Gamma(\pi^0 2\gamma)$ than the one obtained by ALDE 84 from $\Gamma(\pi^0 2\gamma)/\Gamma(2\gamma)$ .

$-0.060 \pm 0.065$	7250	GORMLEY	70	WIRE
$0.12 \pm 0.06$		27 THALER	72	ASPK

••• We do not use the following data for averages, fits, limits, etc. •••

<sup>27</sup>The authors don't believe this indicates  $D$ -wave because the dependence of  $\beta$  on the  $\gamma$  energy is inconsistent with the theoretical prediction. A  $\cos^2\theta$  dependence can also come from  $P$ - and  $F$ -wave interference.

 $\eta$  CP-NONCONSERVING DECAY PARAMETER $\pi^+ \pi^- e^+ e^-$  DECAY-PLANE ASYMMETRY PARAMETER  $A_\phi$ 

In the  $\eta$  rest frame, the total momentum of the  $e^+ e^-$  pair is equal and opposite to that of the  $\pi^+ \pi^-$  pair. Let  $\hat{z}$  be the unit vector along the momentum of the  $e^+ e^-$  pair; let  $\hat{n}_{ee}$  and  $\hat{n}_{\pi\pi}$  be the unit vectors normal to the  $e^+ e^-$  and  $\pi^+ \pi^-$  planes; and let  $\phi$  be the angle between the two normals. Then

$$\sin\phi \cos\phi = [(\hat{n}_{ee} \times \hat{n}_{\pi\pi}) \cdot \hat{z}] (\hat{n}_{ee} \cdot \hat{n}_{\pi\pi}),$$

and

$$A_\phi \equiv \frac{N_{\sin\phi \cos\phi > 0} - N_{\sin\phi \cos\phi < 0}}{N_{\sin\phi \cos\phi > 0} + N_{\sin\phi \cos\phi < 0}}.$$

## NOTE ON SCALAR MESONS BELOW 2 GEV

Revised September 2013 by C. Amšler (Univ of Bern), S. Eidelman (Budker Institute of Nuclear Physics, Novosibirsk), T. Gutsche (University of Tübingen), C. Hanhart (Forschungszentrum Jülich), S. Spanier (University of Tennessee), and N.A. Törnqvist (University of Helsinki).

**I. Introduction:** In contrast to the vector and tensor mesons, the identification of the scalar mesons is a long-standing puzzle. Scalar resonances are difficult to resolve because some of them have large decay widths which cause a strong overlap between resonances and background. In addition, several decay channels sometimes open up within a short mass interval (e.g. at the  $K\bar{K}$  and  $\eta\eta$  thresholds), producing cusps in the line shapes of the near-by resonances. Furthermore, one expects non- $q\bar{q}$  scalar objects, such as glueballs and multi-quark states in the mass range below 2 GeV (for reviews see, e.g., Refs. [1–4]).

Scalars are produced, for example, in  $\pi N$  scattering on polarized/unpolarized targets,  $p\bar{p}$  annihilation, central hadronic production,  $J/\Psi$ ,  $B$ -,  $D$ - and  $K$ -meson decays,  $\gamma\gamma$  formation, and  $\phi$  radiative decays. Especially for the lightest scalar mesons simple parameterizations fail and more advanced theory tools are necessary to extract the resonance parameters from data. In the analyses available in the literature fundamental properties of the amplitudes such as unitarity, analyticity, Lorentz invariance, chiral and flavor symmetry are implemented at different levels of rigor. Especially, chiral symmetry implies the appearance of zeros close to the threshold in elastic  $S$ -wave scattering amplitudes involving soft pions [5,6], which may be shifted or removed in associated production processes [7]. The methods employed are the  $K$ -matrix formalism, the  $N/D$ -method, the Dalitz Tuan ansatz, unitarized quark models with coupled channels, effective chiral field theories and the linear sigma model, etc. Dynamics near the lowest two-body thresholds in

some analyses are described by crossed channel ( $t$ ,  $u$ ) meson exchange or with an effective range parameterization instead of, or in addition to, resonant features in the  $s$ -channel. Dispersion theoretical approaches are applied to pin down the location of resonance poles for the low lying states [8–11].

The mass and width of a resonance are found from the position of the nearest pole in the process amplitude ( $T$ -matrix or  $S$ -matrix) at an unphysical sheet of the complex energy plane, traditionally labeled as

$$\sqrt{s_{\text{Pole}}} = M - i\Gamma/2.$$

It is important to note that the Breit-Wigner parameterization agrees with this pole position only for narrow and well-separated resonances, far away from the opening of decay channels.

In this note, we discuss the light scalars below 2 GeV organized in the listings under the entries ( $I = 1/2$ )  $K_0^*(800)$  (or  $\kappa$ , currently omitted from the summary table),  $K_0^*(1430)$ , ( $I = 1$ )  $a_0(980)$ ,  $a_0(1450)$ , and ( $I = 0$ )  $f_0(500)$  (or  $\sigma$ ),  $f_0(980)$ ,  $f_0(1370)$ ,  $f_0(1500)$ , and  $f_0(1710)$ . This list is minimal and does not necessarily exhaust the list of actual resonances. The ( $I = 2$ )  $\pi\pi$  and ( $I = 3/2$ )  $K\pi$  phase shifts do not exhibit any resonant behavior. See also our notes in previous issues for further comments on, *e.g.*, scattering lengths and older papers.

**II. The  $I = 1/2$  States:** The  $K_0^*(1430)$  [12] is perhaps the least controversial of the light scalar mesons. The  $K\pi$   $S$ -wave scattering has two possible isospin channels,  $I = 1/2$  and  $I = 3/2$ . The  $I = 3/2$  wave is elastic and repulsive up to 1.7 GeV [13] and contains no known resonances. The  $I = 1/2$   $K\pi$  phase shift, measured from about 100 MeV above threshold in  $Kp$  production, rises smoothly, passes  $90^\circ$  at 1350 MeV, and continues to rise to about  $170^\circ$  at 1600 MeV. The first important inelastic threshold is  $K\eta'(958)$ . In the inelastic region the continuation of the amplitude is uncertain since the partial-wave decomposition has several solutions. The data are extrapolated towards the  $K\pi$  threshold using effective range type formulas [12,14] or chiral perturbation predictions [15,16]. From analyses using unitarized amplitudes there is agreement on the presence of a resonance pole around 1410 MeV having a width of about 300 MeV. With reduced model dependence, Ref. 17 finds a larger width of 500 MeV.

Similar to the situation for the  $f_0(500)$ , discussed in the next section, the presence and properties of the light  $K_0^*(800)$  (or  $\kappa$ ) meson in the 700-900 MeV region are difficult to establish since it appears to have a very large width ( $\Gamma \approx 500$  MeV) and resides close to the  $K\pi$  threshold. Hadronic  $D$ -meson decays provide additional data points in the vicinity of the  $K\pi$  threshold - experimental results from E791, *e.g.*, Ref. [18,19], FOCUS [17,20], CLEO [21], and BaBar [22] are discussed in the *Review of Charm Dalitz Plot Analyses*. Precision information from semileptonic  $D$  decays avoiding theoretically ambiguous three-body final state interactions is not available. BES II [23] (re-analyzed in [24]) finds a  $K_0^*(800)$ -like structure in  $J/\psi$  decays to  $\bar{K}^{*0}(892)K^+\pi^-$  where  $K_0^*(800)$  recoils against the

$K^*(892)$ . Also clean with respect to final state interaction is the decay  $\tau^- \rightarrow K_S^0\pi^-\nu_\tau$  studied by Belle [25], with  $K_0^*(800)$  parameters fixed to Ref. 23.

Some authors find a  $K_0^*(800)$  pole in their phenomenological analysis (see, *e.g.*, [21,26–36]), while others do not need to include it in their fits (see, *e.g.*, [16,22,37–39]). Similarly to the case of the  $f_0(500)$  discussed below, all works including constraints from chiral symmetry at low energies naturally seem to find a light  $K_0^*(800)$  below 800 MeV, see, *e.g.*, [40–44]. In these works the  $K_0^*(800)$ ,  $f_0(500)$ ,  $f_0(980)$  and  $a_0(980)$  appear to form a nonet [41,42]. Additional evidence for this assignment is presented in Ref. 11, where the couplings of the nine states to  $\bar{q}q$  sources were compared. The same low lying scalar nonet was also found earlier in the unitarized quark model of Ref. 43. The analysis of Ref. 45 is based on the Roy-Steiner equations, which include analyticity and crossing symmetry. It establishes the existence of a light  $K_0^*(800)$  pole in the  $K\pi \rightarrow K\pi$  amplitude on the second sheet.

**III. The  $I = 1$  States:** Two isovector states are known, the established  $a_0(980)$  and the  $a_0(1450)$ . Independent of any model, the  $K\bar{K}$  component in the  $a_0(980)$  wave function must be large: it lies just below the opening of the  $K\bar{K}$  channel to which it strongly couples [14,46]. This generates an important cusp-like behavior in the resonant amplitude. Hence, its mass and width parameters are strongly distorted. To reveal its true coupling constants, a coupled channel model with energy-dependent widths and mass shift contributions is necessary. All listed  $a_0(980)$  measurements agree on a mass position value near 980 MeV, but the width takes values between 50 and 100 MeV, mostly due to the different models. For example, the analysis of the  $p\bar{p}$ -annihilation data [14] using a unitary  $K$ -matrix description finds a width as determined from the  $T$ -matrix pole of  $92 \pm 8$  MeV, while the observed width of the peak in the  $\pi\eta$  mass spectrum is about 45 MeV.

The relative coupling  $K\bar{K}/\pi\eta$  is determined indirectly from  $f_1(1285)$  [47–49] or  $\eta(1410)$  decays [50–52], from the line shape observed in the  $\pi\eta$  decay mode [54–57], or from the coupled-channel analysis of the  $\pi\pi\eta$  and  $K\bar{K}\pi$  final states of  $p\bar{p}$  annihilation at rest [14].

The  $a_0(1450)$  is seen in  $p\bar{p}$  annihilation experiments with stopped and higher momenta antiprotons, with a mass of about 1450 MeV or close to the  $a_2(1320)$  meson which is typically a dominant feature. A contribution from  $a_0(1450)$  is also found in the analysis of the  $D^\pm \rightarrow K^+K^-\pi^\pm$  decay [58]. The broad structure at about 1300 MeV observed in  $\pi N \rightarrow K\bar{K}N$  reactions [59] needs still further confirmation in its existence and isospin assignment.

**IV. The  $I = 0$  States:** The  $I = 0$ ,  $J^{PC} = 0^{++}$  sector is the most complex one, both experimentally and theoretically. The data have been obtained from  $\pi\pi$ ,  $K\bar{K}$ ,  $\eta\eta$ ,  $4\pi$ , and  $\eta\eta'(958)$  systems produced in  $S$ -wave. Analyses based on several different production processes conclude that probably four poles are needed in the mass range from  $\pi\pi$  threshold to about

## Meson Particle Listings

 $f_0(500)$ 

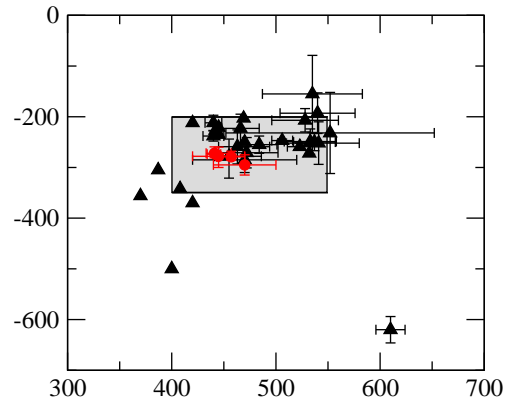

1600 MeV. The claimed isoscalar resonances are found under separate entries  $f_0(500)$  (or  $\sigma$ ),  $f_0(980)$ ,  $f_0(1370)$ , and  $f_0(1500)$ .

For discussions of the  $\pi\pi$   $S$  wave below the  $K\bar{K}$  threshold and on the long history of the  $f_0(500)$ , which was suggested in linear sigma models more than 50 years ago, see our reviews in previous editions and the conference proceedings [60].

Information on the  $\pi\pi$   $S$ -wave phase shift  $\delta_J^f = \delta_0^0$  was already extracted many years ago from  $\pi N$  scattering [61–63], and near threshold from the  $K_{e4}$ -decay [64]. The kaon decays were later revisited leading to consistent data, however, with very much improved statistics [65,66]. The reported  $\pi\pi \rightarrow K\bar{K}$  cross sections [67–70] have large uncertainties. The  $\pi N$  data have been analyzed in combination with high-statistics data (see entries labeled as RVUE for re-analyses of the data). The  $2\pi^0$  invariant mass spectra of the  $p\bar{p}$  annihilation at rest [71–73] and the central collision [74] do not show a distinct resonance structure below 900 MeV, but these data are consistently described with the standard solution for  $\pi N$  data [62,75], which allows for the existence of the broad  $f_0(500)$ . An enhancement is observed in the  $\pi^+\pi^-$  invariant mass near threshold in the decays  $D^+ \rightarrow \pi^+\pi^-\pi^+$  [76–103] and  $J/\psi \rightarrow \omega\pi^+\pi^-$  [79,100], and in  $\psi(2S) \rightarrow J/\psi\pi^+\pi^-$  with very limited phase space [81,82].

The precise  $f_0(500)$  (or  $\sigma$ ) pole is difficult to establish because of its large width, and because it can certainly not be modeled by a naive Breit-Wigner resonance. For the same reason a splitting in background and resonance contributions is not possible in a model-independent way. The  $\pi\pi$  scattering amplitude shows an unusual energy dependence due to the presence of a zero in the unphysical regime close to the threshold [5–6], required by chiral symmetry, and possibly due to crossed channel exchanges, the  $f_0(1370)$ , and other dynamical features. However, most of the analyses listed under  $f_0(500)$  agree on a pole position near  $(500 - i250)$  MeV. In particular, analyses of  $\pi\pi$  data that include unitarity,  $\pi\pi$  threshold behavior, strongly constrained by the  $K_{e4}$  data, and the chiral symmetry constraints from Adler zeroes and/or scattering lengths find a light  $f_0(500)$ , see, *e.g.*, [83,84].

Precise pole positions with an uncertainty of less than 20 MeV (see our table for  $T$ -matrix pole) were extracted by use of Roy equations, which are twice subtracted dispersion relations derived from crossing symmetry and analyticity. In Ref. [9] the subtraction constants were fixed to the  $S$ -wave scattering lengths  $a_0^0$  and  $a_2^0$  derived from matching Roy equations and two-loop chiral perturbation theory [8]. The only additional relevant input to fix the  $f_0(500)$  pole turned out to be the  $\pi\pi$ -wave phase shifts at 800 MeV. The analysis was improved further in Ref. 11. Alternatively, in Ref. 10 only data was used as input inside Roy equations. In that reference also once-subtracted Roy-like equations, called GKPY equations, were used, since the extrapolation into the complex plane based on the twice subtracted equations leads to larger uncertainties mainly due to the limited experimental information on the

**Figure 1:** Location of the  $f_0(500)$  (or  $\sigma$ ) poles in the complex energy plane. Circles denote the recent analyses based on Roy(-like) dispersion relations [8–11], while all other analyses are denoted by triangles. The corresponding references are given in the listing.

isospin 2  $\pi\pi$  scattering length. All these extractions find consistent results. Using analyticity and unitarity only to describe data from  $K_{2\pi}$  and  $K_{e4}$  decays, Ref. 85 finds consistent values for pole position and scattering length  $a_0^0$ . The importance of the  $\pi\pi$  scattering data for fixing the  $f_0(500)$  pole is nicely illustrated by comparing analyses of  $\bar{p}p \rightarrow 3\pi^0$  omitting [71,86] or including [72,87] information on  $\pi\pi$  scattering: while the former analyses find an extremely broad structure above 1 GeV, the latter find  $f_0(500)$  masses of the order of 400 MeV.

As a result of the sensitivity of the extracted  $f_0(500)$  pole position on the high accuracy low energy  $\pi\pi$  scattering data [65,66], the currently quoted range of pole positions for the  $f_0(500)$ , namely

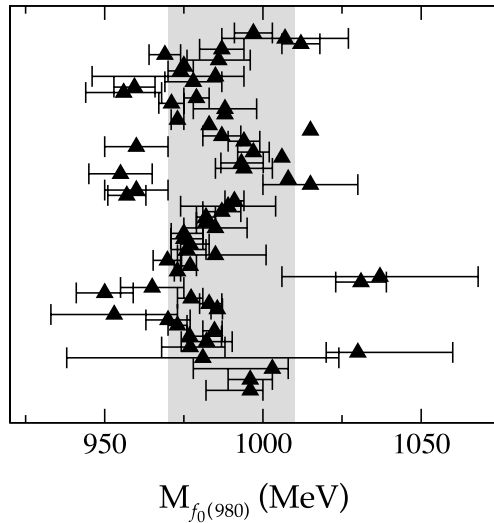

$$\sqrt{s_{\text{Pole}}^{\sigma}} = (400 - 550) - i(200 - 350) \text{ MeV} ,$$

in the listing was fixed including only those analyses consistent with these data, Refs. [29,32,41,43,44,53,56,72], [81–85] and [88–103] as well as the advanced dispersion analyses [8–11]. The pole positions from those references are compared to the range of poles positions quoted above in Fig. 1. Note that this range is labeled as ‘our estimate’ — it is not an average over the quoted analyses but is chosen to include the bulk of the analyses consistent with the mentioned criteria. An averaging procedure is not justified, since the analyses use overlapping or identical data sets.

One might also take the more radical point of view and just average the most advanced dispersive analyses, Refs. [8–11], shown as solid dots in Fig. 1, for they provide a determination of the pole positions with minimal bias. This procedure leads to the much more restricted range of  $f_0(500)$  parameters

$$\sqrt{s_{\text{Pole}}^{\sigma}} = (446 \pm 6) - i(276 \pm 5) \text{ MeV} .$$

Due to the large strong width of the  $f_0(500)$  an extraction of its two-photon width directly from data is not possible.

**Figure 2:** Values of the  $f_0(980)$  masses as they appear in the listing compared to the currently quoted mass estimate. The newest references appear at the bottom, the oldest on the top. The corresponding references are given in the listing.

Thus, the values for  $\Gamma(\gamma\gamma)$  quoted in the literature as well as the listing are based on the expression in the narrow width approximation [104]  $\Gamma(\gamma\gamma) \simeq \alpha^2 |g_\gamma|^2 / (4\text{Re}(\sqrt{s_{\text{pole}}}))$  where  $g_\gamma$  is derived from the residue at the  $f_0(500)$  pole to two photons and  $\alpha$  denotes the electromagnetic fine structure constant. The explicit form of the expression may vary between different authors due to different definitions of the coupling constant, however, the expression given for  $\Gamma(\gamma\gamma)$  is free of ambiguities. According to Refs. [105,106], the data for  $f_0(500) \rightarrow \gamma\gamma$  are consistent with what is expected for a two-step process of  $\gamma\gamma \rightarrow \pi^+\pi^-$  via pion exchange in the  $t$ - and  $u$ -channel, followed by a final state interaction  $\pi^+\pi^- \rightarrow \pi^0\pi^0$ . The same conclusion is drawn in Ref. 107 where the bulk part of the  $f_0(500) \rightarrow \gamma\gamma$  decay width is dominated by re-scattering. Therefore, it might be difficult to learn anything new about the nature of the  $f_0(500)$  from its  $\gamma\gamma$  coupling. For the most recent work on  $\gamma\gamma \rightarrow \pi\pi$ , see Refs. [108,109]. There are theoretical indications (*e.g.*, [110–113]) that the  $f_0(500)$  pole behaves differently from a  $q\bar{q}$ -state – see next section for details.

The  $f_0(980)$  overlaps strongly with the background represented mainly by the  $f_0(500)$  and the  $f_0(1370)$ . This can lead to a dip in the  $\pi\pi$  spectrum at the  $K\bar{K}$  threshold. It changes from a dip into a peak structure in the  $\pi^0\pi^0$  invariant mass spectrum of the reaction  $\pi^-p \rightarrow \pi^0\pi^0n$  [114], with increasing four-momentum transfer to the  $\pi^0\pi^0$  system, which means increasing the  $a_1$ -exchange contribution in the amplitude, while the  $\pi$ -exchange decreases. The  $f_0(500)$  and the  $f_0(980)$  are also observed in data for radiative decays ( $\phi \rightarrow f_0\gamma$ ) from SND [115,116], CMD2 [117], and KLOE [118,119]. A dispersive analysis was used to simultaneously pin down the pole

parameters of both the  $f_0(500)$  and the  $f_0(980)$  [10]; the uncertainty in the pole position quoted for the latter state is of the order of 10 MeV, only (see lowest point in Fig. 2). Compared to the 2010 issue of the *Review of Particle Physics*, in this issue we extended the allowed range of  $f_0(980)$  masses to include the mass value derived in Ref. 10. We now quote for the mass

$$M_{f_0(980)} = 990 \pm 20 \text{ MeV} .$$

As in case of the  $f_0(500)$  (or  $\sigma$ ), this range is not an average, but is labeled as 'our estimate'. A comparison of the mass values in the listing and the allocated range is shown in Fig. 2.

Analyses of  $\gamma\gamma \rightarrow \pi\pi$  data [120–122] underline the importance of the  $K\bar{K}$  coupling of  $f_0(980)$ , while the resulting two-photon width of the  $f_0(980)$  cannot be determined precisely [123]. The prominent appearance of the  $f_0(980)$  in the semi-leptonic  $D_S$  decays and decays of  $B$  and  $B_S$ -mesons implies a dominant ( $\bar{s}s$ ) component: those decays occur via weak transitions that alternatively result in  $\phi(1020)$  production. Ratios of decay rates of  $B$  and  $B_S$  mesons into  $J/\psi$  plus  $f_0(980)$  or  $f_0(500)$  may be used as input to extract the flavor mixing angle and to probe the tetra-quark nature of those mesons as proposed by Refs. [220,221]. The LHCb experiment finds an upper limit for the mixing angle of  $31^\circ$  at 90% C.L. between  $f_0(980)$  and  $f_0(500)$  that corresponds to a substantial ( $\bar{s}s$ ) content in  $f_0(980)$  [222].

**The  $f_0$ 's above 1 GeV.** A meson resonance that is very well studied experimentally, is the  $f_0(1500)$  seen by the Crystal Barrel experiment in five decay modes:  $\pi\pi$ ,  $K\bar{K}$ ,  $\eta\eta$ ,  $\eta\eta'$  (958), and  $4\pi$  [14,72,73]. Due to its interference with the  $f_0(1370)$  (and  $f_0(1710)$ ), the peak attributed to  $f_0(1500)$  can appear shifted in invariant mass spectra. Therefore, the application of simple Breit-Wigner forms arrive at slightly different resonance masses for  $f_0(1500)$ . Analyses of central-production data of the likewise five decay modes Refs. [124,125] agree on the description of the  $S$ -wave with the one above. The  $p\bar{p}$ ,  $p\bar{n}/n\bar{p}$  measurements [126–128,73] show a single enhancement at 1400 MeV in the invariant  $4\pi$  mass spectra, which is resolved into  $f_0(1370)$  and  $f_0(1500)$  [129,130]. The data on  $4\pi$  from central production [131] require both resonances, too, but disagree on the relative content of  $\rho\rho$  and  $f_0(500)f_0(500)$  in  $4\pi$ . All investigations agree that the  $4\pi$  decay mode represents about half of the  $f_0(1500)$  decay width and is dominant for  $f_0(1370)$ .

The determination of the  $\pi\pi$  coupling of  $f_0(1370)$  is aggravated by the strong overlap with the broad  $f_0(500)$  and  $f_0(1500)$ . Since it does not show up prominently in the  $2\pi$  spectra, its mass and width are difficult to determine. Multi-channel analyses of hadronically produced two- and three-body final states agree on a mass between 1300 MeV and 1400 MeV and a narrow  $f_0(1500)$ , but arrive at a somewhat smaller width for  $f_0(1370)$ .

**V. Interpretation of the scalars below 1 GeV:** In the literature, many suggestions are discussed, such as conventional

# Meson Particle Listings

## $f_0(500)$

$q\bar{q}$  mesons,  $q\bar{q}q\bar{q}$  or meson-meson bound states. In addition one expects a scalar glueball in this mass range. In reality, there can be superpositions of these components, and one often depends on models to determine the dominant one. Although we have seen progress in recent years, this question remains open. Here, we mention some of the present conclusions.

The  $f_0(980)$  and  $a_0(980)$  are often interpreted as multi-quark states [140–144] or  $K\bar{K}$  bound states [145]. The insight into their internal structure using two-photon widths [116,146–152] is not conclusive. The  $f_0(980)$  appears as a peak structure in  $J/\psi \rightarrow \phi\pi^+\pi^-$  and in  $D_s$  decays without  $f_0(500)$  background, while being nearly invisible in  $J/\psi \rightarrow \omega\pi^+\pi^-$ . Based on that observation it is suggested that  $f_0(980)$  has a large  $s\bar{s}$  component, which according to Ref. 153 is surrounded by a virtual  $K\bar{K}$  cloud (see also Ref. 154). Data on radiative decays ( $\phi \rightarrow f_0\gamma$  and  $\phi \rightarrow a_0\gamma$ ) from SND, CMD2, and KLOE (see above) are consistent with a prominent role of kaon loops. This observation is interpreted as evidence for a compact four-quark [155] or a molecular [160,156] nature of these states. Details of this controversy are given in the comments [157,158]; see also Ref. 159. It remains quite possible that the states  $f_0(980)$  and  $a_0(980)$ , together with the  $f_0(500)$  and the  $K_0^*(800)$ , form a new low-mass state nonet of predominantly four-quark states, where at larger distances the quarks recombine into a pair of pseudoscalar mesons creating a meson cloud (see *e.g.*, Ref. 161). Different QCD sum rule studies [162–166] do not agree on a tetraquark configuration for the same particle group.

Models that start directly from chiral Lagrangians, either in non-linear [44,28,83,160] or in linear [167–172] realization, predict the existence of the  $f_0(500)$  meson near 500 MeV. Here the  $f_0(500)$ ,  $a_0(980)$ ,  $f_0(980)$ , and  $K_0^*(800)$  (in some models the  $K_0^*(1430)$ ) would form a nonet (not necessarily  $q\bar{q}$ ). In the linear sigma models the lightest pseudoscalars appear as their chiral partners. In these models the light  $f_0(500)$  is often referred to as the "Higgs boson of strong interactions", since here the  $f_0(500)$  plays a role similar to the Higgs particle in electro-weak symmetry breaking: within the linear sigma models it is important for the mechanism of chiral symmetry breaking, which generates most of the proton mass, and what is referred to as the constituent quark mass.

In the non-linear approaches of Ref. 28 [83], the above resonances together with the low lying vector states are generated starting from chiral perturbation theory predictions near the first open channel, and then by extending the predictions to the resonance regions using unitarity and analyticity.

Ref. 167 uses a framework with explicit resonances that are unitarized and coupled to the light pseudo-scalars in a chirally invariant way. Evidence for a non- $q\bar{q}$  nature of the lightest scalar resonances is derived from their mixing scheme. To identify the nature of the resonances generated from scattering equations, in Ref. 175 the large  $N_c$  behavior of the poles was studied, with the conclusion that, while the light vector states behave consistent with what is predicted for  $q\bar{q}$  states, the light scalars behave very differently. This finding provides strong

support for a non- $q\bar{q}$  nature of the light scalar resonances. Note, the more refined study of Ref. 110 found, in case of the  $f_0(500)$ , in addition to a dominant non- $q\bar{q}$  nature, indications for a subdominant  $q\bar{q}$  component located around 1 GeV. A model-independent method to identify hadronic molecules goes back to a proposal by Weinberg [176], shown to be equivalent to the pole counting arguments of Ref. 177 [178] in Ref. 179. The formalism allows one to extract the amount of molecular component in the wave function from the effective coupling constant of a physical state to a nearby continuum channel. It can be applied to near threshold states only and provided strong evidence that the  $f_0(980)$  is a  $\bar{K}K$  molecule, while the situation turned out to be less clear for the  $a_0(980)$  (see also Refs. [152,150]). Further insights into  $a_0(980)$  and  $f_0(980)$  are expected from their mixing [180]. The corresponding signal predicted in Refs. [181,182] was recently observed at BES III [183]. It turned out that in order to get a quantitative understanding of that data in addition to the mixing mechanism itself some detailed understanding of the production mechanism seems necessary [184].

In the unitarized quark model with coupled  $q\bar{q}$  and meson-meson channels, the light scalars can be understood as additional manifestations of bare  $q\bar{q}$  confinement states, strongly mass shifted from the 1.3 - 1.5 GeV region and very distorted due to the strong  $^3P_0$  coupling to  $S$ -wave two-meson decay channels [173–185]. Thus, in these models the light scalar nonet comprising the  $f_0(500)$ ,  $f_0(980)$ ,  $K_0^*(800)$ , and  $a_0(980)$ , as well as the nonet consisting of the  $f_0(1370)$ ,  $f_0(1500)$  (or  $f_0(1710)$ ),  $K_0^*(1430)$ , and  $a_0(1450)$ , respectively, are two manifestations of the same bare input states (see also Ref. 186).

Other models with different groupings of the observed resonances exist and may, *e.g.*, be found in earlier versions of this review.

**VI. Interpretation of the  $f_0$ 's above 1 GeV:** The  $f_0(1370)$  and  $f_0(1500)$  decay mostly into pions ( $2\pi$  and  $4\pi$ ) while the  $f_0(1710)$  decays mainly into  $K\bar{K}$  final states. The  $K\bar{K}$  decay branching ratio of the  $f_0(1500)$  is small [124,187].

If one uses the naive quark model, it is natural to assume that the  $f_0(1370)$ ,  $a_0(1450)$ , and the  $K_0^*(1430)$  are in the same SU(3) flavor nonet, being the  $(u\bar{u} + d\bar{d})$ ,  $u\bar{d}$  and  $u\bar{s}$  states, probably mixing with the light scalars [188], while the  $f_0(1710)$  is the  $s\bar{s}$  state. Indeed, the production of  $f_0(1710)$  (and  $f_2'(1525)$ ) is observed in  $p\bar{p}$  annihilation [189] but the rate is suppressed compared to  $f_0(1500)$  (respectively,  $f_2(1270)$ ), as would be expected from the OZI rule for  $s\bar{s}$  states. The  $f_0(1500)$  would also qualify as  $(u\bar{u} + d\bar{d})$  state, although it is very narrow compared to the other states and too light to be the first radial excitation.

However, in  $\gamma\gamma$  collisions leading to  $K_S^0 K_S^0$  [190] a spin 0 signal is observed at the  $f_0(1710)$  mass (together with a dominant spin 2 component), while the  $f_0(1500)$  is not observed in  $\gamma\gamma \rightarrow K\bar{K}$  nor  $\pi^+\pi^-$  [191]. In  $\gamma\gamma$  collisions leading to  $\pi^0\pi^0$  Ref. 138 reports the observation of a scalar around 1470 MeV

albeit with large uncertainties on the mass and  $\gamma\gamma$  couplings. This state could be the  $f_0(1370)$  or the  $f_0(1500)$ . The upper limit from  $\pi^+\pi^-$  [191] excludes a large  $n\bar{n}$  (here  $n$  stands for the two lightest quarks) content for the  $f_0(1500)$  and hence points to a mainly  $s\bar{s}$  state [192]. This appears to contradict the small  $K\bar{K}$  decay branching ratio of the  $f_0(1500)$  and makes a  $q\bar{q}$  assignment difficult for this state. Hence the  $f_0(1500)$  could be mainly glue due the absence of a  $2\gamma$ -coupling, while the  $f_0(1710)$  coupling to  $2\gamma$  would be compatible with an  $s\bar{s}$  state. This is in accord with the recent high statistics Belle data in  $\gamma\gamma \rightarrow K_S^0 K_S^0$  [193] in which the  $f_0(1500)$  is absent, while a prominent peak at 1710 MeV is observed with quantum numbers  $0^{++}$ , compatible with the formation of an  $s\bar{s}$  state. However, the  $2\gamma$ -couplings are sensitive to glue mixing with  $q\bar{q}$  [194].

Note that an isovector scalar, possibly the  $a_0(1450)$  (albeit at a lower mass of 1317 MeV) is observed in  $\gamma\gamma$  collisions leading to  $\eta\pi^0$  [195]. The state interferes destructively with the non-resonant background, but its  $\gamma\gamma$  coupling is comparable to that of the  $a_2(1320)$ , in accord with simple predictions (see, *e.g.*, Ref. 192).

The small width of  $f_0(1500)$ , and its enhanced production at low transverse momentum transfer in central collisions [199–201] also favor  $f_0(1500)$  to be non- $q\bar{q}$ . In the mixing scheme of Ref. 194, which uses central production data from WA102 and the recent hadronic  $J/\psi$  decay data from BES [202,203], glue is shared between  $f_0(1370)$ ,  $f_0(1500)$  and  $f_0(1710)$ . The  $f_0(1370)$  is mainly  $n\bar{n}$ , the  $f_0(1500)$  mainly glue and the  $f_0(1710)$  dominantly  $s\bar{s}$ . This agrees with previous analyses [204,205].

However, alternative schemes have been proposed (*e.g.*, in Ref. 206 [207]; for a review see, *e.g.*, Ref. 1). In particular, for a scalar glueball, the two-gluon coupling to  $n\bar{n}$  appears to be suppressed by chiral symmetry [208] and therefore the  $K\bar{K}$  decay could be enhanced. This mechanism would imply that the  $f_0(1710)$  can possibly be interpreted as an unmixed glueball [209]. In Ref. 210, a large  $K^+K^-$  scalar signal reported by Belle in  $B$  decays into  $KK\bar{K}$  [211], compatible with the  $f_0(1500)$ , is explained as due to constructive interference with a broad glueball background. However, the Belle data are inconsistent with the BaBar measurements which show instead a broad scalar at this mass for  $B$  decays into both  $K^\pm K^\pm K^\mp$  [135] and  $K^+K^-\pi^0$  [212].

Whether the  $f_0(1500)$  is observed in 'gluon rich' radiative  $J/\psi$  decays is debatable [213] because of the limited amount of data - more data for this and the  $\gamma\gamma$  mode are needed.

In Ref. [214], further refined in Ref. [215],  $f_0(1370)$  and  $f_0(1710)$  (together with  $f_2(1270)$  and  $f_2'(1525)$ ) were interpreted as bound systems of two vector mesons. This picture could be tested in radiative  $J/\psi$  decays [216] as well as radiative decays of the states themselves [217]. The vector-vector component of  $f_0(1710)$  might also be the origin of the enhancement seen in  $J/\psi \rightarrow \gamma\phi\omega$  near threshold [218] observed at BES [219].

- 1 Applying the chiral unitary approach at NLO to the  $K_{e4}$  data of BATLEY 10 and  $\pi N \rightarrow \pi\pi N$  data of HYAMS 73, GRAYER 74, and PROTOPOESCU 73.
- 2 Uses the  $K_{e4}$  data of BATLEY 10c and the  $\pi N \rightarrow \pi\pi N$  data of HYAMS 73, GRAYER 74, and PROTOPOESCU 73.
- 3 Analytic continuation using Roy equations.
- 4 Analytic continuation using GKPY equations.
- 5 Using Roy equations.
- 6 Average of three variants of the analytic K-matrix model. Uses the  $K_{e4}$  data of BATLEY 08a and the  $\pi N \rightarrow \pi\pi N$  data of HYAMS 73 and GRAYER 74.
- 7 Average of the analyses of three data sets in the K-matrix model. Uses the data of BATLEY 08a, HYAMS 73, and GRAYER 74, partially of COHEN 80 or ETKIN 82b.
- 8 From the  $K_{e4}$  data of BATLEY 08a and  $\pi N \rightarrow \pi\pi N$  data of HYAMS 73.
- 9 From the  $K_{e4}$  data of BATLEY 08a and  $\pi N \rightarrow \pi\pi N$  data of PROTOPOESCU 73, GRAYER 74, and ESTABROOKS 74.
- 10 From a mean of three different  $f_0(500)$  parameterizations. Uses 40k events.
- 11 From an isobar model using 2.6k events.
- 12 Reanalysis of ABLIKIM 04A, PISLAK 01, and HYAMS 73 data.
- 13 Using the N/D method.
- 14 From the solution of the Roy equation (ROY 71) for the isoscalar S-wave and using a phase-shift analysis of HYAMS 73 and PROTOPOESCU 73 data.
- 15 Reanalysis of the data from PROTOPOESCU 73, ESTABROOKS 74, GRAYER 74, ROSSELET 77, PISLAK 03, and AKHMETSHIN 04.
- 16 From a mean of six different analyses and  $f_0(500)$  parameterizations.
- 17 Using data on  $\psi(2S) \rightarrow J/\psi \pi\pi$  from BAI 00e and on  $\Upsilon(nS) \rightarrow \Upsilon(mS) \pi\pi$  from BUTLER 94b and ALEXANDER 98.
- 18 Reanalysis of data from PROTOPOESCU 73, ESTABROOKS 74, GRAYER 74, and COHEN 80 in the unitarized ChPT model.
- 19 From a combined analysis of HYAMS 73, AUGUSTIN 89, AITALA 01b, and PISLAK 01.
- 20 A similar analysis (KOMADA 01) finds  $(580 \pm 79) - i(190 \pm 107) \text{ MeV}$ .
- 21 Coupled channel reanalysis of BATON 70, BENSINGER 71, BAILLON 72, HYAMS 73, HYAMS 75, ROSSELET 77, COHEN 80, and ETKIN 82b using the uniformizing variable.
- 22 Using the inverse amplitude method and data of ESTABROOKS 73, GRAYER 74, and PROTOPOESCU 73.
- 23 Reanalysis of data from HYAMS 73, GRAYER 74, SRINIVASAN 75, and ROSSELET 77 using the interfering amplitude method.
- 24 Average and spread of 4 variants ("up" and "down") of KAMINSKI 97B 3-channel model.
- 25 Uses data from BEIER 72b, OCHS 73, HYAMS 73, GRAYER 74, ROSSELET 77, CASON 83, ASTON 88, and ARMSTRONG 91b. Coupled channel analysis with flavor symmetry and all light two-pseudoscalars systems.
- 26 Demonstrates explicitly that  $f_0(500)$  and  $f_0(1370)$  are two different poles.
- 27 Analysis of data from FALVARD 88.
- 28 Analysis of data from OCHS 73, ESTABROOKS 75, ROSSELET 77, and MUKHIN 80.
- 29 Analysis of data from OCHS 73, GRAYER 74, and ROSSELET 77.
- 30 Coupled-channel analysis using data from PROTOPOESCU 73, HYAMS 73, HYAMS 75, GRAYER 74, ESTABROOKS 74, ESTABROOKS 75, FROGGATT 77, CORDEEN 79, BISWAS 81.
- 31 Analysis of data from APEL 73, GRAYER 74, CASON 76, PAWLICKI 77. Includes spread and errors of 4 solutions.
- 32 Analysis of data from BATON 70, BENSINGER 71, COLTON 71, BAILLON 72, PROTOPOESCU 73, and WALKER 67.

 $f_0(500)$  BREIT-WIGNER MASS OR K-MATRIX POLE PARAMETERS

VALUE (MeV)	DOCUMENT ID	TECN	COMMENT
<b>(400-550) OUR ESTIMATE</b>			
• • • We do not use the following data for averages, fits, limits, etc. • • •			
513 ± 32	33 MURAMATSU 02	CLEO	$e^+ e^- \approx 10 \text{ GeV}$
478 ± 24 -23 ± 17	AITALA 01B	E791	$D^+ \rightarrow \pi^- \pi^+ \pi^+$
563 ± 58 -29	34 ISHIDA 01		$\Upsilon(3S) \rightarrow \Upsilon \pi\pi$
555	35 ASNER 00	CLE2	$\tau^- \rightarrow \pi^- \pi^0 \pi^0 \nu_\tau$
540 ± 36	ISHIDA 00B		$p\bar{p} \rightarrow \pi^0 \pi^0 \pi^0$
750 ± 4	ALEKSEEV 99	SPEC	$1.78 \pi^- p_{\text{polar}} \rightarrow \pi^- \pi^+ n$
744 ± 5	ALEKSEEV 98	SPEC	$1.78 \pi^- p_{\text{polar}} \rightarrow \pi^- \pi^+ n$
759 ± 5	36 TROYAN 98		$5.2 np \rightarrow np \pi^+ \pi^-$
780 ± 30	ALDE 97	GAM2	$450 pp \rightarrow pp \pi^0 \pi^0$
585 ± 20	37 ISHIDA 97		$\pi\pi \rightarrow \pi\pi$
761 ± 12	38 SVEC 96	RVUE	$6-17 \pi N_{\text{polar}} \rightarrow \pi^+ \pi^- N$
~ 860	39,40 TORNQVIST 96	RVUE	$\pi\pi \rightarrow \pi\pi, K\bar{K}, K\pi, \eta\pi$
1165 ± 50	41,42 ANISOVICH 95	RVUE	$\pi^- p \rightarrow \pi^0 \pi^0 n, \bar{p} p \rightarrow \pi^0 \pi^0 \pi^0, \pi^0 \pi^0 \eta, \pi^0 \eta\eta$
~ 1000	43 ACHASOV 94	RVUE	$\pi\pi \rightarrow \pi\pi$
414 ± 20	38 AUGUSTIN 89	DM2	

33 Statistical uncertainty only.

34 A similar analysis (KOMADA 01) finds  $526 \pm 48 \text{ MeV}$ .

35 From the best fit of the Dalitz plot.

36  $6\sigma$  effect, no PWA.

37 Reanalysis of data from HYAMS 73, GRAYER 74, SRINIVASAN 75, and ROSSELET 77 using the interfering amplitude method.

38 Breit-Wigner fit to S-wave intensity measured in  $\pi N \rightarrow \pi^- \pi^+ N$  on polarized targets. The fit does not include  $f_0(980)$ .

39 Uses data from ASTON 88, OCHS 73, HYAMS 73, ARMSTRONG 91b, GRAYER 74, CASON 83, ROSSELET 77, and BEIER 72b. Coupled channel analysis with flavor symmetry and all light two-pseudoscalars systems.

40 Also observed by ASNER 00 in  $\tau^- \rightarrow \pi^- \pi^0 \pi^0 \nu_\tau$  decays.

41 Uses  $\pi^0 \pi^0$  data from ANISOVICH 94, AMSLER 94D, and ALDE 95b,  $\pi^+ \pi^-$  data from OCHS 73, GRAYER 74 and ROSSELET 77, and  $\eta\eta$  data from ANISOVICH 94.

42 The pole is on Sheet III. Demonstrates explicitly that  $f_0(500)$  and  $f_0(1370)$  are two different poles.

43 Analysis of data from OCHS 73, ESTABROOKS 75, ROSSELET 77, and MUKHIN 80.

 $\rho(770)$ 

$$I(G^{JPC}) = 1^+(1^-)$$

THE  $\rho(770)$ 

Updated May 2012 by S. Eidelman (Novosibirsk) and G. Venanzoni (Frascati).

The determination of the parameters of the  $\rho(770)$  is beset with many difficulties because of its large width. In physical form fits, the line shape does not correspond to a relativistic Breit-Wigner function with a  $P$ -wave width, but requires some additional shape parameter. This dependence on parameterization was demonstrated long ago [1]. Bose-Einstein correlations are another source of shifts in the  $\rho(770)$  line shape, particularly in multiparticle final state systems [2].

The same model-dependence afflicts any other source of resonance parameters, such as the energy-dependence of the phase shift  $\delta_1^1$ , or the pole position. It is, therefore, not surprising that a study of  $\rho(770)$  dominance in the decays of the  $\eta$  and  $\eta'$  reveals the need for specific dynamical effects, in addition to the  $\rho(770)$  pole [3,4].

The cleanest determination of the  $\rho(770)$  mass and width comes from  $e^+e^-$  annihilation and  $\tau$ -lepton decays. Analysis of ALEPH [5] showed that the charged  $\rho(770)$  parameters measured from  $\tau$ -lepton decays are consistent with those of the

## Meson Particle Listings

 $\rho(770)$ 

neutral one determined from  $e^+e^-$  data [6]. This conclusion is qualitatively supported by the later studies of CLEO [7] and Belle [8]. However, model-independent comparison of the two-pion mass spectrum in  $\tau$  decays, and the  $e^+e^- \rightarrow \pi^+\pi^-$  cross section, gave indications of discrepancies between the overall normalization:  $\tau$  data are about 3% higher than  $e^+e^-$  data [7,9]. A detailed analysis using such two-pion mass spectra from  $\tau$  decays measured by OPAL [10], CLEO [7], and ALEPH [11,12], as well as recent pion form factor measurements in  $e^+e^-$  annihilation by CMD-2 [13,14], showed that the discrepancy can be as high as 10% above the  $\rho$  meson [15,16]. This discrepancy remains after recent measurements of the two-pion cross section in  $e^+e^-$  annihilation at KLOE [17,18] and SND [19,20]. This effect is not accounted for by isospin breaking [21–24], but the accuracy of its calculation may be overestimated [25,26].

This problem seems to be solved after a recent analysis in [27] which showed that after correcting the  $\tau$  data for the missing  $\rho - \gamma$  mixing contribution, besides the other known isospin symmetry violating corrections, the  $\pi\pi I=1$  part of the hadronic vacuum polarization contribution to the muon  $g - 2$  is fully compatible between  $\tau$  based and  $e^+e^-$  based evaluations including more recent BaBar [28] and KLOE [29] data. Further proof of the consistency of the data on  $\tau$  decays to two pions and  $e^+e^-$  annihilation is given by the global fit of the whole set of the  $\rho$ ,  $\omega$ , and  $\phi$  decays, taking into account mixing effects in the hidden local symmetry model [30].

WEIGHTED AVERAGE  
769.0 ± 0.9 (Error scaled by 1.4)

- Using the GOUNARIS 68 parametrization with the complex phase of the  $\rho-\omega$  interference and leaving the masses and widths of the  $\rho(1450)$ ,  $\rho(1700)$ , and  $\rho(2150)$  resonances as free parameters of the fit.
- A combined fit of AKHMETSHIN 07, AULCHENKO 06, and AULCHENKO 05.
- Supersedes ACHASOV 05A.
- A fit of the SND data from 400 to 1000 MeV using parameters of the  $\rho(1450)$  and  $\rho(1700)$  from a fit of the data of BARKOV 85, BISELLO 89 and ANDERSON 00A.
- Using the GOUNARIS 68 parametrization with the complex phase of the  $\rho-\omega$  interference.
- Update of A KHMETSHIN 02.
- Assuming  $m_{\rho^+} = m_{\rho^-}, \Gamma_{\rho^+} = \Gamma_{\rho^-}$ .
- From the GOUNARIS 68 parametrization of the pion form factor.
- Assuming  $m_{\rho^+} = m_{\rho^-} = m_{\rho^0}, \Gamma_{\rho^+} = \Gamma_{\rho^-} = \Gamma_{\rho^0}$ .
- Without limitations on masses and widths.
- Assuming  $m_{\rho^+} = m_{\rho^0}, g_{\rho^+ \pi \pi} = g_{\rho^0 \pi \pi}$ .
- Using the data of BARKOV 85 in the hidden local symmetry model.
- From the fit to  $e^+ e^- \rightarrow \pi^+ \pi^-$  data from the compilations of HEYN 81 and BARKOV 85, including the GOUNARIS 68 parametrization of the pion form factor.
- A fit of BARKOV 85 data assuming the direct  $\omega \pi \pi$  coupling.

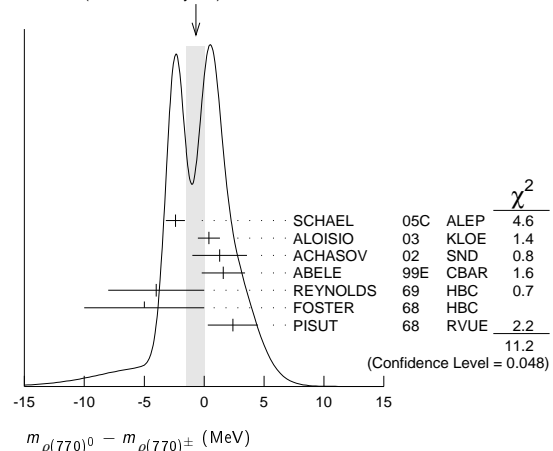

- Applying the S-matrix formalism to the BARKOV 85 data.
- Includes BARKOV 85 data. Model-dependent width definition.
- $|F_\pi(0)|^2$  fixed to 1.
- From the GOUNARIS 68 parametrization of the pion form factor.
- The error combines statistical and systematic uncertainties. Supersedes BARATE 97M.
- $\rho(1700)$  mass and width fixed at 1700 MeV and 235 MeV respectively.
- From the GOUNARIS 68 parametrization of the pion form factor. The second error is a model error taking into account different parametrizations of the pion form factor.
- Using the data of BARATE 97M and the effective chiral Lagrangian.
- From a fit of the model-independent parameterization of the pion form factor to the data of BARATE 97M.
- Assuming the equality of  $\rho^+$  and  $\rho^-$  masses and widths.
- Mass errors enlarged by us to  $\Gamma/\sqrt{N}$ ; see the note with the  $K^*(892)$  mass.
- Phase shift analysis. Systematic errors added corresponding to spread of different fits.
- From fit of 3-parameter relativistic P-wave Breit-Wigner to total mass distribution. Includes BATON 68, MILLER 67B, ALFF-STEINBERGER 66, HAGOPIAN 66, HAGOPIAN 66B, JACOBS 66B, JAMES 66, WEST 66, BLIEDEN 65 and CARMONY 64.
- Using the KUHN 90 parametrization of the pion form factor, neglecting  $\rho-\omega$  interference.
- From the parametrization according to SOEDING 66.
- From the parametrization according to ROSS 66.
- HEYN 81 includes all spacelike and timelike  $F_\pi$  values until 1978.
- From pole extrapolation.
- From phase shift analysis of GRAYER 74 data.
- Includes MALAMUD 69, ARMENISE 68, BACON 67, HUWE 67, MILLER 67B, ALFF-STEINBERGER 66, HAGOPIAN 66, HAGOPIAN 66B, JACOBS 66B, JAMES 66, WEST 66, GOLDBABER 64, ABOLINS 63.
- Breit-Wigner mass from a phase-shift analysis of HYAMS 73 and PROTOPODESCU 73 data.
- Using relativistic Breit-Wigner and taking into account  $\rho-\omega$  interference.
- Systematic errors not evaluated.
- Systematic effects not studied.
- From fit of 3-parameter relativistic Breit-Wigner to helicity-zero part of P-wave intensity. CHABAUD 83 includes data of GRAYER 74.

## $\rho(770)$

### $\rho(770)$ RANGE PARAMETER

The range parameter  $R$  enters an energy-dependent correction to the width, of the form  $(1 + q_r^2 R^2) / (1 + q^2 R^2)$ , where  $q$  is the momentum of one of the pions in the  $\pi\pi$  rest system. At resonance,  $q = q_r$ .

45 Using the GOUNARIS 68 parametrization with the complex phase of the  $\rho-\omega$  interference and leaving the masses and widths of the  $\rho(1450)$ ,  $\rho(1700)$ , and  $\rho(2150)$  resonances as free parameters of the fit.

46 A combined fit of AKHMETSHIN 07, AULCHENKO 06, and AULCHENKO 05.

47 Supersedes ACHASOV 05A.

48 A fit of the SND data from 400 to 1000 MeV using parameters of the  $\rho(1450)$  and  $\rho(1700)$  from a fit of the data of BARKOV 85, BISELLO 89 and ANDERSON 00A.

49 Using the GOUNARIS 68 parametrization with the complex phase of the  $\rho-\omega$  interference.

50 From a fit in the energy range 0.61 to 0.96 GeV. Update of AKHMETSHIN 02.

51 Assuming  $m_{\rho^+} = m_{\rho^-}$ ,  $\Gamma_{\rho^+} = \Gamma_{\rho^-}$ .

52 From the GOUNARIS 68 parametrization of the pion form factor.

53 Assuming  $m_{\rho^+} = m_{\rho^-} = m_{\rho^0}$ ,  $\Gamma_{\rho^+} = \Gamma_{\rho^-} = \Gamma_{\rho^0}$ .

54 Without limitations on masses and widths.

55 Assuming  $m_{\rho^0} = m_{\rho^\pm}$ ,  $g_{\rho^0 \pi \pi} = g_{\rho^\pm \pi \pi}$ .

56 Using the data of BARKOV 85 in the hidden local symmetry model.

57 From the fit to  $e^+e^- \rightarrow \pi^+\pi^-$  data from the compilations of HEYN 81 and BARKOV 85, including the GOUNARIS 68 parametrization of the pion form factor.

58 A fit of BARKOV 85 data assuming the direct  $\omega \pi \pi$  coupling.

59 Applying the S-matrix formalism to the BARKOV 85 data.

60 Includes BARKOV 85 data. Model-dependent width definition.

61  $|F_\pi(0)|^2$  fixed to 1.

62 From the GOUNARIS 68 parametrization of the pion form factor.

63 The error combines statistical and systematic uncertainties. Supersedes BARATE 97M.

64  $\rho(1700)$  mass and width fixed at 1700 MeV and 235 MeV respectively.

65 From the GOUNARIS 68 parametrization of the pion form factor. The second error is a model error taking into account different parametrizations of the pion form factor.

66 Using the data of BARATE 97M and the effective chiral Lagrangian.

67 Assuming the equality of  $\rho^+$  and  $\rho^-$  masses and widths.

68 Width errors enlarged by us to  $4\Gamma/\sqrt{N}$ ; see the note with the  $K^*(892)$  mass.

69 Phase shift analysis. Systematic errors added corresponding to spread of different fits.

70 From fit of 3-parameter relativistic  $P$ -wave Breit-Wigner to total mass distribution. Includes BATON 68, MILLER 67B, ALFF-STEINBERGER 66, HAGOPIAN 66, HAGOPIAN 66B, JACOBS 66B, JAMES 66, WEST 66, BLIEDEN 65 and CARMONY 64.

71 Using the KUHN 90 parametrization of the pion form factor, neglecting  $\rho-\omega$  interference.

See key on page 547

### $\rho(770)$ DECAY MODES

Mode	Fraction ( $\Gamma_i/\Gamma$ )	Scale factor/ Confidence level
$\Gamma_1 \pi\pi$	~ 100	%

### $\rho(770)^\pm$ decays

$\Gamma_2 \pi^\pm \pi^0$	~ 100	%
$\Gamma_3 \pi^\pm \gamma$	( 4.5 ± 0.5 )	$\times 10^{-4}$ S=2.2
$\Gamma_4 \pi^\pm \eta$	< 6	$\times 10^{-3}$ CL=84%
$\Gamma_5 \pi^\pm \pi^+ \pi^- \pi^0$	< 2.0	$\times 10^{-3}$ CL=84%

### $\rho(770)^0$ decays

$\Gamma_6 \pi^+ \pi^-$	~ 100	%
$\Gamma_7 \pi^+ \pi^- \gamma$	( 9.9 ± 1.6 )	$\times 10^{-3}$
$\Gamma_8 \pi^0 \gamma$	( 6.0 ± 0.8 )	$\times 10^{-4}$
$\Gamma_9 \eta \gamma$	( 3.00 ± 0.20 )	$\times 10^{-4}$
$\Gamma_{10} \pi^0 \pi^0 \gamma$	( 4.5 ± 0.8 )	$\times 10^{-5}$
$\Gamma_{11} \mu^+ \mu^-$	[a] ( 4.55 ± 0.28 )	$\times 10^{-5}$
$\Gamma_{12} e^+ e^-$	[a] ( 4.72 ± 0.05 )	$\times 10^{-5}$
$\Gamma_{13} \pi^+ \pi^- \pi^0$	( 1.01 ± 0.54 ± 0.36 )	$\times 10^{-4}$
$\Gamma_{14} \pi^+ \pi^- \pi^+ \pi^-$	( 1.8 ± 0.9 )	$\times 10^{-5}$
$\Gamma_{15} \pi^+ \pi^- \pi^0 \pi^0$	( 1.6 ± 0.8 )	$\times 10^{-5}$
$\Gamma_{16} \pi^0 e^+ e^-$	< 1.2	$\times 10^{-5}$ CL=90%
$\Gamma_{17} \eta e^+ e^-$		

[a] The  $\omega\rho$  interference is then due to  $\omega\rho$  mixing only, and is expected to be small. If  $e\mu$  universality holds,  $\Gamma(\rho^0 \rightarrow \mu^+ \mu^-) = \Gamma(\rho^0 \rightarrow e^+ e^-) \times 0.99785$ .

### CONSTRAINED FIT INFORMATION

An overall fit to the total width and a partial width uses 10 measurements and one constraint to determine 3 parameters. The overall fit has a  $\chi^2 = 10.7$  for 8 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$ , in percent, from the fit to parameters  $p_i$ , including the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

Mode	Rate (MeV)	Scale factor
$\Gamma_2 \pi^\pm \pi^0$	150.2 ± 2.4	
$\Gamma_3 \pi^\pm \gamma$	0.068 ± 0.007	2.3

### CONSTRAINED FIT INFORMATION

An overall fit to the total width, a partial width, and 7 branching ratios uses 21 measurements and one constraint to determine 9 parameters. The overall fit has a  $\chi^2 = 6.0$  for 13 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$ , in percent, from the fit to parameters  $p_i$ , including the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

- 105 Possibly large  $\rho$ - $\omega$  interference leads us to increase the minus error.
- 106 Result contains 11 ± 11% correction using SU(3) for central value. The error on the correction takes account of possible  $\rho$ - $\omega$  interference and the upper limit agrees with the upper limit of  $\omega \rightarrow \mu^+\mu^-$  from this experiment.
- 107 HYAMS 67's mass resolution is 20 MeV. The  $\omega$  region was excluded.
- 108 The  $\rho$  contribution is not taken into account.
- 109 ACHASOV 07B reports  $[\Gamma(\rho(770) \rightarrow \eta\gamma)/\Gamma_{\text{total}}] \times [\text{B}(\rho(770) \rightarrow e^+e^-)] = (1.32 \pm 0.14 \pm 0.08) \times 10^{-8}$  which we divide by our best value  $\text{B}(\rho(770) \rightarrow e^+e^-) = (4.72 \pm 0.05) \times 10^{-5}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value. Supersedes ACHASOV 00D and ACHASOV 06A.
- 110 Solution corresponding to constructive  $\omega$ - $\rho$  interference.
- 111 Using  $\text{B}(\rho \rightarrow e^+e^-) = (4.67 \pm 0.09) \times 10^{-5}$  and  $\text{B}(\eta \rightarrow \gamma\gamma) = 39.43 \pm 0.26\%$ .
- 112 Not independent of the corresponding  $\Gamma(e^+e^-) \times \Gamma(\eta\gamma)/\Gamma_{\text{total}}^2$ .
- 113 The combined fit from 600 to 1380 MeV taking into account  $\rho(770)$ ,  $\omega(782)$ ,  $\phi(1020)$ , and  $\rho(1450)$  (mass and width fixed at 1450 MeV and 310 MeV respectively).
- 114 Using  $\text{B}(\rho \rightarrow e^+e^-) = (4.75 \pm 0.10) \times 10^{-5}$  from AKHMETSHIN 02 and  $\text{B}(\eta \rightarrow 3\pi^0) = (32.24 \pm 0.29) \times 10^{-2}$ .
- 115 Reanalysis of DRUZHININ 84, DOLINSKY 89, and DOLINSKY 91 taking into account a triangle anomaly contribution. Constructive  $\rho$ - $\omega$  interference solution.
- 116 Statistical significance is less than 3 $\sigma$ .
- 117 Model dependent, assumes  $l = 1, 2, \text{ or } 3$  for the 3 $\pi$  system.
- 118 Assuming no interference between the  $\rho$  and  $\omega$  contributions.
- 119 Bremsstrahlung from a decay pion and for photon energy above 50 MeV.
- 120 Superseded by DOLINSKY 91.
- 121 Structure radiation due to quark rearrangement in the decay.
- 122 Using  $\text{B}(\rho \rightarrow e^+e^-) = (4.67 \pm 0.09) \times 10^{-5}$ .
- 123 Not independent of the corresponding  $\Gamma(e^+e^-) \times \Gamma(\pi^0\gamma)/\Gamma_{\text{total}}^2$ .
- 124 Using  $\text{B}(\rho \rightarrow e^+e^-) = (4.54 \pm 0.10) \times 10^{-5}$ .
- 125 Reanalysis of DRUZHININ 84, DOLINSKY 89, and DOLINSKY 91 taking into account a triangle anomaly contribution.
- 126 This branching ratio includes the conventional VMD mechanism  $\rho \rightarrow \omega\pi^0$ ,  $\omega \rightarrow \pi^0\gamma$ , and the new decay mode  $\rho \rightarrow f_0(500)\gamma$ ,  $f_0(500) \rightarrow \pi^0\pi^0$  with a branching ratio  $(2.0_{-0.9}^{+1.1} \pm 0.3) \times 10^{-5}$  differing from zero by 2.0 standard deviations.
- 127 This branching ratio includes the conventional VMD mechanism  $\rho \rightarrow \omega\pi^0$ ,  $\omega \rightarrow \pi^0\gamma$  and the new decay mode  $\rho \rightarrow f_0(500)\gamma$ ,  $f_0(500) \rightarrow \pi^0\pi^0$  with a branching ratio  $(1.9_{-0.9}^{+0.9} \pm 0.4) \times 10^{-5}$  differing from zero by 2.4 standard deviations. Supersedes ACHASOV 00G.
- 128 Superseded by ACHASOV 02F.

$\Gamma_{19}$ $3\pi^0$	C	< 2.3 × 10 <sup>-4</sup>	CL=90%

### CONSTRAINED FIT INFORMATION

An overall fit to 15 branching ratios uses 51 measurements and one constraint to determine 10 parameters. The overall fit has a  $\chi^2 = 51.8$  for 42 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$ , in percent, from the fit to the branching fractions,  $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

$x_2$	22

PARAMETER  $\Lambda$  IN  $\omega \rightarrow \pi^0 \mu^+ \mu^-$  DECAY

In the pole approximation the electromagnetic transition form factor for a resonance of mass  $M$  is given by the expression:

$$|F|^2 = (1 - M^2/\Lambda^2)^{-2},$$

where for the parameter  $\Lambda$  vector dominance predicts  $\Lambda = M_p \approx 0.770$  GeV. The ARNALDI 09 measurement is in obvious conflict with this expectation. Note that for  $\eta \rightarrow \mu^+ \mu^- \gamma$  decay ARNALDI 09 and DZHELYADIN 80 obtain the value of  $\Lambda$  consistent with vector dominance.

## CONSTRAINED FIT INFORMATION

An overall fit to the total width, a partial width, 2 combinations of partial widths obtained from integrated cross section, and 15 branching ratios uses 43 measurements and one constraint to determine 9 parameters. The overall fit has a  $\chi^2 = 48.0$  for 35 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients  $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$ , in percent, from the fit to parameters  $p_i$ , including the branching fractions,  $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$ . The fit constrains the  $x_i$  whose labels appear in this array to sum to one.

 $\eta'(958) \rightarrow \eta\pi\pi$  DECAY PARAMETERS

$$|\text{MATRIX ELEMENT}|^2 = |1 + \alpha Y|^2 + CX + DX^2$$

X and Y are Dalitz variables;  $\alpha$  is complex and C, and D are real-valued. Parameters C and D are not necessarily equal to c and d, respectively, in the generalized parameterization following this one. May be different for  $\eta'(958) \rightarrow \eta\pi^+\pi^-$  and  $\eta'(958) \rightarrow \eta\pi^0\pi^0$  decays. Because of different initial assumptions and strong correlations of the parameters we do not average the parameters in the section below.

- 1 Quoted number refers to real part of pole position.
- 2 Analytic continuation using Roy equations. Uses the  $K_{e4}$  data of BATLEY 10c and the  $\pi N \rightarrow \pi\pi N$  data of HYAMS 73, GRAYER 74, and PROTOPODESCU 73.
- 3 Analytic continuation using GKPY equations. Uses the  $K_{e4}$  data of BATLEY 10c and the  $\pi N \rightarrow \pi\pi N$  data of HYAMS 73, GRAYER 74, and PROTOPODESCU 73.
- 4 Pole position. Used Roy equations.
- 5 Average of the analyses of three data sets in the K-matrix model. Uses the data of BATLEY 08a, HYAMS 73, and GRAYER 74, partially of COHEN 80 or ETKIN 82b.
- 6 On sheet II in a 2-pole solution. The other pole is found on sheet III at (850-100i) MeV
- 7 Using a relativistic Breit-Wigner function and taking into account the finite  $D_S$  mass.
- 8 Breit-Wigner mass. Using finite width corrections according to FLATTE 76 and ACHASOV 05, and the ratio  $g_{f_0} K K / g_{f_0} \pi\pi = 0$ .
- 9 In the kaon-loop fit.
- 10 In the no-structure fit.
- 11 Systematic errors not estimated.
- 12 FLATTE 76 parameterization.  $g_{f_0\pi\pi} = 329 \pm 96$  MeV/c<sup>2</sup> assuming  $g_{f_0} K\bar{K} / g_{f_0} \pi\pi = 2$ .
- 13 Breit-Wigner mass. Using finite width corrections according to FLATTE 76 and ACHASOV 05, and the ratio  $g_{f_0} K K / g_{f_0} \pi\pi = 4.21 \pm 0.25 \pm 0.21$  from ABLIKIM 05.
- 14 In the kaon-loop fit following formalism of ACHASOV 89.
- 15 In the no-structure fit assuming a direct coupling of  $\phi$  to  $f_0\gamma$ .
- 16 FLATTE 76 parameterization. Supersedes GARMASH 05.
- 17 FLATTE 76 parameterization.  $g_{f_0} K\bar{K} / g_{f_0} \pi\pi = 4.21 \pm 0.25 \pm 0.21$ .
- 18 K-matrix pole from combined analysis of  $\pi^-p \rightarrow \pi^0\pi^0 n$ ,  $\pi^-p \rightarrow K\bar{K}n$ ,  $\pi^+\pi^- \rightarrow \pi^+\pi^-$ ,  $\bar{p}p \rightarrow \pi^0\pi^0\pi^0, \pi^0\eta\eta, \pi^0\pi^0\eta, \pi^+\pi^-\pi^0, K^+K^-\pi^0, K_S^0 K_S^0 \pi^0, K^+K_S^0 \pi^0, K^+K_S^0 \pi^-,$  at rest,  $\bar{p}n \rightarrow \pi^-\pi^-\pi^+, K_S^0 K^- \pi^0, K_S^0 K_S^0 \pi^-$  at rest.
- 19 From the negative interference with the  $f_0(500)$  meson of AITALA 01b using the ACHASOV 89 parameterization for the  $f_0(980)$ , a Breit-Wigner for the  $f_0(500)$ , and ACHASOV 01f for the  $\rho\pi$  contribution.
- 20 Coupled-channel Breit-Wigner, couplings  $g_{\pi\pi} = 0.09 \pm 0.01 \pm 0.01, g_K = 0.02 \pm 0.04 \pm 0.03$ .
- 21 Supersedes ACHASOV 98i. Using the model of ACHASOV 89.
- 22 Supersedes ACHASOV 98i.
- 23 In the "narrow resonance" approximation.
- 24 Assuming  $\Gamma(f_0) = 40$  MeV.
- 25 From a narrow pole fit taking into account  $f_0(980)$  and  $f_0(1200)$  intermediate mechanisms.
- 26 From the combined fit of the photon spectra in the reactions  $e^+e^- \rightarrow \pi^+\pi^-\gamma, \pi^0\pi^0\gamma$ .
- 27 Supersedes BARBERIS 99 and BARBERIS 99b
- 28 T-matrix pole.
- 29 From invariant mass fit.
- 30 On sheet II in a 2 pole solution. The other pole is found on sheet III at (1039-93i) MeV.
- 31 On sheet II in a 2 pole solution. The other pole is found on sheet III at (963-29i) MeV.
- 32 Reanalysis of data from HYAMS 73, GRAYER 74, SRINIVASAN 75, and ROSSELET 77 using the interfering amplitude method.
- 33 At high  $|t|$ .

- 34 At low  $|t|$ .
- 35 On sheet II in a 4-pole solution, the other poles are found on sheet III at (953-55i) MeV and on sheet IV at (938-35i) MeV.
- 36 Combined fit of ALDE 95b, ANISOVICH 94, A MSLE 94d.
- 37 On sheet II in a 2 pole solution. The other pole is found on sheet III at (996-103i) MeV.
- 38 From sheet II pole position.
- 39 On sheet II in a 2 pole solution. The other pole is found on sheet III at (797-185i) MeV and can be interpreted as a shadow pole.
- 40 On sheet II in a 2 pole solution. The other pole is found on sheet III at (978-28i) MeV.
- 41 From coupled channel analysis.
- 42 Coupled channel analysis with finite width corrections.
- 43 Included in AGUILAR-BENITEZ 78 fit.

 $f_0(980)$  WIDTH

Width determination very model dependent. Peak width in  $\pi\pi$  is about 50 MeV, but decay width can be much larger.

<sup>1</sup> Analytic continuation using Roy equations. Uses the  $K_{e4}$  data of BATLEY 10c and the  $\pi N \rightarrow \pi\pi N$  data of HYAMS 73, GRAYER 74, and PROTOPODESCU 73.

<sup>2</sup> Quoted number refers to twice imaginary part of pole position.

<sup>3</sup> Analytic continuation using GKP equations. Uses the  $K_{e4}$  data of BATLEY 10c and the  $\pi N \rightarrow \pi\pi N$  data of HYAMS 73, GRAYER 74, and PROTOPODESCU 73.

<sup>4</sup> Pole position. Used Roy equations.

<sup>5</sup> Average of the analyses of three data sets in the K-matrix model. Uses the data of BATLEY 08a, HYAMS 73, and GRAYER 74, partially of COHEN 80 or ETKIN 82b.

<sup>6</sup> On sheet II in a 2-pole solution. The other pole is found on sheet III at  $(850-100i)$  MeV

<sup>7</sup> Using a relativistic Breit-Wigner function and taking into account the finite  $D_S$  mass.

<sup>8</sup> Breit-Wigner  $\pi\pi$  width. Using finite width corrections according to FLATTE 76 and ACHASOV 05, and the ratio  $g_{f_0}^2 K K / g_{f_0}^2 \pi\pi = 0$ .

<sup>9</sup> Systematic errors not estimated.

<sup>10</sup> Breit-Wigner  $\pi\pi$  width. Using finite width corrections according to FLATTE 76 and ACHASOV 05, and the ratio  $g_{f_0}^2 K K / g_{f_0}^2 \pi\pi = 4.21 \pm 0.25 \pm 0.21$  from ABLIKIM 05.

<sup>11</sup> Breit-Wigner, solution 1, PWA ambiguous.

<sup>12</sup> K-matrix pole from combined analysis of  $\pi^-p \rightarrow \pi^0\pi^0n, \pi^-p \rightarrow K\bar{K}n, \pi^+\pi^- \rightarrow \pi^+\pi^-, \bar{p}p \rightarrow \pi^0\pi^0, \pi^0\eta\eta, \pi^0\pi^0\eta, \pi^+\pi^-\pi^0, K^+K^-\pi^0, K_S^0 K_S^0 \pi^0, K^+K_S^0 \pi^-$  at rest,  $\bar{p}n \rightarrow \pi^-\pi^-\pi^+, K_S^0 K^-\pi^0, K_S^0 K_S^0 \pi^-$  at rest.

<sup>13</sup> Using the data of AKHMETSHIN 99c, ACHASOV 00h, and ALOISIO 02d.

<sup>14</sup> Breit-Wigner width.

<sup>15</sup> Supersedes ACHASOV 98i. Using the model of ACHASOV 89.

<sup>16</sup> Supersedes ACHASOV 98i.

<sup>17</sup> In the "narrow resonance" approximation.

<sup>18</sup> From the combined fit of the photon spectra in the reactions  $e^+e^- \rightarrow \pi^+\pi^-\gamma, \pi^0\pi^0\gamma$ .

<sup>19</sup> Supersedes BARBERIS 99 and BARBERIS 99b

<sup>20</sup> T-matrix pole.

<sup>21</sup> On sheet II in a 2 pole solution. The other pole is found on sheet III at  $(1039-93i)$  MeV.

<sup>22</sup> From invariant mass fit.

<sup>23</sup> On sheet II in a 2 pole solution. The other pole is found on sheet III at  $(963-29i)$  MeV.

<sup>24</sup> Reanalysis of data from HYAMS 73, GRAYER 74, SRINIVASAN 75, and ROSSETTE 77 using the interfering amplitude method.

<sup>25</sup> At high  $|t|$ .

<sup>26</sup> At low  $|t|$ .

<sup>27</sup> On sheet II in a 4-pole solution, the other poles are found on sheet III at  $(953-55i)$  MeV and on sheet IV at  $(938-35i)$  MeV.

<sup>28</sup> Combined fit of ALDE 95b, ANISOVICH 94,

<sup>29</sup> On sheet II in a 2 pole solution. The other pole is found on sheet III at  $(996-103i)$  MeV.

<sup>30</sup> From sheet II pole position.

<sup>31</sup> On sheet II in a 2 pole solution. The other pole is found on sheet III at  $(797-185i)$  MeV and can be interpreted as a shadow pole.

<sup>32</sup> On sheet II in a 2 pole solution. The other pole is found on sheet III at  $(978-28i)$  MeV.

<sup>33</sup> From coupled channel analysis.

<sup>34</sup> Coupled channel analysis with finite width corrections.

<sup>35</sup> From coupled channel fit to the HYAMS 73 and PROTOPODESCU 73 data. With a simultaneous fit to the  $\pi\pi$  phase-shifts, inelasticity and to the  $K_S^0 K_S^0$  invariant mass.

<sup>36</sup> Included in AGUILAR-BENITEZ 78 fit.

<sup>1</sup> Recalculated by us using  $\Gamma(K^+K^-) / \Gamma(\pi^+\pi^-) = 0.69 \pm 0.32$  from AUBERT 06o and isospin relations.

<sup>2</sup> Using data from ABLIKIM 04g.

<sup>3</sup> From a combined K-matrix analysis of Crystal Barrel ( $0. p\bar{p} \rightarrow \pi^0\pi^0\pi^0, \pi^0\eta\eta, \pi^0\pi^0\eta$ ), GAMS ( $\pi p \rightarrow \pi^0\pi^0n, \eta\eta n, \eta\eta\eta$ ), and BNL ( $\pi p \rightarrow K\bar{K}n$ ) data.

<sup>4</sup> Measure  $\pi\pi$  elasticity assuming two resonances coupled to the  $\pi\pi$  and  $K\bar{K}$  channels only.

<b>1.17 ± 0.52 ± 0.64</b>	3285	9 AKHMETSHIN 00E	CMD2	$e^+e^- \rightarrow \pi^+\pi^-\pi^+\pi^-$

<sup>1</sup> From the combined fit assuming that the total  $\phi(1020)$  production cross section is saturated by those of  $K^+K^-$ ,  $K_S^0K_L^0$ ,  $\pi^+\pi^-\pi^0$ , and  $\eta\gamma$  decays modes and using ACHASOV 00b for the  $\eta\gamma$  decay mode.

<sup>2</sup> Update of AKHMETSHIN 99d

<sup>3</sup> Recalculated by us from the cross section in the peak.

<sup>4</sup> From a combined fit of  $\sigma(e^+e^- \rightarrow \eta\gamma)$  with  $\eta \rightarrow 3\pi^0$  and  $\eta \rightarrow \pi^+\pi^-\pi^0$ , and fixing  $B(\eta \rightarrow 3\pi^0) / B(\eta \rightarrow \pi^+\pi^-\pi^0) = 1.44 \pm 0.04$ . Recalculated by us from the cross section at the peak. Supersedes ACHASOV 00d and ACHASOV 06a.

<sup>5</sup> From the  $\eta \rightarrow 2\gamma$  decay and using  $B(\eta \rightarrow \gamma\gamma) = 39.43 \pm 0.26\%$ .

<sup>6</sup> From the  $\eta \rightarrow 3\pi^0$  decay and using  $B(\eta \rightarrow 3\pi^0) = (32.24 \pm 0.29) \times 10^{-2}$ .

<sup>7</sup> The combined fit from 600 to 1380 MeV taking into account  $\rho(770)$ ,  $\omega(782)$ ,  $\phi(1020)$ , and  $\rho(1450)$  (mass and width fixed at 1450 MeV and 310 MeV respectively).

<sup>8</sup> From the  $\eta \rightarrow 2\gamma$  decay and using  $B(\eta \rightarrow 2\gamma) = (39.21 \pm 0.34) \times 10^{-2}$ .

<sup>9</sup> Recalculated by the authors from the cross section in the peak.

<sup>10</sup> From the  $\eta \rightarrow \pi^+\pi^-\pi^0$  decay and using  $B(\eta \rightarrow \pi^+\pi^-\pi^0) = (23.1 \pm 0.5) \times 10^{-2}$ .

<sup>11</sup> A simultaneous fit of  $e^+e^- \rightarrow \pi^+\pi^-$ ,  $\pi^+\pi^-\pi^0$ ,  $\pi^0\gamma$ ,  $\eta\gamma$  data.

<sup>12</sup> From the  $\pi^0 \rightarrow 2\gamma$  decay and using  $B(\pi^0 \rightarrow 2\gamma) = (98.798 \pm 0.032) \times 10^{-2}$ .

<sup>13</sup> A simultaneous fit to  $e^+e^- \rightarrow \pi^+\pi^-$ ,  $\pi^+\pi^-\pi^0$ ,  $\pi^0\gamma$ ,  $\eta\gamma$ ,  $K\bar{K}$ , and  $\tau^- \rightarrow \pi^-\pi^0\nu_\tau$  data.

<sup>14</sup> Recalculated by the authors from the cross section at the peak.

<sup>15</sup> AMBROSINO 08g reports  $[\Gamma(\phi(1020) \rightarrow \omega\pi^0)/\Gamma_{\text{total}} \times \Gamma(\phi(1020) \rightarrow e^+e^-)/\Gamma_{\text{total}}] \times [B(\omega(782) \rightarrow \pi^+\pi^-\pi^0)] = (1.22 \pm 0.13 \pm 0.08) \times 10^{-8}$  which we divide by our best value  $B(\omega(782) \rightarrow \pi^+\pi^-\pi^0) = (89.2 \pm 0.7) \times 10^{-2}$ . Our first error is their experiment's error and our second error is the systematic error from using our best value.

<sup>16</sup> Calculated by the authors from the cross section at the peak.

 $\phi(1020)$  BRANCHING RATIOS

$$\Gamma(K^+K^-)/\Gamma_{\text{total}} \quad \Gamma_1/\Gamma$$
