OMITTED FROM SUMMARY TABLE

Seen in the amplitude analysis of the $3\pi^0$ system produced in $\overline{p}p \to 4\pi^0$. Possibly seen in the study of the hadronic structure in decay $\tau \to 3\pi\nu_\tau$ (ABREU 98G and ASNER 00). Needs confirmation.

<6	90	[22] AKHMETSHIN	03B	CMD2	$e^+e\to\eta\pi^0\gamma$

[15] Calculated by us from the cross section at the peak.
[16] From the combined fit of ANTONELLI 92, ACHASOV 01E, ACHASOV 02E, and ACHASOV 03D data on the $\pi^+\pi^-\pi^0$ and ANTONELLI 92 on the $\omega\pi^+\pi^-$ final states. Supersedes ACHASOV 99E and ACHASOV 02E.
[17] From a fit to two Breit-Wigner functions and using the data of DOLINSKY 91 and ANTONELLI 92.
[18] From the partial and leptonic width given by the authors.
[19] From the combined fit of the $\rho\pi$ and $\omega\pi\pi$ final states.
[20] From the product of the leptonic width and partial branching ratio given by the authors.
[21] Using the data of AKHMETSHIN 00D and ANTONELLI 92. The $\rho\pi$ dominance for the energy dependence of the $\omega(1420)$ and $\omega(1650)$ width assumed.
[22] $\omega(1650)$ mass and width fixed at 1700 MeV and 250 MeV, respectively.

CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 6 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 1.9$ for 3 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

CONSTRAINED FIT INFORMATION

An overall fit to 5 branching ratios uses 10 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 14.7$ for 7 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$\rho(1700)$ $I^G(J^{PC}) = 1^+(1^{--})$

THE $\rho(1450)$ AND THE $\rho(1700)$

Updated April 2006 by S. Eidelman (Novosibirsk) and J.J Hernandez-Rey (Valencia).

In our 1988 edition, we replaced the $\rho(1600)$ entry with two new ones, the $\rho(1450)$ and the $\rho(1700)$, because there was emerging evidence that the 1600-MeV region actually contains two ρ-like resonances. ERKAL 86 had pointed out this possibility with a theoretical analysis on the consistency of 2π and 4π electromagnetic form factors and the $\pi\pi$ scattering length. DONNACHIE 87, with a full analysis of data on the 2π and 4π final states in e^+e^- annihilation and photoproduction reactions, had also argued that in order to obtain a consistent picture, two resonances were necessary. The existence of $\rho(1450)$ was supported by the analysis of $\eta\rho^0$ mass spectra obtained in photoproduction and e^+e^- annihilation (DONNACHIE 87B), as well as that of $e^+e^- \to \omega\pi$ (DONNACHIE 91).

The analysis of DONNACHIE 87 was further extended by CLEGG 88, 94 to include new data on 4π systems produced in e^+e^- annihilation, and in τ decays (τ decays to 4π and e^+e^- annihilation to 4π can be related by the Conserved Vector Current assumption). These systems were successfully analyzed using interfering contributions from two ρ-like states, and from the tail of the $\rho(770)$ decaying into two-body states. While specific conclusions on $\rho(1450) \to 4\pi$ were obtained, little could be said about the $\rho(1700)$.

Independent evidence for two 1^- states is provided by KILLIAN 80 in 4π electroproduction at $\langle Q^2 \rangle = 1$ (GeV/c)^2, and by FUKUI 88 in a high-statistics sample of the $\eta\pi\pi$ system in $\pi^- p$ charge exchange.

This scenario with two overlapping resonances is supported by other data. BISELLO 89 measured the pion form factor in the interval 1.35–2.4 GeV and observed a deep minimum around 1.6 GeV. The best fit was obtained with the hypothesis of ρ-like resonances at 1420 and 1770 MeV, with widths of about 250 MeV. ANTONELLI 88 found that the $e^+e^- \to \eta\,\pi^+\,\pi^-$ cross section is better fitted with two fully interfering Breit-Wigners, with parameters in fair agreement with those of DONNACHIE 87 and BISELLO 89. These results can be considered as a confirmation of the $\rho(1450)$.

Decisive evidence for the $\pi\pi$ decay mode of both $\rho(1450)$ and $\rho(1700)$ came from recent results in $\overline{p}p$ annihilation at rest (ABELE 97). It was shown that these resonances also possess a $K\overline{K}$ decay mode (ABELE 98, BERTIN 98B, ABELE 99D). High statistics studies of the decays $\tau \to \pi\pi\nu_\tau$ (BARATE 97M, URHEIM 97), and $\tau \to 4\pi\nu_\tau$ (EDWARDS 00A), also require the $\rho(1450)$, but are not sensitive to the $\rho(1700)$, because it is too close to the τ mass. Recently in a very high statistics study of the $\tau \to \pi\pi\nu_\tau$ decay performed at Belle (ABE 05H) both $\rho(1450)$ and $\rho(1700)$ were observed for the first time in τ decays.

The structure of these ρ states is not yet completely clear. BARNES 97 and CLOSE 97C claim that $\rho(1450)$ has a mass consistent with radial $2S$, but its decays show characteristics of hybrids, and suggest that this state may be a $2S$-hybrid mixture. DONNACHIE 99 argues that hybrid states could have a 4π decay mode dominated by the $a_1\pi$. Such behavior has recently been observed by AKHMETSHIN 99E in $e^+e^- \to 4\pi$ in the energy range 1.05–1.38 GeV, and by EDWARDS 00A in $\tau \to 4\pi$ decays. ALEXANDER 01B observed the $\rho(1450) \to \omega\pi$ decay mode in B-meson decays, however, didn't find $\rho(1700) \to \omega\pi^0$. A similar conclusion is made by AKHMETSHIN 03B who studied the process $e^+e^- \to \omega\pi^0$. Various decay modes of the $\rho(1450)$ and $\rho(1700)$ were observed in $\bar{p}n$ and $\bar{p}p$ annihilation (ABELE 01B, BARGIOTTI 03B), but no definite conclusions could be drawn. More data should be collected to clarify the nature of the ρ states, particularly in the energy range above 1.6 GeV.

We also list under the $\rho(1450)$ the $\phi\pi$ state with $J^{PC} = 1^{--}$ or $C(1480)$ observed by BITYUKOV 87. While ACHASOV 96B shows that it may be a threshold effect, CLEGG 88 and LANDSBERG 92 suggest two independent vector states with this decay mode. Note, however, that $C(1480)$ in its $\phi\pi$ decay mode was not confirmed by e^+e^- (DOLINSKY 91, BISELLO 91C) and $\overline{p}p$ (ABELE 97H) experiments.

Several observations on the $\omega\pi$ system in the 1200-MeV region (FRENKIEL 72, COSME 76, BARBER 80C, ASTON 80C, ATKINSON 84C, BRAU 88, AMSLER 93B) may be interpreted in terms of either $J^P = 1^-$ $\rho(770) \to \omega\pi$ production (LAYSSAC 71), or $J^P = 1^+$ $b_1(1235)$ production (BRAU 88, AMSLER 93B). We argue that no special entry for a $\rho(1250)$ is needed. The LASS amplitude analysis (ASTON 91B) showing evidence for $\rho(1270)$ is preliminary and needs confirmation. For completeness, the relevant observations are listed under the $\rho(1450)$.

Evidence for ρ-like mesons decaying into 6π states was first noted by CLEGG 90 in the analysis of 6π mass spectra from e^+e^- annihilation (BISELLO 81, CASTRO 88) and diffractive photoproduction (ATKINSON 85). CLEGG 90 argued that two states at about 2.1 and 1.8 GeV exist: while the former is a candidate for a new resonance ($\rho(2150)$), the latter could be a manifestation of the $\rho(1700)$ distorted by threshold effects. Recently, the E687 Collaboration at Fermilab reported an observation of a narrow dip structure at 1.9 GeV in the $3\pi^+3\pi^-$ diffractive photoproduction (FRABETTI 01). A similar effect of the dip in the cross section of $e^+e^- \to 6\pi$ around 1.9 GeV has been earlier reported by DM2 (CASTRO 88), where 6π included both $3\pi^+3\pi^-$ and $2\pi^+2\pi^-2\pi^0$. Later the dip in the R value (the total cross section of $e^+e^- \to$ hadrons divided by the cross section of $e^+e^- \to \mu^+\mu^-$) was observed by ANTONELLI 96, again around 1.9 GeV. This energy is close to the $N\bar{N}$ threshold which hints to the possible relation between the dip and $N\bar{N}$, e.g., the frequently discussed narrow $N\bar{N}$ resonance or just a threshold effect. Such behaviour is also characteristic of exotic objects like vector $q\bar{q}$ hybrids. Note that AGNELLO 02 failed to find this state in the reaction $\bar{n}p \to 3\pi^+2\pi^-\pi^0$. A reanalysis of the E687 data by FRABETTI 04 shows that a dip may arise due to interference of a narrow object with a broad $\rho(1700)$ independently of the nature of the former.

Recently BaBar studied the processes $e^+e^- \to 3\pi^+3\pi^-$ and $e^+e^- \to 2\pi^+2\pi^-2\pi^0$ using the radiative return and observed a structure around 1.9 GeV in both final states (AUBERT 06D). The data are not well described by a single Breit-Wigner state, and a good fit is achieved while taking into account the interference of such a structure with a Jacob-Slansky amplitude for continuum. The mass of this state obtained by BaBar is consistent with ANTONELLI 96 and FRABETTI 01, but the width is substantially larger. We list these observations under a separate particle $\rho(1900)$, which needs confirmation.

[16] Assuming $\rho^+ f_0(1370)$ decay mode interferes with $a_1(1260)^+\pi$ background. From a two Breit-Wigner fit.
[17] T-matrix pole.
[18] From phase shift analysis of HYAMS 73 data.
[19] Simple relativistic Breit-Wigner fit with constant width.
[20] An additional 40 MeV uncertainty in both the mass and width is present due to the choice of the background shape.
[21] Included in BECKER 79 analysis.
[22] Simple relativistic Breit-Wigner fit with model-dependent width.
[23] One peak fit result.
[24] Parameters roughly estimated, not from a fit.
[25] Skew mass distribution compensated by Ross-Stodolsky factor.
[26] Width errors enlarged by us to $4\Gamma/\sqrt{N}$; see the note with the $K^*(892)$ mass.
[27] Taking into account both $\rho(1450)$ and $\rho(1700)$ contributions. Using the data of ACHASOV 00I on $e^+e^- \to \omega\pi^0$ and of EDWARDS 00A on $\tau^- \to \omega\pi^-\nu_\tau$. $\rho(1450)$ mass and width fixed at 1400 MeV and 500 MeV respectively.
[28] Taking into account the $\rho(1700)$ contribution only. Using the data of ACHASOV 00I on $e^+e^- \to \omega\pi^0$ and of EDWARDS 00A on $\tau^- \to \omega\pi^-\nu_\tau$.
[29] From a fit with two resonances with the JACOB 72 continuum.

[1] This state may be different from $f_0(1710)$, see CLOSE 05.
[2] $J^P = 0^+$.
[3] T-matrix pole.
[4] Supersedes BARBERIS 99 and BARBERIS 99B.
[5] $J^P = 0^+$, supersedes by ARMSTRONG 89D.
[6] No J^{PC} determination.
[7] $J^P = 2^+$.
[8] Breit-Wigner mass.
[9] Systematic errors not estimated.
[10] K-matrix pole, assuming $J^P = 0^+$, from combined analysis of $\pi^- p \to \pi^0\pi^0 n$, $\pi^- p \to K\overline{K}n$, $\pi^+\pi^- \to \pi^+\pi^-$, $\overline{p}p \to \pi^0\pi^0\pi^0$, $\pi^0\eta\eta$, $\pi^0\pi^0\eta$, $\pi^+\pi^-\pi^0$, $K^+K^-\pi^0$, $K^0_S K^0_S\pi^0$, $K^+K^0_S\pi^-$ at rest, $\overline{p}n \to \pi^-\pi^-\pi^+$, $K^0_S K^-\pi^0$, $K^0_S K^0_S\pi^-$ at rest.
[11] Decaying to $f_0(1370)\pi\pi$.
[12] Spin 2 dominant, isospin not determined, could also be I=1.
[13] $J^P = 0^+$.
[14] Not seen by AMSLER 02.
[15] T-matrix pole, assuming $J^P = 0^+$
[16] No J^{PC} determination.
[17] No J^{PC} determination, width not determined.
[18] From a fit to the 0^+ partial wave.
[19] ALDE 92D combines all the GAMS-2000 data.
[20] $J^P = 2^+$, superseded by FRENCH 99.
[21] From an analysis ignoring interference with $f_2'(1525)$.
[22] From an analysis including interference with $f_2'(1525)$.
[23] Superseded by ALDE 92D.
[24] Uses MRK3 data. From a partial-wave analysis of data using a K-matrix formalism with 5 poles, but assuming spin 2. Fit with constrained inelasticity.
[25] $J^P = 2^+$ preferred.
[26] From fit neglecting nearby $f_2'(1525)$. Replaced by BLOOM 83.
[27] Superseded by LONGACRE 86.

$\eta(1760)$

$I^G(J^{PC}) = 0^+(0^{-+})$

OMITTED FROM SUMMARY TABLE

Seen by DM2 in the $\rho\rho$ system (BISELLO 89B). Structure in this region has been reported before in the same system (BALTRUSAITIS 86B) and in the $\omega\omega$ system (BALTRUSAITIS 85C, BISELLO 87). Needs confirmation.

[4] OAKDEN 94 makes an amplitude analysis of LEAR data on $\overline{p}p \to \pi\pi$ using a method based on Barrelet zeros. This is solution A. The amplitude analysis of HASAN 94 includes earlier data as well, and assume that the data can be parametrized in terms of towers of nearly degenerate resonances on the leading Regge trajectory. See also KLOET 96 and MARTIN 97 who make related analyses.
[5] From solution B of amplitude analysis of data on $\overline{p}p \to \pi\pi$.
[6] $I(J^P) = 0(2^+)$ from simultaneous analysis of $p\overline{p} \to \pi^-\pi^+$ and $\pi^0\pi^0$.
[7] $I^G(J^P) = 0^+(2^+)$ from partial-wave amplitude analysis.

FOOTNOTES for Further States

[5] K-matrix pole from combined analysis of $\pi^- p \rightarrow \pi^0\pi^0 n$, $\pi^- p \rightarrow K\overline{K}n$, $\pi^+\pi^- \rightarrow \pi^+\pi^-$, $\overline{p}p \rightarrow \pi^0\pi^0\pi^0$, $\pi^0\eta\eta$, $\pi^0\pi^0\eta$, $\pi^+\pi^-\pi^0$, $K^+K^-\pi^0$, $K_S^0K_S^0\pi^0$, $K^+K_S^0\pi^-$ at rest, $\overline{p}n \rightarrow \pi^-\pi^-\pi^+$, $K_S^0K^-\pi^0$, $K_S^0K_S^0\pi^-$ at rest.

[6] K-matrix pole from combined analysis of $\pi^- p \rightarrow \pi^0\pi^0 n$, $\pi^- p \rightarrow K\overline{K}n$, $\overline{p}p \rightarrow \pi^0\pi^0\pi^0$, $\pi^0\eta\eta$, $\pi^0\pi^0\eta$ at rest.

[7] Our estimate.

[8] Using the observable fractions of 50.0% $\rho\pi$, 56.5% $f_2\pi$, and 11.8% $\rho_3\pi$.

[9] From the combined analysis of ANISOVICH 00J, ANISOVICH 01D, ANISOVICH 01E, and ANISOVICH 02.

[10] From the combined analysis of ANISOVICH 00D, ANISOVICH 01C, and ANISOVICH 02B.

[11] Cannot determine spin to be 3.

[12] BALTAY 77 favors $J^P = ,3^+$.

[13] Corrected for all decay modes.

[14] See SEMENOV 99 and KLOET 96.

[15] ASTON 81B sees no peak, has 850 events in Ajinenko+Barth bins. ARESTOV 80 sees no peak.

[16] Combined fit along with data of ANISOVICH 00J.

[17] Dominant decay into $\rho^0\rho^0\pi^+$. BALTAY 78 finds confirmation in $2\pi^+\pi^-2\pi^0$ events which contain $\rho^+\rho^0\pi^0$ and $2\rho^+\pi^-$.

STRANGE MESONS
($S = \pm 1$, $C = B = 0$)

$K^+ = u\overline{s}$, $K^0 = d\overline{s}$, $\overline{K}^0 = \overline{d}s$, $K^- = \overline{u}s$, similarly for K^*'s

$K^{\pm}$ $I(J^P) = \frac{1}{2}(0^-)$

THE CHARGED KAON MASS

Revised 1994 by T.G. Trippe (LBNL).

The average of the six charged kaon mass measurements which we use in the Particle Listings is

$$m_{K^\pm} = 493.677 \pm 0.013 \text{ MeV (S = 2.4)} , \quad (1)$$

where the error has been increased by the scale factor S. The large scale factor indicates a serious disagreement between different input data. The average before scaling the error is

$$m_{K^\pm} = 493.677 \pm 0.005 \text{ MeV} ,$$
$$\chi^2 = 22.9 \text{ for 5 D.F., Prob. } = 0.04\% , \quad (2)$$

where the high χ^2 and correspondingly low χ^2 probability further quantify the disagreement.

The main disagreement is between the two most recent and precise results,

$$m_{K^\pm} = 493.696 \pm 0.007 \text{ MeV} \quad \text{DENISOV 91}$$
$$m_{K^\pm} = 493.636 \pm 0.011 \text{ MeV (S = 1.5)} \quad \text{GALL 88}$$
$$\text{Average} = 493.679 \pm 0.006 \text{ MeV}$$
$$\chi^2 = 21.2 \text{ for 1 D.F., Prob. } = 0.0004\% , \quad (3)$$

both of which are measurements of x-ray energies from kaonic atoms. Comparing the average in Eq. (3) with the overall average in Eq. (2), it is clear that DENISOV 91 and GALL 88 dominate the overall average, and that their disagreement is responsible for most of the high χ^2.

The GALL 88 measurement was made using four different kaonic atom transitions, K^- Pb ($9 \to 8$), K^- Pb ($11 \to 10$), K^- W ($9 \to 8$), and K^- W ($11 \to 10$). The $m_{K^\pm}$ values they obtain from each of these transitions is shown in the Particle Listings and in Fig. 1. Their K^- Pb ($9 \to 8$) $m_{K^\pm}$is below and somewhat inconsistent with their other three transitions. The average of their four measurements is

$$m_{K^\pm} = 493.636 \pm 0.007 ,$$
$$\chi^2 = 7.0 \text{ for 3 D.F., Prob. } = 7.2\% . \quad (4)$$

This is a low but acceptable χ^2 probability so, to be conservative, GALL 88 scaled up the error on their average by S=1.5 to obtain their published error ±0.011 shown in Eq. (3) above and used in the Particle Listings average.

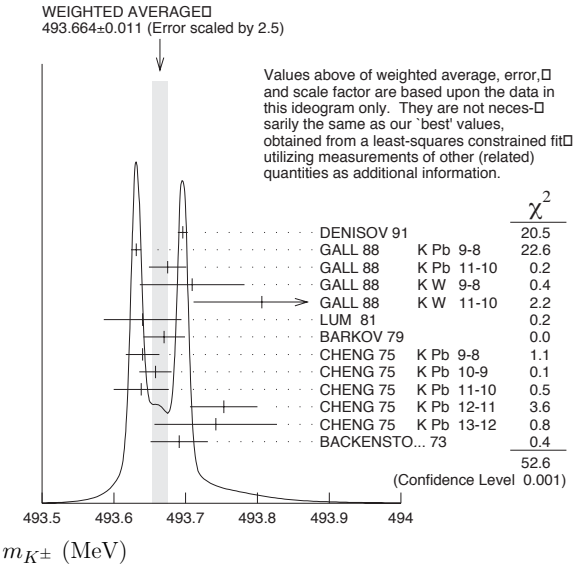

Figure 1: Ideogram of $m_{K^\pm}$ mass measurements. GALL 88 and CHENG 75 measurements are shown separately for each transition they measured.

The ideogram in Fig. 1 shows that the DENISOV 91 measurement and the GALL 88 K^- Pb ($9 \to 8$) measurement yield two well-separated peaks. One might suspect the GALL 88 K^- Pb ($9 \to 8$) measurement since it is responsible both for the internal inconsistency in the GALL 88 measurements and the disagreement with DENISOV 91.

To see if the disagreement could result from a systematic problem with the K^- Pb ($9 \to 8$) transition, we have separated the CHENG 75 data, which also used K^- Pb, into its separate transitions. Figure 1 shows that the CHENG 75 and GALL 88 K^- Pb ($9 \to 8$) values are consistent, suggesting the possibility of a common effect such as contaminant nuclear γ rays near the K^- Pb ($9 \to 8$) transition energy, although the CHENG 75 errors are too large to make a strong conclusion. The average of all 13 measurements has a χ^2 of 52.6 as shown in Fig. 1 and the first line of Table 1, yielding an unacceptable χ^2 probability of 0.00005%. The second line of Table 1 excludes both the GALL 88 and CHENG 75 measurements of the K^- Pb ($9 \to 8$) transition and yields a χ^2 probability of 43%. The third [fourth] line of Table 1 excludes only the GALL 88 K^- Pb ($9 \to 8$) [DENISOV 91] measurement and yields a χ^2 probability of 20% [8.6%]. Table 1 shows that removing both measurements of the K^- Pb ($9 \to 8$) transition produces the most consistent set of data, but that excluding only the GALL 88 K^- Pb ($9 \to 8$) transition or DENISOV 91 also produces acceptable probabilities.

Table 1: $m_{K^{\pm}}$ averages for some combinations of Fig. 1 data.

$m_{K^{\pm}}$ (MeV)	χ^2	D.F.	Prob. (%)	Measurements used
493.664 ± 0.004	52.6	12	0.00005	all 13 measurements
493.690 ± 0.006	10.1	10	43	no K^- Pb(9→8)
493.687 ± 0.006	14.6	11	20	no GALL 88 K^- Pb(9→8)
493.642 ± 0.006	17.8	11	8.6	no DENISOV 91

Yu.M. Ivanov, representing DENISOV 91, has estimated corrections needed for the older experiments because of improved ^{192}Ir and ^{198}Au calibration γ-ray energies. He estimates that CHENG 75 and BACKENSTOSS 73 $m_{K^{\pm}}$ values could be raised by about 15 keV and 22 keV, respectively. With these estimated corrections, Table 1 becomes Table 2. The last line of Table 2 shows that if such corrections are assumed, then GALL 88 K^- Pb (9 → 8) is inconsistent with the rest of the data even when DENISOV 91 is excluded. Yu.M. Ivanov warns that these are rough estimates. Accordingly, we do not use Table 2 to reject the GALL 88 K^- Pb (9 → 8) transition, but we note that a future reanalysis of the CHENG 75 data could be useful because it might provide supporting evidence for such a rejection.

Table 2: $m_{K^{\pm}}$ averages for some combinations of Fig. 1 data after raising CHENG 75 and BACKENSTOSS 73 values by 0.015 and 0.022 MeV respectively.

$m_{K^{\pm}}$ (MeV)	χ^2	D.F.	Prob. (%)	Measurements used
493.666 ± 0.004	53.9	12	0.00003	all 13 measurements
493.693 ± 0.006	9.0	10	53	no K^- Pb(9→8)
493.690 ± 0.006	11.5	11	40	no GALL 88 K^- Pb(9→8)
493.645 ± 0.006	23.0	11	1.8	no DENISOV 91

The GALL 88 measurement uses a Ge semiconductor spectrometer which has a resolution of about 1 keV, so they run the risk of some contaminant nuclear γ rays. Studies of γ rays following stopped π^- and Σ^- absorption in nuclei (unpublished) do not show any evidence for contaminants according to GALL 88 spokesperson, B.L. Roberts. The DENISOV 91 measurement uses a crystal diffraction spectrometer with a resolution of 6.3 eV for radiation at 22.1 keV to measure the 4f-3d transition in K^- ^{12}C. The high resolution and the light nucleus reduce the probability for overlap by contaminant γ rays, compared with the measurement of GALL 88. The DENISOV 91 measurement is supported by their high-precision measurement of the 4d-2p transition energy in π^- ^{12}C, which is good agreement with the calculated energy.

While we suspect that the GALL 88 K^- Pb (9 → 8) measurements could be the problem, we are unable to find clear grounds for rejecting it. Therefore, we retain their measurement in the average and accept the large scale factor until further information can be obtained from new measurements and/or from reanalysis of GALL 88 and CHENG 75 data.

We thank B.L. Roberts (Boston Univ.) and Yu.M. Ivanov (Petersburg Nuclear Physics Inst.) for their extensive help in understanding this problem.

RARE KAON DECAYS

(Revised November 2005 by L. Littenberg, BNL and G. Valencia, Iowa State University)

A. Introduction: There are several useful reviews on rare kaon decays and related topics [1–14]. Activity in rare kaon decays can be divided roughly into four categories:

1. Searches for explicit violations of the Standard Model
2. Measurements of Standard Model parameters
3. Searches for CP violation
4. Studies of strong interactions at low energy.

The paradigm of Category 1 is the lepton flavor violating decay $K_L \to \mu e$. Category 2 includes processes such as $K^+ \to \pi^+ \nu\overline{\nu}$, which is sensitive to $|V_{td}|$. Much of the interest in Category 3 is focused on the decays $K_L \to \pi^0 \ell\overline{\ell}$, where $\ell \equiv e, \mu, \nu$. Category 4 includes reactions like $K^+ \to \pi^+ \ell^+ \ell^-$ which constitute a testing ground for the ideas of chiral perturbation theory. Category 4 also includes $K_L \to \pi^0\gamma\gamma$ and $K_L \to \ell^+\ell^-\gamma$. The former is important in understanding a CP-conserving contribution to $K_L \to \pi^0 \ell^+ \ell^-$, whereas the latter could shed light on long distance contributions to $K_L \to \mu^+\mu^-$.

The interplay between Categories 2-4 can be illustrated in Fig. 1. The modes $K \to \pi\nu\overline{\nu}$ are the cleanest ones theoretically. They can provide accurate determinations of certain CKM parameters (shown in the figure). In combination with alternate determinations of these parameters they also constrain new interactions. The modes $K_L \to \pi^0 e^+ e^-$ and $K_L \to \mu^+\mu^-$ are also sensitive to CKM parameters. However, they suffer from a series of hadronic uncertainties that can be addressed, at least in part, through a systematic study of the additional modes indicated in the figure.

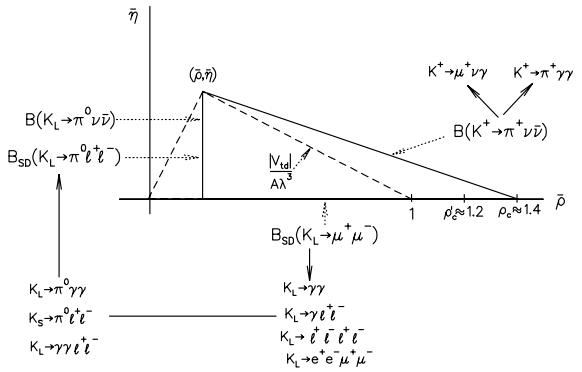

Figure 1: Role of rare kaon decays in determining the unitarity triangle. The solid arrows point to auxiliary modes needed to interpret the main results, or potential backgrounds to them.

B. Explicit violations of the Standard Model: Much activity has focussed on searches for lepton flavor violation (LFV). This is motivated by the fact that many extensions of the minimal Standard Model violate lepton flavor and by the potential to access very high energy scales. For example, the tree-level exchange of a LFV vector boson of mass M_X that couples to left-handed fermions with electroweak strength and without mixing angles yields $\mathrm{B}(K_L \to \mu e) = 4.7 \times 10^{-12}(148\ \mathrm{TeV}/M_X)^4$ [5]. This simple dimensional analysis may be used to read from Table 1 that the reaction $K_L \to \mu e$ is already probing scales of over 100 TeV. Table 1 summarizes the present experimental situation vis a vis LFV. The decays $K_L \to \mu^{\pm} e^{\mp}$ and $K^+ \to \pi^+ e^{\mp} \mu^{\pm}$ (or $K_L \to \pi^0 e^{\mp} \mu^{\pm}$) provide complementary information on potential family number violating interactions since the former is sensitive to parity-odd couplings and the latter is sensitive to parity-even couplings. Limits on certain lepton-number violating kaon decays [15,16] also exist. Related searches in μ and τ processes are discussed in our section "Tests of Conservation Laws".

Table 1: Searches for lepton flavor violation in K decay

Mode	90% CL upper limit	Exp't	Yr./Ref.
$K^+ \to \pi^+ e^- \mu^+$	1.2×10^{-11}	BNL-865	2003/Ref. 17
$K^+ \to \pi^+ e^+ \mu^-$	5.2×10^{-10}	BNL-865	2001/Ref. 15
$K_L \to \mu e$	4.7×10^{-12}	BNL-871	1998/Ref. 18
$K_L \to \pi^0 e\mu$	3.4×10^{-10}	KTeV (prelim.)	2003/Ref. 19

Physics beyond the SM is also pursued through the search for $K^+ \to \pi^+ X^0$, where X^0 is a very light, noninteracting particle (*e.g.* hyperphoton, axion, familon, *etc.*). The 90% CL upper limit on this process is 5.9×10^{-11} [20].

C. Measurements of Standard Model parameters:

Until 1997, searches for $K^+ \to \pi^+ \nu\overline{\nu}$ were motivated by the possibility of observing non-SM physics because the sensitivity attained was far short of the SM prediction for this

decay [21] and long-distance contributions are known to be quite small [2,22,23]. Since then, BNL-787 has observed two candidate events [20,24], and BNL-949 has observed one more, yielding a branching ratio of $(1.47^{+1.30}_{-0.89}) \times 10^{-10}$ [25]. At this level, this reaction becomes interesting from the point of view of constraining SM parameters. A new experiment with a sensitivity goal of $\sim 10^{-12}$/event was proposed [26] at CERN in 2005. In the future this mode may provide grounds for precision tests of the flavor structure of the Standard Model [27]. The branching ratio can be written in terms of the very well-measured K_{e3} rate as [2]:

$$\mathrm{B}(K^+ \to \pi^+ \nu\overline{\nu}) = \frac{\alpha^2 \mathrm{B}(K^+ \to \pi^o e^+ \nu)}{V_{us}^2 2\pi^2 \sin^4\theta_W} \times \sum_{l=e,\mu,\tau} |V_{cs}^* V_{cd} X_{NL}^{\ell} + V_{ts}^* V_{td} X(m_t)|^2 \quad (1)$$

to eliminate the *a priori* unknown hadronic matrix element. Isospin breaking corrections to the ratio of matrix elements reduce this rate by 10% [28]. In Eq. (1) the Inami-Lim function $X(m_t)$ is of order 1 [29], and X_{NL}^{ℓ} is several hundred times smaller. This form exhibits the strong dependence of this branching ratio on $|V_{td}|$. QCD corrections, which mainly affect X_{NL}^{ℓ}, lead to a residual error of $< 5\%$ for the decay amplitude [12,23,30,31]. Evaluating the constants in Eq. (1), one can cast this result in terms of the CKM parameters λ, V_{cb}, $\bar{\rho}$ and $\bar{\eta}$ (see our Section on "The Cabibbo-Kobayashi-Maskawa mixing matrix") [12]

$$\mathrm{B}(K^+ \to \pi^+ \nu\overline{\nu}) \approx 1.6 \times 10^{-5} |V_{cb}|^4 [\sigma \bar{\eta}^2 + (\rho_c - \bar{\rho})^2] \quad (2)$$

where $\rho_c \equiv 1 + (\frac{2}{3} X_{NL}^e + \frac{1}{3} X_{NL}^{\tau})/(|V_{cb}|^2 X(m_t)) \approx 1.4$ and $\sigma \equiv 1/(1 - \frac{1}{2}\lambda^2)^2$. Thus, $\mathrm{B}(K^+ \to \pi^+ \nu\overline{\nu})$ determines an ellipse in the $\bar{\rho}$, $\bar{\eta}$ plane with center $(\rho_c, 0)$ and semi-axes $\approx \frac{1}{|V_{cb}|^2}\sqrt{\frac{\mathrm{B}(K^+ \to \pi^+ \nu\overline{\nu})}{1.6\times10^{-5}}}$ and $\frac{1}{\sigma|V_{cb}|^2}\sqrt{\frac{\mathrm{B}(K^+ \to \pi^+ \nu\overline{\nu})}{1.6\times10^{-5}}}$. Current constraints on the CKM parameters lead to a predicted branching ratio $(8.0 \pm 1.1) \times 10^{-11}$ [31], near the lower end of the BNL-787 measurement.

The decay $K_L \to \mu^+\mu^-$ also has a short distance contribution sensitive to the CKM parameter $\bar{\rho}$, given by [12]:

$$\mathrm{B}_{\mathrm{SD}}(K_L \to \mu^+\mu^-) \approx 2.7 \times 10^{-4} |V_{cb}|^4 (\rho_c' - \bar{\rho})^2 \quad (3)$$

where ρ_c' depends on the charm quark mass and is approximately 1.2. This decay, however, is dominated by a long-distance contribution from a two-photon intermediate state. The absorptive (imaginary) part of the long-distance component is determined by the measured rate for $K_L \to \gamma\gamma$ to be $\mathrm{B}_{\mathrm{abs}}(K_L \to \mu^+\mu^-) = (6.64 \pm 0.07) \times 10^{-9}$; and it almost completely saturates the observed rate $\mathrm{B}(K_L \to \mu^+\mu^-) = (6.87 \pm 0.11) \times 10^{-9}$ [32]. The difference between the observed rate and the absorptive component can be attributed to the (coherent) sum of the short-distance amplitude and the real part of the long-distance amplitude. The latter cannot be derived directly from experiment [33] but can be estimated with certain assumptions [34,35]. The decay $K_L \to e^+e^-$ is completely dominated by long distance physics and is easier to estimate. The result, $B(K_L \to e^+e^-) \sim 9 \times 10^{-12}$ [33,36], is in good agreement with the BNL-871 measurement, $(8.7^{+5.7}_{-4.1}) \times 10^{-12}$ [37].

D. Searches for direct CP violation: The mode $K_L \to \pi^0\nu\overline{\nu}$ is dominantly CP-violating and free of hadronic uncertainties [2,38,39]. In the Standard Model this mode is dominated by an intermediate top-quark state and does not suffer from the small uncertainty associated with the charm-quark intermediate state that affects the mode $K^+ \to \pi^+\nu\overline{\nu}$. The branching ratio is given approximately by Ref. 12:

$$\mathrm{B}(K_L \to \pi^0\nu\overline{\nu}) \approx 7.6 \times 10^{-5} |V_{cb}|^4 \bar{\eta}^2 \ . \quad (4)$$

With current constraints on the CKM parameters this leads to a predicted branching ratio $(3.0 \pm 0.6) \times 10^{-11}$ [40]. The current published experimental upper bound is $\mathrm{B}(K_L \to \pi^0\nu\overline{\nu}) \leq 5.9 \times 10^{-7}$ [41]. The 90% CL bound on $K^+ \to \pi^+\nu\bar{\nu}$ provides a nearly model independent bound $B(K_L \to \pi^0\nu\bar{\nu}) < 1.4 \times 10^{-9}$ [42]. KEK-391a [43], which began data-taking in early 2004, aims to reach this level, and has presented a preliminary result of $\mathrm{B}(K_L \to \pi^0\nu\overline{\nu}) \leq 2.86 \times 10^{-7}$ [44]. A Letter of Intent for an experiment to reach the $\sim 5 \times 10^{-13}$/event level has been submitted to the J-PARC PAC [45].

There has been much theoretical work on possible contributions to rare K decays beyond the SM. While in the simplest case of the MSSM with no new sources of flavor or CP violation the main effect is a suppression of the rare K decays [2,21,46], substantial enhancements are possible in more general SUSY models [47]. A comprehensive discussion can be found in Refs. [40] and [48].

The decay $K_L \to \pi^0 e^+ e^-$ also has sensitivity to the CKM parameter η through its CP-violating component. There are both direct and indirect CP-violating amplitudes which can interfere. The direct CP-violating amplitude is short distance dominated and has been calculated in detail within the SM [9]. The indirect CP-violating amplitude can be inferred from a measurement of $K_S \to \pi^0 e^+ e^-$. The complete CP-violating contribution to the rate can be written as [49]:

$$\mathrm{B}_{\mathrm{CPV}} \approx 10^{-12}\left[15.7|a_S|^2 \pm 1.45\left(\frac{|V_{cb}|^2\bar{\eta}}{10^{-4}}\right)|a_S| + 0.129\left(\frac{|V_{cb}|^2\bar{\eta}}{10^{-4}}\right)^2\right] \quad (5)$$

where the three terms correspond to the indirect CP violation, the interference, and the direct CP violation respectively. The parameter a_S has recently been extracted by NA48 from a measurement of the decay $K_S \to \pi^0 e^+ e^-$ with the result $|a_S| = 1.06^{+0.26}_{-0.21} \pm 0.07$ [50]. With current constraints on the CKM parameters this implies that

$$\mathrm{B}_{\mathrm{CPV}} \approx (17.2 \pm 9.4 + 4.7) \times 10^{-12}. \quad (6)$$

The indirect CP violation is larger than the direct CP violation. While the sign of the interference is *a priori* unknown, arguments in favor of a positive sign have been put forward in Ref. 51 and Ref. 52. NA48 has also obtained the value $a_s = 1.54^{+0.40}_{-0.32} \pm 0.06$ [53] from a measurement of the $K_S \to \pi^0\mu^+\mu^-$ rate, in agreement with the value extracted from $K_S \to \pi^0 e^+ e^-$

This mode also has a CP-conserving component dominated by a two-photon intermediate state that is still subject to a sizable uncertainty. This CP-conserving component can be decomposed into an absorptive and a dispersive part. The absorptive part can be extracted from the measurement of the low $m_{\gamma\gamma}$ region of the $K_L \to \pi^0\gamma\gamma$ spectrum. The rate and the shape of the distribution $d\Gamma/dm_{\gamma\gamma}$ in $K_L \to \pi^0\gamma\gamma$ are well described in chiral perturbation theory in terms of three (a priori) unknown parameters [54,55]. Both KTeV and NA48 have studied the mode $K_L \to \pi^0\gamma\gamma$ reporting conflicting results. KTeV finds $B(K_L \to \pi^0\gamma\gamma) = (1.68 \pm 0.07_{\rm stat} \pm 0.08_{\rm sys}) \times 10^{-6}$ [56], whereas NA48 finds $B(K_L \to \pi^0\gamma\gamma) = (1.36 \pm 0.03_{\rm stat} \pm 0.03_{\rm sys} \pm 0.03_{\rm norm}) \times 10^{-6}$ [57]. Furthermore, the NA48 data indicates a negligible rate in the low $m_{\gamma\gamma}$ region suggesting a very small CP-conserving component $B_{\rm CP}(K_L \to \pi^0 e^+ e^-) \sim \mathcal{O}(10^{-13})$ [51,55,57]. KTeV, on the other hand, reports a larger rate in the low $m_{\gamma\gamma}$ region, which suggests a larger $B_{\rm CP}(K_L \to \pi^0 e^+ e^-)$ between $1 - 2 \times 10^{-12}$ [56]. In addition to this difference between the two experiments, there remains some model dependence in the estimate of the dispersive part of the CP-conserving $K_L \to \pi^0 e^+ e^-$ [51].

The related process, $K_L \to \pi^0\gamma e^+ e^-$, is potentially an additional background in some region of phase space [58]. This process has been observed with a branching ratio of $(2.34 \pm 0.35_{\rm stat} \pm 0.13_{\rm sys}) \times 10^{-8}$ [59].

The decay $K_L \to \gamma\gamma e^+ e^-$ constitutes the dominant background to $K_L \to \pi^0 e^+ e^-$. It was first observed by BNL-845 [60] and subsequently confirmed with a much larger sample by FNAL-799 [61]. It has been estimated that this background will enter at about the 10^{-10} level [62,63], comparable to or larger than the signal level. Because of this, the observation of $K_L \to \pi^0 e^+ e^-$ at the SM level will depend on background subtraction with good statistics. Possible alternative strategies are discussed in Ref. 51 and references cited therein.

The 90% CL upper bound for the process $K_L \to \pi^0 e^+ e^-$ is 2.8×10^{-10} [63]. For the closely related muonic process, the published upper bound is $B(K_L \to \pi^0\mu^+\mu^-) \leq 3.8 \times 10^{-10}$ [64] compared with the SM prediction of $(1.5 \pm 0.3) \times 10^{-11}$ [65] (assuming positive interference between the direct- and indirect-CP violating components). KTeV has additional data corresponding to about a factor 1.3 in sensitivity for the latter reaction that is under analysis.

A recent study of $K_L \to \pi^0\mu^+\mu^-$ has indicated that it might be possible to extract the direct CP-violating contribution by a joint study of the Dalitz plot variables and the components of the μ^+ polarization [66]. The latter tends to be quite substantial so that large statistics may not be necessary.

E. Other long distance dominated modes:

The decays $K^+ \to \pi^+\ell^+\ell^-$ ($\ell = e$ or μ) have received considerable attention. The rate and spectrum have been measured for both the electron and muon modes [67,68]. Ref. 49 has proposed a parameterization inspired by chiral perturbation theory, which provides a successful description of data but indicates the presence of large corrections beyond leading order. More work is needed to fully understand the origin of these large corrections.

Much information has been recorded by KTeV and NA48 on the rates and spectrum for the Dalitz pair conversion modes $K_L \to \ell^+\ell^-\gamma$ [69,70], and $K_L \to \ell^+\ell^-\ell'^+\ell'^-$ for $\ell, \ell' = e$ or μ [16,70–72]. All these results are used to test hadronic models and could further our understanding of the long distance component in $K_L \to \mu^+\mu^-$.

K^+ DECAY MODES

K^- modes are charge conjugates of the modes below.

	Mode	Fraction (Γ_i/Γ)	Scale factor/ Confidence level
	Leptonic and semileptonic modes		
Γ_1	$e^+\nu_e$	$(1.55 \pm 0.07) \times 10^{-5}$	
Γ_2	$\mu^+\nu_\mu$	(63.44 ± 0.14) %	S=1.2
Γ_3	$\pi^0 e^+\nu_e$	(4.98 ± 0.07) %	S=1.3
	Called K^+_{e3}.		
Γ_4	$\pi^0\mu^+\nu_\mu$	(3.32 ± 0.06) %	S=1.2
	Called $K^+_{\mu3}$.		
Γ_5	$\pi^0\pi^0 e^+\nu_e$	$(2.2 \pm 0.4) \times 10^{-5}$	
Γ_6	$\pi^+\pi^- e^+\nu_e$	$(4.09 \pm 0.09) \times 10^{-5}$	
Γ_7	$\pi^+\pi^-\mu^+\nu_\mu$	$(1.4 \pm 0.9) \times 10^{-5}$	
Γ_8	$\pi^0\pi^0\pi^0 e^+\nu_e$	$< 3.5 \times 10^{-6}$	CL=90%
	Hadronic modes		
Γ_9	$\pi^+\pi^0$	(20.92 ± 0.12) %	S=1.1
Γ_{10}	$\pi^+\pi^0\pi^0$	(1.757 ± 0.024) %	S=1.1
Γ_{11}	$\pi^+\pi^+\pi^-$	(5.590 ± 0.031) %	S=1.1
	Leptonic and semileptonic modes with photons		
Γ_{12}	$\mu^+\nu_\mu\gamma$	[a,b] $(6.2 \pm 0.8) \times 10^{-3}$	
Γ_{13}	$\mu^+\nu_\mu\gamma(\mathrm{SD}^+)$	[c] $< 3.0 \times 10^{-5}$	CL=90%
Γ_{14}	$\mu^+\nu_\mu\gamma(\mathrm{SD}^+\mathrm{INT})$	[c] $< 2.7 \times 10^{-5}$	CL=90%
Γ_{15}	$\mu^+\nu_\mu\gamma(\mathrm{SD}^- + \mathrm{SD}^-\mathrm{INT})$	[c] $< 2.6 \times 10^{-4}$	CL=90%
Γ_{16}	$e^+\nu_e\gamma(\mathrm{SD}^+)$	[c] $(1.52 \pm 0.23) \times 10^{-5}$	
Γ_{17}	$e^+\nu_e\gamma(\mathrm{SD}^-)$	[c] $< 1.6 \times 10^{-4}$	CL=90%
Γ_{18}	$\pi^0 e^+\nu_e\gamma$	[a,b] $(2.69 \pm 0.20) \times 10^{-4}$	
Γ_{19}	$\pi^0 e^+\nu_e\gamma(\mathrm{SD})$	[c] $< 5.3 \times 10^{-5}$	CL=90%
Γ_{20}	$\pi^0\mu^+\nu_\mu\gamma$	[a,b] $(2.4 \pm 0.8) \times 10^{-5}$	
Γ_{21}	$\pi^0\pi^0 e^+\nu_e\gamma$	$< 5 \times 10^{-6}$	CL=90%
	Hadronic modes with photons		
Γ_{22}	$\pi^+\pi^0\gamma$	[a,b] $(2.75 \pm 0.15) \times 10^{-4}$	
Γ_{23}	$\pi^+\pi^0\gamma(\mathrm{DE})$	[b,d] $(4.4 \pm 0.7) \times 10^{-6}$	
Γ_{24}	$\pi^+\pi^0\pi^0\gamma$	[a,b] $(7.6\ ^{+5.6}_{-3.0}) \times 10^{-6}$	
Γ_{25}	$\pi^+\pi^+\pi^-\gamma$	[a,b] $(1.04 \pm 0.31) \times 10^{-4}$	
Γ_{26}	$\pi^+\gamma\gamma$	[b] $(1.10 \pm 0.32) \times 10^{-6}$	
Γ_{27}	$\pi^+ 3\gamma$	[b] $< 1.0 \times 10^{-4}$	CL=90%

Leptonic modes with $\ell\overline{\ell}$ pairs

Γ_{28}	$e^+\nu_e\nu\overline{\nu}$	<	6	$\times 10^{-5}$	CL=90%
Γ_{29}	$\mu^+\nu_\mu\nu\overline{\nu}$	<	6.0	$\times 10^{-6}$	CL=90%
Γ_{30}	$e^+\nu_e e^+ e^-$		(2.48 ±0.20)	$\times 10^{-8}$	
Γ_{31}	$\mu^+\nu_\mu e^+ e^-$		(7.06 ±0.31)	$\times 10^{-8}$	
Γ_{32}	$e^+\nu_e\mu^+\mu^-$		(1.7 ±0.5)	$\times 10^{-8}$	
Γ_{33}	$\mu^+\nu_\mu\mu^+\mu^-$	<	4.1	$\times 10^{-7}$	CL=90%

Lepton Family number (LF), Lepton number (L), $\Delta S = \Delta Q$ (SQ) violating modes, or $\Delta S = 1$ weak neutral current ($S1$) modes

Γ_{34}	$\pi^+\pi^+e^-\overline{\nu}_e$	SQ	<	1.2	$\times 10^{-8}$	CL=90%
Γ_{35}	$\pi^+\pi^+\mu^-\overline{\nu}_\mu$	SQ	<	3.0	$\times 10^{-6}$	CL=95%
Γ_{36}	$\pi^+ e^+ e^-$	$S1$		(2.88 ±0.13)	$\times 10^{-7}$	
Γ_{37}	$\pi^+\mu^+\mu^-$	$S1$		(8.1 ±1.4)	$\times 10^{-8}$	S=2.7
Γ_{38}	$\pi^+\nu\overline{\nu}$	$S1$		(1.5 $^{+1.3}_{-0.9}$)	$\times 10^{-10}$	
Γ_{39}	$\pi^+\pi^0\nu\overline{\nu}$	$S1$	<	4.3	$\times 10^{-5}$	CL=90%
Γ_{40}	$\mu^-\nu e^+ e^+$	LF	<	2.0	$\times 10^{-8}$	CL=90%
Γ_{41}	$\mu^+\nu_e$	LF	[e] <	4	$\times 10^{-3}$	CL=90%
Γ_{42}	$\pi^+\mu^+ e^-$	LF	<	1.3	$\times 10^{-11}$	CL=90%
Γ_{43}	$\pi^+\mu^- e^+$	LF	<	5.2	$\times 10^{-10}$	CL=90%
Γ_{44}	$\pi^-\mu^+ e^+$	L	<	5.0	$\times 10^{-10}$	CL=90%
Γ_{45}	$\pi^- e^+ e^+$	L	<	6.4	$\times 10^{-10}$	CL=90%

[a] Most of this radiative mode, the low-momentum γ part, is also included in the parent mode listed without γ's.

[b] See the Particle Listings below for the energy limits used in this measurement.

[c] Structure-dependent part.

[d] Direct-emission branching fraction.

[e] Derived from an analysis of neutrino-oscillation experiments.

[f] Violates angular-momentum conservation.

CONSTRAINED FIT INFORMATION

An overall fit to the mean life, a decay rate, and 12 branching ratios uses 26 measurements and one constraint to determine 8 parameters. The overall fit has a $\chi^2 = 30.0$ for 19 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

0.53±0.22		[44] ROMANO	71	HLBC	+	$E(\gamma) > 30$ MeV

[41] BARMIN 91 quotes branching ratio $\Gamma(K \to e\pi^0\nu\gamma)/\Gamma_{\text{all}}$. The measured normalization is $[\Gamma(K \to e\pi^0\nu) + \Gamma(K \to \pi^+\pi^+\pi^-)]$. For comparison with other experiments we used $\Gamma(K \to e\pi^0\nu)/\Gamma_{\text{all}} = 0.0482$ to calculate the values quoted here.
[42] $\cos\theta(e\gamma)$ between 0.6 and 0.9.
[43] First LJUNG 73 value is for $\cos\theta(e\gamma) < 0.9$, second value is for $\cos\theta(e\gamma)$ between 0.6 and 0.9 for comparison with ROMANO 71.
[44] Both ROMANO 71 values are for $\cos\theta(e\gamma)$ between 0.6 and 0.9. Second value is for comparison with second LJUNG 73 value. We use lowest $E(\gamma)$ cut for Summary Table value. See ROMANO 71 for E_γ dependence.

$\Gamma(\pi^0 e^+\nu_e\gamma(\text{SD}))/\Gamma_{\text{total}}$ Γ_{19}/Γ

[72] AOKI 94 measures $\xi P_\mu = -0.9996 \pm 0.0030 \pm 0.0048$. The above limit is obtained by summing the statistical and systematic errors in quadrature, normalizing to the physically significant region ($|\xi P_\mu| < 1$) and assuming that ξ=1, its maximum value.

[73] Assumes ξ=1.

DALITZ PLOT PARAMETERS FOR $K \to 3\pi$ DECAYS

Revised 1999 by T.G. Trippe (LBNL).

The Dalitz plot distribution for $K^\pm \to \pi^\pm\pi^\pm\pi^\mp$, $K^\pm \to \pi^0\pi^0\pi^\pm$, and $K_L^0 \to \pi^+\pi^-\pi^0$ can be parameterized by a series expansion such as that introduced by Weinberg [1]. We use the form

$$\left|M\right|^2 \propto 1 + g\frac{(s_3 - s_0)}{m_{\pi^+}^2} + h\left[\frac{s_3 - s_0}{m_{\pi^+}^2}\right]^2 + j\ \frac{(s_2 - s_1)}{m_{\pi^+}^2} + k\left[\frac{s_2 - s_1}{m_{\pi^+}^2}\right]^2 + f\ \frac{(s_2 - s_1)}{m_{\pi^+}^2}\frac{(s_3 - s_0)}{m_{\pi^+}^2} + \cdots , \quad (1)$$

where $m_{\pi^+}^2$ has been introduced to make the coefficients g, h, j, and k dimensionless, and

$$s_i = (P_K - P_i)^2 = (m_K - m_i)^2 - 2m_K T_i\ ,\ i = 1, 2, 3,$$
$$s_0 = \frac{1}{3}\sum_i s_i = \frac{1}{3}(m_K^2 + m_1^2 + m_2^2 + m_3^2) \quad .$$

Here the P_i are four-vectors, m_i and T_i are the mass and kinetic energy of the i^{th} pion, and the index 3 is used for the odd pion.

The coefficient g is a measure of the slope in the variable s_3 (or T_3) of the Dalitz plot, while h and k measure the quadratic dependence on s_3 and $(s_2 - s_1)$, respectively. The coefficient j is related to the asymmetry of the plot and must be zero if CP invariance holds. Note also that if CP is good, g, h, and k must be the same for $K^+ \to \pi^+\pi^+\pi^-$ as for $K^- \to \pi^-\pi^-\pi^+$.

Since different experiments use different forms for $\left|M\right|^2$, in order to compare the experiments we have converted to g, h, j, and k whatever coefficients have been measured. Where such conversions have been done, the measured coefficient a_y, a_t, a_u, or a_v is given in the comment at the right. For definitions of these coefficients, details of this conversion, and discussion of the data, see the April 1982 version of this note [2].

ALTERNATIVE PARAMETERIZATION OF $K^{\pm} \to \pi^{\pm}\pi^0\pi^0$ DALITZ PLOT

The following functional form for the matrix element suggested by $\pi\pi$ rescattering in $K^+ \to \pi^+$"$\pi^+\pi^-$"$\to \pi^+\pi^0\pi^0$ is used for this fit (CABIBBO 04A, CABIBBO 05): Matrix element = $M_0 + M_1$ where $M_0 = 1 + (1/2)g_0\, u + (1/2)\, h'\, u^2$ with $u = (s_3 - s_0)/(m_{\pi^+})^2$ and where M_1 takes into account the non-analytic piece due to pi pi rescattering amplitudes a_0 and a_2; The parameters g_0 and h' are related to the parameters g and h of the matrix element squared given in the previous section by the approximations $g_0 \sim g^{PDG}$ and $h' \sim h^{PDG} - (g/2)^2$.

$K^{\pm}_{\ell 3}$ AND $K^{0}_{\ell 3}$ FORM FACTORS

Revised June 2006 by T.G. Trippe (LBNL).

Assuming that only the vector current contributes to $K \to \pi\ell\nu$ decays, we write the matrix element as

$$M \propto f_+(t)\left[(P_K + P_\pi)_\mu \overline{\ell}\gamma_\mu(1+\gamma_5)\nu\right] + f_-(t)\left[m_\ell \overline{\ell}(1+\gamma_5)\nu\right] \ , \quad (1)$$

where P_K and P_π are the four-momenta of the K and π mesons, m_ℓ is the lepton mass, and f_+ and f_- are dimensionless form factors which can depend only on $t = (P_K - P_\pi)^2$, the square of the four-momentum transfer to the leptons. If time-reversal invariance holds, f_+ and f_- are relatively real. $K_{\mu 3}$ experiments, discussed immediately below, measure f_+ and f_-, while K_{e3} experiments, discussed further below, are sensitive only to f_+ because the small electron mass makes the f_- term negligible.

$K_{\mu 3}$ Experiments. Analyses of $K_{\mu 3}$ data frequently assume a linear dependence of f_+ and f_- on t, *i.e.*,

$$f_\pm(t) = f_\pm(0)\left[1 + \lambda_\pm(t/m^2_{\pi^+})\right] \quad (2)$$

Most $K_{\mu 3}$ data are adequately described by Eq. (2) for f_+ and a constant f_- (*i.e.*, $\lambda_- = 0$).

There are two equivalent parametrizations commonly used in these analyses:

(1) $\lambda_+, \xi(0)$ parametrization. Older analyses of $K_{\mu 3}$ data often introduce the ratio of the two form factors

$$\xi(t) = f_-(t)/f_+(t) \ . \quad (3)$$

The $K_{\mu 3}$ decay distribution is then described by the two parameters λ_+ and $\xi(0)$ (assuming time reversal invariance and $\lambda_- = 0$).

(2) λ_+, λ_0 parametrization. More recent $K_{\mu 3}$ analyses have parameterized in terms of the form factors f_+ and f_0 which are associated with vector and scalar exchange, respectively, to the lepton pair. f_0 is related to f_+ and f_- by

$$f_0(t) = f_+(t) + \left[t/(m_K^2 - m_\pi^2)\right] f_-(t) \ . \quad (4)$$

Here $f_0(0)$ must equal $f_+(0)$ unless $f_-(t)$ diverges at $t = 0$. The earlier assumption that f_+ is linear in t and f_- is constant leads to f_0 linear in t:

$$f_0(t) = f_0(0)\left[1 + \lambda_0(t/m^2_{\pi^+})\right] \ . \quad (5)$$

With the assumption that $f_0(0) = f_+(0)$, the two parametrizations, $(\lambda_+, \xi(0))$ and (λ_+, λ_0) are equivalent as long as correlation information is retained. (λ_+, λ_0) correlations tend to be less strong than $(\lambda_+, \xi(0))$ correlations.

In this edition of the *Review* we no longer quote results in the $(\lambda_+, \xi(0))$ parameterization. We have removed many older low statistics results from the listings. See the 2004 version of this note [4] for these older results and the 1982 version [5] for additional discussion of the $K^0_{\mu 3}$ parameters, correlations, and conversion between parametrizations.

Quadratic Parameterization. More recent high statistics experiments have included a quadratic term in the expansion of $f_+(t)$,

$$f_+(t) = f_+(0)\left[1 + \lambda_+^{'}(t/m^2_{\pi^+}) + \frac{\lambda_+^{''}}{2}(t/m^2_{\pi^+})^2\right] \quad (6)$$

If there is a non-vanishing quadratic term, then λ_+ of Eq. (2) represents the average slope, which is then different from $\lambda_+^{'}$. Our convention is to include the factor $\frac{1}{2}$ in the quadratic term and to use m_{π^+} even for K^+_{e3} and $K^+_{\mu 3}$ decays. We have converted other's parameterizations to match our conventions, as noted in the beginning of the *$K^{\pm}_{\ell 3}$ and $K^0_{\ell 3}$ Form Factors* sections of the *Data Listings*.

Pole Parameterization. The pole model describes the t dependence of $f_+(t)$ and $f_0(t)$ in terms of the exchange of the lightest vector and scalar K^* mesons with masses M_v and M_s, respectively:

$$f_+(t) = f_+(0)\left[\frac{M_v^2}{M_v^2 - t}\right] \ , \qquad f_0(t) = f_0(0)\left[\frac{M_s^2}{M_s^2 - t}\right] \ . \quad (7)$$

K_{e3} Experiments. Analysis of K_{e3} data is simpler than that of $K_{\mu 3}$ because the second term of the matrix element assuming a pure vector current [Eq. (1) above] can be neglected. Here f_+ can be assumed to be linear in t, in which case the linear coefficient λ_+ of Eq. (2) is determined, or quadratic, in which case the linear coefficient $\lambda_+^{'}$ and quadratic coefficient $\lambda_+^{''}$ of Eq. (6) are determined.

If we remove the assumption of a pure vector current, then the matrix element for the decay, in addition to the terms in Eq. (1), would contain

$$+2m_K f_S \overline{\ell}(1+\gamma_5)\nu + (2f_T/m_K)(P_K)_\lambda(P_\pi)_\mu \overline{\ell}\,\sigma_{\lambda\mu}(1+\gamma_5)\nu \ , \quad (8)$$

where f_S is the scalar form factor, and f_T is the tensor form factor. In the case of the K_{e3} decays where the f_- term can be neglected, experiments have yielded limits on $|f_S/f_+|$ and $|f_T/f_+|$.

Fits for $K_{\ell 3}$ Form Factors. For K_{e3} data we determine best values for the three parameterizations: linear (λ_+), quadratic ($\lambda_+^{'}$, $\lambda_+^{''}$) and pole (M_v). For $K_{\mu 3}$ data we determine best values for the three parameterizations: linear (λ_+, λ_0), quadratic ($\lambda_+^{'}$, $\lambda_+^{''}$, λ_0)) and pole (M_v, M_s). We then assume $\mu - e$ universality so that we can combine K_{e3} and $K_{\mu 3}$ data and again determine best values for the three parameterizations: linear (λ_+, λ_0), quadratic ($\lambda_+^{'}, \lambda_+^{''}$, λ_0)) and pole (M_v, M_s). When there is more than one parameter, fits are done including input correlations. Simple averages suffice in the two K_{e3} cases where there is only one parameter: linear (λ_+) and pole (M_v).

Both KTeV and KLOE see an improvement in the quality of their fits relative to linear fits when a quadratic term is introduced, as well as when the pole parameterization is used. The quadratic parameterization has the disadvantage that the quadratic parameter $\lambda_+^{''}$ is highly correlated with the linear

parameter λ'_+, in the neighborhood of 95%, and that neither parameter is very well determined. The pole fit has the same number of parameters as the linear fit but yields slightly better fit probabilities so that it would be advisable for all experiments to include the pole parameterization as one of their choices [6].

The *Kaon Particle Listings* show the results with and without assuming μ-e universality. The *Meson Summary Tables* show all of the results assuming μ-e universality, but most results not assuming μ-e universality are given only in the *Listings*.

$K^{\pm}_{\ell 3}$ FORM FACTORS

In the form factor comments, the following symbols are used.

f_+ and f_- are form factors for the vector matrix element.

f_S and f_T refer to the scalar and tensor term.

$f_0 = f_+ + f_- \, t/(m^2_{K^+} - m^2_{\pi^0})$.

t = momentum transfer to the π.

λ_+ and λ_0 are the linear expansion coefficients of f_+ and f_0:

$f_+(t) = f_+(0)\,(1 + \lambda_+ t\,/m^2_{\pi^+})$

For quadratic expansion

$f_+(t) = f_+(0)\,(1 + \lambda'_+ t\,/m^2_{\pi^+} + \frac{\lambda''_+}{2}\, t^2/m^4_{\pi^+})$

as used by KTeV. If there is a non-vanishing quadratic term, then λ_+ represents an average slope, which is then different from λ'_+.

NA48 and ISTRA quadratic expansion coefficients are converted with

$\lambda'_+{}^{PDG} = \lambda_+{}^{NA48}$ and $\lambda''_+{}^{PDG} = 2\,\lambda'_+{}^{NA48}$

$\lambda'_+{}^{PDG} = (\frac{m_{\pi^+}}{m_{\pi^0}})^2\,\lambda_+{}^{ISTRA}$ and

$\lambda''_+{}^{PDG} = 2\,(\frac{m_{\pi^+}}{m_{\pi^0}})^4\,\lambda'_+{}^{ISTRA}$

ISTRA linear expansion coefficients are converted with

$\lambda_+{}^{PDG} = (\frac{m_{\pi^+}}{m_{\pi^0}})^2\,\lambda_+{}^{ISTRA}$ and $\lambda_0{}^{PDG} = (\frac{m_{\pi^+}}{m_{\pi^0}})^2\,\lambda_0{}^{ISTRA}$

The pole parametrization is

$f_+(t) = f_+(0)\,(\frac{M_V^2}{M_V^2 - t})$

$f_0(t) = f_0(0)\,(\frac{M_S^2}{M_S^2 - t})$

where M_V and M_S are the vector and scalar pole masses.

The following abbreviations are used:

DP = Dalitz plot analysis.

PI = π spectrum analysis.

MU = μ spectrum analysis.

POL= μ polarization analysis.

BR = $K^{\pm}_{\mu 3}/K^{\pm}_{e3}$ branching ratio analysis.

E = positron or electron spectrum analysis.

RC = radiative corrections.

λ_+ (LINEAR ENERGY DEPENDENCE OF f_+ IN $K^{\pm}_{e3}$ DECAY)

These results are for a linear expansion only. See the next section for fits including a quadratic term. For radiative correction of the $K^{\pm}_{e3}$ Dalitz plot, see GINSBERG 67, BECHERRAWY 70, CIRIGLIANO 02, CIRIGLIANO 04, and ANDRE 04. Results labeled OUR FIT are discussed in the review "$K^{\pm}_{\ell 3}$ and $K^0_{\ell 3}$ Form Factors" above. For earlier, lower statistics results, see the 2004 edition of this review, Phys. Lett. B592, 1 (2004).

T-VIOLATION PARAMETER IN K^0-$\overline{K}^0$ MIXING

The asymmetry $A_T = \frac{\Gamma(\overline{K}^0 \to K^0) - \Gamma(K^0 \to \overline{K}^0)}{\Gamma(\overline{K}^0 \to K^0) + \Gamma(K^0 \to \overline{K}^0)}$ must vanish if T invariance holds.

ASYMMETRY A_T IN K^0-$\overline{K}^0$ MIXING

VALUE (units 10^{-3})	EVTS	DOCUMENT ID		TECN
6.6±1.3±1.0	640k	[1] ANGELOPO...	98E	CPLR

[1] ANGELOPOULOS 98E measures the asymmetry $A_T = [\Gamma(\overline{K}^0_{t=0} \to e^+\pi^-\nu_{t=\tau}) - \Gamma(K^0_{t=0} \to e^-\pi^+\overline{\nu}_{t=\tau})]/[\Gamma(\overline{K}^0_{t=0} \to e^+\pi^-\nu_{t=\tau}) + \Gamma(K^0_{t=0} \to e^-\pi^+\overline{\nu}_{t=\tau})]$ as a function of the neutral-kaon eigentime τ. The initial strangeness of the neutral kaon is tagged by the charge of the accompanying charged kaon in the reactions $p\overline{p} \to K^-\pi^+ K^0$ and $p\overline{p} \to K^+\pi^-\overline{K}^0$. The strangeness at the time of the decay is tagged by the lepton charge. The reported result is the average value of A_T over the interval $1\tau_S < \tau < 20\tau_S$. From this value of A_T ANGELOPOULOS 01B, assuming CPT invariance in the $e\pi\nu$ decay amplitude, determine the T-violating as $\Delta S = \Delta S$ conserving parameter (for its definition, see Review below) $4\mathrm{Re}(\epsilon) = (6.2 \pm 1.4 \pm 1.0) \times 10^{-3}$.

CPT INVARIANCE TESTS IN NEUTRAL KAON DECAY

Revised June 2006 by P. Bloch (CERN).

The time evolution of a neutral kaon state state is described by

$$\frac{d}{dt}\Psi = -i\Lambda\Psi \ , \qquad \Lambda \equiv M - \frac{i}{2}\Gamma \tag{1}$$

where M and Γ are Hermitian 2×2 matrices known as the mass and decay matrices. The corresponding eigenvalues are $\lambda_{L,S} = m_{L,S} - \frac{i}{2}\gamma_{L,S}$. CPT invariance requires the diagonal elements of Λ to be equal. The CPT-violation complex parameter δ is defined as

$$\delta = \frac{\Lambda_{\overline{K}^0\overline{K}^0} - \Lambda_{K^0K^0}}{2(\lambda_L - \lambda_S)}$$
$$= \delta_\parallel \exp(i\phi_{SW}) + \delta_\perp \exp(i(\phi_{SW} + \frac{\pi}{2})) \tag{2}$$

where we have introduced the projections $\delta_\parallel$ and $\delta_\perp$ respectively parallel and perpendicular to the superweak direction $\phi_{SW} = \tan^{-1}(2\Delta m/\Delta\gamma)$, where $\Delta m = m_L - m_S$ and $\Delta\gamma = \gamma_S - \gamma_L$, the positive mass and width differences between K_L and K_S. These projections are linked to the mass and width difference between K^0 and $\overline{K}^0$:

$$\delta_\parallel = \frac{1}{4}\frac{\gamma_{K^0} - \gamma_{\overline{K}^0}}{\sqrt{\Delta m^2 + \left(\frac{\Delta\gamma}{2}\right)^2}} \ , \ \delta_\perp = \frac{1}{2}\frac{m_{K^0} - m_{\overline{K}^0}}{\sqrt{\Delta m^2 + \left(\frac{\Delta\gamma}{2}\right)^2}} \ . \tag{3}$$

$\mathrm{Re}(\delta)$ can be directly measured by studying the time evolution of the strangeness content of initially pure K^0 and $\overline{K}^0$ states, for example through the asymmetry

$$A_{CPT} = \frac{P[\overline{K}^0 \to \overline{K}^0(t)] - P[K^0 \to K^0(t)]}{P[\overline{K}^0 \to \overline{K}^0(t)] + P[K^0 \to K^0(t)]} = 4\mathrm{Re}(\delta) \tag{4}$$

where $P[a \to b(t)]$ is the probability that the pure initial state a is seen as state b at proper time t. This method has been used by tagging the initial strangeness with strong interactions and the final strangeness with the semileptonic decay (a more appropriate combination of semileptonic rates allows to be independent of any direct CPT violation in the decay itself) and yields today's best value of $\mathrm{Re}(\delta)$, compatible with zero with an error of $\sim 3\times 10^{-4}$.

As an alternative it has been proposed to compare the semileptonic charge asymmetries for K_L and K_S

$$A_{L,S} = \frac{R(K_{L,S} \to \pi^-\ell^+\nu) - R(K_{L,S} \to \pi^+\ell^-\overline{\nu})}{R(K_{L,S} \to \pi^-\ell^+\nu) + R(K_{L,S} \to \pi^+\ell^-\overline{\nu})} \ ,$$
$$A_S - A_L = 4\mathrm{Re}(\delta) \ . \tag{5}$$

A_L has been accurately measured. A_S has been recently measured with tagged K_S at ϕ factories, however not yet with the required accuracy. Note however that Eq. (5) assumes CPT invariance in the $\Delta S = -\Delta Q$ semileptonic decay amplitude.

$\delta_\perp$ can be obtained from the measurement of the $\pi\pi$ decays CP-violation parameters η_{+-} and η_{00}. Figure 1 shows the various contributions to $\eta_{\pi\pi}$ [1]. The T-violation parameter ϵ_T

$$\epsilon_T = i\frac{|\Lambda_{K^0\overline{K}^0}|^2 - |\Lambda_{\overline{K}^0K^0}|^2}{\Delta\gamma(\lambda_L - \lambda_S)} \tag{6}$$

has been defined in such a way that it is exactly aligned along the superweak direction [‡]. A_I (resp. B_I) is the CPT-conserving (resp. violating) decay amplitude for the $\pi\pi$ Isospin I state, ε' is the direct CP/CPT-violation parameter $[\varepsilon' = 1/3(\eta_{+-} - \eta_{00})]$ and $\delta\phi = \frac{1}{2}\left[\varphi_\Gamma - \arg(A_0^*\overline{A}_0)\right]$ is the phase difference between

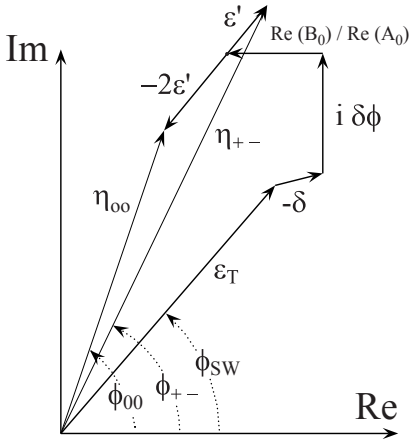

Figure 1: *CP*- and *CPT*-violation parameters in 2π decay.

the $I = 0$ component of the decay amplitude and the matrix element $\Gamma_{K^0\overline{K}^0}$. From Fig. 1 one obtains

$$\delta_\perp = |\eta_{+-}|(\phi_{SW} - \frac{2}{3}\phi_{+-} - \frac{1}{3}\phi_{00}) - \frac{\mathrm{Re}(B_0)}{\mathrm{Re}(A_0)}\sin(\phi_{SW}) + \delta\phi \ \cos(\phi_{SW}) \ . \quad (7)$$

The present accuracy on the term $|\eta_{+-}|(\phi_{SW} - \frac{2}{3}\phi_{+-} - \frac{1}{3}\phi_{00})$ is 2.6×10^{-5}. $\delta\phi$ gets contributions from *CP* violation in semileptonic and 3π decays [2,3] and can only be neglected at the present time if one assumes that η_{000} is not significantly larger than η_{+-0}. Furthermore, B_0 is not directly measured, so additional assumptions (for example, *CPT* conservation in the decay which implies $B_0 = 0$) or a combination with other measurements are necessary to obtain $\delta_\perp$.

If one assumes unitarity, one can measure $\mathrm{Im}(\delta)$ using the Bell-Steinberger relation which relates K_S and K_L decay amplitudes into all final states f:

$$\mathrm{Re}(\epsilon_T) - i\mathrm{Im}(\delta) = \frac{1}{2(i\Delta m + \frac{1}{2}(\gamma_L + \gamma_S))} \times \sum A_{f_L} A^*_{f_S} \ . \quad (8)$$

Since the $\pi\pi$ amplitudes dominate, the result relies also strongly on the $\phi_{\pi\pi}$ phase measurements. The advantage is that B_0 does not enter. Using all available data, one obtains a value of $\mathrm{Im}(\delta)$ compatible with zero with a precision of 2×10^{-5}. The precision here is limited by the measurement of η_{+-}.

The results on $\mathrm{Re}(\delta)$ and $\mathrm{Im}(\delta)$ can be combined to obtain $\delta_\parallel$ and $\delta_\perp$ and therefore the K^0–$\overline{K}^0$ mass and width difference shown in Fig. 2. The current accuracy is a few 10^{-18} GeV for both.

If one assumes that *CPT* is conserved in the decays ($\gamma_{K^0} = \gamma_{\overline{K}^0}$, $\delta_\parallel = 0$, $B_I = 0$), the phase of δ is known, and the $\delta_\perp$ and Bell-Steinberger methods are identical. One in this case obtains a limit for $|m_{K^0} - m_{\overline{K}^0}|$ of 4.7×10^{-19} GeV (90%CL).

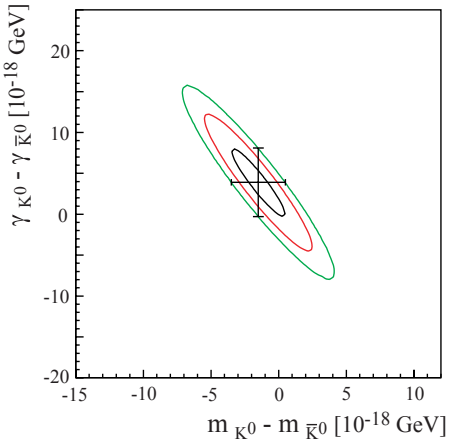

Figure 2: K^0–$\overline{K}^0$ mass vs width difference.

Footnotes and References

[‡] Many authors have a different definition of the T-violation parameter, $\epsilon = (\Lambda_{\overline{K}^0 K^0} - \Lambda_{K^0\overline{K}^0})/(2(\lambda_L - \lambda_S))$. ϵ is not exactly aligned with the superweak direction. The two definitions can be related through $\epsilon = \epsilon_T + i\delta\phi$.

CP-VIOLATION PARAMETERS

Re(ϵ)

VALUE (units 10^{-3})	*DOCUMENT ID*		*TECN*
1.664±0.010	[2] LAI	05A	NA48

[2] LAI 05A values are obtained through unitarity (Bell-Steinberger relations), improving determination of η_{000} and combining other data from PDG and APOSTOLAKIS 99B.

CPT-VIOLATION PARAMETERS

In K^0-$\overline{K}^0$ mixing, if *CP*-violating interactions include a *T* conserving part then

$$|K_S\rangle = [|K_1\rangle + (\epsilon + \delta)|K_2\rangle]/\sqrt{1+|\epsilon+\delta|^2}$$
$$|K_L\rangle = [|K_2\rangle + (\epsilon - \delta)|K_1\rangle]/\sqrt{1+|\epsilon-\delta|^2}$$

where

$$|K_1\rangle = [|K^0\rangle + |\overline{K}^0\rangle]/\sqrt{2}$$
$$|K_2\rangle = [|K^0\rangle - |\overline{K}^0\rangle]/\sqrt{2}$$

and

$$|\overline{K}^0\rangle = CP|K^0\rangle.$$

The parameter δ specifies the *CPT*-violating part.

Estimates of δ are given below assuming the validity of the $\Delta S = \Delta Q$ rule. See also THOMSON 95 for a test of *CPT*-symmetry conservation in K^0 decays using the Bell-Steinberger relation.

[1] This ALAVI-HARATI 03 fit has Δm and τ_S free but constrains ϕ_{+-} to the Superweak value, i.e. assumes CPT. This τ_S value is correlated with their $\Delta m = m_{K^0_L} - m_{K^0_S}$ measurement in the K^0_L listings. The correlation coefficient $\rho(\tau_S, \Delta m) = -0.396$.

[2] The two ALAVI-HARATI 03 values use the same data. The first enters the "assuming CPT" fit and the second enters the "not assuming CPT" fit.

[3] This ALAVI-HARATI 03 fit has Δm, ϕ_{+-}, and τ_{K_S} free. See ϕ_{+-} in the "K_L CP violation" section for correlation information.

[4] ARONSON 82 find that K^0_S mean life may depend on the kaon energy.

[5] CARITHERS 75 measures the Δm dependence of the total decay rate (inverse mean life) to be $\Gamma(K^0_S) = [(1.122 \pm 0.004) + 0.16(\Delta m - 0.5348)/\Delta m]10^{10}$/s, or, in terms of mean life, CARITHERS 75 measures $\tau_S = (0.8913 \pm 0.0032) - 0.238\,[\Delta m - 0.5348]$ (10^{-10} s). We have adjusted the measurement to use our best values of ($\Delta m = 0.5292 \pm 0.0009$) ($10^{10}\ \hbar\ \mathrm{s}^{-1}$). Our first error is their experiment's error and our second error is the systematic error from using our best values.

[6] HILL 68 has been changed by the authors from the published value (0.865 ± 0.009) because of a correction in the shift due to η_{+-}. SKJEGGESTAD 72 and HILL 68 give detailed discussions of systematics encountered in this type of experiment.

[7] Pre-1971 experiments are excluded from the average because of disagreement with later more precise experiments.

[8] HILL 68 has been changed by the authors from the published value (0.865 ± 0.009) because of a correction in the shift due to η_{+-}. SKJEGGESTAD 72 and HILL 68 give detailed discussions of systematics encountered in this type of experiment.

[a] Most of this radiative mode, the low-momentum γ part, is also included in the parent mode listed without γ's.

[b] See the Particle Listings below for the energy limits used in this measurement.

[c] The value is for the sum of the charge states or particle/antiparticle states indicated.

[d] Not a measurement. Calculated as $0.666\cdot B(\pi^\pm e^\mp\nu_e)$.

CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 4 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2=0.1$ for 1 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle\delta x_i\delta x_j\rangle/(\delta x_i\cdot\delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$3.9\ ^{+5.4}_{-1.8}\ ^{+0.9}_{-0.7}$		[22] THOMSON	94	E621	Sup. by ZOU 96

[18] BATLEY 05 is obtained by measuring the interference parameters in K_S, $K_L\to\pi^+\pi^-\pi^0$: $\mathrm{Re}(\lambda)=0.038\pm0.008\pm0.006$ and $\mathrm{Im}(\lambda)=-0.013\pm0.005\pm0.004$; the correlation coeff. between $\mathrm{Re}(\lambda)$ and $\mathrm{Im}(\lambda)$ is 0.66 (statistical only).

[19] ADLER 97B find the *CP*-conserving parameters $\mathrm{Re}(\lambda)=(28\pm7\pm3)\times10^{-3}$, $\mathrm{Im}(\lambda)=(-10\pm8\pm2)\times10^{-3}$. They estimate $B(K^0_S\to\pi^+\pi^-\pi^0)$ from $\mathrm{Re}(\lambda)$ and the K^0_L decay parameters. See also ANGELOPOULOS 98C.

[20] ZOU 96 is from the the measured quantities $|\rho_{+-0}|=0.039\ ^{+0.009}_{-0.006}\pm0.005$ and $\phi_\rho=(-9\pm18)^\circ$.

[21] ADLER 96E is from the measured quantities $\mathrm{Re}(\lambda)=0.036\pm0.010\ ^{+0.002}_{-0.003}$ and $\mathrm{Im}(\lambda)$ consistent with zero. Note that the quantity λ is the same as ρ_{+-0} used in other footnotes.

[22] THOMSON 94 calculates this branching ratio from their measurements $|\rho_{+-0}|=0.035\ ^{+0.019}_{-0.011}\pm0.004$ and $\phi_\rho=(-59\pm48)^\circ$ where $|\rho_{+-0}|e^{i\phi_\rho}=A(K^0_S\to\pi^+\pi^-\pi^0, I=2)/A(K^0_L\to\pi^+\pi^-\pi^0)$.

7.2 ±1.4	75	AKHMETSHIN	99	CMD2	Tagged K^0_S using $\phi \to K^0_L K^0_S$

[32] Obtained by imposing Σ_i B($K^0_S \to i$) = 1, where i runs over all the four branching ratios $\pi^+\pi^-$, $\pi^0\pi^0$, $\pi e\nu$, and $\pi\mu\nu$. Input value of B($K^0_S \to \pi^+\pi^-$) / B($K^0_S \to \pi^0\pi^0$) from AMBROSINO 06C is used. To derive $\Gamma(K^0_S \to \pi^+\mu\nu)$ / $\Gamma(K^0_S \to \pi^+e\nu)$, lepton universality is assumed, radiative corrections from ANDRE 04 are used, and phase space integrals are taken from KTeV, ALEXOPOULOS 04A. This branching fraction enters our fit via their $\Gamma(\pi^\pm e^\mp\nu_e)$ / $\Gamma(\pi^+\pi^-)$ branching ratio measurement.
[33] Uses the PDG 00 value for B($K^0_S \to \pi^+\pi^-$).

$\Gamma(\pi^\pm\mu^\mp\nu_\mu)/\Gamma_{total}$ Γ_9/Γ

The PDG 06 value below has not been measured but is computed to be 0.666 times the $K_S \to \pi^\pm e^\mp \nu_e$ branching fraction. It is included in the fit that constrains the four branching ratios $\pi^+\pi^-$, $\pi^0\pi^0$, $\pi e\nu$, and $\pi\mu\nu$ to sum to 1. This treatment, used by AMBROSINO 06E, is preferable to our previous practice of constraining the $\pi^+\pi^-$ and $\pi^0\pi^0$ modes to sum to 1. The 0.666 factor is obtained from AMBROSINO 06E and assumes lepton universality, radiative corrections from ANDRE 04, and phase space integrals from KTeV, ALEXOPOULOS 04A.

[38] Background estimate is $0.22^{+0.18}_{-0.11}$ events. Branching ratio assumes a vector matrix element and unit form factor.

K^0_S FORM FACTORS

For discussion, see note on $K_{\ell 3}$ form factors in the $K^\pm$ section of the Particle Listings above. Because the semileptonic branching fraction is smaller in K^0_S than K^0_L by the ratio of the mean lives, the K^0_S semileptonic form factor has so far been measured only in the K_{e3} mode using the linear expansion $f_+(t) = f_+(0)\ (1 + \lambda_+ t\ /m^2_{\pi^+})$, which gives the vector form factor $f_+(t)$ relative to its value at $t = 0$.

CP VIOLATION IN $K_S \to 3\pi$

Written 1996 by T. Nakada (Paul Scherrer Institute) and L. Wolfenstein (Carnegie-Mellon University).

The possible final states for the decay $K^0 \to \pi^+\pi^-\pi^0$ have isospin I = 0, 1, 2, and 3. The I = 0 and I = 2 states have CP = +1 and K_S can decay into them without violating CP symmetry, but they are expected to be strongly suppressed by centrifugal barrier effects. The I = 1 and I = 3 states, which

have no centrifugal barrier, have $CP = -1$ so that the K_S decay to these requires CP violation.

In order to see CP violation in $K_S \to \pi^+\pi^-\pi^0$, it is necessary to observe the interference between K_S and K_L decay, which determines the amplitude ratio

$$\eta_{+-0} = \frac{A(K_S \to \pi^+\pi^-\pi^0)}{A(K_L \to \pi^+\pi^-\pi^0)} \ . \qquad (1)$$

If η_{+-0} is obtained from an integration over the whole Dalitz plot, there is no contribution from the $I = 0$ and $I = 2$ final states and a nonzero value of η_{+-0} is entirely due to CP violation.

Only $I = 1$ and $I = 3$ states, which are $CP = -1$, are allowed for $K^0 \to \pi^0\pi^0\pi^0$ decays and the decay of K_S into $3\pi^0$ is an unambiguous sign of CP violation. Similarly to η_{+-0}, η_{000} is defined as

$$\eta_{000} = \frac{A(K_S \to \pi^0\pi^0\pi^0)}{A(K_L \to \pi^0\pi^0\pi^0)} \ . \qquad (2)$$

If one assumes that CPT invariance holds and that there are no transitions to $I = 3$ (or to nonsymmetric $I = 1$ states), it can be shown that

$$\eta_{+-0} = \eta_{000} = \epsilon + i\frac{\mathrm{Im}\ a_1}{\mathrm{Re}\ a_1} \ . \qquad (3)$$

With the Wu-Yang phase convention, a_1 is the weak decay amplitude for K^0 into $I = 1$ final states; ϵ is determined from CP violation in $K_L \to 2\pi$ decays. The real parts of η_{+-0} and η_{000} are equal to $\mathrm{Re}(\epsilon)$. Since currently-known upper limits on $|\eta_{+-0}|$ and $|\eta_{000}|$ are much larger than $|\epsilon|$, they can be interpreted as upper limits on $\mathrm{Im}(\eta_{+-0})$ and $\mathrm{Im}(\eta_{000})$ and so as limits on the CP-violating phase of the decay amplitude a_1.

CP-VIOLATION PARAMETERS IN K^0_S DECAY

$A_S = [\ \Gamma(K^0_S \to \pi^- e^+ \nu_e) - \Gamma(K^0_S \to \pi^+ e^- \bar{\nu}_e)\ ] \ /$ SUM

Such asymmetry violates CP. If CPT is assumed then $A_S = 2\,\mathrm{Re}(\epsilon)$.

<0.1	90	632	[43] BARMIN	83	HLBC	
<0.28	90		[44] GJESDAL	74B	SPEC	Indirect meas.

[43] BARMIN 83 find $\mathrm{Re}(\eta_{000}) = (-0.08 \pm 0.18)$ and $\mathrm{Im}(\eta_{000}) = (-0.05 \pm 0.27)$. Assuming CPT invariance they obtain the limit quoted above.

[44] GJESDAL 74B uses $K2\pi$, $K_{\mu 3}$, and K_{e3} decay results, unitarity, and CPT. Calculates $|(\eta_{000})| = 0.26 \pm 0.20$. We convert to upper limit.

$\mathrm{Im}(\eta_{000}) = \mathrm{Im}(A(K^0_S \to \pi^0\pi^0\pi^0)/A(K^0_L \to \pi^0\pi^0\pi^0))$

$K^0_S \to \pi^0\pi^0\pi^0$ violates CP conservation, in contrast to $K^0_S \to \pi^+\pi^-\pi^0$ which has a CP-conserving part.

$\mathbf{(-0.1 \pm 1.6) \times 10^{-2}}$ **OUR AVERAGE**					
$0.000 \pm 0.009 \pm 0.013$	4.9M	[45] LAI	05A	NA48	Assumes CPT
$-0.05 \pm 0.12 \pm 0.05$	17300	[46] ANGELOPO...	98B	CPLR	Assumes CPT

[45] LAI 05A assumes $\mathrm{Re}(\eta_{000}) = \mathrm{Re}(\epsilon) = 1.66 \times 10^{-3}$. The equivalent limit is $|\eta_{000}|_{CPT} < 0.025$ at 90% CL Without assuming CPT invariance, they obtain $\mathrm{Re}(\eta_{000}) = -0.002 \pm 0.011 \pm 0.015$ and $\mathrm{Im}(\eta_{000}) = -0.003 \pm 0.013 \pm 0.017$ with a statistical correlation coefficient of 0.77 and an overall correlation coefficient of 0.57 between imaginary and real part. The equivalent limit is $|\eta_{000}| < 0.045$ at 90% CL

[46] ANGELOPOULOS 98B assumes $\mathrm{Re}(\eta_{000}) = \mathrm{Re}(\epsilon) = 1.635 \times 10^{-3}$. Without assuming CPT invariance, they obtain $\mathrm{Re}(\eta_{000}) = 0.18 \pm 0.14 \pm 0.06$ and $\mathrm{Im}(\eta_{000}) = 0.15 \pm 0.20 \pm 0.03$.

$|\eta_{000}| = |A(K^0_S \to 3\pi^0)/A(K^0_L \to 3\pi^0)|$

A non-zero value violates CP invariance.

DECAY-PLANE ASYMMETRY IN $\pi^+\pi^- e^+ e^-$ DECAYS

This is the CP-violating asymmetry

$$A = \frac{N_{\sin\phi\cos\phi>0.0} - N_{\sin\phi\cos\phi<0.0}}{N_{\sin\phi\cos\phi>0.0} + N_{\sin\phi\cos\phi<0.0}}$$

where ϕ is the angle between the e^+e^- and $\pi^+\pi^-$ planes in the K^0_S rest frame.

CP asymmetry A in $K^0_S \to \pi^+\pi^- e^+ e^-$

K^0_L

$I(J^P) = \frac{1}{2}(0^-)$

$m_{K^0_L} - m_{K^0_S}$

For earlier measurements, beginning with GOOD 61 and FITCH 61, see our 1986 edition, Physics Letters **170B** 132 (1986).

OUR FIT is described in the note on "*CP* violation in K_L decays" in the K^0_L Particle Listings. The result labeled "OUR FIT Assuming *CPT*" ["OUR FIT Not assuming *CPT*"] includes all measurements except those with the comment "Not assuming *CPT*" ["Assuming *CPT*"]. Measurements with neither comment do not assume *CPT* and enter both fits.

[1] ALAVI-HARATI 03 fit Δm and $\tau_{K^0_S}$ simultaneously. ϕ_{+-} is constrained to the Superweak value, i.e. *CPT* is assumed. See "K^0_S Mean Life" section for correlation information.

[2] The two ALAVI-HARATI 03 values use the same data. The first enters the "Assuming *CPT*" fit and the second enters the "Not assuming *CPT*" fit. They use 40–160 GeV K beams.

[3] ALAVI-HARATI 03 fit Δm, ϕ_{+-}, and τ_{K_S} simultaneously. See ϕ_{+-} in the "K_L *CP* violation" section for correlation information.

[4] Fits Δm and ϕ_{+-} simultaneously. GIBBONS 93C systematic error is from B. Winstein via private communication. 20–160 GeV K beams.

[5] GIBBONS 93 value assume $\phi_{+-} = \phi_{00} = \phi_{SW} = (43.7 \pm 0.2)^\circ$, i.e. assumes *CPT*. 20–160 GeV K beams.

[6] These two experiments have a common systematic error due to the uncertainty in the momentum scale, as pointed out in WAHL 89.

[7] GJESDAL 74 uses charge asymmetry in $K^0_{\ell 3}$ decays.

[8] ANGELOPOULOS 01 uses strong interactions strangeness tagging at two different times.

[9] Uses $\overline{K}^0_{e3}$ and K^0_{e3} strangeness tagging at production and decay. Assumes *CPT* conservation on $\Delta S = -\Delta Q$ transitions.

[10] ADLER 96C is the result of a fit which includes nearly the same data as entered into the "OUR FIT" value above.

[11] ARONSON 82 find that Δm may depend on the kaon energy.

[12] ARONSON 70 and CARNEGIE 71 use K^0_S mean life = $(0.862 \pm 0.006) \times 10^{-10}$ s. We have not attempted to adjust these values for the subsequent change in the K^0_S mean life or in η_{+-}.

K^0_L MEAN LIFE

5.092±0.017±0.025	15M	AMBROSINO	05C	KLOE	
5.154±0.044	0.4M	VOSBURGH	72	CNTR	
• • • We do not use the following data for averages, fits, limits, etc. • • •					
5.15 ±0.14		DEVLIN	67	CNTR	

[13] AMBROSINO 06 uses $\phi \to K_L K_S$ with K_L tagged by $K_S \to \pi^+\pi^-$. The four major K_L BR's are measured, the small remainder ($\pi^+\pi^-$,$\pi^0\pi^0$,$\gamma\gamma$) is taken from PDG 04. This KLOE K_L lifetime is obtained by imposing $\sum_i B_i = 1$. The correlation matrix among the four measured K_L BR's and this K_L lifetime is

	K_{e3}	$K_{\mu 3}$	$3\pi^0$	$\pi^+\pi^-\pi^0$	τ_{K_L}
K_{e3}	1	−0.25	−0.56	−0.07	0.25
$K_{\mu 3}$		1	−0.43	−0.20	0.33
$3\pi^0$			1	−0.39	−0.21
$\pi^+\pi^-\pi^0$				1	−0.39
τ_{K_L}					1

These correlations are taken into account in our fit. The average of this KLOE mean life measurement and the independent KLOE measurement in AMBROSINO 05C is (5.084 ± 0.023) × 10^{-8} s.

Γ_{32}	$\pi^0\mu^\pm e^\mp$	*LF*	[a] $<$	6.2×10^{-9}		CL=90%

[a] The value is for the sum of the charge states or particle/antiparticle states indicated.

[b] Most of this radiative mode, the low-momentum γ part, is also included in the parent mode listed without γ's.

[c] See the Particle Listings below for the energy limits used in this measurement.

[d] Allowed by higher-order electroweak interactions.

[e] Violates *CP* in leading order. Test of direct *CP* violation since the indirect *CP*-violating and *CP*-conserving contributions are expected to be suppressed.

CONSTRAINED FIT INFORMATION

An overall fit to the mean life and 10 branching ratios uses 17 measurements and one constraint to determine 8 parameters. The overall fit has a $\chi^2 = 14.8$ for 10 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

V_{ud}, V_{us}, THE CABIBBO ANGLE, AND CKM UNITARITY

Written October 2005 by E. Blucher (Univ. of Chicago) and W.J. Marciano (BNL)

The Cabibbo-Kobayashi-Maskawa (CKM) [1,2] three-generation quark mixing matrix written in terms of the Wolfenstein parameters (λ, A, ρ, η) [3] nicely illustrates the orthonormality constraint of unitarity and central role played by λ.

$$V_{CKM} = \begin{pmatrix} V_{ud} & V_{us} & V_{ub} \\ V_{cd} & V_{cs} & V_{cb} \\ V_{td} & V_{ts} & V_{tb} \end{pmatrix}$$

$$= \begin{pmatrix} 1-\lambda^2/2 & \lambda & A\lambda^3(\rho - i\eta) \\ -\lambda & 1-\lambda^2/2 & A\lambda^2 \\ A\lambda^3(1-\rho-i\eta) & -A\lambda^2 & 1 \end{pmatrix} + \mathcal{O}(\lambda^4) \quad (1)$$

That cornerstone is a carryover from the two-generation Cabibbo angle, $\lambda = sin(\theta_{\text{Cabibbo}}) = V_{us}$. Its value is a critical ingredient in determinations of the other parameters and in tests of CKM unitarity.

Unfortunately, the precise value of λ has been somewhat controversial in the past, with kaon decays suggesting [4] $\lambda \simeq 0.220$ while hyperon decays [5] and indirect determinations via nuclear β-decays imply a somewhat larger $\lambda \simeq 0.225 - 0.230$. That discrepancy is often discussed in terms of a deviation from the unitarity requirement

$$|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 1. \quad (2)$$

For many years, using a value of V_{us} derived from $K \to \pi e\nu$ (K_{e3}) decays, that sum was consistently 2–2.5 sigma below unity, a potential signal [6] for new physics effects. Below, we discuss the current status of V_{ud}, V_{us}, and their associated unitarity test in Eq. (2). (Since $|V_{ub}|^2 \simeq 1\times10^{-5}$ is negligibly small, it is ignored in this discussion.)

V_{ud}

The value of V_{ud} has been obtained from superallowed nuclear, neutron, and pion decays. Currently, the most precise determination of V_{ud} comes from superallowed nuclear beta-decays [6] ($0^+ \to 0^+$ transitions). Measuring their half-lives, t, and Q values which give the decay rate factor, f, leads to a precise determination of V_{ud} via the master formula [7–9]

$$|V_{ud}|^2 = \frac{2984.48(5)\,\text{sec}}{ft(1+\text{RC})} \quad (3)$$

where RC denotes the entire effect of electroweak radiative corrections, nuclear structure, and isospin violating nuclear effects. RC is nucleus dependent, ranging from about +3.1% to +3.6% for the nine best measured superallowed decays. In Table 1, we give the ft values along with their implied V_{ud} for the nine best measured superallowed decays [6, 10]. They collectively give a weighted average (with errors combined in quadrature) of

$$V_{ud} = 0.97377(27)\ \text{(superallowed)} \quad (4)$$

which, assuming unitarity, corresponds to $\lambda = 0.2275(12)$. We note, however, that a recent remeasurement [10] of the ^{46}V Q value has significantly affected its ft and V_{ud} values, with the latter now about 2.7 sigma below the average. That recent shift may point to a potential problem with the Q values and ft values of the other superallowed beta decays. Remeasurement of all Q values using modern atomic trapping techniques is called for and in progress.

Combined measurements of the neutron lifetime, τ_n, and the ratio of axial-vector/vector couplings, $g_A \equiv G_A/G_V$, via neutron decay asymmetries can also be used to determine V_{ud}:

$$|V_{ud}|^2 = \frac{4908.7(1.9)\text{sec}}{\tau_n(1+3g_A^2)}, \quad (5)$$

where the error stems from uncertainties in the electroweak radiative corrections [8] due to hadronic loop effects. Those effects have been recently updated and their error was reduced by about a factor of 2 [9], leading to a ±0.0002 theoretical uncertainty in V_{ud} (common to all V_{ud} extractions). Using the world averages from this *Review*

$$\tau_n^{\text{ave}} = 885.7(8)\text{sec}$$
$$g_A^{\text{ave}} = 1.2695(29) \quad (6)$$

leads to

$$V_{ud} = 0.9746(4)_{\tau_n}(18)_{g_A}(2)_{\text{RC}} \quad (7)$$

Table 1: Values of V_{ud} implied by various precisely measured superallowed nuclear beta decays. The ft values are taken from a recent update by Savard et al. [10]. Uncertainties in V_{ud} correspond to 1) nuclear structure and $Z^2\alpha^3$ uncertainties [6, 11] added in quadrature with the ft error, 2) a common error assigned to nuclear Coulomb distortion effects [11], and 3) a common uncertainty in the radiative corrections from quantum loop effects [9]. Only the first error is used to obtain the weighted average.

Nucleus	ft (sec)	V_{ud}
^{10}C	3039.5(47)	0.97381(77)(15)(19)

Weighted Ave.		0.97377(11)(15)(19)

with the error dominated by g_A uncertainties (which have been expanded due to experimental inconsistencies). We note that a recent precise measurement [12] of $\tau_n = 878.5(7)(3)$ sec is also inconsistent with the world average from this *Review* and would lead to a considerably larger $V_{ud} = 0.9786(4)(18)(2)$. Future neutron studies are expected to resolve these inconsistencies and significantly reduce the uncertainties in g_A and τ_n, potentially making them the best way to determine V_{ud}.

The recently completed PIBETA experiment at PSI measured the very small ($\mathcal{O}(10^{-8})$) branching ratio for $\pi^+ \to \pi^o e^+ \nu_e$ with about $\pm 1/2\%$ precision. Their result gives [13]

$$V_{ud} = 0.9749(26) \left[\frac{BR(\pi^+ \to e^+ \nu_e(\gamma))}{1.2352 \times 10^{-4}} \right]^{\frac{1}{2}} \quad (8)$$

which is normalized using the very precisely determined theoretical prediction for $BR(\pi^+ \to e^+ \nu_e(\gamma)) = 1.2352(5) \times 10^{-4}$ [7] rather than the experimental branching ratio from this *Review* of $1.230(4) \times 10^{-4}$ which would lower the value to $V_{ud} = 0.9728(30)$. Theoretical uncertainties in that determination are very small; however, much higher statistics would be required to make this approach competitive with others.

V_{us}

$|V_{us}|$ may be determined from kaon decays, hyperon decays, and tau decays. Previous determinations have most often used $K\ell 3$ decays:

$$\Gamma_{K\ell 3} = \frac{G_F^2 M_K^5}{192\pi^3} S_{EW} (1 + \delta_K^\ell + \delta_{SU2}) C^2 |V_{us}|^2 f_+^2(0) I_K^\ell. \quad (9)$$

Here, ℓ refers to either e or μ, G_F is the Fermi constant, M_K is the kaon mass, S_{EW} is the short-distance radiative correction, δ_K^ℓ is the mode-dependent long-distance radiative correction, $f_+(0)$ is the calculated form factor at zero momentum transfer for the $\ell\nu$ system, and I_K^ℓ is the phase-space integral, which depends on measured semileptonic form factors. For charged kaon decays, δ_{SU2} is the deviation from one of the ratio of $f_+(0)$ for the charged to neutral kaon decay; it is zero for the neutral kaon. C^2 is 1 (1/2) for neutral (charged) kaon decays. Previous PDG determinations of $|V_{us}|$ have been based only on $K \to \pi e \nu$ decays; $K \to \pi \mu \nu$ decays have not been used because of large uncertainties in I_K^μ. The experimental measurements are the semileptonic decay widths (based on the semileptonic branching fractions and lifetime) and form factors (allowing calculation of the phase space integrals). Theory is needed for S_{EW}, δ_K^ℓ, δ_{SU2}, and $f_+(0)$. These experimental and theoretical inputs are discussed in the following paragraphs.

Branching Fractions. Recent measurements of the $K \to \pi e \nu$ branching fractions are significantly different from previous PDG averages, probably as a result of inadequate treatment of radiation in older experiments. We therefore choose to base averages on recent measurements where the treatment of radiation is clear.

For the K_L branching fractions, we consider the following experimental inputs:

- KTeV measured the following 5 partial width ratios [14, 15]: $\Gamma(K_L \to \pi^\pm \mu^\mp \nu)/\Gamma(K_L \to \pi^\pm e^\mp \nu)$, $\Gamma(K_L \to \pi^+\pi^-\pi^0)/\Gamma(K_L \to \pi^\pm e^\mp \nu)$, $\Gamma(K_L \to \pi^0\pi^0\pi^0)/\Gamma(K_L \to \pi^\pm e^\mp \nu)$, $\Gamma(K_L \to \pi^+\pi^-)/\Gamma(K_L \to \pi^\pm e^\mp \nu)$, and $\Gamma(K_L \to \pi^0\pi^0)/\Gamma(K_L \to \pi^0\pi^0\pi^0)$. Since the six decay modes listed above account for more than 99.9% of the total decay rate, the five partial width ratios may be converted into measurements of the branching fractions for the six decay modes.
- KLOE uses a tagged K_L sample to measure the 4 largest K_L branching fractions [16].
- NA48 measures the following 2 ratios: $\Gamma_{Ke3}/\Gamma(2\ track)$ [17] and $\Gamma_{000}/\Gamma(K_S \to \pi^0\pi^0)$ [18]. These ratios may be used to determine $B(K_{e3})$.

A fit to all of these measurements, accounting for correlations, gives the K_L semileptonic branching fractions in Table 2. Figure 1 shows a comparison of the new experimental measurements, the best fit values, and the 2002 PDG fit values [19]. Note that the new measurements are consistent with each other, but are shifted significantly from the PDG fit.

Table 2: Average K_L semileptonic branching fractions and widths based on fit to new measurements from KTeV, KLOE, and NA48. The partial width measurements use the average K_L lifetime quoted in Table 3.

Decay Mode	Branching fraction	Γ_i ($10^7 s^{-1}$)
$K_L \to \pi^\pm e^\mp \nu$	0.4040 ± 0.0008	0.7908 ± 0.0032
$K_L \to \pi^\pm \mu^\mp \nu$	0.2699 ± 0.0008	0.5283 ± 0.0023

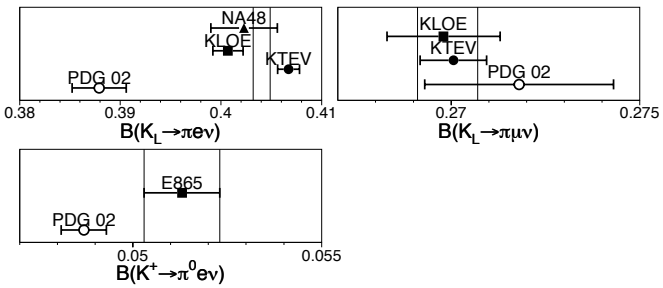

Figure 1: Recent $K_L \to \pi e\nu$, $K_L \to \pi\mu\nu$, and $K^\pm \to \pi^0 e^\pm \nu$ branching fraction measurements (solid points) compared to PDG 2002 fit (open circles). The vertical lines indicate the $\pm 1\sigma$ bounds from a fit to all recent measurements (from KTeV, KLOE, NA48, and E865).

For $K_S \to \pi e\nu$, we use the new KLOE measurement [20]: $B(K_S \to \pi e\nu) = (7.06 \pm 0.06 \pm 0.04) \times 10^{-4}$.

For $K^\pm \to \pi^0 e^\pm \nu$, we use the BNL E865 [21] measurement of $B(K^\pm \to \pi^0 e^\pm \nu) = (5.13 \pm 0.1)\%$. Preliminary measurements from NA48, KLOE, and ISTRA+ are consistent with this result.

Kaon Lifetime. KLOE has performed two new measurements of the K_L lifetime: one based on exploiting the lifetime dependence of the detector acceptance to find the K_L lifetime required to make the sum of branching fractions equal to 1 [16], and another based on the $K_L \to 3\pi^0$ decay distribution [22]. These new results and the old PDG average are listed in Table 3. The new average value, which we use for the results quoted below, is $\tau_L = (50.98 \pm 0.21) ns$.

Combining the K_L branching fractions with the new lifetime gives the partial decay widths quoted in Table 2. Note that correlations between the KLOE branching fractions and the "indirect" KLOE lifetime determination have been taken into account.

For the K_S and K^+ lifetimes, we use the PDG average values.

Table 3: K_L lifetime measurements.

Source	Lifetime (ns)
PDG 2004 Average	51.5 ± 0.4
KLOE (sum of branching fractions)	50.72 ± 0.37
KLOE ($3\pi^0$ distribution)	50.87 ± 0.31
New Average	50.98 ± 0.21

Phase Space Integrals. Recent experiments have also remeasured the semileptonic form factors needed to calculate the phase space integrals. These recent measurements of the semileptonic form factors are much more precise than previous averages, making it possible to use both the muon and electron decay modes for K_L.

We use the KTeV quadratic form factor results [23] for neutral kaon decays and the ISTRA+ quadratic form factor measurements [24] for charged kaons. For both charged and neutral decays, we include an additional 0.7% uncertainty in the phase space integrals, as suggested by KTeV [23], to account for differences between the quadratic and pole model form factor parametrizations, both of which give acceptable fits to the data. The resulting phase space integrals are $I^e_{K0} = 0.1535 \pm 0.0011$, $I^\mu_{K0} = 0.10165 \pm 0.0008$, and $I^e_{K+} = 0.1591 \pm 0.0012$.

Theoretical Inputs. We use the following theoretical inputs to calculate $f_+(0)|V_{us}|$ from Eq. (9).

- Short-distance radiative correction [7, 25]: $S_{EW} = 1.023$;
- Long-distance radiative corrections [26, 27]: $\delta^e_{K0} = 0.0104 \pm 0.002$, $\delta^\mu_{K0} = 0.019 \pm 0.003$, $\delta^e_{K+} = 0.0006 \pm 0.002$;
- SU2 breaking correction [26,28] $\delta_{SU2} = 0.046 \pm 0.004$.

$K_{\ell 3}$ results for $|V_{us}|$. Figure 2 shows a comparison of the PDG and the averages of recent measurements for $|V_{us}|f_+(0)$ for $K^\pm$, K_L, and K_S. The average of all recent measurements gives

$$f_+^{K^0\pi^-}(0)|V_{us}| = 0.2169 \pm 0.0009. \quad (10)$$

The figure also shows $f_+(0)(1 - |V_{ud}|^2 - |V_{ub}|^2)^{1/2}$, the expectation for $f_+(0)|V_{us}|$ assuming unitarity, based on $|V_{ud}| = 0.9738 \pm 0.0003$, $|V_{ub}| = (3.6 \pm 0.7) \times 10^{-3}$, and the Leutwyler-Roos calculation of $f_+(0) = 0.961 \pm 0.008$ [28]. Using the result in Eq. (10) with the Leutwyler-Roos calculation of $f_+(0)$ gives

$$|V_{us}| = \lambda = 0.2257 \pm 0.0021. \quad (11)$$

A similar result for $f_+(0)$ was recently obtained from a quenched lattice gauge theory calculation [29]. Other calculations of $f_+(0)$ result in $|V_{us}|$ values that differ by as much as 2% from the result in Eq. (11). For example, a recent chiral perturbation theory calculation [30, 31] gives $f_+(0) = 0.974 \pm 0.012$, which implies a lower value of $|V_{us}| = 0.2227 \pm 0.0029$ [32].

A value of V_{us} can also be obtained from a comparison of the radiative inclusive decay rates for $K \to \mu\nu(\gamma)$ and $\pi \to \mu\nu(\gamma)$ combined with a lattice gauge theory calculation of f_K/f_π via [33]

$$\frac{|V_{us}|f_K}{|V_{ud}|f_\pi} = 0.2387(4) \left[\frac{\Gamma(K \to \mu\nu(\gamma))}{\Gamma(\pi \to \mu\nu(\gamma))}\right]^{\frac{1}{2}} \quad (12)$$

with the small error coming from electroweak radiative corrections. Employing

$$\frac{\Gamma(K \to \mu\nu(\gamma))}{\Gamma(\pi \to \mu\nu(\gamma))} = 1.3383(46), \quad (13)$$

which incorporates the KLOE result [34], $B(K \to \mu\nu(\gamma)) = 63.66(9)(15)\%$ and [35, 36]

$$f_K/f_\pi = 1.198(3)(+16/-5) \quad (14)$$

along with the value of V_{ud} in Eq. (4) leads to

$$|V_{us}| = 0.2245(5)(1.198 f_\pi/f_K). \quad (15)$$

It should be mentioned that hyperon decay fits suggest [5]

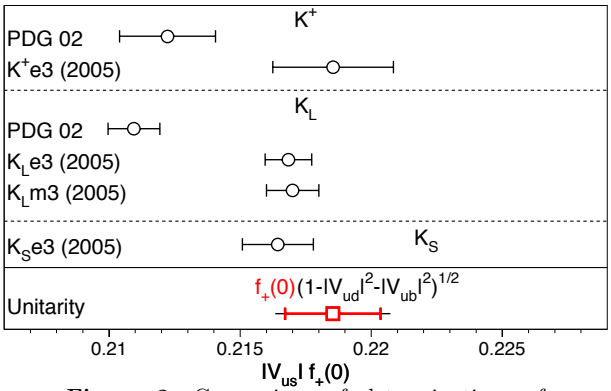

Figure 2: Comparison of determinations of $|V_{us}|f_+(0)$ from this review (labeled 2005), from the PDG 2002, and with the prediction from unitarity using $|V_{ud}|$ and the Leutwyler-Roos calculation of $f_+(0)$ [28]. For $f_+(0)(1-|V_{ud}|^2-|V_{ub}|^2)^{1/2}$, the inner error bars are from the quoted uncertainty in $f_+(0)$; the total uncertainties include the $|V_{ud}|$ and $|V_{ub}|$ errors. See full-color version on color pages at end of book.

$$|V_{us}| = 0.2250(27) \text{ Hyperon Decays} \tag{16}$$

modulo SU(3) breaking effects that could shift that value up or down. We note that a recent representative effort [37] that incorporates SU(3) breaking found $V_{us} = 0.226(5)$. Similarly, strangeness changing tau decays give [38]

$$|V_{us}| = 0.2208(34) \text{ Tau Decays} \tag{17}$$

where the central value depends on the strange quark mass.

Employing the value of V_{ud} in Eq. (4) and V_{us} in Eq. (11) leads to the unitarity consistency check

$$|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 0.9992(5)(9), \tag{18}$$

where the first error is the uncertainty from $|V_{ud}|^2$ and the second error is the uncertainty from $|V_{us}|^2$. The result is in good agreement with unitarity. Averaging the direct determination of λ (V_{us}) with the determination derived from unitarity and V_{ud} gives $\lambda = 0.227(1)$. Although unitarity now seems well established, issues regarding the Q values in superallowed nuclear β-decays, $\tau_n, g_A, f_+(0)$ and f_K/f_π must still be resolved before a definitive confirmation is possible.

LINEAR COEFFICIENT J FOR $K^0_L \to \pi^+\pi^-\pi^0$ (*CP*-VIOLATING TERM)

Listed in *CP*-violation section below.

QUADRATIC COEFFICIENT f FOR $K^0_L \to \pi^+\pi^-\pi^0$ (*CP*-VIOLATING TERM)

Listed in *CP*-violation section below.

QUADRATIC COEFFICIENT h FOR $K^0_L \to \pi^0\pi^0\pi^0$

VALUE (units 10^{-3})	EVTS	DOCUMENT ID		TECN
−5.0±1.4 OUR AVERAGE		Error includes scale factor of 1.7.		
−6.1±0.9±0.5	14.7M	LAI	01B	NA48
−3.3±1.1±0.7	5M	[71] SOMALWAR	92	E731

[71] SOMALWAR 92 chose m_{π^+} as normalization to make it compatible with the Particle Data Group $K^0_L \to \pi^+\pi^-\pi^0$ definitions.

K^0_L FORM FACTORS

For discussion, see note on form factors in the $K^\pm$ section of the Particle Listings above.

In the form factor comments, the following symbols are used.

f_+ and f_- are form factors for the vector matrix element.
f_S and f_T refer to the scalar and tensor term.
$f_0 = f_+ + f_- \, t/(m^2_{K^0} - m^2_{\pi^+})$.
t = momentum transfer to the π.
λ_+ and λ_0 are the linear expansion coefficients of f_+ and f_0:
$f_+(t) = f_+(0)\,(1 + \lambda_+ t\,/m^2_{\pi^+})$
For quadratic expansion
$f_+(t) = f_+(0)\,(1 + \lambda'_+ t\,/m^2_{\pi^+} + \frac{\lambda''_+}{2}\, t^2/m^4_{\pi^+})$
as used by KTeV. If there is a non-vanishing quadratic term, then λ_+ represents an average slope, which is then different from λ'_+.
NA48 and ISTRA quadratic expansion coefficients are converted with
$\lambda'_+{}^{PDG} = \lambda_+{}^{NA48}$ and $\lambda''_+{}^{PDG} = 2\,\lambda'_+{}^{NA48}$
$\lambda'_+{}^{PDG} = (\frac{m_{\pi^+}}{m_{\pi^0}})^2\,\lambda_+{}^{ISTRA}$ and
$\lambda''_+{}^{PDG} = 2\,(\frac{m_{\pi^+}}{m_{\pi^0}})^4\,\lambda'_+{}^{ISTRA}$
ISTRA linear expansion coefficients are converted with
$\lambda_+{}^{PDG} = (\frac{m_{\pi^+}}{m_{\pi^0}})^2\,\lambda_+{}^{ISTRA}$ and $\lambda_0{}^{PDG} = (\frac{m_{\pi^+}}{m_{\pi^0}})^2\,\lambda_0{}^{ISTRA}$
The pole parametrization is
$f_+(t) = f_+(0)\,(\frac{M_V^2}{M_V^2 - t})$
$f_0(t) = f_0(0)\,(\frac{M_S^2}{M_S^2 - t})$
where M_V and M_S are the vector and scalar pole masses.
The following abbreviations are used:
DP = Dalitz plot analysis.
PI = π spectrum analysis.
MU = μ spectrum analysis.
POL= μ polarization analysis.
BR = $K^0_{\mu 3}/K^0_{e3}$ branching ratio analysis.
E = positron or electron spectrum analysis.
RC = radiative corrections.

λ_+ (LINEAR ENERGY DEPENDENCE OF f_+ IN K^0_{e3} DECAY)

For radiative correction of K^0_{e3} DP, see GINSBERG 67, BECHERRAWY 70, CIRIGLIANO 02, CIRIGLIANO 04, and ANDRE 04. Results labeled OUR FIT are discussed in the review "$K^\pm_{\ell 3}$ and $K^0_{\ell 3}$ Form Factors" in the $K^\pm$ Listings. For earlier, lower statistics results, see the 2004 edition of this review, Phys. Lett. B592, 1 (2004).

$\alpha^{\rm eff}_{K^*}$ DECAY FORM FACTOR FOR $K_L \to e^+e^-e^+e^-$

$\alpha^{\rm eff}_{K^*}$ is the parameter describing the relative strength of an intermediate pseudoscalar decay amplitude and a vector meson decay amplitude in the model of BERGSTROM 83. It takes into account both the radiative effects and the form factor. Since there are two e^+e^- pairs here compared with one in $e^+e^-\gamma$ decays, a factorized expression is used for the $e^+e^-e^+e^-$ decay form factor.

CP VIOLATION IN K_L DECAYS

Revised May 2006 by L. Wolfenstein (Carnegie-Mellon University) and T.G. Trippe (LBNL).

The symmetries C (particle-antiparticle interchange) and P (space inversion) hold for strong and electromagnetic interactions. After the discovery of large C and P violation in the weak interactions, it appeared that the product CP was a good symmetry. In 1964 CP violation was observed in K^0 decays at a level given by the parameter $\epsilon \approx 2.3 \times 10^{-3}$.

A unified treatment of CP violation in K, D, B, and B_s mesons is given in "CP Violation in Meson Decays" by D. Kirkby and Y. Nir in this *Review*. A more detailed review including a thorough discussion of the experimental techniques used to determine CP violation parameters is given in a book

by K. Kleinknecht [1]. Here we give a concise summary of the formalism needed to define the parameters of CP violation in K_L decays and a description of our fits for the best values of these parameters.

1. Formalism for CP violation in Kaon decay:

CP violation has been observed in the semi-leptonic decays $K_L^0 \to \pi^\mp \ell^\pm \nu$ and in the nonleptonic decay $K_L^0 \to 2\pi$. The experimental numbers that have been measured are

$$A_L = \frac{\Gamma(K_L^0 \to \pi^- \ell^+ \nu) - \Gamma(K_L^0 \to \pi^+ \ell^- \nu)}{\Gamma(K_L^0 \to \pi^- \ell^+ \nu) + \Gamma(K_L^0 \to \pi^+ \ell^- \nu)} \quad (1a)$$

$$\eta_{+-} = A(K_L^0 \to \pi^+\pi^-)/A(K_S^0 \to \pi^+\pi^-) = |\eta_{+-}|\, e^{i\phi_{+-}} \quad (1b)$$

$$\eta_{00} = A(K_L^0 \to \pi^0\pi^0)/A(K_S^0 \to \pi^0\pi^0) = |\eta_{00}|\, e^{i\phi_{00}} \ . \quad (1c)$$

CP violation can occur either in the K^0–$\overline{K}^0$ mixing or in the decay amplitudes. Assuming CPT invariance, the mass eigenstates of the K^0–$\overline{K}^0$ system can be written

$$|K_S\rangle = p|K^0\rangle + q|\overline{K}^0\rangle \ , \qquad |K_L\rangle = p|K^0\rangle - q|\overline{K}^0\rangle \ . \quad (2)$$

If CP invariance held, we would have $q = p$ so that K_S would be CP even and K_L CP odd. (We define $|\overline{K}^0\rangle$ as CP $|K^0\rangle$). CP violation in K^0–$\overline{K}^0$ mixing is then given by the parameter $\widetilde{\epsilon}$ where

$$\frac{p}{q} = \frac{(1+\widetilde{\epsilon})}{(1-\widetilde{\epsilon})} \ . \quad (3)$$

CP violation can also occur in the decay amplitudes

$$A(K^0 \to \pi\pi(I)) = A_I e^{i\delta_I} \ , \qquad A(\overline{K}^0 \to \pi\pi(I)) = A_I^* e^{i\delta_I} \ , \quad (4)$$

where I is the isospin of $\pi\pi$, δ_I is the final-state phase shift, and A_I would be real if CP invariance held. The CP-violating observables are usually expressed in terms of ϵ and ϵ' defined by

$$\eta_{+-} = \epsilon + \epsilon' \ , \qquad \eta_{00} = \epsilon - 2\epsilon' \ , \quad (5a)$$

One can then show [2]

$$\epsilon = \widetilde{\epsilon} + i\ (\mathrm{Im}\ A_0/\mathrm{Re}\ A_0) \ , \quad (5b)$$

$$\sqrt{2}\epsilon' = ie^{i(\delta_2-\delta_0)}(\mathrm{Re}\, A_2/\mathrm{Re}\, A_0)\ (\mathrm{Im}\, A_2/\mathrm{Re}\, A_2 - \mathrm{Im}\, A_0/\mathrm{Re}\ A_0) \ , \quad (5c)$$

$$A_L = 2\mathrm{Re}\ \epsilon/(1+|\epsilon|^2) \approx 2\mathrm{Re}\ \epsilon \ . \quad (5d)$$

In Eqs. (5a) small corrections [3] of order $\epsilon' \times \mathrm{Re}\ (A_2/A_0)$ are neglected and Eq. (5d) assumes the $\Delta S = \Delta Q$ rule.

The quantities Im A_0, Im A_2, and Im $\widetilde{\epsilon}$ depend on the choice of phase convention since one can change the phases of K^0 and $\overline{K}^0$ by a transformation of the strange quark state $|s\rangle \to |s\rangle\ e^{i\alpha}$; of course, observables are unchanged. It is possible by a choice of phase convention to set Im A_0 or Im A_2 or Im $\widetilde{\epsilon}$ to zero, but none of these is zero with the usual phase conventions in the Standard Model. The choice Im $A_0 = 0$ is called the Wu-Yang phase convention [4] in which case $\epsilon = \widetilde{\epsilon}$. The value of ϵ' is independent of phase convention and a nonzero value demonstrates CP violation in the decay amplitudes, referred to as direct CP violation. The possibility that direct CP violation is essentially zero and that CP violation occurs only in the mixing matrix was referred to as the superweak theory [5].

By applying CPT invariance and unitarity the phase of ϵ is given approximately by

$$\phi_\epsilon \approx \tan^{-1}\frac{2(m_{K_L} - m_{K_S})}{\Gamma_{K_S} - \Gamma_{K_L}} \approx 43.51 \pm 0.05^\circ \quad (6a)$$

while Eq. (5c) gives the phase of ϵ' to be

$$\phi_{\epsilon'} = \delta_2 - \delta_0 + \frac{\pi}{2} \approx 42.3 \pm 1.5^\circ \ , \quad (6b)$$

where the numerical value is based on an analysis of π–π scattering using chiral perturbation theory [6]. The approximation in Eq. (6a) depends on the assumption that direct CP violation is very small in all K^0 decays. This is expected to be good to a few tenths of a degree as indicated by the small value of ϵ' and of η_{+-0} and η_{000}, the CP-violation parameters in the decays $K_S \to \pi^+\pi^-\pi^0$ [7] and $K_S \to \pi^0\pi^0\pi^0$ [8]. The relation in Eq. (6a) is exact in the superweak theory so this is sometimes called the superweak phase $\phi_{\rm SW}$. An important point for the analysis is that $\cos(\phi_{\epsilon'}-\phi_\epsilon) \simeq 1$. The consequence is that only two real quantities need be measured, the magnitude of ϵ and the value of (ϵ'/ϵ) including its sign. The measured quantity $|\eta_{00}/\eta_{+-}|^2$ is very close to unity so that we can write

$$|\eta_{00}/\eta_{+-}|^2 \approx 1 - 6\mathrm{Re}\ (\epsilon'/\epsilon) \approx 1 - 6\epsilon'/\epsilon \ . \quad (7a)$$

$$\mathrm{Re}(\epsilon'/\epsilon) \approx \tfrac{1}{3}(1 - |\eta_{00}/\eta_{+-}|) \ . \quad (7b)$$

From the experimental measurements in this Edition of the *Review of Particle Physics* and the fits discussed in the next section, one finds

$$|\epsilon| = (2.232 \pm 0.007) \times 10^{-3} \ , \quad (8a)$$

$$\phi_\epsilon = (43.5 \pm 0.7)^\circ \ , \quad (8b)$$

$$\mathrm{Re}(\epsilon'/\epsilon) \approx \epsilon'/\epsilon = (1.66 \pm 0.26) \times 10^{-3} \ , \quad (8c)$$

$$\phi_{+-} = (43.4 \pm 0.7)^\circ \ , \quad (8d)$$

$$\phi_{00} - \phi_{+-} = (0.2 \pm 0.4)^\circ \ , \quad (8e)$$

$$A_L = (3.32 \pm 0.06) \times 10^{-3} \ . \quad (8f)$$

Direct CP violation, as indicated by ϵ'/ϵ, is expected in the Standard Model. However the numerical value cannot be reliably predicted because of theoretical uncertainties [9]. The value of A_L agrees with Eq. (5d). The values of ϕ_{+-} and $\phi_{00} - \phi_{+-}$ are used to set limits on CPT violation. [See Tests of Conservation Laws.]

2. Fits for K_L^0 CP-violation parameters:

In recent years, K_L^0 CP-violation experiments have improved our knowledge of CP-violation parameters and their consistency with the expectations of CPT invariance and unitarity. To determine the best values of the CP-violation parameters in $K_L^0 \to \pi^+\pi^-$ and $\pi^0\pi^0$ decay, we make two types of fits, one for the phases ϕ_{+-} and ϕ_{00} jointly with Δm and τ_S,

See key on page 347

and the other for the amplitudes $|\eta_{+-}|$ and $|\eta_{00}|$ jointly with the $K_L^0 \to \pi\pi$ branching fractions.

Fits to ϕ_{+-}, ϕ_{00}, $\Delta\phi$, Δm, and τ_S data: These are joint fits to the data on ϕ_{+-}, ϕ_{00}, the phase difference $\Delta\phi = \phi_{00} - \phi_{+-}$, the $K_L^0 - K_S^0$ mass difference Δm, and the K_S^0 mean life τ_S, including the effects of correlations.

Measurements of ϕ_{+-} and ϕ_{00} are highly correlated with Δm and τ_S. Some measurements of τ_S are correlated with Δm. The correlations are given in the footnotes of the ϕ_{+-} and ϕ_{00} sections of the K_L^0 Particle Listings and the τ_S section of the K_S^0 Particle listings.

In most cases, the correlations are quoted as 100%, *i.e.*with the value and error of ϕ_{+-} or ϕ_{00} given at a fixed value of Δm and τ_S with additional terms specifying the dependence of the value on Δm and τ_S. These cases lead to diagonal bands in Figs. [1] and [2]. The KTeV experiment [10] quotes its results as values of ϕ_{+-}, Δm, and τ_S with correlations, leading to the ellipses labeled "b".

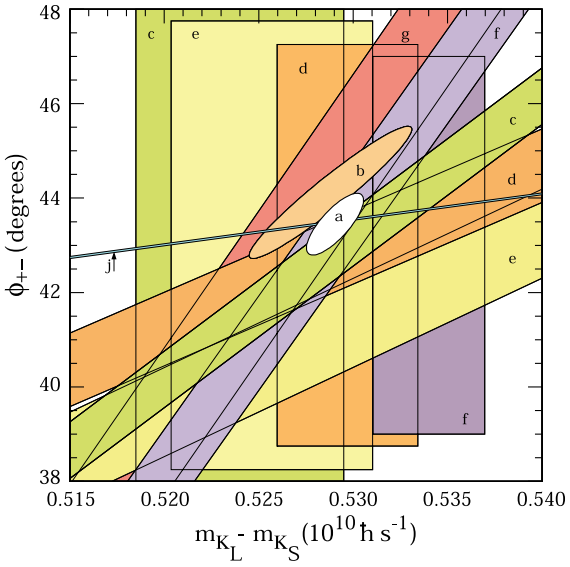

Figure 1: ϕ_{+-} vs Δm for experiments which do not assume CPT invariance. Δm measurements appear as vertical bands spanning $\Delta m \pm 1\sigma$, cut near the top and bottom to aid the eye. Most ϕ_{+-} measurements appear as diagonal bands spanning $\phi_{+-} \pm \sigma_\phi$. Data are labeled by letters: "b"–FNAL KTeV, "c"–CERN CPLEAR, "d"–FNAL E773, "e"–FNAL E731, "f"–CERN, "g"–CERN NA31, and are cited in Table 1. The narrow band "j" shows ϕ_{SW}. The ellipse "a" shows the $\chi^2 = 1$ contour of the fit result. See full-color version on color pages at end of book.

Table 1: References, Document ID's, and sources corresponding to the letter labels in the figures. The data are given in the ϕ_{+-} and Δm sections of the K_L Particle Listings, and the τ_S section of the K_S Particle Listings.

j	this review	SUPERWEAK 04	

The data on τ_S, Δm, and ϕ_{+-} shown in Figs. [1] and [2]. are combined with data on ϕ_{00} and $\phi_{00} - \phi_{+-}$ in two fits, one without assuming CPT and the other with this assumption. The results without assuming CPT are shown as ellipses labeled "a". These ellipses are seen to be in good agreement with the superweak phase

$$\phi_{SW} = \tan^{-1}\left(\frac{2\Delta m}{\Delta\Gamma}\right) = \tan^{-1}\left(\frac{2\Delta m \tau_S \tau_L}{\hbar(\tau_L - \tau_S)}\right) . \qquad (9)$$

In Figs. [1] and [2], ϕ_{SW} is shown as narrow bands labeled "j".

Table 2 column 2, "Fit w/o CPT," gives the resulting fitted parameters, while Table 3 gives the correlation matrix for this fit. The white ellipses labeled "a" in Fig. 1 and Fig. 2 are the $\chi^2 = 1$ contours for this fit.

For experiments which have dependencies on unseen fit parameters, that is, parameters other than those shown on the x or y axis of the figure, their band positions are evaluated using the fit results and their band widths include the fitted uncertainty in the unseen parameters. This is also true for the ϕ_{SW} bands.

If CPT invariance and unitarity are assumed, then by Eq. (6*a*), the phase of ϵ is constrained to be approximately equal to

$$\phi_{SW} = (43.507 \pm 0.0004)^\circ + 54(\Delta m - 0.5290)^\circ + 32(\tau_S - 0.8958) \qquad (10)$$

where we have linearized the Δm and τ_S dependence of Eq. (9). The error ± 0.0004 is due to the uncertainty in τ_L. Here Δm has units $10^{10}\,\hbar\,s^{-1}$ and τ_S has units 10^{-10} s.

If in addition we use the observation that $Re(\epsilon'/\epsilon) \ll 1$ and $cos(\phi_{\epsilon'} - \phi_\epsilon) \simeq 1$, as well as the numerical value of $\phi_{\epsilon'} - \phi_\epsilon$ given in Eq. (6*b*), then Eqs. (5a), which are sketched in Fig. 3, lead to the constraint

$$\begin{aligned} \phi_{00} - \phi_{+-} &\approx -3\ \mathrm{Im}\left(\frac{\epsilon'}{\epsilon}\right) \\ &\approx -3\ \mathrm{Re}\left(\frac{\epsilon'}{\epsilon}\right)\tan(\phi_{\epsilon'} - \phi_\epsilon) \\ &\approx -0.023^\circ \pm 0.020^\circ \end{aligned} \qquad (11)$$

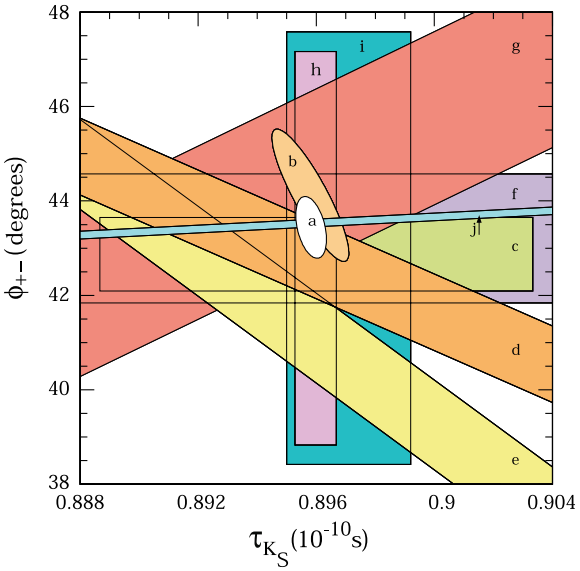

Figure 2: ϕ_{+-} vs τ_S. τ_S measurements appear as vertical bands spanning $\tau_S \pm 1\sigma$, some of which are cut near the top and bottom to aid the eye. Most ϕ_{+-} measurements appear as diagonal or horizontal bands spanning $\phi_{+-} \pm \sigma_\phi$. Data are labeled by letters: "b"–FNAL KTeV, "c"–CERN CPLEAR, "d"–FNAL E773, "e"–FNAL E731, "f"–CERN, "g"–CERN NA31, "h"–CERN NA48, "i"–CERN NA31, and are cited in Table 1. The narrow band "j" shows ϕ_{SW}. The ellipse "a" shows the fit result's $\chi^2 = 1$ contour. Color version at end of book.

so that $\phi_{+-} \approx \phi_{00} \approx \phi_\epsilon \approx \phi_{SW}$.

In the fit assuming CPT we constrain $\phi_\epsilon = \phi_{SW}$ using the linear expression in Eq. (10) and constrain $\phi_{00} - \phi_{+-}$ using Eq. (11). These constraints are inserted into the Data Listings with the Document ID of SUPERWEAK 04. Some additional data for which the authors assumed CPT are added to this fit or substitute for other less precise data for which the authors did not make this assumption. See the data listings for details.

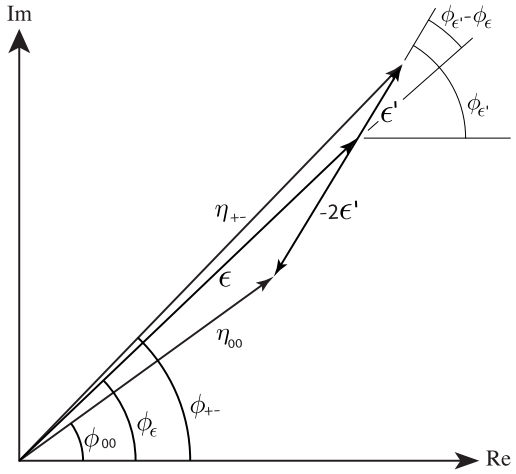

Figure 3: Sketch of Eqs. (5a). Not to scale.

The results of this fit are shown in Table 2, column 3, "Fit w/CPT," and the correlation matrix is shown in Table 4. The Δm precision is improved by the CPT assumption.

Table 2: Fit results for ϕ_{+-}, Δm, τ_S, ϕ_{00}, $\Delta\phi = \phi_{00} - \phi_{+-}$, and ϕ_ϵ without and with the CPT assumption.

Fits for ϵ'/ϵ, $|\eta_{+-}|$, $|\eta_{00}|$, and $\mathrm{B}(K_L \to \pi\pi)$

We list measurements of $|\eta_{+-}|$, $|\eta_{00}|$, $|\eta_{00}/\eta_{+-}|$ and ϵ'/ϵ. Independent information on $|\eta_{+-}|$ and $|\eta_{00}|$ can be obtained from measurements of the K_L^0 and K_S^0 lifetimes (τ_L, τ_S) and branching ratios (B) to $\pi\pi$, using the relations

$$|\eta_{+-}| = \left[\frac{\mathrm{B}(K_L^0 \to \pi^+\pi^-)}{\tau_L}\,\frac{\tau_S}{\mathrm{B}(K_S^0 \to \pi^+\pi^-)}\right]^{1/2}, \quad (12a)$$

$$|\eta_{00}| = \left[\frac{\mathrm{B}(K_L^0 \to \pi^0\pi^0)}{\tau_L}\,\frac{\tau_S}{\mathrm{B}(K_S^0 \to \pi^0\pi^0)}\right]^{1/2}. \quad (12b)$$

For historical reasons the branching ratio fits and the CP-violation fits are done separately, but we want to include the influence of $|\eta_{+-}|$, $|\eta_{00}|$, $|\eta_{00}/\eta_{+-}|$, and ϵ'/ϵ measurements on $B(K_L^0 \to \pi^+\pi^-)$ and $B(K_L^0 \to \pi^0\pi^0)$ and vice versa. We approximate a global fit to all of these measurements by first performing two independent fits: 1) BRFIT, a fit to the K_L^0 branching ratios, rates, and mean life, and 2) ETAFIT, a fit to the $|\eta_{+-}|$, $|\eta_{00}|$, $|\eta_{+-}/\eta_{00}|$, and ϵ'/ϵ measurements. The results from fit 1, along with the K_S^0 values from this edition are used to compute values of $|\eta_{+-}|$ and $|\eta_{00}|$ which are included as measurements in the $|\eta_{00}|$ and $|\eta_{+-}|$ sections with a document ID of BRFIT 06. Thus the fit values of $|\eta_{+-}|$ and $|\eta_{00}|$ given in this edition include both the direct measurements and the results from the branching ratio fit.

The process is reversed in order to include the direct $|\eta|$ measurements in the branching ratio fit. The results from fit 2 above (before including BRFIT 06 values) are used along with the K_L^0 and K_S^0 mean lives and the $K_S^0 \to \pi\pi$ branching fractions to compute the K_L^0 branching ratio $\Gamma(K_L^0 \to \pi^0\pi^0)/\Gamma(K_L^0 \to \pi^+\pi^-)$. This branching ratio value is included as a measurement in the branching ratio section with a document ID of ETAFIT 06. Thus the K_L^0 branching ratio fit values in this edition include the results of the direct measurement of $|\eta_{00}/\eta_{+-}|$ and ϵ'/ϵ. Most individual measurements of $|\eta_{+-}|$ and $|\eta_{00}|$ enter our fits directly via the corresponding measurements of $\Gamma(K_L^0 \to \pi^+\pi^-)/\Gamma(\text{total})$ and $\Gamma(K_L^0 \to \pi^0\pi^0)/\Gamma(\text{total})$ and those that do not have too large errors to have any influence on the fitted values of these branching ratios. A more detailed discussion of these fits is given in the 1990 edition of this *Review* [20].

In this 2006 edition of the *Review of Particle Physics*, the values of $|\epsilon|$, $|\eta_{+-}|$, and $|\eta_{00}|$ decrease significantly as a result of the high precision measurements of K_L^0 branching ratios from KTeV, KLOE, and NA48. These measurements reduce the branching ratio $\Gamma(K_L^0 \to \pi^+\pi^-)/\Gamma(\text{total})$ by 5.5 percent, a 4.6σ decrease relative to the 2004 edition [21]. The resulting BRFIT 06 value of $|\eta_{+-}|$ reduces the fitted value of $|\eta_{+-}|$ by 3.7σ. Earlier high precision measurements of ϵ'/ϵ constrain $|\eta_{00}|$ to be nearly equal to $|\eta_{+-}|$ and $\sim$100% correlated with it. Since to a very good approximation

$$|\epsilon| = \frac{2}{3}|\eta_{+-}| + \frac{1}{3}|\eta_{00}|, \qquad (13)$$

then $|\epsilon|$, $|\eta_{+-}|$, and $|\eta_{00}|$ are all approximately equal and $\sim$100% correlated with each other. Therefore they are all reduced by 3.7σ.

CP-VIOLATION PARAMETERS IN K_L^0 DECAYS

CHARGE ASYMMETRY IN $K_{\ell 3}^0$ DECAYS

Such asymmetry violates CP. It is related to $\mathrm{Re}(\epsilon)$.

A_L = weighted average of $A_L(\mu)$ and $A_L(e)$

In previous editions and in the literature the symbol used for this asymmetry was δ_L or δ. We use A_L for consistency with B^0 asymmetry notation and with recent K_S^0 notation.

[101] CHOLLET 70 gives $|\eta_{00}| = (1.23 \pm 0.24)\times$(regeneration amplitude, 2 GeV/c Cu)/10000mb. WOLFF 71 gives $|\eta_{00}| = (1.13 \pm 0.12)\times$(regeneration amplitude, 2 GeV/c Cu)/10000mb. We compute both $|\eta_{00}|$ values for (regeneration amplitude, 2 GeV/c Cu) = 24 ± 2mb. This regeneration amplitude results from averaging over FAISSNER 69, extrapolated using optical-model calculations of Bohm et al., Physics Letters **27B** 594 (1968) and the data of BALATS 71. (From H. Faissner, private communication).

$|\eta_{+-}| = |A(K_L^0 \to \pi^+\pi^-) / A(K_S^0 \to \pi^+\pi^-)|$

[102] AMBROSINO 06F uses KLOE branching ratios and τ_L together with τ_S from PDG 04. Their $|\eta_{+-}|$ value is not directly used in our fit, but enters the fit via their branching ratio and lifetime measurements.

[103] ALEXOPOULOS 04 $|\eta_{+-}|$ uses their $K_L^0 \to \pi\pi$ branching fractions, $\tau_S = (0.8963 \pm 0.0005)\times 10^{-10}$ s from the average of KTeV and NA48 τ_S measurements, and assumes that $\Gamma(K_S^0 \to \pi\ell\nu_\ell) = \Gamma(K_L^0 \to \pi\ell\nu_\ell)$ giving $B(K_S^0 \to \pi\ell\nu_\ell) = 0.118\%$. Their η_{+-} is not directly used in our fit, but enters our fit via their branching ratio measurements.

[104] APOSTOLAKIS 99C report $(2.264 \pm 0.023 \pm 0.026 + 9.1[\tau_S - 0.8934]) \times 10^{-3}$. We evaluate for our 2006 best value $\tau_S = (0.8958 \pm 0.0005) \times 10^{-10}$ s.

[105] ADLER 95B report $(2.312 \pm 0.043 \pm 0.030 - 1[\Delta m - 0.5274] + 9.1[\tau_S - 0.8926]) \times 10^{-3}$. We evaluate for our 1996 best values $\Delta m = (0.5304 \pm 0.0014) \times 10^{10}\ \hbar s^{-1}$ and $\tau_S = (0.8927 \pm 0.0009) \times 10^{-10}$ s. Superseded by APOSTOLAKIS 99C.

$|\epsilon| = (2|\eta_{+-}| + |\eta_{00}|)/3$

This expression is a very good approximation, good to about one part in 10^{-4} because of the small measured value of $\phi_{00} - \phi_{+-}$ and small theoretical ambiguities.

0.9899±0.0020±0.0025		[106] BURKHARDT	88	NA31

[106] This is the square root of the ratio R given by BURKHARDT 88 and BARR 93D.

[107] This is the combined results from BARR 93D and BURKHARDT 88, taking into account a common systematic uncertainty of 0.0014.

[108] We calculate $|\eta_{00}/\eta_{+-}| = 1 - 3(\epsilon'/\epsilon)$ from WOODS 88 (ϵ'/ϵ) value.

$\mathrm{Re}(\epsilon'/\epsilon) = (1 - |\eta_{00}/\eta_{+-}|)/3$

We have neglected terms of order $\omega \cdot \mathrm{Re}(\epsilon'/\epsilon)$, where $\omega = \mathrm{Re}(A_2)/\mathrm{Re}(A_0) \simeq 1/22$. If included, this correction would lower $\mathrm{Re}(\epsilon'/\epsilon)$ by about 0.04×10^{-3}. See SOZZI 04.

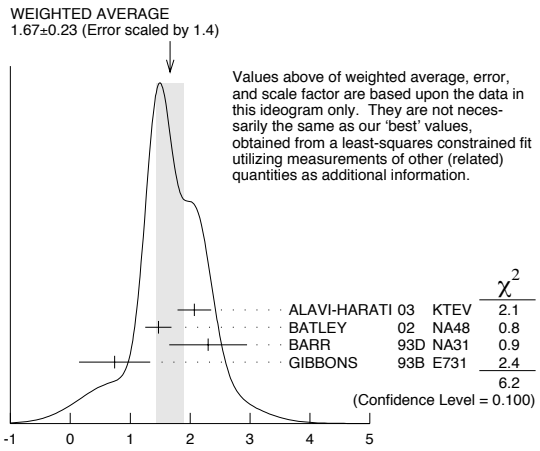
[109] These values are derived from $|\eta_{00}/\eta_{+-}|$ measurements. They enter the average in this section but enter the fit via the $|\eta_{00}/\eta_{+-}|$ only.

[110] This is the combined results from BARR 93D and BURKHARDT 88, taking into account their common systematic uncertainty.

[111] These values are derived from $|\eta_{00}/\eta_{+-}|$ measurements.



$\mathrm{Re}(\epsilon'/\epsilon) = (1 - |\eta_{00}/\eta_{+-}|)/3$

ϕ_{+-}. PHASE of η_{+-}

The dependence of the phase on Δm and τ_S is given for each experiment in the comments below, where Δm is the $K_L^0 - K_S^0$ mass difference in units $10^{10}\ \hbar s^{-1}$ and τ_S is the K_S mean life in units 10^{-10} s. We also give the regeneration phase ϕ_f in the comments below.

OUR FIT is described in the note on "*CP* violation in K_L decays" in the K_L^0 Particle Listings. Most experiments in this section are included in both the "Not Assuming *CPT*" and "Assuming *CPT*" fits. In the latter fit, they have little direct influence on ϕ_{+-} because their errors are large compared to that assuming *CPT*, but they influence Δm and τ_S through their dependencies on these parameters, which are given in the footnotes. Only ALAVI-HARATI 03 is excluded from the "Assuming *CPT*" fit because we explicitly include their Δm and τ_S measurements which assume *CPT*.

44.3 ±2.8 ±0.2		[124] CARITHERS	75	SPEC	C regenerator

[112] ALAVI-HARATI 03 ϕ_{+-} is correlated with their $\Delta m = m_{K_L^0} - m_{K_S^0}$ and τ_{K_S} measurements in the K_L^0 and K_S^0 sections respectively. The correlation coefficients are $\rho(\phi_{+-},\Delta m) = +0.955$, $\rho(\phi_{+-},\tau_S) = -0.871$, and $\rho(\tau_S,\Delta m) = -0.840$. *CPT* is not assumed. Uses scintillator Pb regenerator.

[113] APOSTOLAKIS 99C measures $\phi_{+-} = (43.19 \pm 0.53 \pm 0.28) + 300\ [\Delta m - 0.5301]$ (°). We have adjusted the measurement to use our best values of ($\Delta m = 0.5292 \pm 0.0009$) ($10^{10}\ \hbar\ s^{-1}$). Our first error is their experiment's error and our second error is the systematic error from using our best values.

[114] SCHWINGENHEUER 95 measures $\phi_{+-} = (43.53 \pm 0.76) + 173\,[\Delta m - 0.5282] - 275\,[\tau_S - 0.8926]$ (°). We have adjusted the measurement to use our best values of ($\Delta m = 0.5292 \pm 0.0009$) ($10^{10}\ \hbar\ s^{-1}$), ($\tau_S = 0.8953 \pm 0.0005$) ($10^{-10}$ s). Our first error is their experiment's error and our second error is the systematic error from using our best values.

[115] These experiments measure ϕ_{+-}-ϕ_f and calculate the regeneration phase from the power law momentum dependence of the regeneration amplitude using analyticity and dispersion relations. SCHWINGENHEUER 95 [GIBBONS 93] includes a systematic error of 0.35° [0.5°] for uncertainties in their modeling of the regeneration amplitude.

[116] GIBBONS 93 measures $\phi_{+-} = (42.21 \pm 0.9) + 189\,[\Delta m - 0.5257] - 460\,[\tau_S - 0.8922]$ (°). We have adjusted the measurement to use our best values of ($\Delta m = 0.5292 \pm 0.0009$) ($10^{10}\ \hbar\ s^{-1}$), ($\tau_S = 0.8953 \pm 0.0005$) ($10^{-10}$ s). Our first error is their experiment's error and our second error is the systematic error from using our best values. This is actually reported in SCHWINGENHEUER 95, footnote 8. GIBBONS 93 reports ϕ_{+-} (42.2 ± 1.4)°. They measure ϕ_{+}-ϕ_f and calculate the regeneration phase ϕ_f from the power law momentum dependence of the regeneration amplitude using analyticity. An error of 0.6° is included for possible uncertainties in the regeneration phase.

[117] CAROSI 90 measures $\phi_{+-} = (46.9 \pm 1.4 \pm 0.7) + 579\,[\Delta m - 0.5351] + 303\,[\tau_S - 0.8922]$ (°). We have adjusted the measurement to use our best values of ($\Delta m = 0.5292 \pm 0.0009$) ($10^{10}\ \hbar\ s^{-1}$), ($\tau_S = 0.8953 \pm 0.0005$) ($10^{-10}$ s). Our first error is their experiment's error and our second error is the systematic error from using our best values.

[118] GEWENIGER 74B measures $\phi_{+-} = (49.4 \pm 1.0) + 565\,[\Delta m - 0.540]$ (°). We have adjusted the measurement to use our best values of ($\Delta m = 0.5292 \pm 0.0009$) ($10^{10}\ \hbar\ s^{-1}$). Our first error is their experiment's error and our second error is the systematic error from using our best values.

[119] ADLER 96C measures $\phi_{+-} = (43.82 \pm 0.41) + 339\,[\Delta m - 0.5307] - 252\,[\tau_S - 0.8922]$ (°). We have adjusted the measurement to use our best values of ($\Delta m = 0.5292 \pm 0.0009$) ($10^{10}\ \hbar\ s^{-1}$), ($\tau_S = 0.8953 \pm 0.0005$) ($10^{-10}$ s). Our first error is their experiment's error and our second error is the systematic error from using our best values.

[120] ADLER 96C is the result of a fit which includes nearly the same data as entered into the "OUR FIT" value in the 1996 edition of this Review (Physical Review **D54** 1 (1996)).

[121] ADLER 95B measures $\phi_{+-} = (42.7 \pm 0.9 \pm 0.6) + 316\,[\Delta m - 0.5274] + 30\,[\tau_S - 0.8926]$ (°). We have adjusted the measurement to use our best values of ($\Delta m = 0.5292 \pm 0.0009$) ($10^{10}\ \hbar\ s^{-1}$), ($\tau_S = 0.8953 \pm 0.0005$) ($10^{-10}$ s). Our first error is their experiment's error and our second error is the systematic error from using our best values.

[122] ADLER 92B quote separately two systematic errors: ±0.4 from their experiment and ±1.0 degrees due to the uncertainty in the value of Δm.

[123] KARLSSON 90 systematic error does not include regeneration phase uncertainty.

[124] CARITHERS 75 measures $\phi_{+-} = (45.5 \pm 2.8) + 224\,[\Delta m - 0.5348]$ (°). We have adjusted the measurement to use our best values of ($\Delta m = 0.5292 \pm 0.0009$) ($10^{10}\ \hbar\ s^{-1}$). Our first error is their experiment's error and our second error is the systematic error from using our best values. $\phi_f = -40.9 \pm 2.6$°.

ϕ_{00}, PHASE OF η_{00}

See comment in ϕ_{+-} header above for treatment of Δm and τ_S dependence, as well as for the inclusion of data in both the "Assuming *CPT*" and "Not Assuming *CPT*" fits.

OUR FIT is described in the note on "*CP* violation in K_L decays" in the K^0_L Particle Listings.

VALUE (°)	DOCUMENT ID		TECN	COMMENT
43.50±0.06 OUR FIT	Error includes scale factor of 1.2. Assuming *CPT*			
43.7 ±0.8 OUR FIT	Error includes scale factor of 1.2. Not assuming *CPT*			
44.5 ±2.3 ±0.6	[125] CAROSI	90	NA31	
• • • We do not use the following data for averages, fits, limits, etc. • • •				
41.6 ±5.9 ±0.2	[126] ANGELOPO...	98	CPLR	
50.8 ±7.1 ±1.7	[127] ADLER	96B	CPLR	Sup. by ANGELOPOULOS 98
47.4 ±1.4 ±0.9	[128] KARLSSON	90	E731	

[125] CAROSI 90 measures $\phi_{00} = (47.1 \pm 2.1 \pm 1.0) + 579\,[\Delta m - 0.5351] + 252\,[\tau_S - 0.8922]$ (°). We have adjusted the measurement to use our best values of ($\Delta m = 0.5292 \pm 0.0009$) ($10^{10}\ \hbar\ s^{-1}$), ($\tau_S = 0.8953 \pm 0.0005$) ($10^{-10}$ s). Our first error is their experiment's error and our second error is the systematic error from using our best values.

[126] ANGELOPOULOS 98 measures $\phi_{00} = (42.0 \pm 5.6 \pm 1.9) + 240\,[\Delta m - 0.5307]$ (°). We have adjusted the measurement to use our best values of ($\Delta m = 0.5292 \pm 0.0009$) ($10^{10}\ \hbar\ s^{-1}$). Our first error is their experiment's error and our second error is the systematic error from using our best values. The τ_S dependence is negligible.

[127] ADLER 96B identified initial neutral kaon individually as being a K^0 or a $\overline{K^0}$. The systematic uncertainty is ±1.5° combined in quadrature with ±0.8° due to Δm.

[128] KARLSSON 90 systematic error does not include regeneration phase uncertainty.

$\phi_\epsilon = (2\phi_{+-} + \phi_{00})/3$

This expression is a very good approximation, good to about 10^{-3} degrees because of the small measured values of $\phi_{00} - \phi_{+-}$ and Re ϵ'/ϵ, and small theoretical ambiguities.

VALUE (°)			DOCUMENT ID	COMMENT
43.51	**±0.05**	**OUR FIT**	Error includes scale factor of 1.1. Assuming *CPT*	
43.5	**±0.7**	**OUR FIT**	Error includes scale factor of 1.3. Not assuming *CPT*	
43.5105±0.0004±0.0533			[129] SUPERWEAK 04	Assuming *CPT*

[129] SUPERWEAK 04 is a fake measurement used to impose the *CPT* or Superweak constraint $\phi_{+-} = \phi_{SW} = 2\,\frac{\Delta m}{\hbar}\,(\frac{\tau_S \tau_L}{\tau_L - \tau_S})$. This "measurement" is linearized using values near the RPP 2004 edition values of Δm, τ_S and τ_L, and then adjusted to our current values as described in the following "measurement". SUPERWEAK 04 measures $\phi_\epsilon = (43.5131 \pm 0.0004) + 54\,[\Delta m - 0.5290] + 32\,[\tau_S - 0.8958]$ (°). We have adjusted the measurement to use our best values of ($\Delta m = 0.5292 \pm 0.0009$) ($10^{10}\ \hbar\ s^{-1}$), ($\tau_S = 0.8953 \pm 0.0005$) ($10^{-10}$ s). Our first error is their experiment's error and our second error is the systematic error from using our best values.

DECAY-PLANE ASYMMETRY IN $\pi^+\pi^-e^+e^-$ DECAYS

This is the *CP*-violating asymmetry

$$A = \frac{N_{\sin\phi\cos\phi>0.0} - N_{\sin\phi\cos\phi<0.0}}{N_{\sin\phi\cos\phi>0.0} + N_{\sin\phi\cos\phi<0.0}}$$

where ϕ is the angle between the e^+e^- and $\pi^+\pi^-$ planes in the K^0_L rest frame.

0.62 ±0.71	±0.75	SCHWINGEN...	95	E773	
−1.6 ±1.2		[137] GIBBONS	93	E731	
0.2 ±2.6	±1.2	[138] CAROSI	90	NA31	
−0.3 ±2.4	±1.2	KARLSSON	90	E731	

[134] SUPERWEAK 04 is a fake experiment to constrain ϕ_{00}-ϕ_{+-} to a small value as described in the note "CP violation in K_L decays."

[135] ALAVI-HARATI 03 fit Re(ϵ'/ϵ), Im(ϵ'/ϵ), Δm, τ_S, and ϕ_{+-} simultaneously, not assuming CPT. Phase difference is obtained from $\phi_{00} - \phi_{+-} \approx -3\mathrm{Im}(\epsilon'/\epsilon)$ for small $|\epsilon'/\epsilon|$.

[136] This SCHWINGENHEUER 95 values is the combined result of SCHWINGENHEUER 95 and GIBBONS 93, accounting for correlated systematic errors.

[137] GIBBONS 93 give detailed dependence of systematic error on lifetime (see the section on the K^0_S mean life) and mass difference (see the section on $m_{K^0_L} - m_{K^0_S}$).

[138] CAROSI 90 is excluded from the fit because it it is not independent of ϕ_{+-} and ϕ_{00} values.

PHASE DIFFERENCE $\phi_{+-} - \phi_{SW}$

Test of CPT. The Superweak phase $\phi_{SW} \equiv \tan^{-1}(2\Delta m/\Delta\Gamma)$ where $\Delta m = m_{K^0_L} - m_{K^0_S}$ and $\Delta\Gamma = \hbar(\tau_L - \tau_S)/(\tau_L\tau_S)$.

VALUE (°)	DOCUMENT ID		TECN
0.61±0.62±1.01	[139] ALAVI-HARATI	03	KTEV

[139] ALAVI-HARATI 03 fit is the same as their ϕ_{+-}, τ_{K_S}, Δm fit, except that the parameter $\phi_{+-} - \phi_{SW}$ is used in place of ϕ.

Re($\frac{2}{3}\eta_{+-} + \frac{1}{3}\eta_{00}$)−$\frac{\delta_L}{2}$

Test of CPT

VALUE (units 10^{-6})	DOCUMENT ID		TECN	COMMENT
−3±35	[140] ALAVI-HARATI	02	E799	Uses δ_L from K_{e3} decays

[140] ALAVI-HARATI 02 uses PDG 00 values of η_{+-} and η_{00}.

$\Delta S = \Delta Q$ IN K^0 DECAYS

The relative amount of $\Delta S \neq \Delta Q$ component present is measured by the parameter x, defined as

$$x = A(\overline{K}^0 \to \pi^-\ell^+\nu)/A(K^0 \to \pi^-\ell^+\nu) \ .$$

We list Re$\{x\}$ and Im$\{x\}$ for K_{e3} and $K_{\mu 3}$ combined.

$x = A(\overline{K}^0 \to \pi^-\ell^+\nu)/A(K^0 \to \pi^-\ell^+\nu) = A(\Delta S{=}-\Delta Q)/A(\Delta S{=}\Delta Q)$

$K_0^*(800)$ or κ

$I(J^P) = \frac{1}{2}(0^+)$

OMITTED FROM SUMMARY TABLE

Needs confirmation.

$K_0^*(800)$ MASS

VALUE (MeV)	EVTS	DOCUMENT ID		TECN	COMMENT
$841 \pm 30^{+81}_{-73}$	25k	[1] ABLIKIM	06C	BES2	$J/\psi \to \overline{K}^*(892)^0 K^+ \pi^-$
• • • We do not use the following data for averages, fits, limits, etc. • • •					
750^{+30}_{-55}		[2] BUGG	06	RVUE	
753 ± 52		[3] PELAEZ	04A	RVUE	$K\pi \to K\pi$
594 ± 79		[4] ZHENG	04	RVUE	$K^- p \to K^- \pi^+ n$
722 ± 60		[5] BUGG	03	RVUE	11 $K^- p \to K^- \pi^+ n$
$797 \pm 19 \pm 43$	15090	[6] AITALA	02	E791	$D^+ \to K^- \pi^+ \pi^+$
905^{+65}_{-30}		[7] ISHIDA	97B	RVUE	11 $K^- p \to K^- \pi^+ n$

[1] S-matrix pole.

[2] S-matrix pole. Reanalysis of ASTON 88, AITALA 02, and ABLIKIM 06C using for the κ an s-dependent width with an Adler zero near threshold.

[3] T-matrix pole. Reanalysis of data from LINGLIN 73, ESTABROOKS 78, and ASTON 88 in the unitarized ChPT model.

[4] Using ASTON 88.

[5] T-matrix pole. Reanalysis of ASTON 88 data.

[6] Not seen by KOPP 01 using 7070 events of $D^0 \to K^- \pi^+ \pi^0$. LINK 02E and LINK 05I show clear evidence for a constant non-resonant scalar amplitude rather than $K_0^*(800)$ in their high statistics analysis of $D^+ \to K^- \pi^+ \mu^+ \nu_\mu$.

[7] Reanalysis of ASTON 88 using interfering Breit-Wigner amplitudes.

$K_0^*(800)$ WIDTH

[1] Inclusive reaction. Complicated background and phase-space effects.
[2] Mass errors enlarged by us to $\Gamma/\sqrt{N}$. See note.
[3] Number of events in peak reevaluated by us.
[4] K-matrix pole.
[5] From a partial wave amplitude analysis.
[6] Fit to $K\pi$ mass spectrum includes a non-resonant scalar component.
[7] From pole extrapolation.

$K^*(892)$ MASSES AND MASS DIFFERENCES

Unrealistically small errors have been reported by some experiments. We use simple "realistic" tests for the minimum errors on the determination of a mass and width from a sample of N events:

$$\delta_{\min}(m) = \frac{\Gamma}{\sqrt{N}}, \quad \delta_{\min}(\Gamma) = 4\frac{\Gamma}{\sqrt{N}} \ . \tag{1}$$

We consistently increase unrealistic errors before averaging. For a detailed discussion, see the 1971 edition of this Note.

CONSTRAINED FIT INFORMATION

An overall fit to the total width and a partial width uses 13 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 7.8$ for 11 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

x_5	−100	
Γ	19	−19
	x_2	x_5

	Mode	Rate (MeV)
Γ_2	$(K\pi)^\pm$	50.7 ±0.9
Γ_5	$K^\pm\gamma$	0.050±0.005

CONSTRAINED FIT INFORMATION

An overall fit to the total width and a partial width uses 20 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 22.6$ for 18 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$K_2^*(1430)$

$I(J^P) = \frac{1}{2}(2^+)$

We consider that phase-shift analyses provide more reliable determinations of the mass and width.

CONSTRAINED FIT INFORMATION

An overall fit to the total width, a partial width, and 10 branching ratios uses 31 measurements and one constraint to determine 8 parameters. The overall fit has a $\chi^2 = 20.2$ for 24 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \cdot \delta p_j)$, in percent, from the fit to parameters p_i, including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 4 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 2.9$ for 2 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

Γ_5	$K_2^*(1430)\pi$	< 16 %	95%

CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 4 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 0.0$ for 1 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$K(3100)$

$I^G(J^{PC}) = ?^?(?^{??})$

OMITTED FROM SUMMARY TABLE

Narrow peak observed in several ($\Lambda\overline{p}$ + pions) and ($\overline{\Lambda}p$ + pions) states in Σ^- Be reactions by BOURQUIN 86 and in np and nA reactions by ALEEV 93. Not seen by BOEHNLEIN 91. If due to strong decays, this state has exotic quantum numbers (B=0,Q=+1,S=−1 for $\Lambda\overline{p}\pi^+\pi^+$ and $I \geq 3/2$ for $\Lambda\overline{p}\pi^-$). Needs confirmation.

D^+ DECAY MODES

Most decay modes (other than the semileptonic modes) that involve a neutral K meson are now given as K^0_S modes, not as $\overline{K}^0$ modes. Nearly always it is a K^0_S that is measured, and interference between Cabibbo-allowed and doubly Cabibbo-suppressed modes can invalidate the assumption that $2\,\Gamma(K^0_S) = \Gamma(\overline{K}^0)$.

	Mode	Fraction (Γ_i/Γ)	Scale factor/ Confidence level

Γ_{166}	A dummy mode used by the fit.		(30 ±5) %	S=1.2

[a] This is a weighted average of $D^{\pm}$ (44%) and D^0 (56%) branching fractions. See "D^+ and $D^0 \to$ (η anything) / (total D^+ and D^0)" under "D^+ Branching Ratios" in these Particle Listings.

Meson Particle Listings

$D^{\pm}$

[b] An ℓ indicates an e or a μ mode, not a sum over these modes.

[c] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers.

[d] These subfractions of the $K^-\pi^+\pi^+$ mode are uncertain: see the Particle Listings.

[e] The two experiments measuring this fraction are in serious disagreement. See the Particle Listings.

[f] This is *not* a test for the ΔC=1 weak neutral current, but leads to the $\pi^+ e^+ e^-$ final state.

[g] This mode is not a useful test for a ΔC=1 weak neutral current because both quarks must change flavor in this decay.

[h] The value is for the sum of the charge states or particle/antiparticle states indicated.

CONSTRAINED FIT INFORMATION

An overall fit to 32 branching ratios uses 51 measurements and one constraint to determine 21 parameters. The overall fit has a $\chi^2 = 30.9$ for 31 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

DALITZ PLOT ANALYSIS FORMALISM

Written January 2006 by D. Asner (Carleton University)

Introduction: Weak nonleptonic decays of D and B mesons are expected to proceed dominantly through resonant two-body decays [1]; see Ref. [2] for a review of resonance phenomenology. The amplitudes are typically calculated with the Dalitz-plot analysis technique [3], which uses the minimum number of independent observable quantities. For three-body decays of a spin-0 particle to all pseudo-scalar final states, D or $B \to abc$, the decay rate [4] is

$$\Gamma = \frac{1}{(2\pi)^3 32\sqrt{s^3}} |\mathcal{M}|^2 \, dm^2_{ab} \, dm^2_{bc} \,, \qquad (1)$$

where m_{ij} is the invariant mass of particles i and j. The coefficient of the amplitude includes all kinematic factors, and $|\mathcal{M}|^2$ contains the dynamics. The scatter plot in m^2_{ab} versus m^2_{bc} is the Dalitz plot. If $|\mathcal{M}|^2$ is constant, the kinematically allowed region of the plot will be populated uniformly with events. Any variation in the population over the Dalitz plot is due to dynamical rather than kinematical effects. It is straightforward to extend the formalism beyond three-body final states. For N-body final states with only spin-0 particles, phase space has dimension $3N-7$. Other decays of interest include one vector particle or a fermion/anti-fermion pair (*e.g.*, $B \to D^*\pi\pi$, $B \to \overline{\Lambda}_c p\pi$, $B \to K\ell\ell$) in the final state. For the first case, phase space has dimension $3N-5$, and for the latter two the dimension is $3N-4$.

Formalism: The amplitude for the process, $R \to rc, r \to ab$ where R is a D or B, r is an intermediate resonance, and a, b, c are pseudo-scalars, is given by

$$\mathcal{M}_r(J,L,l,m_{ab},m_{bc}) = \sum_\lambda \langle ab|r_\lambda\rangle \, T_r(m_{ab}) \, \langle cr_\lambda|R_J\rangle \qquad (2)$$

$$= Z(J,L,l,\vec{p},\vec{q}) B^R_L(|\vec{p}|) B^r_L(|\vec{q}|) T_r(m_{ab}) \,.$$

The sum is over the helicity states λ of r, J is the total angular momentum of R (for D and B decays, J=0), L is the orbital angular momentum between r and c, l is the orbital angular momentum between a and b (the spin of r), $\vec{p}$ and $\vec{q}$ are the momenta of c and of a in the r rest frame, Z describes the angular distribution of the final-state particles, B^R_L and B^r_L are the barrier factors for the production of rc and of ab, and T_r is the dynamical function describing the resonance r. The amplitude for modeling the Dalitz plot is a phenomenological object. Differences in the parametrizations of Z, B_L, and T_r, as well as in the set of resonances r, complicate the comparison of results from different experiments.

Usually the resonances are modeled with a Breit-Wigner form, although some more recent analyses use a K-matrix formalism [5,6,7] with the P-vector approximation [8] to describe the $\pi\pi$ S-wave.

The nonresonant (NR) contribution to $D \to abc$ is parametrized as constant (S-wave) with no variation in magnitude or phase across the Dalitz plot. The available phase space is much greater for B decays, and the nonresonant contribution to $B \to abc$ requires a more sophisticated parametrization. Theoretical models of the NR amplitude [9-12] do not reproduce the distributions observed in the data. Experimentally, several parametrizations have been used [13,14].

Barrier Factor B_L: The maximum angular momentum L in a strong decay is limited by the linear momentum q. Decay particles moving slowly with an impact parameter (meson radius) d of order 1 fm have difficulty generating sufficient angular momentum to conserve the spin of the resonance. The Blatt-Weisskopf [15,16] functions B_L, given in Table 1, weight the reaction amplitudes to account for this spin-dependent effect. These functions are normalized to give $B_L = 1$ for $z = (|q|\,d)^2 = 1$. Another common formulation, B'_L, also in Table 1, is normalized to give $B'_L = 1$ for $z = z_0 = (|q_0|\,d)^2$ where q_0 is the value of q when $m_{ab} = m_r$.

Table 1: Blatt-Weisskopf barrier factors.

L	$B_L(q)$	$B'_L(q, q_0)$
0	1	1
1	$\sqrt{\frac{2z}{1+z}}$	$\sqrt{\frac{1+z_0}{1+z}}$
2	$\sqrt{\frac{13z^2}{(z-3)^2+9z}}$	$\sqrt{\frac{(z_0-3)^2+9z_0}{(z-3)^2+9z}}$
where $z = (\|q\|\,d)^2$ and $z_0 = (\|q_0\|\,d)^2$		

Angular distribution: The tensor or Zemach formalism [17,18] and the helicity formalism [19,18] yield identical descriptions of the angular distributions for the decay process $R \to rc, r \to ab$ when a, b and c all have spin-0. The angular distributions for $L = 0, 1,$ and 2 are given in Table 2. For final-state particles with non-zero spin (*e.g.*, radiative decays), the helicity formalism is required.

Table 2: Angular distributions for $L = 0, 1, 2$ where θ is the angle between particles a and c in the rest frame of resonance r, $\sqrt{1+\zeta^2} = E_r/m_{ab}$ is a relativistic correction, and $E_r = (m_R^2 + m_{ab}^2 - m_c^2)/2m_R$.

$J \to L + l$	Angular distribution
$0 \to 0+0$	uniform
$0 \to 1+1$	$(1+\zeta^2)\cos^2\theta$
$0 \to 2+2$	$\left(\zeta^2+\frac{3}{2}\right)^2 (\cos^2\theta - 1/3)^2$

Dynamical Function T_r: The dynamical function T_r is derived from the S-matrix formalism. In general, the amplitude that a final state f couples to an initial state i is $S_{fi} = \langle f|S|i\rangle$, where the scattering operator S is unitary and satisfies $SS^\dagger = S^\dagger S = I$. The Lorentz-invariant transition operator $\hat{T}$ is defined by separating the probability that $f = i$, yielding

$$S = I + 2iT = I + 2i\,\{\rho\}^{1/2}\,\hat{T}\,\{\rho\}^{1/2}\,, \tag{3}$$

where I is the identity operator, ρ is the diagonal phase-space matrix, with $\rho_{ii} = 2q_i/m$, and q_i is the momentum of a in the r rest frame for decay channel i. In the single-channel S-wave case, $S = e^{2i\delta}$ satisfies unitarity and

$$\hat{T} = \frac{1}{\rho}\,e^{i\delta}\sin\delta. \tag{4}$$

There are three common formulations of the dynamical function. The Breit-Wigner formalism—the first term in a Taylor expansion about a T-matrix pole—is the simplest formulation. The K-matrix formalism [5] is more general (allowing more than one T-matrix pole and coupled channels while preserving unitarity). The Flatté distribution [20] is used to parametrize resonances near threshold and is equivalent to a one-pole, two-channel K-matrix.

Breit-Wigner Formulation: The common formulation of a Breit-Wigner resonance decaying to spin-0 particles a and b is

$$T_r(m_{ab}) = \frac{1}{m_r^2 - m_{ab}^2 - im_r\Gamma_{ab}(q)}\,. \tag{5}$$

The "mass-dependent" width Γ is

$$\Gamma = \Gamma_r \left(\frac{q}{q_r}\right)^{2L+1} \left(\frac{m_r}{m_{ab}}\right) B'_L(q, q_0)^2\,, \tag{6}$$

and $B'_L(q, q_0)$ is the Blatt-Weisskopf barrier factor from Table 1. A Breit-Wigner parametrization best describes isolated, non-overlapping resonances far from the threshold of additional decay channels. For the ρ and $\rho(1450)$ a more complex parametrization suggested by Gounaris-Sakarai [21] is often used [22-26]. Unitarity can be violated when the dynamical function is parametrized as the sum of two or more overlapping Breit-Wigners. The proximity of a threshold to a resonance distorts the line shape from a simple Breit-Wigner. Here the Flatté formula provides a better description and is discussed below.

K-matrix Formalism: The T matrix can be written as

$$\hat{T} = (I - i\hat{K}\rho)^{-1}\hat{K}, \tag{7}$$

where $\hat{K}$ is the Lorentz-invariant K-matrix describing the scattering process and ρ is the phase-space factor. Resonances appear as poles in the K-matrix:

$$\hat{K}_{ij} = \sum_\alpha \frac{\sqrt{m_\alpha\Gamma_{\alpha i}(m) m_\alpha \Gamma_{\alpha j}(m)}}{(m_\alpha^2 - m^2)\sqrt{\rho_i\rho_j}}. \tag{8}$$

The K-matrix is real by construction, and so the associated T-matrix respects unitarity.

For a single pole in a single channel, K is

$$K = \frac{m_0\,\Gamma(m)}{m_0^2 - m^2} \tag{9}$$

and

$$T = K(1 - iK)^{-1} = \frac{m_0\Gamma(m)}{m_0^2 - m^2 - im_0\Gamma(m)}\,, \tag{10}$$

which is the relativistic Breit-Wigner formula. For two poles in a single channel, K is

$$K = \frac{m_\alpha\Gamma_\alpha(m)}{m_\alpha^2 - m^2} + \frac{m_\beta\Gamma_\beta(m)}{m_\beta^2 - m^2}\,. \tag{11}$$

If m_α and m_β are far apart relative to the widths, the T matrix is approximately the sum of two Breit-Wigners, $T(K_\alpha + K_\beta) \approx T(K_\alpha) + T(K_\beta)$, each of the form of Eq. (10). This approximation is not valid for two nearby resonances, in which case T can violate unitarity.

This formulation, which applies to S-channel production in two-body scattering, $ab \to cd$, can be generalized to describe the production of resonances in processes such as the decay of charm mesons. The key assumption here is that the two-body system described by the K-matrix does *not* interact with the rest of the final state [8]. The validity of this assumption varies with the production process and is appropriate for reactions such as $\pi^- p \to \pi^0\pi^0 n$ and semileptonic decays such as $D \to K\pi\ell\nu$. The assumption may be of limited validity for production processes such as $p\overline{p} \to \pi\pi\pi$ or $D \to \pi\pi\pi$. In these cases, the two-body Lorentz-invariant amplitude, $\hat{F}$, is given by

$$\hat{F}_i = (I - i\hat{K}\rho)^{-1}_{ij}\hat{P}_j = (\hat{T}\hat{K}^{-1})_{ij}\hat{P}_j\,, \tag{12}$$

where P is the production vector that parametrizes the resonance production in the open channels.

For the $\pi\pi$ S-wave, a common formulation of the K-matrix [7,24,25] is

$$K_{ij}(s) = \left[\sum_\alpha \left(\frac{g_i^{(\alpha)} g_j^{(\alpha)}}{m_\alpha^2 - s}\right) + f_{ij}^{sc}\frac{1 - s_0^{sc}}{s - s_0^{sc}}\right]\left[\frac{(s - s_A m_\pi^2/2)(1 - s_{A0})}{(s - s_{A0})}\right]. \tag{13}$$

The factor $g_i^{(\alpha)}$ is the real coupling constant of the K-matrix pole m_α to meson channel i; the parameters f_{ij}^{sc} and s_0^{sc} describe a smooth part of the K-matrix elements; the second factor in square brackets suppresses a false kinematical singularity near the $\pi\pi$ threshold (the Adler zero); and the number 1 has units GeV^2.

The production vector, with $i = 1$ denoting $\pi\pi$, is

$$P_j(s) = \left[\sum_\alpha \left(\frac{\beta_\alpha g_j^{(\alpha)}}{m_\alpha^2 - s}\right) + f_{1j}^{pr}\frac{1 - s_0^{pr}}{s - s_0^{pr}}\right]\left[\frac{(s - s_A m_\pi^2/2)(1 - s_{A0})}{(s - s_{A0})}\right]. \tag{14}$$

where the free parameters of the Dalitz plot fit are the complex production couplings β_α and the production-vector background parameters f_{1j}^{pr} and s_0^{pr}. All other parameters are fixed by scattering experiments. Ref. [6] describes the $\pi\pi$ scattering data with a 4-pole, 2-channel ($\pi\pi$, $K\bar{K}$) model, while Ref. [7] describes the scattering data with 5-pole, 5-channel ($\pi\pi$, $K\bar{K}$, $\eta\eta$, $\eta'\eta'$ and 4π) model. The former has been implemented by CLEO [27] and the latter by FOCUS [25] and BABAR [24]. In both cases, only the $\pi\pi$ channel was analyzed. A more complete coupled-channel analysis would simultaneously fit all final states accessible by rescattering.

Flatté Formalism: The Flatté formulation is used when a second channel opens close to a resonance:

$$\hat{T}(m_{ab}) = \frac{1}{m_r^2 - m_{ab}^2 - i(\rho_1 g_1^2 + \rho_2 g_2^2)}\,, \tag{15}$$

where $g_1^2 + g_2^2 = m_0\Gamma_r$. This situation occurs in the $\pi\pi$ S-wave where the $f_0(980)$ is near the $K\overline{K}$ threshold, and in the $\pi\eta$ channel where the $a_0(980)$ also lies near the $K\overline{K}$ threshold. For the $a_0(980)$ resonance, the relevant coupling constants are $g_1 = g_{\pi\eta}$ and $g_2 = g_{KK}$, and the phase space terms are $\rho_1 = \rho_{\pi\eta}$ and $\rho_2 = \rho_{KK}$, where

$$\rho_{ab} = \sqrt{\left(1 - (\frac{m_a - m_b}{m_{ab}})^2\right)\left(1 + (\frac{m_a - m_b}{m_{ab}})^2\right)}. \tag{16}$$

For the $f_0(980)$ the relevant coupling constants are $g_1 = g_{\pi\pi}$ and $g_2 = g_{KK}$, and the phase space terms are $\rho_1 = \rho_{\pi\pi}$ and $\rho_2 = \rho_{KK}$. The charged and neutral K channels are usually assumed to have the same coupling constant but different phase space factors, due to $m_{K^+} \neq m_{K^0}$; the result is

$$\rho_{KK} = \frac{1}{2}\left(\sqrt{1 - \left(\frac{2m_{K^\pm}}{m_{KK}}\right)^2} + \sqrt{1 - \left(\frac{2m_{K^0}}{m_{KK}}\right)^2}\right). \tag{17}$$

Branching Ratios from Dalitz Plot Fits: A fit to the Dalitz plot distribution using either a Breit-Wigner or a K-matrix formalism factorizes into a resonant contribution to the amplitude $\mathcal{M}_j$ and a complex coefficient, $a_j e^{i\delta_j}$, where a_j and δ_j are real. The definition of a rate of a single process, given a set of amplitudes a_j and phases δ_j, is the square of the relevant matrix element (see Eq. (1)). The "fit fraction" is usually defined as the integral over the Dalitz plot (m_{ab} vs. m_{bc}) of a single amplitude squared divided by the integral over the Dalitz plot of the square of the coherent sum of all amplitudes, or

$$\text{fit fraction}_j = \frac{\int \left|a_j e^{i\delta_j}\mathcal{M}_j\right|^2 dm_{ab}^2 dm_{bc}^2}{\int \left|\sum_k a_k e^{i\delta_k}\mathcal{M}_k\right|^2 dm_{ab}^2 dm_{bc}^2}, \tag{18}$$

where $\mathcal{M}_j$ is defined in Eq. (2) and described in Ref. [28]. In general, the sum of the fit fractions for all components will not be unity due to interference.

When the K-matrix of Eq. (12) is used to describe a wave (*e.g.*, the $\pi\pi$ S-wave), then $\mathcal{M}_j$ refers to the entire wave. In this case, it may not be straightforward to separate $\mathcal{M}_j$ into a sum of individual resonances unless these are narrow and well separated.

Reconstruction Efficiency and Resolution: The efficiency for reconstructing an event as a function of position on the Dalitz plot is in general non-uniform. Typically, a Monte Carlo

sample generated with a uniform distribution in phase space is used to determine the efficiency. The variation in efficiency across the Dalitz plot varies with experiment and decay mode. Most recent analyses utilize a full GEANT [29] detector simulation.

Finite detector resolution can usually be safely neglected as most resonances are comparatively broad. Notable exceptions where detector resolution effects must be modeled are $\phi \to K^+K^-$, $\omega \to \pi^+\pi^-$, and $a_0 \to \eta\pi^0$. One approach is to convolve the resolution function in the Dalitz-plot variables m^2_{ab} and m^2_{bc} with the function that parametrizes the resonant amplitudes. In high-statistics data samples, resolution effects near the phase-space boundary typically contribute to a poor goodness of fit. The momenta of the final-state particles can be recalculated with a D or B mass constraint, which forces the kinematic boundaries of the Dalitz plot to be strictly respected. If the three-body mass is not constrained, then the efficiency (and the parametrization of background) may also depend on the reconstructed mass.

Backgrounds: The contribution of background to the D and B samples varies by experiment and final state. The background naturally falls into five categories: (i) purely combinatoric background containing no resonances; (ii) combinatoric background containing intermediate resonances, such as a real K^{*-} or ρ, plus additional random particles; (iii) final states containing identical particles as in $D^0 \to K^0_S\pi^0$ background to $D^0 \to \pi^+\pi^-\pi^0$ and $B \to D\pi$ background to $B \to K\pi\pi$; (iv) mistagged decays such as a real $\overline{D}^0$ or $\overline{B}^0$ incorrectly identified as a D^0 or B^0; and (v) particle misidentification of the decay products such as $D^+ \to \pi^-\pi^+\pi^+$ or $D^+_s \to K^-K^+\pi^+$ reconstructed as $D^+ \to K^-\pi^+\pi^+$.

The contribution from combinatoric background with intermediate resonances is distinct from the resonances in the signal because the former do *not* interfere with the latter since they are not from true resonances. Similarly, $D^0 \to \rho\pi$ and $D^0 \to K^0_S\pi^0$ do not interfere since strong and weak transitions proceed on different time scales. The usual identification tag of the initial particle as a D^0 or a $\overline{D}^0$ is the charge of the distinctive slow pion in the decay sequence $D^{*+} \to D^0\pi^+_s$ or $D^{*-} \to \overline{D}^0\pi^-_s$. Another possibility is the identification or "tagging" of one of the D mesons from $\psi(3770) \to D^0\overline{D}^0$, as is done for B mesons from $\Upsilon(4S)$. The mistagged background is subtle and may be mistakenly enumerated in the *signal* fraction determined by a D^0 mass fit. Mistagged decays contain true $\overline{D}^0$'s or $\overline{B}^0$'s and so the resonances in the mistagged sample exhibit interference on the Dalitz plot.

REVIEW OF CHARM DALITZ PLOT ANALYSES

Written January 2006 by D. Asner (Carleton University)

For references given here in the form SMITH 05, see the references at the end of the D^+, D^0, and D^+_s Listings.

The formalism of Dalitz-Plot analysis is reviewed in the preceeding note. Table 1 lists reported analyses of D mesons. In the following, we discuss a number of subjects of current interest: (1) $D^0 \to K^0_S\pi^+\pi^-$; (2) $D \to \pi\pi\pi$: a $\sigma(500)$ or $f_0(600)$;

(3) $D^+ \to K^-\pi^+\pi^+$: a $\kappa(800)$? (4) the $f_0(980)$, $f_0(1370)$ and $f_0(1500)$; (5) doubly Cabibbo-suppressed decays; and (6) CP violation.

Table 1: Reported Dalitz plot analyses.

Decay	Experiment(s)
$D^0 \to K^0_S\pi^+\pi^-$	Mark II [a], Mark III [b], E691 [c], E687 [d,e], ARGUS [f], CLEO [g], Belle [10,11], BABAR [12,13]
$D^0 \to K^-\pi^+\pi^0$	Mark III [b], E687 [e], E691 [c], CLEO [h]
$D^0 \to \overline{K}^0K^+\pi^-$	BABAR [14]
$D^0 \to K^0K^-\pi^+$	BABAR [14]
$D^0 \to K^0_S\eta\pi^0$	CLEO [i]
$D^0 \to \pi^+\pi^-\pi^0$	CLEO [j]
$D^0 \to K^0_SK^+K^-$	BABAR [k]
$D^0 \to K^-K^+K^-\pi^+$	FOCUS [l]
$D^0 \to K^-K^+\pi^-\pi^+$	FOCUS [m]
$D^+ \to K^-\pi^+\pi^+$	Mark III [b], E687 [e], E691 [c], E791 [n]
$D^+ \to \overline{K}^0\pi^+\pi^0$	Mark III [b]
$D^+ \to \pi^+\pi^+\pi^-$	E687 [o], E791 [p], FOCUS [5] [q]
$D^+ \to K^+K^-\pi^+$	FOCUS [15], E687 [r], BABAR [s]
$D^+ \to K^+\pi^+\pi^-$	E791 [t], FOCUS [u]
$D^+_s \to K^+K^-\pi^+$	E687 [r], FOCUS [15]
$D^+_s \to \pi^+\pi^+\pi^-$	E687 [o], E791 [v], FOCUS [5]
$D^+_s \to K^+\pi^+\pi^-$	FOCUS [u]

See the end of the D^+, D^0 and D^+_s Listings for these references: [a]SCHINDLER 81, [b]ADLER 87, [c]ANJOS 93, [d]FRABETTI 92B, [e]FRABETTI 94G, [f]ALBRECHT 93D, [g]MURAMATSU 02, [h]KOPP 01, [i]RUBIN 04, [j]CRONIN-HENNESSY 05, [k]AUBERT 05B, [l]LINK 03G, [m]LINK 05C, [n]AITALA 02, [o]FRABETTI 97D, [p]AITALA 01B, [q]LINK 04, [r]FRABETTI 95B, [s]AUBERT 05A, [t]AITALA 97C, [u]LINK 04F, [v]AITALA 01A.

$D^0 \to K^0_S\pi^+\pi^-$: Several experiments have analyzed $D^0 \to K^0_S\pi^+\pi^-$ decay (see Table 1). The most precise results are from CLEO (BABAR and Belle, discussed below, have not yet evaluated systematic uncertainties). The CLEO analysis included ten resonances: $K^0_S\rho^0$, $K^0_S\omega$, $K^0_Sf_0(980)$, $K^0_Sf_2(1270)$, $K^0_Sf_0(1370)$, $K^*(892)^-\pi^+$, $K^*_0(1430)^-\pi^+$, $K^*_2(1430)^-\pi^+$, $K^*(1680)^-\pi^+$, and the doubly Cabibbo-suppressed mode $K^*(892)^+\pi^-$. CLEO found a much smaller nonresonant contribution than did the earliest experiments.

The source of the nonresonant component found in the early experiments has been attributed to the broad scalar resonances, the $K^*_0(1430)^-$ and $f_0(1370)$, found in the later, larger data samples. The observation of a small but significant nonresonant component in the largest data samples suggests the presence of additional broad scalar resonances, the $\kappa(800)$ and $\sigma(500)$. The CLEO analysis could accommodate the $\sigma(500)$ in lieu of the nonresonant component, but found no evidence for the $\kappa(800)$.

The ten quasi-two-body intermediate states in the CLEO analysis include both CP-even and CP-odd eigenstates and one doubly Cabibbo-suppressed channel. A time-dependent analysis of the Dalitz plot allows simultaneous determination of the strong transition amplitudes and phases and the mixing parameters x and y without phase or sign ambiguity. Using 9 fb^{-1}, CLEO obtained $(-4.5 < x < 9.3)\%$ and $(-6.4 < y < 3.6)\%$ [1].

The decay $D^0 \to K^0_S\pi^+\pi^-$, important for the study of the CKM angle γ/ϕ_3 [6], is under study by Belle [10,11] and BABAR [12,13]. The CLEO model does not provide a good description of the higher-statistics BABAR and Belle data samples. An improved description is obtained in two ways: First, by adding more Breit-Wigner resonances, including two $\pi\pi$ resonances with arbitrary mass and width, denoted as σ_1 and σ_2. Second, following the methodology of FOCUS [LINK 04], by applying a K-matrix model to the $\pi\pi$ S-wave [12].

Charm Dalitz-plot analyses might also prove useful for calibrating tools used to study B decays: specifically, to extract α from $B^0 \to \pi^+\pi^-\pi^0$, β from $b \to s$ penguin decays (*e.g.*, $B^0 \to \overline{K}^0K^+K^-$), and γ from $B^\pm \to DK^\pm$ followed by $D^0 \to \pi^+\pi^-\pi^0$ or $K^0_SK^+K^-$ or $K^+K^-\pi^0$, in addition to the well-studied $D^0 \to K^0_S\pi^+\pi^-$[2, 3].

***D* → ππππ: a σ(500) or f_0(600)**: The decay $D^+ \to \pi^+\pi^+\pi^-$ has been studied by the E687, E791 and FOCUS experiments (see Table 1). The E687 analysis considered the modes $\rho(770)^0\pi^+$, $f_0(980)\pi^+$, $f_2(1270)\pi^+$, and a nonresonant component. E791 included, in addition, $f_0(1370)\pi^+$ and $\rho(1450)^0\pi^+$. Both analyses found a very large fraction ($\sim 50\%$) for the nonresonant component, perhaps indicating a broad scalar contribution. E791 found the nonresonant amplitude to be consistent with zero if a broad scalar resonance was included. FOCUS analyzed its data using both the Breit-Wigner formalism and the K-matrix formalism for the $\pi^+\pi^-$ S-wave, following a 5-pole, 5-resonance model of Anisovich and Sarantsev [16]. The Breit-Wigner analysis included $\rho(770)^0$, $f_0(980)$, $f_2(1270)^0$, $f_0(1500)$, $\sigma(500)$, and a nonresonant component. The K-matrix formalism, with Breit-Wigner forms for the $\rho(770)$ and $f_2(1270)$, also describe the FOCUS data well. None of these analyses has modeled the dynamics of the $\pi^+\pi^+$ interaction. Consideration of the $I = 2$ S- and D-wave phase shifts, also measured in $\pi^+p \to \pi^+\pi^+n$ [18], could affect the $\pi^+\pi^-$ S-wave result.

Using the E791 data, Bediaga and Miranda [19] found additional evidence that the low-mass $\pi^+\pi^-$ feature is resonant by examining the phase of the $\pi^+\pi^-$ amplitude in the vicinity of the reported $\sigma(500)$ mass. The phase variation with invariant mass is consistent with a resonant interpretation.

Table 1 gives the parameters of the $\sigma(500)$ determined in charm Dalitz-plot analyses. A consistent relative phase between the $\sigma(500)$ and $\rho(770)$ resonances is observed.

Table 2: Parameters of the $\sigma(500)$ resonance. The amplitude and phase are relative to the $\rho(770)$.

Experiment	E791[a]	CLEO[b]	FOCUS [5]
Decay mode	$D^+ \to \pi^+\pi^+\pi^-$	$D^0 \to K^0_S\pi^+\pi^-$	$D^+ \to \pi^+\pi^+\pi^-$
Amplitude	$1.17 \pm 0.13 \pm 0.06$	0.57 ± 0.13	—
Phase (°)	$205.7 \pm 8.0 \pm 5.2$	214 ± 11	200 ± 31
m (MeV/c^2)	$478^{+24}_{-23} \pm 17$	513 ± 32	443 ± 27
Γ (MeV/c^2)	$324^{+42}_{-40} \pm 21$	335 ± 67	443 ± 80

See the end of the D^+ and D^0 listings for these references: [a]AITALA 01B, [b]MURAMATSU 02.

CLEO has studied $D^0 \to \pi^+\pi^-\pi^0$ (see Table 1). Only the three $\rho(770)\pi$ resonant contributions are observed. No evidence is found for any $\pi\pi$ S-wave, either with the Breit-Wigner or with a K-matrix parametrization, using the 4-pole, 2-resonance model of Au, Morgan, and Pennington [17].

$D^+ \to K^-\pi^+\pi^+$: a $\kappa(800)$?: Evidence for a broad $K\pi$ scalar resonance has been found by E791 in $D^+ \to K^-\pi^+\pi^+$ (see Table 1). Fitting the Dalitz plot with $\overline{K}^*(892)^0\pi^+$, $\overline{K}^*_0(1430)^0\pi^+$, $\overline{K}^*_2(1430)^0\pi^+$, and $\overline{K}^*(1680)^0\pi^+$, plus a constant nonresonant component, E791 found results consistent with earlier analyses by E691 and E687, with a nonresonant fit fraction of over 90%. With more events than the other experiments, E791 was then led to include an extra low-mass S-wave $\overline{K}\pi$ resonance to account for the poor fit already seen by earlier experiments. A $\kappa(800)$ with mass $797 \pm 19 \pm 43$ MeV and width $410 \pm 43 \pm 87$ MeV much improved the fit. The $\kappa(800)$ became the dominant resonance and the nonresonant fit fraction was reduced from $90.9 \pm 2.6\%$ to $13.0 \pm 5.8 \pm 4.4\%$.

In addition, E791 modeled the $K\pi$ S-wave phase variation as a function of $K\pi$ mass with only the $K^*_0(1430)$ resonance and a nonresonant component following a parametrization of LASS [20]. It was necessary to relax the unitarity constraint to describe the data [21]. The $K\pi$ S-wave phase behavior in this model was consistent with the model that included the κ resonance.

Finally, E791 performed a model-independent partial-wave analysis [AITALA 05] of the S-wave component of the $K\pi$ system, finding the amplitude and phase from the $K\pi$ threshold up to 1.72 GeV. No assumptions were made regarding dependence on invariant mass, but the analysis did use the relatively well-understood P- and D-waves, described by the $K^*(892)$ and $K^*(1680)$ and by the $K_2(1430)$, respectively. The results were similar to those obtained by AITALA 02, which parametrized the S-wave with κ and $K_0(1430)$ Breit-Wigner forms and a constant complex non-resonant term. As with the $\sigma(500)$, the $K^-\pi^+$ S-wave result could be affected by including dynamics of the $I = 2$ $\pi^+\pi^+$ interaction; however in AITALA 05, the $I = 2$ elastic amplitude was found to be negligible compared to the κ.

CLEO allowed scalar $K\pi$ resonances in fits to $D^0 \to K^-\pi^+\pi^0$ and $D^0 \to K^0_S\pi^+\pi^-$ (see Table 1), and observed a significant contribution from only the $K^*_0(1430)$ [22]. BABAR fit $D^0 \to K^0K^-\pi^+$ with both positively charged and neutral $\overline{K}^*(892)$, $\overline{K}^*_0(1430)$, $\overline{K}^*_2(1430)$, and $\overline{K}^*(1680)$ resonances, as well as the $a_0(980)^-$, $a_0(1450)^-$, and $a_2(1310)^-$ resonances, and a nonresonant component [14]. BABAR also fit $D^0 \to \overline{K}^0K^+\pi^-$ with the same resonances except for the $a_2(1310)^-$. In both cases, a good fit was obtained without including the κ.

FOCUS has conclusively observed a $K\pi$ S-wave as a distortion of the $K^*(892)$ line-shape in semileptonic charm decays [LINK 02E, LINK 05D].

The $f_0(980)$, $f_0(1370)$ and $f_0(1500)$: The meson content of the 0^{++} nonet and the quark content of the $f_0(980)$, $a_0(980)$, $f_0(1370)$, $f_0(1500)$, and $f_0(1710)$ mesons are current puzzles in light-meson spectroscopy [22]. Measuring branching fractions and couplings to different final states and comparing scalar-meson production rates among D^0, D^+, and D^+_s mesons may help solve these puzzles.

For example: A large contribution of $f_0(980)$ to $D^0 \to K^0_SK^+K^-$ was reported by ARGUS [ALBRECHT 87E] and by BABAR [14]. This is inconsistent with the smaller contribution of $f_0(980)$ observed in $D^0 \to K^0_S\pi^+\pi^-$ by CLEO. The explanation is that $D^0 \to K^0_SK^+K^-$ has a large contribution from $a_0(980)^0 \to K^+K^-$. Therefore CLEO studied $D^0 \to K^0_S\eta\pi^0$ [RUBIN 04], where the dominant contribution is from $K^0_S\,a_0(980)^0, a_0(980)^0 \to \eta\pi^0$, and there can be no $f_0(980)$. A more recent BABAR analysis of $D^0 \to K^0_sK^+K^-$ found a large amount of $a_0(980) \to K\overline{K}$ and little $f_0(980)$ [AUBERT 05B].

The proximity of the $K\overline{K}$ threshold requires either a coupled-channel Breit-Wigner function [23] or a Flatte parametrization [24] of the $f_0(980)$. The width of the $f_0(980)$ is poorly known. E791 and FOCUS [LINK 05C] [5] used a coupled-channel Breit-Wigner function to describe the $f_0(980)$ in $D^+_s \to \pi^+\pi^+\pi^-$. BESII studied the $f_0(980)$ in $J/\psi \to \phi\pi^+\pi^-$ and ϕK^+K^- [25]. The values found for the couplings to the $\pi\pi$ and $K\overline{K}$ channels, $g_{\pi\pi}$ and g_{KK}, were not consistent. Results such as these are desirable for input to the analysis of $D^+_s \to K^+K^-\pi^+$ [15], which includes both the $f_0(980)$ and $a_0(980)$.

The quark content of the $f_0(1370)$ and $f_0(1500)$ can perhaps be inferred from how they populate various Dalitz plots. Results so far are confusing. The E791 analysis of $D^+ \to \pi^+\pi^+\pi^-$ [AITALA 01B] found some $f_0(1370)$ but no $f_0(1500)$, while the FOCUS analysis [5] of this mode found little $f_0(1370)$. In $D^+_s \to \pi^+\pi^+\pi^-$, E687 and FOCUS [5] found no $f_0(1370)$, but did find a resonance with parameters similar to the $f_0(1500)$, whereas E791 found a $\pi^+\pi^-$ resonance with mass $1434 \pm 18 \pm 9$ MeV and width $172 \pm 32 \pm 6$ MeV, consistent with neither the $f_0(1370)$ or $f_0(1500)$. BABAR [AUBERT 05B] in $D^0 \to \overline{K}^0K^+K^-$ found neither the $f_0(1370)$ nor the $f_0(1500)$, but did observe a K^+K^- resonance consistent with the values from E791 given above, while CLEO has observed the $f_0(1370)$ in $D^0 \to K^0_S\pi^+\pi^-$. The FOCUS

analysis that used the K-matrix formalism for the $\pi\pi$ S-wave observed significant couplings to five T-matrix poles—$f_0(980)$, $f_0(1300)$, $f_0(1200-1600)$, $f_0(1500)$, $f_0(1750)$— in both $D^+ \to \pi^+\pi^-\pi^+$ and $D_s^+ \to \pi^+\pi^-\pi^+$. Again, the quark content of each pole might be inferred from the coupling to various Dalitz plots.

It is noteworthy that the S-wave observed in B Dalitz-plot analyses appears to be different than that observed in D-meson decays.

Doubly Cabibbo-Suppressed Decays: There are two classes of multibody doubly Cabibbo-suppressed (DCS) decays of D mesons. The first consists of those in which the DCS and corresponding Cabbibo-favored (CF) decays populate distinct Dalitz plots: the pairs $D^0 \to K^+\pi^-\pi^0$ and $D^0 \to K^-\pi^+\pi^0$, or $D^+ \to K^+\pi^+\pi^-$ and $D^+ \to K^-\pi^+\pi^+$, are examples. CLEO [BRANDENBURG 01] and Belle [TIAN 05] have reported $\Gamma(D^0 \to K^+\pi^-\pi^0)/\Gamma(D^0 \to K^-\pi^+\pi^0) = (0.43^{+0.11}_{-0.10} \pm 0.07)\%$ and $(0.229 \pm 0.015^{+0.013}_{-0.009})\%$, respectively. E791 and FOCUS have reported $\Gamma(D^+ \to K^+\pi^-\pi^+)/\Gamma(D^+ \to K^-\pi^+\pi^+) = (0.77 \pm 0.17 \pm 0.08)\%$ and $(0.65 \pm 0.08 \pm 0.04)\%$, respectively.

The second class consists of decays in which the DCS and CF modes populate the same Dalitz plot; for example, $D^0 \to K^{*-}\pi^+$ and $D^0 \to K^{*+}\pi^-$ both contribute to $D^0 \to K^0_S\pi^+\pi^-$. In this case, the potential for interference of DCS and CF amplitudes increases the sensitivity to the DCS amplitude. CLEO found the relative amplitude and phase to be $(7.1 \pm 1.3^{+2.6\,+2.6}_{-0.6\,-0.6})\%$ and $(189 \pm 10 \pm 3^{+15}_{-5})^\circ$, corresponding to $\Gamma(D^0 \to K^*(892)^+\pi^-)/\Gamma(D^0 \to K^*(892)^-\pi^+) = (0.5 \pm 0.2^{+0.5\,+0.4}_{-0.1\,-0.1})\%$. In addition to $D^0 \to K^*(892)^+\pi^-$, Belle [10,11] and BABAR [12,13] have found evidence for $D^0 \to K_0(1430)^+\pi^-$ and $K_2(1430)^+\pi^-$, and Belle has also found evidence for $K^*(1680)^+\pi^-$.

CP Violation: In the limit of CP conservation, charge conjugate decays will have the same Dalitz-plot distribution. The $D^{*\pm}$ tag enables the discrimination between D^0 and $\overline{D}^0$. The integrated CP violation across the Dalitz plot is determined in two ways. The first uses

$$\mathcal{A}_{CP} = \int \left(\frac{|\mathcal{M}|^2 - |\overline{\mathcal{M}}|^2}{|\mathcal{M}|^2 + |\overline{\mathcal{M}}|^2} \right) dm^2_{ab}\, dm^2_{bc} \;\Big/ \int dm^2_{ab}\, dm^2_{bc}\,, \quad (1)$$

where $\mathcal{M}$ and $\overline{\mathcal{M}}$ are the D^0 and $\overline{D}^0$ Dalitz-plot amplitudes. The second uses the asymmetry in the efficiency-corrected D^0 and $\overline{D}^0$ yields,

$$\mathcal{A}_{CP} = \frac{N_{D^0} - N_{\overline{D}^0}}{N_{D^0} + N_{\overline{D}^0}}\,. \quad (2)$$

These expressions are less sensitive to CP violation than are the individual resonant submodes [ASNER 04A]. Table 3 lists the results for CP violation. No evidence of CP violation has been observed in D-meson decays.

Table 3: Dalitz-plot-integrated CP violation. Measurements computing $\mathcal{A}_{CP}$ with Eq. (2) rather than Eq. (1) are denoted †.

Experiment	Decay mode	$\mathcal{A}_{CP}(\%)$
BABAR [a]	$D^+ \to K^+K^-\pi^+$	$1.4 \pm 1.0 \pm 0.8$
Belle [b†]	$D^0 \to K^+\pi^-\pi^0$	-0.6 ± 5.3
Belle [b†]	$D^0 \to K^+\pi^-\pi^+\pi^-$	-1.8 ± 4.4
CLEO [c]	$D^0 \to K^-\pi^+\pi^0$	-3.1 ± 8.6
CLEO [d†]	$D^0 \to K^+\pi^-\pi^0$	$+9^{+22}_{-25}$
CLEO [e]	$D^0 \to K^0_S\pi^+\pi^-$	$-0.9 \pm 2.1^{+1.0+1.3}_{-4.3-3.7}$
CLEO [f]	$D^0 \to \pi^+\pi^-\pi^0$	$+1^{+9}_{-7} \pm 9$

See the end of the D^+ and D^0 Listings for these references: [a]AUBERT 05A, [b]TIAN 05, [c]KOPP 01, [d]BRANDENBURG 01, [e]ASNER 04A, [f]CRONIN-HENNESSY 05.

The possibility of interference between CP–conserving and CP–violating amplitudes provides a more sensitive probe of CP violation. The constraints on the square of the CP–violating amplitude obtained in the resonant submodes of $D^0 \to K^0_S\pi^+\pi^-$ range from 3.5×10^{-4} to 28.4×10^{-4} at 95% confidence level [ASNER 04A].

$\Gamma(\overline{K}_0^*(800)^0\pi^+, \overline{K}_0^*(800) \to K^-\pi^+)/\Gamma(K^-\pi^+\pi^+)$ Γ_{43}/Γ_{42}

This is the "fit fraction" from the Dalitz-plot analysis. The $K_0^*(800)$ is a broad scalar resonance that may not exist and is not included in the Summary Tables. AITALA 02 finds that including such a resonance in the fit to the $D^+ \to K^-\pi^+\pi^+$ Dalitz plot greatly improves the fit. However, the results of AITALA 02 for the $D^+ \to K^-\pi^+\pi^+$ Dalitz plot analysis so disagree with earlier analyses that averaging the results makes no sense. For now, we exclude AITALA 02 from the average.

0.033 ±0.008 ±0.002	168	ADLER	88C	MRK3	e^+e^- 3.77 GeV
0.122 $^{+0.032}_{-0.021}$ ±0.021	11	[63] AGUILAR-...	87F	HYBR	πp, pp 360, 400 GeV
0.06 ±0.03	21	[64] SCHINDLER	81	MRK2	e^+e^- 3.771 GeV

[62] HE 05 uses single- and double-tagged events in an overall fit. The fraction here includes (unobserved) final-state photons.

[63] AGUILAR-BENITEZ 87F and BARLAG 92C compute the branching fraction by topological normalization.

[64] SCHINDLER 81 (MARK-2) measures $\sigma(e^+e^- \to \psi(3770)) \times$ branching fraction to be 0.51 ± 0.08 nb. We use the MARK-3 (ADLER 88C) value of $\sigma = 4.2 \pm 0.6 \pm 0.3$ nb.

$\Gamma(K^0_S\pi^+\pi^+\pi^-)/\Gamma(K^-\pi^+\pi^+)$ Γ_{62}/Γ_{42}

D^+-D^- T-VIOLATING DECAY-RATE ASYMMETRIES

$A_{Tviol}(K_S^0K^{\pm}\pi^+\pi^-)$ in $D^{\pm} \to K_S^0K^{\pm}\pi^+\pi^-$

$C_T \equiv \vec{p}_{K^+} \cdot (\vec{p}_{\pi^+} \times \vec{p}_{\pi^-})$ is a T-odd correlation of the K^+, π^+, and π^- momenta for the D^+. $\overline{C}_T \equiv \vec{p}_{K^-} \cdot (\vec{p}_{\pi^-} \times \vec{p}_{\pi^+})$ is the corresponding quantity for the D^-. $A_T \equiv [\Gamma(C_T > 0) - \Gamma(C_T < 0)] / [\Gamma(C_T > 0) + \Gamma(C_T < 0)]$ would, in the absence of strong phases, test for T violation in D^+ decays (the Γ's are partial widths). With $\overline{A}_T \equiv [\Gamma(-\overline{C}_T > 0) - \Gamma(-\overline{C}_T < 0)] / [\Gamma(-\overline{C}_T > 0) + \Gamma(-\overline{C}_T < 0)]$, the asymmetry $A_{Tviol} \equiv \frac{1}{2}(A_T - \overline{A}_T)$ tests for T violation even with nonzero strong phases.

D^0–$\overline{D}^0$ MIXING

Revised January 2006 by D. Asner (Carleton University)

Standard Model contributions to D^0–$\overline{D}^0$ mixing are strongly suppressed by CKM and GIM factors. Thus the observation of D^0–$\overline{D}^0$ mixing might be evidence for physics beyond the Standard Model. See Burdman and Shipsey [1] for a review of D^0–$\overline{D}^0$ mixing, Ref. [2] for a compilation of mixing predictions, and Ref. [3] for later predictions.

Formalism: The time evolution of the D^0–$\overline{D}^0$ system is described by the Schrödinger equation

$$i\frac{\partial}{\partial t}\begin{pmatrix}D^0(t)\\ \overline{D}^0(t)\end{pmatrix} = \left(\mathbf{M}-\tfrac{i}{2}\mathbf{\Gamma}\right)\begin{pmatrix}D^0(t)\\ \overline{D}^0(t)\end{pmatrix}, \quad (1)$$

where the $\mathbf{M}$ and $\mathbf{\Gamma}$ matrices are Hermitian, and CPT invariance requires that $M_{11} = M_{22} \equiv M$ and $\Gamma_{11} = \Gamma_{22} \equiv \Gamma$. The off-diagonal elements of these matrices describe the dispersive and absorptive parts of D^0–$\overline{D}^0$ mixing.

The two eigenstates D_1 and D_2 of the effective Hamiltonian matrix $(\mathbf{M}-\frac{i}{2}\mathbf{\Gamma})$ are given by

$$|D_{1,2}\rangle = p|D^0\rangle \pm q|\overline{D}^0\rangle\,. \quad (2)$$

The corresponding eigenvalues are

$$\lambda_{1,2} \equiv m_{1,2} - \tfrac{i}{2}\Gamma_{1,2} = \left(M-\tfrac{i}{2}\Gamma\right) \pm \frac{q}{p}\left(M_{12}-\tfrac{i}{2}\Gamma_{12}\right), \quad (3)$$

where m_1 and Γ_1 are the mass and width of the D_1, *etc.*, and

$$\left|\frac{q}{p}\right|^2 = \frac{M_{12}^* - \frac{i}{2}\Gamma_{12}^*}{M_{12}-\frac{i}{2}\Gamma_{12}}. \quad (4)$$

We define reduced mixing amplitudes x and y by

$$x \equiv 2M_{12}/\Gamma = (m_1-m_2)/\Gamma = \Delta m/\Gamma \quad (5)$$

and

$$y \equiv \Gamma_{12}/\Gamma = (\Gamma_1-\Gamma_2)/2\Gamma = \Delta\Gamma/2\Gamma\,, \quad (6)$$

where $\Gamma \equiv (\Gamma_1+\Gamma_2)/2$. The mixing rate, R_M, is approximately $(x^2+y^2)/2$. In Eq. (5) and Eq. (6), the middle relation holds only in the limit of CP conservation, in which case the subscripts 1 and 2 denote the CP-even and CP-odd eigenstates.

The parameters x and y are measured in several ways. The most precise constraints are obtained using the time-dependence of D decays. Since D^0–$\overline{D}^0$ mixing is a small effect, the identification tag of the initial particle as a D^0 or a $\overline{D}^0$ must be extremely accurate. The usual tag is the charge of the distinctive slow pion in the decay sequence $D^{*+} \to D^0\pi^+$ or $D^{*-} \to \overline{D}^0\pi^-$. In current experiments, the probability of mistagging is about 0.1%. Another tag of comparable accuracy is identification of one of the D's produced from $\psi(3770) \to D^0\overline{D}^0$. Time-dependent analyses are not possible at symmetric charm threshold facilities (the D^0 and $\overline{D}^0$ do not travel far enough). However, the quantum coherent $D^0\overline{D}^0$ $C=-1$ state provides time-integrated sensitivity [4, 5].

Time-Dependent Analyses: We extend the formalism of this *Review*'s note on "B^0–$\overline{B}^0$ Mixing" [6]. In addition to the "right-sign" instantaneous decay amplitudes $\overline{A}_f \equiv \langle f|H|\overline{D}^0\rangle$ and $A_{\overline{f}} \equiv \langle \overline{f}|H|D^0\rangle$ for CP conjugate final states f and $\overline{f}$, we include the "wrong-sign" amplitudes $\overline{A}_{\overline{f}} \equiv \langle \overline{f}|H|\overline{D}^0\rangle$ and $A_f \equiv \langle f|H|D^0\rangle$.

It is usual to normalize the wrong-sign decay distributions to the integrated rate of right-sign decays and to express time in units of the precisely measured D^0 mean lifetime, $\overline{\tau}_{D^0} = 1/\Gamma = 2/(\Gamma_1+\Gamma_2)$. Starting from a pure $|D^0\rangle$ or $|\overline{D}^0\rangle$ state at $t=0$, the time-dependent rates of production of the wrong-sign final states relative to the integrated right-sign states are then

$$r(t) = \frac{\left|\langle f|H|D^0(t)\rangle\right|^2}{\left|\overline{A}_f\right|^2} = \left|\frac{q}{p}\right|^2\left|g_+(t)\,\chi_f^{-1} + g_-(t)\right|^2 \quad (7)$$

and

$$\overline{r}(t) = \frac{\left|\langle \overline{f}|H|\overline{D}^0(t)\rangle\right|^2}{\left|A_{\overline{f}}\right|^2} = \left|\frac{p}{q}\right|^2\left|g_+(t)\,\chi_{\overline{f}} + g_-(t)\right|^2, \quad (8)$$

where

$$\chi_f \equiv q\overline{A}_f/pA_f\,, \quad \chi_{\bar{f}} \equiv q\overline{A}_{\bar{f}}/pA_{\bar{f}}\,, \quad (9)$$

and

$$g_\pm(t) = \frac{1}{2}\left(e^{-iz_1t} \pm e^{-iz_2t}\right), \quad z_{1,2} = \frac{\lambda_{1,2}}{\Gamma}\,. \quad (10)$$

Note that a change in the convention for the relative phase of D^0 and $\overline{D}^0$ would cancel between q/p and $\overline{A}_f/A_f$ and leave χ_f invariant.

We expand $r(t)$ and $\overline{r}(t)$ to second order in time for modes where the ratio of decay amplitudes $R_D = |A_f/\overline{A}_f|^2$ is very small.

Semileptonic decays: In semileptonic D decays, $A_f = \overline{A}_{\overline{f}} = 0$ in the Standard Model. Then in the limit of weak mixing, where $|ix+y| \ll 1$, $r(t)$ is given by

$$r(t) = |g_-(t)|^2\left|\frac{q}{p}\right|^2 \approx \frac{e^{-t}}{4}(x^2+y^2)\,t^2\left|\frac{q}{p}\right|^2. \quad (11)$$

For $\overline{r}(t)$ one replaces q/p here with p/q. In the limit of CP conservation, $r(t) = \overline{r}(t)$, and the time-integrated mixing rate relative to the time-integrated right-sign decay rate is

$$R_M = \int_0^\infty r(t)dt = \left|\frac{q}{p}\right|^2\frac{x^2+y^2}{2+x^2-y^2} \approx \frac{1}{2}(x^2+y^2)\,. \quad (12)$$

Table 1 summarizes results from semileptonic decays.

Table 1: Results for R_M in D^0 semileptonic decays.

Wrong-sign decays to hadronic non-CP eigenstates: Consider the final state $f = K^+\pi^-$, where A_f is doubly Cabibbo-suppressed. The ratio of decay amplitudes is

$$\frac{A_f}{\overline{A}_f} = -\sqrt{R_D}\, e^{-i\delta}, \quad \left|\frac{A_f}{\overline{A}_f}\right| \sim O(\tan^2\theta_c)\,, \tag{13}$$

where R_D is the doubly Cabibbo-suppressed (DCS) decay rate relative to the Cabibbo-favored (CF) rate, the minus sign originates from the sign of V_{us} relative to V_{cd}, and δ is the phase difference between DCS and CF processes not attributed to the first-order electroweak spectator diagram.

We characterize the violation of CP in the mixing amplitude, the decay amplitude, and the interference between mixing and decay, by real-valued parameters A_M, A_D, and ϕ. We adopt a parametrization similar to that of Nir [8] and CLEO [GODANG 00] and express these quantities in a way that is convenient to describe the three types of CP violation:

$$\left|\frac{q}{p}\right| = 1 + A_M\,, \tag{14}$$

$$\chi_f^{-1} \equiv \frac{pA_f}{q\overline{A}_f} = \frac{-\sqrt{R_D}(1+A_D)}{(1+A_M)}\, e^{-i(\delta+\phi)}\,, \tag{15}$$

$$\chi_{\overline{f}} \equiv \frac{q\overline{A}_{\overline{f}}}{pA_{\overline{f}}} = -\frac{-\sqrt{R_D}(1+A_M)}{(1+A_D)}\, e^{-i(\delta-\phi)}\,. \tag{16}$$

In general, $\chi_{\overline{f}}$ and χ_f^{-1} are independent complex numbers. To leading order,

$$r(t) = e^{-t} \times \Big[R_D(1+A_D)^2 + \sqrt{R_D}(1+A_M)(1+A_D)y'_- t + \frac{(1+A_M)^2 R_M}{2}\, t^2\Big] \tag{17}$$

and

$$\overline{r}(t) = e^{-t} \times \Big[\frac{R_D}{(1+A_D)^2} + \frac{\sqrt{R_D}}{(1+A_D)(1+A_M)} y'_+ t + \frac{R_M}{2(1+A_M)^2}\, t^2\Big]. \tag{18}$$

Here

$$y'_\pm \equiv y'\cos\phi \pm x'\sin\phi = y\cos(\delta \mp \phi) - x\sin(\delta \mp \phi) \tag{19}$$

$$y' \equiv y\cos\delta - x\sin\delta, \quad x' \equiv x\cos\delta + y\sin\delta\,, \tag{20}$$

and R_M is the mixing rate relative to the time-integrated right-sign rate.

The three terms in Eq. (17) and Eq. (18) probe the three fundamental types of CP violation. In the limit of CP conservation, A_M, A_D, and ϕ are all zero, and then

$$r(t) = \overline{r}(t) = e^{-t}\left(R_D + \sqrt{R_D}\, y' t + \frac{1}{2} R_M\, t^2\right), \tag{21}$$

and the time-integrated wrong-sign rate relative to the integrated right-sign rate is

$$R = \int_0^\infty r(t)\, dt = R_D + \sqrt{R_D}\, y' + R_M\,. \tag{22}$$

The ratio R is the most readily accessible experimental quantity. Table 2 gives recent measurements of R in $D^0 \to K^+\pi^-$ decay. The average of these results, $R = (0.376 \pm 0.009)\,\%$, is about two standard deviations from the average of earlier, less precise results, $R = (0.81 \pm 0.23)\,\%$, which we have omitted.

Table 2: Results for R in $D^0 \to K^+\pi^-$.

2000	CLEO[d]	$e^+e^- \to \Upsilon(4S)$	$3.32^{+0.63}_{-0.65} \pm 0.40$	$2^{+19}_{-20} \pm 1$

See the end of the D^0 listings for these references: [a]ZHANG 06, [b]LINK 05, [c]AUBERT 03Z, [d]GODANG 00.

The contributions to R—allowing for CP violation—can be extracted by fitting the $D^0 \to K^+\pi^-$ and $\overline{D}^0 \to K^-\pi^+$ decay rates. Table 2 gives the constraints on A_D with $x' = y' = 0$. Table 3 summarizes the results for y' and $x'^2/2$. Figure 1 shows the two-dimensional allowed regions. No meaningful constraints on A_M and ϕ have been reported.

Extraction of the amplitudes x and y from the results in Table 3 requires knowledge of the relative strong phase δ, a subject of theoretical discussion [4,9–11]. In most cases, it appears difficult for theory to accommodate $\delta > 25°$, although the judicious placement of a $K\pi$ resonance could allow δ to be as large as 40°.

A quantum interference effect that provides useful sensitivity to δ arises in the decay chain $\psi(3770) \to D^0\overline{D}^0 \to (f_{cp})(K^+\pi^-)$, where f_{cp} denotes a CP eigenstate from D^0 decay, such as K^+K^-[1, 16]. Here, the amplitude triangle relation

$$\sqrt{2}\, A(D_\pm \to K^-\pi^+) = A(D^0 \to K^-\pi^+) \pm A(\overline{D}^0 \to K^-\pi^+), \tag{23}$$

where $D_\pm$ denotes a CP eigenstate, implies that

$$\cos\delta = \frac{B(D_+ \to K^-\pi^+) - B(D_- \to K^-\pi^+)}{2\sqrt{R_D}\, B(D^0 \to K^-\pi^+)}\,, \tag{24}$$

neglecting CP violation and exploiting $R_D \ll \sqrt{R_D}$.

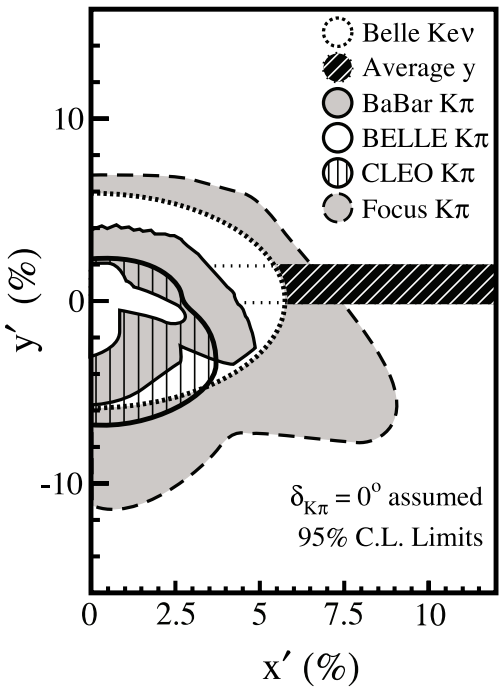

Figure 1: Allowed regions in the $x'y'$ plane. The allowed region for y is the average of the results from E791[a], FOCUS[b], CLEO[c], BABAR[d], and Belle[e]. Also shown is the limit from $D^0 \to K^{(*)}\ell\nu$ from Belle[f] and limits from $D \to K\pi$ from CLEO[g], BABAR[h], Belle[i] and FOCUS[j]. The CLEO, BABAR and Belle results allow CP violation in the decay and mixing amplitudes, and in the interference between these two processes. The FOCUS result does not allow CP violation. We assume $\delta = 0$ to place the y results. A non-zero δ would rotate the $D^0 \to CP$ eigenstates confidence region clockwise about the origin by δ. All results are consistent with the absence of mixing. See the end of the D^0 listings for these references: [a]AITALA 99E, [b]LINK 00, [c]CSORNA 02, [d]AUBERT 03P, [e]ABE 02I, [f]BITENC 05, [g]GODANG 00, [h]AUBERT 03Z, [i]ZHANG 06, [j]LINK 05. See full-color version on color pages at end of book.

The strong phase δ might also be determined by constructing amplitude quadrangles from a complete set of branching fraction measurements of the other DCS D decays to two pseudoscalars [12]. This analysis would have to assume that the amplitudes from both $\Delta I = 1$ and $\Delta I = 0$ that populate the total $I = 1/2$ $K\pi$ state have the same strong phase relative to the amplitude that populates the total $I = 3/2$ $K\pi$ state.

The Dalitz-plot analyses of DCS D decays to a pseudoscalar and a vector allow the measurement of the relative strong phase between some amplitudes, providing additional constraints to the amplitude quadrangle [13] and thus the determination of the strong phase difference between the relevant DCS and CF amplitudes. In $D^0 \to K^0_S\pi^+\pi^-$, the DCS and CF decay amplitudes populate the same Dalitz plot, which allows direct measurement of the relative strong phase. CLEO has measured the relative phase between $D^0 \to K^*(892)^+\pi^-$ and $D^0 \to K^*(892)^-\pi^+$ to be $(189 \pm 10 \pm 3^{+15}_{-5})^\circ$ [MURAMATSU 02], consistent with the 180° expected from Cabibbo factors and a small strong phase.

There are several results for R measured in multibody final states with nonzero strangeness. Here R, defined in Eq. (22), becomes an average over the Dalitz space, weighted by experimental efficiencies and acceptance. Table 4 summarizes the results.

Table 4: Results for R in $D^0 \to K^{(*)+}\pi^-(n\pi)$.

Year	Exper.	D^0 final state	$R(\%)$
2005	Belle[a]	$K^+\pi^-\pi^+\pi^-$	$0.320 \pm 0.019^{+0.018}_{-0.013}$
2005	Belle[a]	$K^+\pi^-\pi^0$	$0.229 \pm 0.017^{+0.013}_{-0.009}$
2002	CLEO[b]	$K^{*+}\pi^-$	$0.5 \pm 0.2^{+0.6}_{-0.1}$
2001	CLEO[c]	$K^+\pi^-\pi^+\pi^-$	$0.41^{+0.12}_{-0.11} \pm 0.04$
2001	CLEO[d]	$K^+\pi^-\pi^0$	$0.43^{+0.11}_{-0.10} \pm 0.07$
1998	E791[e]	$K^+\pi^-\pi^+\pi^-$	$0.68^{+0.34}_{-0.33} \pm 0.07$

See the end of the D^0 listings for these references: [a]TIAN 05, [b]MURAMATSU 02, [c]DYTMAN 01, [d]BRANDENBURG 01, [e]AITALA 98.

For multibody final states, Eqs. (13)–(22) apply to one point in the Dalitz space. Although x and y do not vary across the space, knowledge of the resonant substructure is needed to extrapolate the strong phase difference δ from point to point. Both the sign and magnitude of x and y may be measured using the time-dependent resonant substructure of multibody D^0 decays. CLEO has performed a time-dependent Dalitz-plot analysis of $D^0 \to K^0_S\pi^+\pi^-$, and reports $(-4.5 < x < 9.3)\%$ and $(-6.4 < y < 3.6)\%$ at the 95% confidence level, without phase or sign ambiguity [ASNER 05], as shown in Figure 2.

Decays to CP Eigenstates: When the final state f is a CP eigenstate, there is no distinction between f and $\overline{f}$, and then $A_f = A_{\overline{f}}$ and $\overline{A}_{\overline{f}} = \overline{A}_f$. We denote final states with CP eigenvalues ± 1 by $f_\pm$. In analogy with Eqs. (7)–(8), the decay rates to CP eigenstates are then

$$\begin{aligned} r_\pm(t) &= \frac{\left|\langle f_\pm|H|D^0(t)\rangle\right|^2}{\left|\overline{A}_\pm\right|^2} \\ &= \frac{1}{4}\left|h_\pm(t)\left(\frac{A_\pm}{\overline{A}_\pm} \pm \frac{q}{p}\right) + h_\mp(t)\left(\frac{A_\pm}{\overline{A}_\pm} \mp \frac{q}{p}\right)\right|^2, \\ &\propto \frac{1}{|p|^2}\left|h_\pm(t) + \eta_\pm h_\mp(t)\right|^2, \end{aligned} \tag{25}$$

and

$$\overline{r}_\pm(t) = \frac{\left|\langle f_\pm|H|\overline{D}^0(t)\rangle\right|^2}{|A_\pm|^2} \propto \frac{1}{|q|^2}\left|h_\pm(t) - \eta_\pm h_\mp(t)\right|^2, \tag{26}$$

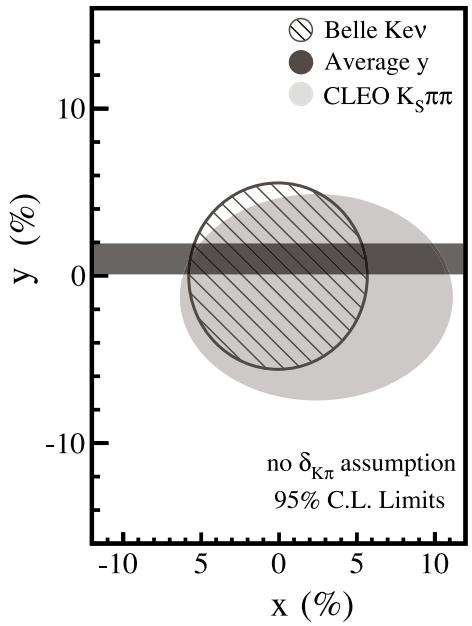

Figure 2: Allowed regions in the xy plane. No assumption is made regarding δ. The allowed region for y is the average of the results from E791[a], FOCUS[b], CLEO[c], BABAR[d], and Belle[e]. Also shown is the limit from $D^0 \to K^{(*)}\ell\nu$ from Belle[f]. The CLEO experiment has constrained x and y with the time-dependent Dalitz-plot analysis of $D^0 \to K^0_S\pi^+\pi^-$[g]. All results are consistent with the absence of mixing. See the end of the D^0 listings for these references: [a]AITALA 99E, [b]LINK 00, [c]CSORNA 02, [d]AUBERT 03P, [e]ABE 02I, [f]BITENC 05, [g]ASNER 05.

where

$$h_\pm(t) = g_+(t) \pm g_-(t) = e^{-iz_\pm t}, \tag{27}$$

and

$$\eta_\pm \equiv \frac{pA_\pm \mp q\overline{A}_\pm}{pA_\pm \pm q\overline{A}_\pm} = \frac{1 \mp \chi_\pm}{1 \pm \chi_\pm}. \tag{28}$$

The variable $\eta_\pm$ describes CP violation; it can receive contributions from each of the three fundamental types of CP violation.

The quantity y may be measured by comparing the rate for decays to non-CP eigenstates such as $D^0 \to K^-\pi^+$ with decays to CP eigenstates such as $D^0 \to K^+K^-$ [11]. A positive y would make K^+K^- decays appear to have a shorter lifetime than $K^-\pi^+$ decays. The decay rate for a D^0 into a CP eigenstate is not described by a single exponential in the presence of CP violation.

In the limit of weak mixing, where $|ix + y| \ll 1$, and small CP violation, where $|A_M|$, $|A_D|$, and $|\sin\phi| \ll 1$, the time dependence of decays to CP eigenstates is proportional to a single exponential:

$$r_\pm(t) \propto \exp\left(-[1 \pm \left|\frac{p}{q}\right|(y\cos\phi - x\sin\phi)]t\right), \tag{29}$$

$$\overline{r}_\pm(t) \propto \exp\left(-[1 \pm \left|\frac{q}{p}\right|(y\cos\phi + x\sin\phi)]t\right), \tag{30}$$

$$r_\pm(t) + \overline{r}_\pm(t) \propto e^{-(1\pm y_{CP})t}. \tag{31}$$

Here

$$y_{CP} = y\cos\phi\left[\frac{1}{2}\left(\left|\frac{p}{q}\right| + \left|\frac{q}{p}\right|\right) + \frac{A_{\rm prod}}{2}\left(\left|\frac{p}{q}\right| - \left|\frac{q}{p}\right|\right)\right] - x\sin\phi\left[\frac{1}{2}\left(\left|\frac{p}{q}\right| - \left|\frac{q}{p}\right|\right) + \frac{A_{\rm prod}}{2}\left(\left|\frac{p}{q}\right| + \left|\frac{q}{p}\right|\right)\right], \tag{32}$$

and

$$A_{\rm prod} \equiv \frac{N(D^0) - N(\overline{D}^0)}{N(D^0) + N(\overline{D}^0)} \tag{33}$$

is defined as the production asymmetry of the D^0 and $\overline{D}^0$.

The possibility of CP violation has been considered in the limit of weak mixing and small CP violation. In this limit there is no sensitivity to CP violation in direct decay. Belle [14] and BABAR [AUBERT 03P] have measure A_Γ, where

$$A_\Gamma \equiv \frac{r_\pm(t) - \overline{r}_\pm(t)}{r_\pm(t) - \overline{r}_\pm(t)} \approx A_M\, y\cos\phi - x\sin\phi,$$

allowing CP violation in interference and mixing.

In the limit of CP conservation, $A_\pm = \pm\overline{A}_\pm$, $\eta_\pm = 0$, $y = y_{CP}$, and

$$r_\pm(t)\left|\overline{A}_\pm\right|^2 = \overline{r}_\pm(t)\left|A_\pm\right|^2 \propto e^{-(1\pm y_{CP})t}. \tag{34}$$

All measurements of y and A_Γ are relative to the $D^0 \to K^-\pi^+$ decay rate. Table 5 summarizes the current status of measurements. The average of the six y_{CP} measurements is $0.90 \pm 0.42\,\%$.

Table 5: Results for y from $D^0 \to K^+K^-$ and $\pi^+\pi^-$.

Year	Exper.	D^0 final state(s)	$y_{CP}(\%)$	$A_\Gamma(\times 10^{-3})$
2003	Belle [14]	K^+K^-	$1.15 \pm 0.69 \pm 0.38$	$-2.0 \pm 6.3 \pm 3.0$
2003	BABAR[a]	$K^+K^-, \pi^+\pi^-$	$0.8 \pm 0.4^{+0.5}_{-0.4}$	$-8 \pm 6 \pm 2$

Substantial work on the integrated CP asymmetries in decays to CP eigenstates indicates that A_{CP} is consistent with zero at the few percent level [15]. The expression for the integrated CP asymmetry that includes the possibility of CP violation in mixing is

$$A_{CP} = \frac{\Gamma(D^0 \to f_\pm) - \Gamma(\overline{D}^0 \to f_\pm)}{\Gamma(D^0 \to f_\pm) + \Gamma(\overline{D}^0 \to f_\pm)} \quad (35)$$

$$= \frac{|q|^2 - |p|^2}{|q|^2 + |p|^2} + 2\mathrm{Re}(\eta_\pm)\,. \quad (36)$$

Coherent $D^0\overline{D}^0$ Analyses: Measurements of R_D, $\cos\delta$, x, and y can be made simultaneously in a combined fit to the single-tag (ST) and double-tag (DT) yields or individually by a series of "targeted" analyses [16, 17].

The "comprehensive" analysis simultaneously measures mixing and DCS parameters by examining various ST and DT rates. Due to quantum correlations in the $C = -1$ and $C = +1$ $D^0\overline{D}^0$ pairs produced in the reactions $e^+e^- \to D^0\overline{D}^0(\pi^0)$ and $e^+e^- \to D^0\overline{D}^0\gamma(\pi^0)$, respectively, the time-integrated $D^0\overline{D}^0$ decay rates are sensitive to interference between amplitudes for indistinguishable final states. The size of this interference is governed by the relevant amplitude ratios and can include contributions from D^0-$\overline{D}^0$ mixing.

Table 6: CLEO-c results from time-integrated yields at $\psi(3770) \to D\bar{D}$.

Parameter	CLEO-c fitted value	Other results
y (Table 5)	-0.058 ± 0.066	$(0.90 \pm 0.42)\%$
$\cos\delta_{K\pi}$	1.09 ± 0.66	—
R_M (Table 1)	$(1.7 \pm 1.5) \times 10^{-3}$	$<0.1\%$ (95% C.L.)
$x^2/2$ (Table 3)	$< 0.44\%$ @(95% C.L.)	$<0.036\%$ (95% C.L.)

The following categories of final states are considered:

f or $\bar{f}$: Hadronic states accessed from either D^0 or $\overline{D}^0$ decay but that are not CP eigenstates. An example is $K^-\pi^+$, which results from Cabibbo-favored D^0 transitions or DCS $\overline{D}^0$ transitions.

ℓ^+ or ℓ^-: Semileptonic or purely leptonic final states, which, in the absence of mixing, tag unambiguously the flavor of the parent D.

S_+ or S_-: CP-even and CP-odd eigenstates, respectively.

The decay rates for $D^0\overline{D}^0$ pairs to all possible combinations of the above categories of final states are calculated in Ref. [4], for both $C = -1$ and $C = +1$, reproducing the work of Refs. [5, 10]. Such $D^0\overline{D}^0$ combinations, where both D final states are specified, are double tags. In addition, the rates for single tags, where either the D^0 or $\overline{D}^0$ is identified and the other neutral D decays generically are given in Ref. [4].

CLEO-c has reported results using 281 pb^{-1} of $e^+e^- \to \psi(3770)$ data [18], where the quantum coherent $D^0\overline{D}^0$ pairs are in the $C = -1$ state. The values of y, R_M, and $\cos\delta$ are determined from a combined fit to the ST (hadronic only) and DT yields. The hadronic final states included in the analysis are $K^-\pi^+$ (f), $K^+\pi^-$ ($\bar{f}$), K^-K^+ ($S+$), $\pi^+\pi^-$ (S_+), $K^0_S\pi^0\pi^0$ (S_+), and $K^0_S\pi^0$ (S_-). Both of the two flavored final states, $K^-\pi^+$ and $K^+\pi^-$, can be reached via CF or DCS transitions.

Semileptonic DT yields are also included, where one D is fully reconstructed in one of the hadronic modes listed above, and the other D is partially reconstructed, requiring that only the electron be found. When the electron is accompanied by a flavor tag ($D \to K^-\pi^+$ or $K^+\pi^-$), only the "right-sign" DT sample, where the electron and kaon charges are the same, is used. Extraction of the DCS "wrong-sign" semileptonic yield is not feasible with the current CLEO-c data sample, and the parameter $r_{K\pi}$ is constrained to the world average. Table 6 shows the results of the fit to the CLEO-c data.

[5] The AUBERT 03Z, LI 05A, and ZHANG 06 limits are inferred from the D^0-$\overline{D}^0$ mixing ratio $\Gamma(K^+\pi^-$ (via $\overline{D}^0))/\Gamma(K^-\pi^+)$ given near the end of this D^0 Listings. Decay-time information is used to distinguish DCS decays from D^0-$\overline{D}^0$ mixing. The limit allows interference between the DCS and mixing ratios, and also allows CP violation. AUBERT 03Z assumes the strong phase between $D^0 \to K^+\pi^-$ and $\overline{D}^0 \to K^+\pi^-$ amplitudes is small; if an arbitrary phase is allowed, the limit degrades by 20%. The LI 05A and ZHANG 06 limits are valid for an arbitrary strong phase.

[6] This ASNER 05 limit is from the time-dependent Dalitz-plot analysis of $D^0 \to K^0_S\pi^+\pi^-$. Decay-time information and interference on the Dalitz plot are used to distinguish doubly Cabibbo-suppressed decays from mixing and to measure the relative phase between $D^0 \to K^{*+}\pi^-$ and $\overline{D}^0 \to K^{*+}\pi^-$. This limit allows CP violation and is sensitive to the sign of Δm.

[7] This LINK 05H limit is inferred from the D^0-$\overline{D}^0$ mixing ratio $\Gamma(K^+\pi^-$ (via $\overline{D}^0))/\Gamma(K^-\pi^+)$ given near the end of this D^0 Listings. Decay-time information is used to distinguish DCS decays from D^0-$\overline{D}^0$ mixing. The limit allows interference between the DCS and mixing ratios, and also allows CP violation. The strong phase between $D^0 \to K^+\pi^-$ and $\overline{D}^0 \to K^+\pi^-$ is assumed to be small. If an arbitrary relative strong phase is allowed, the limit degrades by 25%.

[8] This GODANG 00 limit is inferred from the D^0-$\overline{D}^0$ mixing ratio $\Gamma(K^+\pi^-$ (via $\overline{D}^0))/\Gamma(K^-\pi^+)$ given near the end of this D^0 Listings. Decay-time information is used to distinguish DCS decays from D^0-$\overline{D}^0$ mixing. The limit allows interference between the DCS and mixing ratios, and also allows CP violation. The strong phase between $D^0 \to K^+\pi^-$ and $\overline{D}^0 \to K^+\pi^-$ is assumed to be small. If an arbitrary relative strong phase is allowed, the limit degrades by a factor of two.

[9] AITALA 98 allows interference between the doubly Cabibbo-suppressed and mixing amplitudes, and also allows CP violation in this term, but assumes that $A_D = A_R = 0$. See the note on "D^0-$\overline{D}^0$ Mixing," above.

[10] This limit is inferred from R_M for $f = K^+\pi^-$ and $f = K^+\pi^-\pi^+\pi^-$. See the note on "D^0-$\overline{D}^0$ Mixing," above. Decay-time information is used to distinguish doubly Cabibbo-suppressed decays from D^0-$\overline{D}^0$ mixing.

[11] This limit is inferred from R_M for $f = K^+\ell^-\overline{\nu}_\ell$. See the note on "$D^0$-$\overline{D}^0$ Mixing," above.

[12] ANJOS 88C assumes that $y = 0$. See the note on "D^0-$\overline{D}^0$ Mixing," above. Without this assumption, the limit degrades by about a factor of two.

$(\Gamma_{D_1^0} - \Gamma_{D_2^0})/\Gamma = 2y$

The D_1^0 and D_2^0 are the mass eigenstates of the D^0 meson, as described in the note on "D^0-$\overline{D}^0$ Mixing," above.

[13] This ASNER 05 limit is from the time-dependent Dalitz-plot analysis of $D^0 \to K^0_S\pi^+\pi^-$. Decay-time information and interference on the Dalitz plot are used to distinguish doubly Cabibbo-suppressed decays from mixing and to measure the relative phase between $D^0 \to K^{*+}\pi^-$ and $\overline{D}^0 \to K^{*+}\pi^-$. This limit allows CP violation.

[14] AUBERT 03P measures $Y \equiv 2\tau^0/(\tau^+ + \tau^-) - 1$, where τ^0 is the $D^0 \to K^-\pi^+$ (and $\overline{D}^0 \to K^+\pi^-$) lifetime, and τ^+ and τ^- are the D^0 and $\overline{D}^0$ lifetimes to CP-even states (here K^-K^+ and $\pi^-\pi^+$). In the limit of CP conservation, $Y = y \equiv \Delta\Gamma/2\Gamma$ (we list $2y = \Delta\Gamma/\Gamma$). AUBERT 03P also uses $\tau^+ - \tau^-$ to get $\Delta Y = -0.008 \pm 0.006 \pm 0.002$.

[15] LINK 00, AITALA 99E, and ABE 02I measure the lifetime difference between $D^0 \to K^-K^+$ (CP even) decays and $D^0 \to K^-\pi^+$ (CP mixed) decays, or $y_{CP} = [\Gamma(CP+) - \Gamma(CP-)]/[\Gamma(CP+) + \Gamma(CP-)]$. We list $2y_{CP} = \Delta\Gamma/\Gamma$.

[16] CSORNA 02 measures the lifetime difference between $D^0 \to K^-K^+$ and $\pi^-\pi^+$ (CP even) decays and $D^0 \to K^-\pi^+$ (CP mixed) decays, or $y_{CP} = [\Gamma(CP+) - \Gamma(CP-)]/[\Gamma(CP+) + \Gamma(CP-)]$. We list $2y_{CP} = \Delta\Gamma/\Gamma$.

[17] The ranges of AUBERT 03Z, LINK 05H, LI 05A, and ZHANG 06 measurements are for 95% confidence level.

[18] The GODANG 00, AUBERT 03Z, LINK 05H, LI 05A, and ZHANG 06 limits are inferred from the D^0-$\overline{D}^0$ mixing ratio $\Gamma(K^+\pi^-$ (via $\overline{D}^0))/\Gamma(K^-\pi^+)$ given near the end of this D^0 Listings. Decay-time information is used to distinguish DCS decays from D^0-$\overline{D}^0$ mixing. The limit allows interference between the DCS and mixing ratios, and also allows CP violation. The phase between $D^0 \to K^+\pi^-$ and $\overline{D}^0 \to K^+\pi^-$ is assumed to be small. This is a measurement of y' and is not the same as the y_{CP} of our note above on "D^0-$\overline{D}^0$ Mixing."

[19] AITALA 98 allows interference between the doubly Cabibbo-suppressed and mixing amplitudes, and also allows CP violation in this term, but assumes that $A_D = A_R = 0$. See the note on "D^0-$\overline{D}^0$ Mixing," above.

[20] This limit is inferred from R_M for $f = K^+\pi^-$ and $f = K^+\pi^-\pi^+\pi^-$. See the note on "D^0-$\overline{D}^0$ Mixing," above. Decay-time information is used to distinguish doubly Cabibbo-suppressed decays from D^0-$\overline{D}^0$ mixing.

[21] This limit is inferred from R_M for $f = K^+\ell^-\overline{\nu}_\ell$. See the note on "$D^0$-$\overline{D}^0$ Mixing," above.

[22] ANJOS 88C assumes that $y = 0$. See the note on "D^0-$\overline{D}^0$ Mixing," above. Without this assumption, the limit degrades by about a factor of two.

D^0 DECAY MODES

Most decay modes (other than the semileptonic modes) that involve a neutral K meson are now given as K^0_S modes, not as $\overline{K}^0$ modes. Nearly always it is a K^0_S that is measured, and interference between Cabibbo-allowed and doubly Cabibbo-suppressed modes can invalidate the assumption that $2\Gamma(K^0_S) = \Gamma(\overline{K}^0)$.

Γ_{240} A dummy mode used by the fit. (38.0 ± 1.9) %

[a] This value is obtained by subtracting the branching fractions for 2-, 4- and 6-prongs from unity.

[b] This is the sum of our $K^-\pi^+\pi^+\pi^-$, $K^-\pi^+\pi^+\pi^-\pi^0$, $\overline{K}^0 2\pi^+ 2\pi^-$, $2\pi^+ 2\pi^-$, $2\pi^+ 2\pi^-\pi^0$, $K^+K^-\pi^+\pi^-$, and $K^+K^-\pi^+\pi^-\pi^0$, branching fractions.

[c] The branching fractions for the $K^- e^+\nu_e$, $K^*(892)^- e^+\nu_e$, $\pi^- e^+\nu_e$, and $\rho^- e^+\nu_e$ modes add up to 6.14 ± 0.20 %.

[d] This is a weighted average of $D^\pm$ (44%) and D^0 (56%) branching fractions. See "D^+ and $D^0 \to$ (η anything) / (total D^+ and D^0)" under "D^+ Branching Ratios" in these Particle Listings.

[e] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers.

[f] This is a doubly Cabibbo-suppressed mode.

[g] The two experiments measuring this fraction are in serious disagreement. See the Particle Listings.

[h] This branching fraction includes all the decay modes of the resonance in the final state.

[i] The experiments on the division of this charge mode amongst its submodes disagree, and the submode branching fractions here add up to considerably more than the charged-mode fraction.

[j] However, these upper limits are in serious disagreement with values obtained in another experiment.

[k] This mode is not a useful test for a ΔC=1 weak neutral current because both quarks must change flavor in this decay.

[l] The value is for the sum of the charge states or particle/antiparticle states indicated.

CONSTRAINED FIT INFORMATION

An overall fit to 41 branching ratios uses 78 measurements and one constraint to determine 22 parameters. The overall fit has a χ^2 = 42.6 for 57 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$4.1\ \pm0.6$	263 ± 17	[53] SCHINDLER	81	MRK2	e^+e^- 3.771 GeV
$4.3\ \pm1.0$	130	[54] PERUZZI	77	MRK1	e^+e^- 3.77 GeV

[46] HE 05 uses single- and double-tagged events in an overall fit. The fraction here includes (unobserved) final-state photons.

[47] This combines the CLEO results of ARTUSO 98, COAN 98, and AKERIB 93.

[48] ABACHI 88, DECAMP 91J, AKERIB 93, ALBRECHT 94F, and BARATE 97C use $D^*(2010)^+\ \to\ D^0\pi^+$ decays. The π^+ is both slow and of low p_T with respect to the event thrust axis or nearest jet ($\approx D^{*+}$ direction). The excess number of such π^+'s over background gives the number of $D^*(2010)^+\ \to\ D^0\pi^+$ events, and the fraction with $D^0\ \to\ K^-\pi^+$ gives the $D^0\ \to\ K^-\pi^+$ branching fraction.

[49] ARTUSO 98, following ALBRECHT 94, uses D^0 mesons from $\overline{B}^0\ \to\ D^*(2010)^+ X\ell^-\overline{\nu}_\ell$ decays. Our average uses the CLEO average of this value with the values of COAN 98 and AKERIB 93.

[50] COAN 98 assumes that $\Gamma(B\ \to\ \overline{D}X\ell^+\nu)/\Gamma(B\ \to\ X\ell^+\nu) = 1.0\ -3\left|V_{ub}/V_{cb}\right|^2 - 0.010\pm0.005$, the last term accounting for $\overline{B}\ \to\ D_s^+ KX\ell^-\overline{\nu}$. COAN 98 is included in the CLEO average in ARTUSO 98.

[51] ALBRECHT 94 uses D^0 mesons from $\overline{B}^0\ \to\ D^{*+}\ell^-\overline{\nu}_\ell$ decays. This is a different set of events than used by ALBRECHT 94F.

[52] This AKERIB 93 value includes radiative corrections; without them, the value is $0.0391\pm0.0008\pm0.0017$. AKERIB 93 is included in the CLEO average in ARTUSO 98.

[53] SCHINDLER 81 (MARK-2) measures $\sigma(e^+e^-\ \to\ \psi(3770))\ \times$ branching fraction to be 0.24 ± 0.02 nb. We use the MARK-3 (ADLER 88C) value of $\sigma = 5.8\pm0.5\pm0.6$ nb.

[54] PERUZZI 77 (MARK-1) measures $\sigma(e^+e^-\ \to\ \psi(3770))\ \times$ branching fraction to be 0.25 ± 0.05 nb. We use the MARK-3 (ADLER 88C) value of $\sigma = 5.8\pm0.5\pm0.6$ nb.

$6.2\ \pm1.9$	44	[66] PERUZZI	77	MRK1	e^+e^- 3.77 GeV

[62] HE 05 uses single- and double-tagged events in an overall fit. The fraction here includes (unobserved) final-state photons.

[63] ALBRECHT 94 uses D^0 mesons from $\overline{B}^0 \to D^{*+}\ell^-\overline{\nu}_\ell$ decays. This is a different set of events than used by ALBRECHT 94F.

[64] See the footnote on the ALBRECHT 94F measurement of $\Gamma(K^-\pi^+)/\Gamma_{\text{total}}$ for the method used.

[65] SCHINDLER 81 (MARK-2) measures $\sigma(e^+e^- \to \psi(3770)) \times$ branching fraction to be 0.68 ± 0.11 nb. We use the MARK-3 (ADLER 88C) value of $\sigma = 5.8 \pm 0.5 \pm 0.6$ nb.

[66] PERUZZI 77 (MARK-1) measures $\sigma(e^+e^- \to \psi(3770)) \times$ branching fraction to be 0.36 ± 0.10 nb. We use the MARK-3 (ADLER 88C) value of $\sigma = 5.8 \pm 0.5 \pm 0.6$ nb.

VALUE	CL%	DOCUMENT ID		TECN	COMMENT
<2.6 × 10^{-4}	95	[82] CRONIN-HEN...05		CLEO	$e^+e^- \approx$ 10 GeV

[82] The CRONIN-HENNESSY 05 fit here includes, in addition to the three $\rho\pi$ charged states, only the $f_0(980)\pi^0$ mode. See also the next entries for limits obtained in the same way for the $f_0(600)\pi^0$ mode and for an S-wave $\pi^+\pi^-$ parametrized using a K-matrix. Our $\rho\pi$ branching ratios, given above, use the fit with the K-matrix S wave.

$\Gamma(f_0(600)\pi^0, f_0(600) \to \pi^+\pi^-)/\Gamma(\pi^+\pi^-\pi^0)$ $\Gamma_{137}/\Gamma_{132}$

The $f_0(600)$ is the σ.

[96] AUBERT,B 04Q, CAWLFIELD 05, and BITENC 05 use $D^{*+}\to D^0\pi^+$ (and charge conjugate) decays to identify the charm at production and the charge of the e to identify the charm at decay. These limits do not allow CP violation.

$\Gamma(K^+\pi^-)/\Gamma(K^-\pi^+)$ Γ_{187}/Γ_{29}

This is R_D in the note on "D^0-$\overline{D}^0$ Mixing," near the start of the D^0 Listings. The experiments here use the charge of the pion in $D^*(2010)^\pm\to(D^0\text{ or }\overline{D}^0)\pi^\pm$ decay to tell whether a D^0 or a $\overline{D}^0$ was born. The $D^0\to K^+\pi^-$ decay can occur directly by doubly Cabibbo-suppressed (DCS) decay, or indirectly by $D^0\to\overline{D}^0$ mixing followed by $\overline{D}^0\to K^+\pi^-$ decay. Some of the experiments can use the decay-time information to disentangle the two mechanisms. Here, we list the experimental branching ratio, which if there is no mixing is the DCS ratio. See the next data block for limits on the mixing ratio R_M, see the section on CP-violating asymmetries near the end of this D^0 Listing for values of A_D, and see the note on "D^0-$\overline{D}^0$ Mixing" for limits on x' and y'.

Some early limits have been omitted from this Listing; see our 1998 edition (EPJ **C3** 1).

[97] This ZHANG 06 result assumes no mixing. If mixing but no *CP* violation is allowed, $R_D = (3.64 \pm 0.17) \times 10^{-3}$.

[98] This LINK 05H result assumes no mixing or *CP* violation. Allowing *CP* violation but no mixing, $R_D = (4.29 \pm 0.63 \pm 0.28) \times 10^{-3}$ — negligibly different. Allowing mixing but no *CP* violation, $R_D = (3.81^{+1.67}_{-1.63} \pm 0.92) \times 10^{-3}$. Allowing mixing and *CP* violation, $R_D = (5.17^{+1.47}_{-1.58} \pm 0.76) \times 10^{-3}$.

[99] This AUBERT 03Z result is for no mixing or *CP* violation. If *CP* violation but no mixing is allowed, R_D=0.00357 ± 0.00022 ± 0.00027. If only mixing is allowed, the 95% confidence-level interval is $(2.4 < R_D < 4.9)\times10^{-3}$. If both mixing and *CP* violation are allowed, this interval becomes $(2.3 < R_D < 5.2)\times10^{-3}$.

[100] This GODANG 00 result assumes no D^0-$\overline{D}^0$ mixing (R_M=0 in the note on "D^0-$\overline{D}^0$ Mixing" near the start of the D^0 Listings) but allows *CP* violation. The DCS ratio becomes 0.0048 ± 0.0012 ± 0.0004 when mixing is allowed.

[101] This AITALA 98 result assumes no *CP* violation or mixing (R_M=0 in the note on "D^0-$\overline{D}^0$ Mixing" near the start of the D^0 Listings). The DCS ratio becomes $0.0090^{+0.0120}_{-0.0109}$ ± 0.0044 when mixing is allowed.

[102] This LI 05A result assumes no mixing or *CP* violation. If mixing but no *CP* violation is allowed, $R_D = (2.87 \pm 0.37) \times 10^{-3}$.

[103] This LINK 01 result assumes no mixing or *CP* violation; see Fig. 4 of the paper for the DCS value as a function of the (unknown) mixing parameters *x*' and *y*'. See also the note on "D^0-$\overline{D}^0$ Mixing" near the start of the D^0 Listings for results on *x*' and *y*' from FOCUS and other experiments.

[104] BARATE 98W gets $0.0177^{+0.0060}_{-0.0056}$ ± 0.0031 for the DCS ratio when mixing is allowed, assuming no interference between the DCS and mixing amplitudes ($y' = 0$ in the note on "D^0-$\overline{D}^0$ Mixing" near the start of the D^0 Listings).

[105] CINABRO 94, AMMAR 91, and ALBRECHT 87K cannot distinguish between doubly Cabibbo-suppressed decay and D^0-$\overline{D}^0$ mixing.

[106] ANJOS 88C allows mixing but assumes no interference between the DCS and mixing amplitudes ($y' = 0$ in the note on "D^0-$\overline{D}^0$ Mixing" near the start of the D^0 Listings). When interference is allowed, the limit degrades to 0.049.

$\Gamma(K^+\pi^-(\text{via } \overline{D}^0))/\Gamma(K^-\pi^+)$ Γ_{188}/Γ_{29}

This is R_M in the note on "D^0-$\overline{D}^0$ Mixing" near the start of the D^0 Listings. The experiments here (1) use the charge of the pion in $D^*(2010)^\pm \to (D^0 \text{ or } \overline{D}^0)\ \pi^\pm$ decay to tell whether a D^0 or a $\overline{D}^0$ was born; and (2) use the decay-time distribution to disentangle doubly Cabibbo-suppressed decay and mixing. For the limits on $|m_1 - m_2|$ and $(\Gamma_1 - \Gamma_2)/\Gamma$ that come from the best mixing limit, see near the beginning of these D^0 Listings.

[119] AITALA 98 uses decay-time information to distinguish doubly Cabibbo-suppressed decays from D^0-$\overline{D}^0$ mixing. The fit allows interference between the two amplitudes, and also allows *CP* violation in this term. The central value obtained is $0.0039^{+0.0036}_{-0.0032}$ ± 0.0016. When interference is disallowed, the result becomes 0.0021 ± 0.0009 ± 0.0002.

[120] This combines results of ANJOS 88C on $K^+\pi^-$ and $K^+\pi^-\pi^+\pi^-$ (via $\overline{D}^0$) reported in the data block above (see footnotes there). It assumes no interference.

$\Gamma(\mu^-\text{anything (via } \overline{D}^0))/\Gamma(\mu^+\text{anything})$ Γ_{195}/Γ_6

This is a D^0-$\overline{D}^0$ mixing limit. See the somewhat better limits above.

[138] This ZHANG 06 result allows mixing.

[139] This LINK 05H result assumes no mixing. If mixing is allowed, it becomes $0.13^{+0.33}_{-0.25}\pm0.10$.

[140] This AUBERT 03Z limit assumes no mixing. If mixing is allowed, the 95% confidence-level interval is $(-2.8 < A_D < 4.9)\times10^{-3}$.

[141] This GODANG 00 result assumes no D^0-$\overline{D}^0$ mixing; it becomes $-0.01^{+0.16}_{-0.17}\pm0.01$ when mixing is allowed.

[142] This LI 05A result allows mixing.

D^0-$\overline{D}^0$ T-VIOLATING DECAY-RATE ASYMMETRIES

D^0 and $\overline{D}^0$ are distinguished by the charge of the parent D^*: $D^{*+} \to D^0\pi^+$ and $D^{*-} \to D^0\pi^-$.

$A_{Tviol}(K^+K^-\pi^+\pi^-)$ in $D^0, \overline{D}^0 \to K^+K^-\pi^+\pi^-$

$C_T \equiv \vec{p}_{K^+}\cdot(\vec{p}_{\pi^+}\times\vec{p}_{\pi^-})$ is a T-odd correlation of the K^+, π^+, and π^- momenta for the D^0. $\overline{C}_T \equiv \vec{p}_{K^-}\cdot(\vec{p}_{\pi^-}\times\vec{p}_{\pi^+})$ is the corresponding quantity for the $\overline{D}^0$. $A_T \equiv [\Gamma(C_T>0)-\Gamma(C_T<0)]\ /\ [\Gamma(C_T>0)+\Gamma(C_T<0)]$ would, in the absence of strong phases, test for T violation in D^0 decays (the Γ's are partial widths). With $\overline{A}_T \equiv [\Gamma(-\overline{C}_T>0)-\Gamma(-\overline{C}_T<0)]\ /\ [\Gamma(-\overline{C}_T>0)+\Gamma(-\overline{C}_T<0)]$, the asymmetry $A_{Tviol} \equiv \frac{1}{2}(A_T - \overline{A}_T)$ tests for T violation even with nonzero strong phases.

Meson Particle Listings

D^0

D^0 CPT-VIOLATING DECAY-RATE ASYMMETRIES

$A_{CPT}(K^{\mp}\pi^{\pm})$ in $D^0 \to K^-\pi^+$, $\overline{D}{}^0 \to K^+\pi^-$

$A_{CPT}(t)$ is defined in terms of the time-dependent decay probabilities $P(D^0 \to K^-\pi^+)$ and $\overline{P}(\overline{D}{}^0 \to K^+\pi^-)$ by $A_{CPT}(t) = (\overline{P}-P)/(\overline{P}+P)$. For small mixing parameters $x \equiv \Delta m/\Gamma$ and $y \equiv \Delta\Gamma/2\Gamma$ (as is the case), and times t, $A_{CPT}(t)$ reduces to $[\, y\, Re\,\xi - x\, Im\,\xi\,]\,\Gamma t$, where ξ is the CPT-violating parameter.

The following is actually $y\, Re\,\xi - x\, Im\,\xi$.

CONSTRAINED FIT INFORMATION

An overall fit to a branching ratio uses 3 measurements and one constraint to determine 2 parameters. The overall fit has a $\chi^2 = 0.5$ for 2 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

[6] The branching ratios are not independent, they have been constrained by the authors to sum to 100%.
[7] Systematic error includes theoretical error on the prediction of the ratio of hadronic modes.
[8] Assuming that isospin is conserved in the decay.
[9] Not independent of $\Gamma(D^0\pi^+)/\Gamma_{total}$ and $\Gamma(D^+\pi^0)/\Gamma_{total}$ measurement.

CHARMED, STRANGE MESONS ($C = S = \pm 1$)

$D_s^+ = c\bar{s}$, $D_s^- = \bar{c}s$, similarly for D_s^*'s

$D_s^\pm$ was $F^\pm$

$I(J^P) = 0(0^-)$

The angular distributions of the decays of the ϕ and $\overline{K}^*(892)^0$ in the $\phi\pi^+$ and $K^+\overline{K}^*(892)^0$ modes strongly indicate that the spin is zero. The parity given is that expected of a $c\bar{s}$ ground state.

$D_s^\pm$ MASS

The fit includes $D^\pm$, D^0, $D_s^\pm$, $D^{*\pm}$, D^{*0}, and $D_s^{*\pm}$ mass and mass difference measurements. Measurements of the $D_s^\pm$ mass with an error greater than 10 MeV are omitted from the fit and average. A number of early measurements have been omitted altogether.

Γ_{87}	A dummy mode used by the fit.		(79.8 ± 2.8) %		S=1.1

[a] For now, we average together measurements of the $X\,e^+\nu_e$ and $X\,\mu^+\nu_\mu$ branching fractions. This is the *average*, not the *sum*.

[b] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers.

[c] This branching fraction includes all the decay modes of the final-state resonance.

[d] This comes from a K-matrix parametrization of the $\pi^+\pi^-$ S-wave and is a sum over the $f_0(980)$, $f_0(1300)$, $f_0(1200–1600)$, $f_0(1500)$, and $f_0(1750)$. Not all of these correspond to particles in our Tables.

[e] This mode is not a useful test for a $\Delta C=1$ weak neutral current because both quarks must change flavor in this decay.

[f] The value is for the sum of the charge states or particle/antiparticle states indicated.

CONSTRAINED FIT INFORMATION

An overall fit to 11 branching ratios uses 19 measurements and one constraint to determine 9 parameters. The overall fit has a $\chi^2 = 11.4$ for 11 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle\delta x_i\delta x_j\rangle/(\delta x_i\cdot\delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

Leptonic and semileptonic modes

D_s^+ DECAY CONSTANT

Revised March 2006 by A. Edwards and P. Burchat (Stanford University)

In the Standard Model, the D_s^+ leptonic branching fractions are related to the D_s^+ decay constant f_{D_s} by the equation [1]

$$\mathrm{B}(D_s^+ \to \ell^+\nu_\ell) = \frac{G_F^2}{8\pi}|V_{cs}|^2 f_{D_s}^2 \frac{\tau_{D_s}}{\hbar} m_{D_s} m_\ell^2 \left(1 - \frac{m_\ell^2}{m_{D_s}^2}\right)^2 . \quad (1)$$

Hence, measurements of $\mathrm{B}(D_s^+ \to \ell^+\nu_\ell)$ can be used to extract f_{D_s}. The most precise measurements of $D_s^+ \to \ell^+\nu_\ell$ branching fractions come from L3 (ACCIARRI 97F), CLEO (CHADHA 98), BEATRICE (ALEXANDROV 00), OPAL (ABBIENDI 01L), and ALEPH (HEISTER 02I); see the end of the D_s^+ Data Listings for the references. All of these measurements either explicitly or implicitly measure the leptonic branching fraction relative to the branching fraction for $D_s^+ \to \phi\pi^+$. This fraction has, since our 2004 edition, changed from $3.6 \pm 0.9\%$ to $4.4 \pm 0.6\%$. The $D_s^+ \to \ell^+\nu_\ell$ measurements of CLEO and BEATRICE are explicitly normalized to $D_s^+ \to \phi\pi^+$, and so can be easily updated. The LEP experiments (L3, OPAL, ALEPH) share a 23% correlated uncertainty in the normalization of the leptonic branching fraction. They use the partial decay rate for $Z \to c\overline{c}$ and the D_s^+ production rate in $Z \to c\overline{c}$ events, which in turn depends on the assumed value of $\mathrm{B}(D_s^+ \to \phi\pi^+)$.

We determine an average value of f_{D_s} from the above-mentioned five most precise measurements of the $D_s^+ \to \ell^+\nu_\ell$ branching fractions, assuming lepton universality, taking into account correlated uncertainties, and using a consistent and up-to-date set of input parameters [2] for the μ, τ, and D_s^+ masses, the D_s^+ lifetime, V_{cs}, $\mathrm{B}(D_s^+ \to \phi\pi^+)$, and other relevant branching fractions. Although the uncertainty on $\mathrm{B}(D_s^+ \to \phi\pi^+)$ is by far the largest uncertainty, we also take into account correlated uncertainties in other input parameters. Using both $D_s^+ \to \mu^+\nu_\mu$ and $D_s^+ \to \tau^+\nu_\tau$ branching fractions, and assuming lepton universality, we obtain

$$\mathrm{B}(D_s^+ \to \mu^+\nu_\mu) = 0.0074 \pm 0.0013 . \quad (2)$$

Using this value (which is not the same as the $D_s^+ \to \mu^+\nu_\mu$ branching fraction in our Summary Tables, because we do not there use lepton universality), and including the relatively minor uncertainties on the other parameters in Eq. (1), we extract the world average D_s^+ decay constant:

$$f_{D_s} = (294 \pm 27)\ \mathrm{MeV} . \quad (3)$$

• • • We do not use the following data for averages, fits, limits, etc. • • •				
$0.0068 \pm 0.0011 \pm 0.0018$	553	[5] HEISTER	02I ALEP	Z decays
$0.015\ {}^{+0.013}_{-0.006}\ {}^{+0.003}_{-0.002}$	3	[6] BAI	95 BES	$e^+e^- \to D_s^+ D_s^-$
$0.004\ {}^{+0.0018}_{-0.0014}\ {}^{+0.0020}_{-0.0019}$	8	[7] AOKI	93 WA75	π^- emulsion 350 GeV
<0.03	0	[8] AUBERT	83 SPEC	μ^+Fe, 250 GeV

[5] This HEISTER 02I result is not actually an independent measurement of the absolute $\mu^+\nu_\mu$ branching fraction, but is in fact based on our $\phi\pi^+$ branching fraction of $3.6 \pm 0.9\%$, so it cannot be included in our overall fit. HEISTER 02I combines its $D_s^+ \to \tau^+\nu_\tau$ and $\mu^+\nu_\mu$ branching fractions to get $f_{D_s} = (285 \pm 19 \pm 40)$ MeV.

[6] BAI 95 uses one actual $D_s^+ \to \mu^+\nu_\mu$ event together with two $D_s^+ \to \tau^+\nu_\tau$ events and assumes μ-τ universality. This value of $\Gamma(\mu^+\nu_\mu)/\Gamma_{\mathrm{total}}$ gives a pseudoscalar decay constant of $(430\ {}^{+150}_{-130} \pm 40)$ MeV.

[7] AOKI 93 assumes the ratio of production cross sections of the D_s^+ and D^0 is 0.27. The value of $\Gamma(\mu^+\nu_\mu)/\Gamma_{\mathrm{total}}$ gives a pseudoscalar decay constant $f_{D_s} = (232 \pm 45 \pm 52)$ MeV.

[8] AUBERT 83 assume that the $D_s^\pm$ production rate is 20% of total charm production rate.

[21] AUBERT 05V uses the ratio of $B^0 \to D^{*-}D_s^{*+}$ events seen in two different ways, in both of which the $D^{*-} \to \overline{D}^0\pi^-$ decay is fully reconstructed: (1) The $D_s^{*+} \to D_s^+\gamma$, $D_s^+ \to \phi\pi^+$ decay is fully reconstructed. (2) The number of events in the D_s^+ peak in the missing mass spectrum against the $D^{*-}\gamma$ is measured.
[22] ARTUSO 96 uses partially reconstructed $\overline{B}^0 \to D^{*+}D_s^{*-}$ decays to get a model-independent value for $\Gamma(D_s^- \to \phi\pi^-)/\Gamma(D^0 \to K^-\pi^+)$ of 0.92 ± 0.20 ± 0.11.
[23] BAI 95C uses $e^+e^- \to D_s^+D_s^-$ events in which one or both of the $D_s^\pm$ are observed to obtain the first model-independent measurement of the $D_s^+ \to \phi\pi^+$ branching fraction, without assumptions about $\sigma(D_s^\pm)$. However, with only two "doubly-tagged" events, the statistical error is very large. ADLER 90B used the same method to set a limit.
[24] BUTLER 94, FRABETTI 93G, ALBRECHT 91, ALEXANDER 90B, and ANJOS 90B measure the ratio $\Gamma(D_s^+ \to \phi\ell^+\nu_\ell)/\Gamma(D_s^+ \to \phi\pi^+)$, where $\ell = e$ and/or μ, and then use a theoretical calculation of the ratio of widths $\Gamma(D_s^+ \to \phi\ell^+\nu_\ell)/\Gamma(D^+ \to \overline{K}^{*0}\ell^+\nu)$. Not everyone uses the same value for this ratio.
[25] The two MUHEIM 94 values here are model-dependent calculations based on distinct data sets. The first uses measurements of the $D_2^*(2460)^0$ and $D_{s1}(2536)^+$, the second uses B-decay factorization and $\Gamma(D_s^+ \to \mu^+\nu_\mu)/\Gamma(D_s^+ \to \phi\ell^+\nu_\ell)$. A third calculation using the semileptonic width of $D_s^+ \to \phi\ell^+\nu_\ell$ is not independent of other results listed here. Note also the upper limit, based on the sum of established D_s^+ branching ratios.
[26] ALVAREZ 90C relies on the Lund model to estimate the ratio of D_s^+ to D^+ cross sections.
[27] Values based on crude estimates of the $D_s^\pm$ production level. DERRICK 85B errors are statistical only.

VALUE	DOCUMENT ID	TECN	COMMENT
0.8704±0.0560±0.0438	[31] LINK 04	FOCS	Dalitz fit, 1475 ± 50 evts

[31] LINK 04 borrows a K-matrix parametrization from ANISOVICH 03 of the full π-π S-wave isoscalar scattering amplitude to describe the $\pi^+\pi^-$ S-wave component of the $\pi^+\pi^+\pi^-$ state. The fit fraction given above is a sum over five f_0 mesons, the $f_0(980)$, $f_0(1300)$, $f_0(1200$–$1600)$, $f_0(1500)$, and $f_0(1750)$. See LINK 04 for details and discussion.

$\Gamma(f_0(980)\pi^+, f_0\to\pi^+\pi^-)/\Gamma(\pi^+\pi^+\pi^-)$ Γ_{44}/Γ_{41}

This is the "fit fraction" from the Dalitz-plot analysis.

$D_s^+ - D_s^-$ T-VIOLATING DECAY-RATE ASYMMETRIES

$A_{Tviol}(K_S^0 K^\pm \pi^+ \pi^-)$ in $D_s^\pm \to K_S^0 K^\pm \pi^+ \pi^-$

$C_T \equiv \vec{p}_{K^+} \cdot (\vec{p}_{\pi^+} \times \vec{p}_{\pi^-})$ is a T-odd correlation of the K^+, π^+, and π^- momenta for the D_s^+. $\overline{C}_T \equiv \vec{p}_{K^-} \cdot (\vec{p}_{\pi^-} \times \vec{p}_{\pi^+})$ is the corresponding quantity for the D_s^-. $A_T \equiv [\Gamma(C_T > 0) - \Gamma(C_T < 0)] / [\Gamma(C_T > 0) + \Gamma(C_T < 0)]$ would, in the absence of strong phases, test for T violation in D_s^+ decays (the Γ's are partial widths). With $\overline{A}_T \equiv [\Gamma(-\overline{C}_T > 0) - \Gamma(-\overline{C}_T < 0)] / [\Gamma(-\overline{C}_T > 0) + \Gamma(-\overline{C}_T < 0)]$, the asymmetry $A_{Tviol} \equiv \frac{1}{2}(A_T - \overline{A}_T)$ tests for T violation even with nonzero strong phases.

D_s^{*+} DECAY MODES

D_s^{*-} modes are charge conjugates of the modes below.

	Mode	Fraction (Γ_i/Γ)
Γ_1	$D_s^+\gamma$	(94.2±0.7) %
Γ_2	$D_s^+\pi^0$	(5.8±0.7) %

CONSTRAINED FIT INFORMATION

An overall fit to a branching ratio uses 2 measurements and one constraint to determine 2 parameters. The overall fit has a χ^2 = 0.0 for 1 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$D_{s1}(2536)^{\pm}$

$I(J^P) = 0(1^+)$
J, P need confirmation.

Seen in $D^*(2010)^+ K^0$. Not seen in $D^+ K^0$ or $D^0 K^+$. $J^P = 1^+$ assignment strongly favored.

BOTTOM MESONS ($B = \pm 1$)

$B^+ = u\overline{b}$, $B^0 = d\overline{b}$, $\overline{B}^0 = \overline{d}b$, $B^- = \overline{u}b$, similarly for B^*'s

B-particle organization

Many measurements of B decays involve admixtures of B hadrons. Previously we arbitrarily included such admixtures in the $B^\pm$ section, but because of their importance we have created two new sections: "$B^\pm/B^0$ Admixture" for $\Upsilon(4S)$ results and "$B^\pm/B^0/B_s^0$/b-baryon Admixture" for results at higher energies. Most inclusive decay branching fractions and χ_b at high energy are found in the Admixture sections. B^0-$\overline{B}^0$ mixing data are found in the B^0 section, while B_s^0-$\overline{B}_s^0$ mixing data and B-$\overline{B}$ mixing data for a B^0/B_s^0 admixture are found in the B_s^0 section. CP-violation data are found in the $B^\pm$, B^0, and $B^\pm$ B^0 Admixture sections. b-baryons are found near the end of the Baryon section. Recently, we also created a new section: "V_{cb} and V_{ub} CKM Matrix Elements."

The organization of the B sections is now as follows, where bullets indicate particle sections and brackets indicate reviews.

PRODUCTION AND DECAY OF b-FLAVORED HADRONS

Updated February 2006 by Y. Kwon (Yonsei U., Seoul, Korea) and G. Punzi (INFN, Pisa, Italy).

The b quark belongs to the third generation of quarks and is a weak doublet partner of the t quark. The existence of the third generation quark doublet was proposed in 1973 by Kobayashi and Maskawa [1] in their model of the quark mixing matrix ("CKM" matrix). In this model, the CP violation can be explained within the Standard Model (SM) by an irreducible phase of the 3×3 unitary matrix. Since b quark is the lighter element of the third generation quark doublet, the decay of b-flavored hadrons should occur via generation-changing processes through this matrix. Because of this and the CKM matrix being close to a 3×3 unit matrix, many interesting features such as loop and box diagrams, $B_{(s)}^0$-$\overline{B}_{(s)}^0$ mixing, as well as the CP violations, can be observed in the weak decays of b-flavored hadrons.

In the summer of 2001—almost four decades after CP violation was first discovered in the decay of neutral kaons—the BABAR and Belle collaborations reported the first observation of CP violation in the B meson system [2,3]. The measurement of the CP-violation parameter $\sin 2\beta (= \sin 2\phi_1)$ [4] marks the culmination of a very significant experimental and theoretical program that started in 1973 [1]. Other recent developments in the physics of B mesons include new results on penguin decays, rare hadronic decays where improved measurements on nonstrange B have been supplemented by first measurements on strange B, improved limits on B_s^0 mixing [5], as well as new determinations of the CKM matrix elements V_{cb} and V_{ub} [6], and of angles α and γ of the unitarity triangle.

The structure of this mini-review is organized as follows. First, we briefly update the results on b quark production and discuss the spectroscopy and the lifetimes of b-flavored hadrons. Then after a brief description of basic properties of B meson decays, we give a short description of the experimental results on CP violation in B meson decays. More details about formalism and implications of CP violations are described in a separate mini-review [7] in this *Review*. This review closes with a description and update on hadronic and rare decays of B mesons. There are separate mini-reviews on the $B\overline{B}$ mixing [5] and on the extraction of the CKM matrix elements V_{cb} and V_{ub} from B decays [6] in this *Review*.

Production and spectroscopy: Elementary particles are characterized by their masses, lifetimes, and internal quantum numbers. The bound states with a $\overline{b}$ antiquark and a u, d

, s, or c quark are referred to as the B_u (B^+), B_d (B^0), B_s (B_s^0), and B_c (B_c^+) mesons, respectively. The first excitation is called the B^* meson. B^{**} is the generic name for the four orbitally excited ($L = 1$) B-meson states that correspond to the P-wave mesons in the charm system, D^{**}. Although the b quark was discovered in a fixed-target experiment at Fermilab in 1977, most of the experimental information on b-flavored hadrons has come from colliding-beam machines. Experimental studies of b decay have been performed at the $\Upsilon(4S)$ resonance near production threshold, as well as at higher energies in proton-antiproton collisions and Z decays. Currently, there is no experiment running at Z resonance; in a year or two, experiments at LHC with proton-proton collisions will start producing b-flavored hadrons. The $b\overline{b}$ production cross-section at the Z and $\Upsilon(4S)$ resonances are about 6.6 nb and 1.1 nb, respectively. High-energy $p\overline{p}$ collisions at the Tevatron produce b-flavored hadrons of all species with very large cross-section ($\sigma_{b\overline{b}} \sim 50\mu b$), but due to the large backgrounds, only a selection of modes can be studied that are easier to trigger and reconstruct, notably the final states with leptons, and the exclusive modes into all charged particles.

Large samples of a rich variety of modes of the B^0 and B^+ mesons have been collected by the e^+e^- collider detectors running at $\Upsilon(4S)$ ("B-Factories"). As of this writing, BABAR and Belle have accumulated approximately 300 fb^{-1} and 500 fb^{-1}, respectively. The $\Upsilon(4S)$ resonance decays only to $B^0\overline{B}^0$ and B^+B^- pairs; the current experimental limit for non-$B\overline{B}$ decays of the $\Upsilon(4S)$ is less than 4% at the 95% confidence level (CL) [8].

For quantitative studies of B decays, the initial composition of the data sample must be known. In particular, the ratio f_+/f_0 of charged to neutral $\Upsilon(4S)$ decays is crucial to calculate the decay branching fractions for B-factory experiments. CLEO and BABAR have measured the ratio $(f_+/f_0)(\tau_+/\tau_0)$ with exclusive $B \to \psi K^{(*)}$ [9,10] and $B \to D^*\ell\nu$ [11] decays, where τ_+/τ_0 is the B^+/B^0 lifetime ratio (see next section). By using the world-average value of τ_+ and τ_0 Belle also extracted the value of f_+/f_0 [12]. Using the current average of τ_+/τ_0, the average becomes $f_+/f_0 = 1.020 \pm 0.034$ [13]. This is consistent with equal production of B^+B^- and $B^0\overline{B}^0$ pairs, and unless explicitly stated otherwise, we will assume $f_+/f_0 = 1$. This assumption is further supported by the near equality of the B^+ and B^0 masses: our fit of CLEO, ARGUS, and CDF measurements yields $m(B^0) = 5279.4 \pm 0.5$ MeV/c^2, $m(B^+) = 5279.0 \pm 0.5$ MeV/c^2, and $m(B^0) - m(B^+) = 0.33 \pm 0.28$ MeV/c^2.

In high-energy collisions, the produced $\bar{b}$ (or b) quarks can hadronize as B^0, B^+, B_s^0, and B_c^+ mesons (or their antiparticles), or as baryons containing $\bar{b}$ (or b) quarks; to date, all mesons, the Λ_b baryon, and various excitations have been established. Table 1 shows the fractions f_d, f_u, f_s, and $f_{\rm baryon}$ of B^0, B^+, B_s^0, and b baryons in an unbiased sample of weakly decaying b hadrons produced at the Z resonance and in $p\overline{p}$ collisions [13]. A detailed account can be found elsewhere in this *Review* [5]. The values assume identical hadronization in $p\overline{p}$ collisions and in Z decay, even though these could, in principle, differ because of the different momentum distributions of the b–quark in these processes. With the availability of sizeable samples of B_s^0 mesons and Λ_b baryons at $p\overline{p}$ colliders, the knowledge of these fractions has also become an important limiting factor in the determination of their branching fractions.

Table 1: Fractions of weakly-decaying b-hadron species in $Z \to b\overline{b}$ decay and in $p\overline{p}$ collisions at $\sqrt{s} = 1.8$ TeV.

b hadron	Fraction [%]
B^+, B^0	39.8 ± 1.0
B_s^0	10.4 ± 1.4
b baryons	9.9 ± 1.7

Using exclusive hadronic decays, such as $B_s^0 \to J/\psi\phi$ and $\Lambda_b \to J/\psi\Lambda$, the masses of these states are now known at the MeV level. The recent measurement by CDF [17] yields: $m(B_s^0) = 5366.01 \pm 0.73 \pm 0.33$ MeV/c^2 and $m(\Lambda_b) = 5619.7 \pm 1.2 \pm 1.2$ MeV/c^2.

Clear evidence for the B_c^+, the last weakly decaying bottom meson, has been obtained by both CDF and D0 in the semileptonic mode [18]; CDF also observes the fully reconstructed mode $B_c^+ \to J/\Psi\pi^+$, which allows an accurate mass measurement: $6285.7 \pm 5 \pm 1.2$ MeV/c^2 [19].

First indications of Ξ_b production have been presented by the LEP Collaborations [21,22].

Excited B-meson states have been observed by CLEO, LEP, CUSB, D0, and CDF. The current world average of the B^*–B mass difference is 45.78 ± 0.35 MeV/c^2. Evidence for B^{**} production has been presented by the LEP and CDF experiments [23], as a broad resonance in the mass of an inclusively reconstructed bottom hadron candidate combined with a charged pion from the primary vertex. Preliminary results with exclusive modes have been obtained by D0, allowing separation of the narrow states, B_1 and B_2^*, with masses $m(B_1) = 5724 \pm 4 \pm 7$MeV/$c^2$ and $m(B_2^*) - m(B_1) = 23.6 \pm 7.7 \pm 3.9$ MeV/c^2 [24].

The LEP experiments have also provided evidence for excited B_s^{**} states.

Lifetimes: Precise lifetimes are key in extracting the weak parameters that are important for understanding the role of the CKM matrix in CP violation, such as the determination of V_{cb} and $B_s^0\overline{B}_s^0$ mixing measurements. In the naive spectator model, the heavy quark can decay only via the external spectator mechanism, and thus, the lifetimes of all mesons and baryons containing b quarks would be equal. Nonspectator effects, such as the interference between contributing amplitudes, modify this simple picture and give rise to a lifetime hierarchy for b-flavored hadrons similar to the one in the charm sector. However, since the lifetime differences are expected to scale as $1/m_Q^2$, where m_Q is the mass of the heavy quark, the variation in the b system

should be significantly smaller, of order 10% or less [25]. For the b system we expect

$$\tau(B^+) \geq \tau(B^0) \approx \tau(B_s^0) > \tau(\Lambda_b^0) \gg \tau(B_c^+) \,. \quad (1)$$

In the B_c^+, both quarks can decay weakly, resulting in its much shorter lifetime. Measurements of lifetimes for the various b-flavored hadrons thus provide a means to determine the importance of non-spectator mechanisms in the b sector.

Over the past years, advanced algorithms based on impact parameter or decay length measurements exploiting the potential of silicon vertex detectors resulted in improvement of lifetime measurements. However, in order to reach the precision necessary to test theoretical predictions, the results from different experiments need to be averaged. This is a challenging task that requires detailed knowledge of common systematic uncertainties, and correlations between the results from different experiments. The average lifetimes for b-flavored hadrons given in this edition have been determined by the Heavy Flavor Averaging Group (HFAG) [13]. A detailed description of the procedures and the treatment of correlated and uncorrelated errors can be found in [26]. The asymmetric B factories are now making significant contributions to the B^+ and B^0 lifetime measurements. Their use of fully–reconstructed B decays yield measurements with much reduced statistical and systematic uncertainties. The measurements are free, for example, from systematics associated with modelling of fragmentation. The new world average b-hadron lifetimes are summarized in Table 2.

Table 2: Summary of inclusive and exclusive b-hadron lifetime measurements.

Particle	Lifetime [ps]
B^+	1.643 ± 0.010
B^0	1.527 ± 0.008
B_s^0	1.454 ± 0.040
B_c^+	0.469 ± 0.065
Λ_b	1.288 ± 0.065
Ξ_b mixture	$1.39^{+0.34}_{-0.28}$
b baryon mixture	1.242 ± 0.046
b hadron mixture	1.568 ± 0.009

For comparison with theory, lifetime ratios are preferred. Experimentally we find

$$\frac{\tau_{B^+}}{\tau_{B^0}} = 1.076 \pm 0.008 \,, \; \frac{\tau_{B_s^0}}{\tau_{B^0}} = 0.914 \pm 0.030 \,,$$

$$\frac{\tau_{\Lambda_b}}{\tau_{B^0}} = 0.844 \pm 0.043 \,,$$

while theory makes the following predictions [27,28]

$$\frac{\tau_{B^+}}{\tau_{B^0}} = 1.06 \pm 0.02 \;, \; \frac{\tau_{B_s^0}}{\tau_{B^0}} = 1.00 \pm 0.01 \;, \; \frac{\tau_{\Lambda_b}}{\tau_{B^0}} = 0.86 \sim 0.95 \;.$$

The short B_c^+ lifetime has been predicted correctly. The long-standing discrepancy between Λ_b-baryon lifetime and its predicted value has now been reduced by updated calculations that include higher-order effects [28]. Conversely, the ratio of B_s to B^0 lifetimes now exhibits an almost 3-sigma deviation from expectations.

Similar to the kaon system, neutral B mesons contain short- and long-lived components. The SM predicts that the lifetime difference is significantly smaller. The most stringent limit on the lifetime difference of neutral B_d mesons is recently obtained by BABAR: $-0.156 < \Delta\Gamma_d/\Gamma_d < 0.042$ at 90% CL [29], where $\Delta\Gamma_d \equiv \Gamma_H - \Gamma_L$ with $\Gamma_H(\Gamma_L)$ being the decay width of the heavier (lighter) B_d meson. They measure the time-dependence of $\Upsilon(4S)$ decays where one neutral B is fully reconstructed and the other B is identified as being either B^0 or $\overline{B}^0$. In this analysis, possible violations in CP, T, and CPT are fully considered.

The lifetime difference for B_s^0 currently predicted by the Standard Model is $\Delta\Gamma_s/\Gamma_s = 0.12 \pm 0.05$ [30]. The experimental knowledge has improved due to new measurements from CDF and D0, based on angular analysis of the mode $B_s \to J/\psi\phi$ to separate CP even and CP odd components. By appropriately combining all available measurements, the HFAG group obtains a world average: $\Delta\Gamma_s/\Gamma_s = 0.31^{+0.10}_{-0.11}$; the quoted uncertainties are, however, non-gaussian, and a better representation of the current uncertainty is given by the 95% CL confidence interval: $0.01 < \Delta\Gamma_s/\Gamma_s < 0.59$ [13] that barely excludes zero. The measurement includes constraints from flavor-specific measurements, but they have only a small effect. The assumption of $\Gamma_s = \Gamma_d$ is no longer used, due to the 2.9 σ difference between their current estimates.

***B* meson decay properties:** B^+ and B^0 mesons are the lightest elements of the b-flavored hadrons, hence they decay via weak interactions. Since the mass of a b-quark is much larger than its partner quark (d or u), B meson decays are mostly described by the decay of the b quark ("spectator model"). The dominant decay mode of a b-quark is $b \to cW^*$, where the virtual W^* eventually materializes either into a pair of leptons, $\ell\nu$ ("semileptonic decay"), or into a pair of quarks which then hadronizes. The decays in which the spectator quark combines with one of the quarks from W^* are suppressed because the colors of the quarks from different sources must match ("color-suppression").

Couplings of quarks to the W boson are described by the Cabibbo-Kobayashi-Maskawa (CKM) matrix. The regular pattern of the three lepton and quark families is one of the most intriguing puzzles in particle physics. The existence of families gives rise to many of the free parameters in the Standard Model, in particular the fermion masses, and the elements of the CKM matrix. In the Standard Model (SM) of three generations, the CKM matrix is parameterized by three real parameters and one complex phase. This complex phase can become a source of CP violations in B meson decays. A more detailed discussion of the CKM matrix and CP violation can be found elsewhere in this *Review* [7,31].

Semileptonic B decays $B \to X_c\ell\nu$ and $B \to X_u\ell\nu$ provide an excellent laboratory to measure CKM elements $|V_{cb}|$

and $|V_{ub}|$ respectively, because the strong interaction effects are much simplified due to the two leptons in the final state. Both exclusive decays and inclusive decays can be used, and the nature of uncertainties are quite complimentary. For exclusive decay analysis, a knowledge about the form factors for the exclusive hadronic system $X_{c(u)}$ is required. For inclusive analysis, it is usually required to restrict the available phase-space of the decay products to suppress backgrounds; subsequently uncertainties are introduced in the extrapolation to the full phase-space. Moreover, restriction to a small corner of the phase-space may result in breakdown of the operator product expansion scheme, thus making theoretical calculations unreliable. A more detailed discussion of the B semileptonic decays and extraction of $|V_{cb}|$ and $|V_{ub}|$ are described elsewhere in this *Review* [6].

On the other hand, hadronic decays of B are complicated because of strong interaction effects caused by the surrounding cloud of light quarks and gluons. While this complicates the extraction of CKM matrix elements, it also provides a great opportunity to study perturbative and non-perturbative QCD, hadronization, and Final State Interaction (FSI) effects, *etc.*

Other (non-spectator) decay processes include W-exchange and annihilation decays, both of which occur at tree-level processes. Higher-order loop-induced flavor-changing neutral current (FCNC) decay processes ("Penguin decays") are also available. In the Standard Model, these decays are much suppressed in comparison to the spectator decays. Penguin decays are experimentally established by observations of $B \to K^*\gamma$ and recently $B \to K^{(*)}\ell^+\ell^-$. Some observed decay modes such as $B^0 \to D_s^- K^+$ may be interpreted as a W-exchange process.

There has been so far no experimental evidence for pure-annihilation decays of B mesons. Measurement of the branching fractions of these modes would be very useful to reduce uncertainty in the predictions for many other modes, as the contribution of annihilation diagrams is very difficult to predict with the current theoretical tools. Limits on these modes have recently improved and are now an order of magnitude above typical theoretical predictions: $\mathcal{B}(B_d^0 \to K^+K^-) < 3.7 \times 10^{-7}$ [14] and $\mathcal{B}(B_s^0 \to \pi^+\pi^-) < 1.7 \times 10^{-6}$ [16,13].

Experimental results on CP violation in B decays: The determination of all the parameters of the CKM matrix is required to fully define the SM, and is central to the experimental program in heavy-flavor physics. In the framework of the SM, the CKM matrix must be unitary, *i.e.* $VV^\dagger = 1$. This gives rise to relationships between the matrix elements that can be visualized as triangles in the complex plane, for example

$$V_{ub}^* V_{ud} + V_{cb}^* V_{cd} + V_{tb}^* V_{td} = 0\,.$$

The interior angles of the triangle can be expressed in terms of the CKM elements

$$\alpha = \phi_2 = arg(-\frac{V_{ud}V_{ub}^*}{V_{td}V_{tb}^*})\,,$$

$$\beta = \phi_1 = arg(-\frac{V_{cd}V_{cb}^*}{V_{td}V_{tb}^*})\,,$$

$$\gamma = \phi_3 = arg(-\frac{V_{cd}V_{cb}^*}{V_{ud}V_{ub}^*})\,.$$

The most precise measurements of the angle β have come from the two energy-asymmetric B-factories running at $\Upsilon(4S)$, KEKB and PEP-II, by analyzing time-dependent CP asymmetries in $b \to c\bar{c}s$ decay modes including $B \to J/\psi K_S$. Since the B mesons receive very little boost in the $\Upsilon(4S)$ rest frame, asymmetric beam energies are required to improve the precision of time-dependence measurement. At KEKB, for example, the boost is $\beta\gamma = 0.43$, and the typical B meson decay length is dilated from $\approx 20\ \mu m$ to $\approx 200\ \mu m$. PEP-II uses a slightly larger boost, $\beta\gamma = 0.55$.

In the decay chain $\Upsilon(4S) \to B^0\overline{B}^0 \to f_{CP}f_{\rm tag}$, in which one of the B mesons decays at time t_{CP} to f_{CP} and the other decays at time $t_{\rm tag}$ to a final state $f_{\rm tag}$ that distinguishes between B^0 and $\overline{B}^0$, the decay rate has a time dependence given by [7]

$$\mathcal{P}^q_{f_{CP}}(\Delta t) = \frac{e^{-|\Delta t|/\tau}}{4\tau}\left[1 + q\cdot\{S\sin(\Delta m_d \Delta t) - C\cos(\Delta m_d \Delta t)\}\right],$$

where τ is the B^0 lifetime, Δm_d is the mass difference between the two B^0 mass eigenstates, and $\Delta t = t_{CP} - t_{\rm tag}$. The parameter q is determined by identifying the b-quark flavor of the accompanying B meson ("flavor tagging") using inclusive features of the charged particles in $f_{\rm tag}$. For instance, $q = +1(-1)$ when the tagging B meson is a B^0 ($\overline{B}^0$). The CP-violating parameters S and C are expressed as

$$C = \frac{1-|\lambda|^2}{1+|\lambda|^2}, \qquad S = \frac{2Im\lambda}{1+|\lambda|^2},$$

where λ is a complex parameter that depends on both B^0-$\overline{B}^0$ mixing and on the amplitudes for B^0 and $\overline{B}^0$ decay to f_{CP}. In the SM, to a good approximation, $|\lambda|$ is equal to the absolute value of the ratio of the $\overline{B}^0$ to B^0 decay amplitudes. In the absence of direct CP violation, $|\lambda| = 1$. For $b \to c\bar{c}s$ transition, the SM predicts $S = -\xi \sin 2\beta$, where $\xi = +1(-1)$ for CP-even (-odd) final states, and $C = 0$.

In the summer of 2001, both BABAR [2] and Belle [3] reported first significant non-zero measurements of $\sin 2\beta$, thereby establishing CP violation in the B^0 meson decays. Both experiments have updated their results recently. Using a data sample of 227 million $B\overline{B}$ pairs, BABAR [40] obtained $\sin 2\beta = 0.722 \pm 0.040 \pm 0.023$, while with 386 million $B\overline{B}$ pairs, Belle [41] reported $\sin 2\beta = 0.652 \pm 0.039 \pm 0.020$ in $B^0 \to J/\psi K^0$ decays. Averaging the latest results from the two experiments, HFAG finds [13] $\sin 2\beta = \sin 2\phi_1 = 0.685 \pm 0.032$. Including the measurements from higher energy collider experiments, the average becomes

$$\sin 2\beta = \sin 2\phi_1 = 0.687 \pm 0.032.$$

The average for C is 0.026 ± 0.041 which is consistent with zero. These values are consistent with CKM expectations.

From the average of $\sin 2\beta$ above, we obtain the following two solutions for β (in $[0,\pi]$): $\beta = (21.7^{+1.3}_{-1.2})^\circ$ or $\beta = (68.3^{+1.2}_{-1.3})^\circ$. This ambiguity may be resolved by measuring time-dependent CP asymmetry in $B^0 \to \overline{D}^0 h^0$ decays, where $\overline{D}^0$ decays to a CP-eigenstate, *e.g.* $K^0_S\pi^+\pi^-$. Using a sample of 386 million $B\overline{B}$ pairs, Belle has performed a Dalitz plot analysis of $\overline{D}^0 \to K^0_S\pi^+\pi^-$ for a time-dependent CP asymmetry in $B^0 \to \overline{D}^0 h^0$ (where $h = \pi^0$ or η), and obtained $\beta = (16) \pm 21 \pm 12^\circ$. The 95% CL region is $-32^\circ < \beta < 62^\circ$, which disfavors the $\beta = 68.3^\circ$ solution.

Charmless B decays mediated by the $b \to s$ penguin transition are potentially sensitive to new CP-violating phases from physics beyond the SM [42]. In the SM, measurement of S in the $b \to s\bar{s}s$ transition should yield approximately the same value $(-\xi \sin 2\beta)$ as in the $b \to c\bar{c}s$ modes. Both BABAR and Belle measured S for $b \to s\bar{s}s$ modes, including $B \to \eta' K^0_S$ and ϕK^0_S. The "naïve" average value of effective $\sin 2\beta (\equiv \sin 2\beta_{\rm eff})$ for $b \to sq\bar{q}$ transitions (the cases where $q = s$ are believed to be mostly penguin, but others may have significant non-penguin contributions) calculated by HFAG is 0.50 ± 0.06 where the error is dominantly statistical. Since each mode can have different uncertainties in the SM, this "naïve" average should not be taken too seriously. At this moment, the comparison of $S_{sq\bar{q}}$ with $\sin 2\beta$ obtained from $b \to c\bar{c}s$ is inconclusive. The largest deviation from $b \to c\bar{c}s$ result $(\sin 2\beta = 0.687)$ comes from $\eta' K^0$. With a sample of 232 million $B\overline{B}$ pairs, BABAR measures $-\xi S_{\eta' K^0} = 0.36 \pm 0.13 \pm 0.03$, while Belle measures $-\xi S_{\eta' K^0} = 0.62 \pm 0.12 \pm 0.04$, with a sample of 386 million $B\overline{B}$ pairs. The HFAG average of the two is 0.50 ± 0.09. A B_s mode mediated by the $b \to s\bar{s}s$ transition has also been observed: $B_s \to \phi\phi$. Its measured branching fraction: $\mathcal{B}(B_s \to \phi\phi) = (14^{+6}_{-5} \pm 6) \times 10^{-6}$ [74], is in agreement with SM expectations at the current level of precision.

The $b \to c\bar{c}d$ transition can occur via a $b \to c$ tree or a $b \to d$ penguin process. The weak phase of the penguin amplitude relative to that of the tree contains the information of CP-violating phase other than that from $B^0\overline{B}^0$ mixing. Both Belle and BABAR investigated this using the final states $J/\psi\pi^0$, $D^{*+}D^{*-}$, and $D^{*\pm}D^{\mp}$. The results in all these modes are consistent with being dominated by tree amplitude, and with the $\sin 2\beta$ measured from $b \to c\bar{c}s$ modes.

Experimental work on the determination of the other two angles, α and γ of the unitarity triangle, is also underway. Much larger data samples will be needed to obtain precision results and to challenge the SM. Information on $\sin 2\alpha$ can be extracted from time-dependent CP asymmetry measurements of $b \to u\bar{u}d$ processes, such as $B^0 \to \pi^+\pi^-$, $\rho^+\rho^-$, and $\rho^\pm\pi^\mp$ decays, following a procedure similar to the one outlined above. Unfortunately, these decays suffer from fairly small branching fractions ($\mathcal{O}(10^{-6})$) and sizeable contributions from penguin diagrams that complicate the extraction of the CP phases. Because of this, the time-dependent asymmetry in $B \to \pi^+\pi^-$, for example, will not be proportional to $\sin\alpha$, but to $\sin 2\alpha_{\rm eff}$, with an unknown correction to α.

Despite these difficulties, attempts to measure CP asymmetries in the $b \to u\bar{u}d$ modes have been reported. For the $B^0 \to \pi^+\pi^-$ mode, BABAR [43] extracts $S(= \sqrt{1-C^2} \times \sin 2\alpha_{\rm eff}) = -0.30 \pm 0.17 \pm 0.03$, using 227 million $B\overline{B}$ pairs, and Belle [44] finds $S = -0.67 \pm 0.16 \pm 0.16$ with 275 million events. The contribution from direct CP violation in the $B \to \pi^+\pi^-$ decay shows up as a nonzero amplitude C. Both experiments have determined C simultaneously with S. BABAR finds $C = -0.09 \pm 0.15 \pm 0.04$, while Belle measures $C = -0.56 \pm 0.12 \pm 0.06$, by which Belle claims an evidence of direct CP violation at a significance of 4.0σ. The difference of BaBar and Belle corresponds to 2.3σ discrepancy. Extracting the angle α from $\pi^+\pi^-$ is not easy because of large branching fraction of $B^0 \to \pi^0\pi^0$ [45,46], resulting in a large uncertainty in the isospin analysis.

On the other hand, BABAR searched for $B^0 \to \rho^0\rho^0$ and finds that the branching fraction is less than 1.1×10^{-6} (90% CL) [47], which is much smaller than the isospin-related modes. Therefore, the penguin pollution in the $B^0 \to \rho^+\rho^-$ is small, making extraction of α easier than the $\pi^+\pi^-$ mode. BABAR [48] extracts $S = -0.33 \pm 0.24^{+0.08}_{-0.14}$ for the $\rho^+\rho^-$ mode, while Belle [49] obtains $S = 0.08 \pm 0.41 \pm 0.09$. The C value is consistent with zero in both analyses. Using the upper limit on $\mathcal{B}(B^0 \to \rho^+\rho^-)$ determined by BABAR, isospin analyses are performed for both results to constrain α: BABAR obtains $\alpha = (100 \pm 13)^\circ$, while Belle obtains $\alpha = (88 \pm 17)^\circ$. BABAR uses the combined average for $\mathcal{B}(B^+ \to \rho^+\rho^0)$; Belle uses the combined averages for both $\mathcal{B}(B^0 \to \rho^+\rho^-)$ and $\mathcal{B}(B^+ \to \rho^+\rho^0)$. In both analyses, electroweak penguins and possible $I = 1$ amplitudes are ignored.

CP asymmetry in $B^0 \to \rho^\pm\pi^\mp$ mode is also studied to extract the angle α. BABAR used a Dalitz plot analysis for $\pi^+\pi^-\pi^0$ [50] while Belle used a quasi 2-body model [51]. In both analyses, the S value is consistent with zero, but the HFAG average of the C value is 0.31 ± 0.10 which is away from zero with a significance of 3.4σ.

Several methods have been suggested to measure the third angle, $\gamma \approx \arg(V_{ub})$ [52]. However, they require very large data samples (such as for $B \to DK$), measurements of B^0_s decays, or suffer from large theoretical uncertainties, rendering γ particularly difficult to measure.

The decay amplitudes for $B^+ \to D^{(*)0}K^{(*)+}$ and $B^+ \to \overline{D}^{(*)0}K^{(*)+}$ can interfere if the $D^{(*)0}$ and $\overline{D}^{(*)0}$ decay to a common final state, for example $D^{*0} \to D^0\pi^0$ and $D^0 \to K^0_S\pi^+\pi^-$. Since the Cabibbo-suppressed $B^+ \to D^{(*)0}K^{(*)+}$ amplitude involves V_{ub}, the interference is sensitive to the angle γ. There have been several methods suggested to extract γ by using this interference, including those where the $D^{(*)0}$ is reconstructed as a CP eigenstate (GLW) [53], in a suppressed final state (ADS) [54]. Analyzing the $D^0 \to K^0_S\pi^+\pi^-$ Dalitz plot is another method to exploit this interference. [55]

Both BABAR [56] and Belle [57] applied GLW and ADS methods to obtain CP asymmetries and related parameters. At the moment, the results from Dalitz plot analyses give

tightest restriction on γ. Using 275 million $B\overline{B}$ pairs, Belle measured $\gamma = (68^{+14}_{-15} \pm 13 \pm 11)^\circ$ by combining DK^+ and D^*K^+ modes [58]. BABAR measured, with a sample of 227 million events, $\gamma = (67 \pm 28 \pm 13 \pm 11)^\circ$ by combining DK^+, D^*K^+ and DK^{*+} modes [59]. The attempts to combine all these measurements for γ have been made by the CKMfitter and UTFit groups [60].

The Cabibbo-favoured $B^0 \to D^{(*)-}\pi^+$ amplitude can have interference with the doubly Cabibbo-suppressed amplitude of $\overline{B}^0 \to D^{(*)-}\pi^+$. The relative weak phase between these two amplitudes is γ and, when combined with the $B^0\overline{B}^0$ mixing phase, the total phase difference is $-(2\beta+\gamma)$. Therefore $B^0 \to D^{(*)\pm}\pi^\mp$ decays can provide sensitivity to γ. The interpretation of the observables in terms of unitarity angles requires external input on the ratio of magnitude of the two amplitudes. Due to the disparate strength of the two interfering amplitudes, CP asymmetry is expected to be small, hence the possible occurrence of CP violation on the tag side may become an important obstacle. Both Belle and BABAR have measured the CP-violation parameters for $D^\pm\pi^\mp$ and $D^{*\pm}\pi^\mp$ modes. For the $D^{*\pm}\pi^\mp$ mode, both full and partial reconstruction techniques were used by both experiments. BABAR also studied $D^\pm\rho^\mp$ mode.

Hadronic B decays: The experimental results on hadronic B decays have steadily improved over the past years and the measurements have reached a sufficient precision to challenge our understanding of the dynamics of these decays. It has been suggested that in analogy to semileptonic decays, two-body hadronic decays of B mesons can be expressed as the product of two independent hadronic currents, one describing the formation of a charm meson, and the other the hadronization of the remaining $\overline{u}d$ (or $\overline{c}s$) system from the virtual W^-. Qualitatively, for a B decay with a large energy release, the $\overline{u}d$ pair, which is produced as a color singlet, travels fast enough to leave the interaction region without influencing the second hadron formed from the c quark and the spectator antiquark. The assumption that the amplitude can be expressed as the product of two hadronic currents is called "factorization" in this paper. Recent theoretical work has provided a more solid foundation for this hypothesis [61,62].

With a good neutral particle detection and hadron identification capabilities of B-factory detectors, a substantial fraction of hadronic B decay events can be fully reconstructed. Because of the kinematic constraint of $\Upsilon(4S)$, the energy sum of the final-state particles of a B meson decay is always equal to one half of the total energy in the center of mass frame. As a result, the two variables, ΔE (energy difference) and M_B (B candidate mass with a beam-energy constraint) are very effective to suppress combinatorial background both from $\Upsilon(4S)$ and $e^+e^- \to q\bar{q}$ continuum events. In particular, the energy-constraint in M_B improves the signal resolution by almost an order of magnitude.

Such a kinematically clean environment of B meson decays provides a very nice laboratory to search for new states. For instance, quark-level $b \to c\bar{c}s$ decays have been used to search for new charmonium and charm-strange mesons and study their properties in detail. In 2003, BABAR discovered a new narrow charm-strange state $D^*_{sJ}(2317)$ [63], and CLEO observed a similar state $D_{sJ}(2460)$ [64]. But the properties of these new states were largely unknown until Belle observed $B \to DD^*_{sJ}(2317)$ and $B \to DD_{sJ}(2460)$, which helped identify some quantum numbers of $D_{sJ}(2460)$ [65]. Further studies of $D^{(*)}_{sJ}$ meson productions in B decays have been made by Belle and BABAR. In particular, BABAR has observed $B \to D^*_{sJ}(2317)^+\overline{D}^{(*)}$ $(D^*_{sJ}(2317)^+ \to D^+_s\pi^0)$ and $B \to D_{sJ}(2460)^+\overline{D}^{(*)}$ $(D_{sJ}(2460)^+ \to D^{*+}_s\pi^0,\ D^+_s\gamma)$ decays. The angular analysis of $B \to D_{sJ}(2460)^+\overline{D}$ with $D_{sJ}(2460)^+ \to D^+_s\gamma$ supports the $J^P = 1^+$ assignment for $D_{sJ}(2460)$. With 152 million $B\overline{B}$ pairs, Belle studied the $\overline{B}^0 \to D^+_{sJ}K^-$ and $\overline{B}^0 \to D^-_{sJ}\pi^+$ decays. A significant signal for $\overline{B}^0 \to D^*_{sJ}(2317)^+K^-$ is observed with $\mathcal{B}(\overline{B}^0 \to D^*_{sJ}(2317)^+K^-) \times \mathcal{B}(D^*_{sJ}(2317)^+ \to D^+_s\pi^0) = (5.3^{+1.5}_{-1.3} \pm 0.7 \pm 1.4) \times 10^{-5}$.

Studies have been made to understand the properties of the new charmonium-like exotic particle, $X(3872)$, which was discovered by Belle [66] and later confirmed by other experiments [67]. In addition, more charmonium-like exotic particles have been observed in B decays.

Belle has searched for possible decays to $D\overline{D}$ and $D^0\overline{D}^0\pi^0$ of $X(3872)$ and set upper limits for $\mathcal{B}(B^+ \to X(3872)K^+) \times \mathcal{B}(X(3872) \to D\overline{D})$ and $\mathcal{B}(B^+ \to X(3872)K^+) \times \mathcal{B}(X(3872) \to D^0\overline{D}^0\pi^0)$ [68]. In a related analysis [68], Belle observed the $B^+ \to \psi(3770)K^+$ where $\psi(3770)$ is reconstructed in $D^0\overline{D}^0$ and D^+D^- channels. The obtained branching fraction is $\mathcal{B}(B^+ \to \psi(3770)K^+) = (0.48 \pm 0.11 \pm 0.07) \times 10^{-3}$.

BABAR has searched for $X(3872) \to J/\psi\eta$ and set upper limits for $\mathcal{B}(B^+ \to X(3872)K^+) \times \mathcal{B}(X(3872) \to J/\psi\eta)$ [69]. In a related analysis [69], BABAR observed the $B \to J/\psi\eta K$ decays. The obtained branching fractions are $\mathcal{B}(B^+ \to J/\psi\eta K^+) = (10.8 \pm 2.3 \pm 2.4) \times 10^{-5}$ and $\mathcal{B}(B^0 \to J/\psi\eta K^0_S) = (8.4 \pm 2.6 \pm 2.7) \times 10^{-5}$. BABAR also made a search for a charged partner of the $X(3872)$ in $B \to X^-K$ decays and set upper limits on product branching fractions, ruling out the isovector-X hypothesis [70].

More charmonium-like exotic particles have been observed in B decays. Belle has observed a near-threshold enhancement in the $\omega J/\psi$ invariant mass for $B \to K\omega J/\psi$ decays [71]. If treated as an S-wave Breit-Wigner resonance, the mass is $(3943 \pm 11 \pm 13)$ MeV/c^2 and the total width is $87 \pm 22 \pm 26$ MeV. BABAR has studied the $B \to J/\psi\pi^+\pi^-K$ and, in particular, the $J/\psi\pi^+\pi^-$ mass distribution in a region above the $X(3872)$ [72]. They found an excess of $J/\psi\pi^+\pi^-$ events with a mass just above 4.2 GeV/c^2, which is consistent with $Y(4260)$ that was observed by BABAR in ISR events [73].

There have been nearly 50 papers on hadronic B decays to open-charm and charmonium final states published since 2004. These results are nicely summarized in a recent report by HFAG [13].

Rare B decays: All B-meson decays that do not occur through the usual $b \to c$ transition are usually called rare B decays. These include both semileptonic and hadronic $b \to u$ decays that are suppressed at leading order by the small CKM matrix element V_{ub}, as well as higher order $b \to s$ processes such as electroweak and gluonic penguin decays.

Charmless B meson decays into two-body hadronic final states such as $B \to \pi\pi$ and $K\pi$ are experimentally clean, and provide good opportunities to probe new physics and search for indirect and direct CP violations. The final state particles in these decays tend to have larger momenta than average B decay products, therefore the event environment is cleaner than $b \to c$ decays. Branching fractions are typically around 10^{-5}, for exclusive channels. Over the past years, many such modes have been observed by BABAR, Belle, and CLEO. More recently, comparable samples of the modes with all charged final particles have been reconstructed in $p\bar{p}$ collisions by CDF, by triggering on impact parameter of final particles. This also allowed to observe charmless decays of the B_s for the first time, in modes $B_s^0 \to \phi\phi$ [74] and $B_s^0 \to K^+K^-$ [15].

Because of relatively high-momenta for final state particles, the dominant source of background in e^+e^- collisions is $q\bar{q}$ continuum events, and sophisticated background suppression techniques exploiting the event shape variables are essential for these analyses. In hadron collisions, the dominant background comes from QCD or partially reconstructed heavy flavors, and is similarly suppressed by a combination of kinematical and isolation requirements. The results are in general consistent among the four experiments.

Recent additions to the list of observed two-body charmless hadronic decays include $B^+ \to \overline{K}^0 K^+$ and $B^0 \to K^0\overline{K}^0$. Analyzing a sample of 227 million $B\overline{B}$ pairs, BABAR measured $\mathcal{B}(B^+ \to K^0\overline{K}^0) = (1.19^{+0.40}_{-0.35} \pm 0.13) \times 10^{-6}$, and $\mathcal{B}(B^+ \to \overline{K}^0 K^+) = (1.5 \pm 0.5 \pm 0.1) \times 10^{-6}$, with significance of 4.5σ and 3.5σ, respectively [75]. Similarly, using a sample of 275 million $B\overline{B}$ pairs, Belle measured $\mathcal{B}(B^+ \to K^0\overline{K}^0) = (0.8 \pm 0.3 \pm 0.1) \times 10^{-6}$ and $\mathcal{B}(B^+ \to \overline{K}^0 K^+) = (1.0 \pm 0.4 \pm 0.1) \times 10^{-6}$ with significance of 3.5σ and 3.0σ, respectively [14]. These are evidences for hadronic $b \to d$ transitions.

Several rare decay modes such as $B^0 \to K^+\pi^-$ have contributions from both $b \to u$ tree and $b \to sg$ penguin diagram processes. If the size of each contribution is comparable to each other, the interference between them may cause direct CP violation which can show up as a charge asymmetry in time-independent decay rate measurement. Recently, both BABAR and Belle found evidences for direct CP violation in $B^0 \to K^+\pi^-$ decays [76]. Including the improved preliminary measurement from Belle [77], the new average for charge asymmetry in the $K^+\pi^-$ mode is -0.115 ± 0.018 [13]. Under SM assumptions, the observation of CP asymmetry in this mode requires asymmetries to exist in other modes at non-negligible levels. Examples are the isospin-related mode $B^+ \to K^+\pi^0$, which is expected to have a similar asymmetry, and the as yet unobserved mode $B_s \to K^-\pi^+$, where a large asymmetry is expected [78,79]. Their comparisons will be an important check of SM interpretation of the observed CP asymmetry.

There is a B^+ decay mode which also appears to indicate direct CP violation: $B^+ \to \rho^0 K^+$. By analyzing the Dalitz plot for $B^+ \to K^+\pi^-\pi^+$ decays using a sample of 386 million $B\overline{B}$ pairs, Belle measured the charge asymmetry for $B^+ \to \rho^0 K^+$ as $(30 \pm 11^{+11}_{-5})\%$ [80], which is different from zero with a significance of 3.9σ. In a similar analysis using a sample of 226 million $B\overline{B}$ events, BABAR measured the charge asymmetry of $\rho^0 K^+$ as $(32 \pm 13^{+10}_{-8})\%$ [81].

The fact that $B^0 \to \pi^+\pi^-$ can have interference between tree and penguin processes makes it difficult to extract a unitarity angle α from time-dependent CP asymmetry measurements. In order to extract α unambiguously, an isospin analysis has been suggested [82]. A crucial element for the isospin analysis is a flavor-specific measurement of $B^0 \to \pi^0\pi^0$ and $\overline{B}^0 \to \pi^0\pi^0$. Recently, both BABAR and Belle updated the measurements: $\mathcal{B}(B^0 \to \pi^+\pi^-) = (2.3^{+0.4+0.2}_{-0.5-0.3}) \times 10^{-6}$ for Belle (with 275 million $B\overline{B}$ events) [46], and $\mathcal{B}(B^0 \to \pi^+\pi^-) = (1.17 \pm 0.32 \pm 0.10) \times 10^{-6}$ for BABAR (with 227 million events) [45]. Similarly, $B^0 \to \rho^0\rho^0$ plays a crucial role in extracting α from CP asymmetry measurements in $B^0 \to \rho^+\rho^-$. BABAR obtained a stringent upper limit on this mode: $\mathcal{B}(B^0 \to \rho^0\rho^0) < 1.1 \times 10^{-6}$ [84].

Since $B \to \rho\rho$ consists of two vector mesons in the final state, the CP eigenvalue of the final state depends on the longitudinal polarization fraction f_L for the decay. Therefore, a precise knowledge of f_L is crucial to extract CKM angle α. Both BABAR and Belle have observed $B^0 \to \rho^+\rho^-$ [48,49] and $B^+ \to \rho^+\rho^0$ [85] decays and measured their polarizations. The average value of f_L is: $f_L = 0.971^{+0.031}_{-0.030}$ for $\rho^+\rho^-$ and $0.97^{+0.05}_{-0.07}$ for $\rho^+\rho^0$ [13].

By analyzing the angular distributions of the B decays to two vector mesons, we can learn a lot about both weak- and strong-interaction dynamics in B decays. A detailed description of the angular analysis of B decays to two vector mesons can be found in a separate mini-review [86] in this *Review* .

The recently observed $B_s \to K^+K^-$ mode is related to $B^0 \to \pi^+\pi^-$ by U-spin symmetry, and is similary determined by a superposition of tree and penguin diagrams. Combining the observables from these two modes is another way of eliminating hadron uncertainties and extracting relevant CKM information [83].

The decay $B^0 \to D_s^+\pi^-$ proceeds via $b \to u$ tree diagram, where D_s is produced from the vertex of virtual W hadronization. Therefore, it is sensitive to $|V_{ub}|$, although actual extraction of $|V_{ub}|$ becomes obscured by unknown non-factorizable strong-interaction effects. Both Belle [87] and BABAR [88] found evidences for this mode, and the average branching fraction is $\mathcal{B}(B^0 \to D_s^+\pi^-) = (2.7 \pm 1.0) \times 10^{-5}$.

In the SM, the decay $B^+ \to D_s^{(*)+}\phi$ is expected to occur via a weak annihilation diagram, which is highly suppressed. As a result, this mode is very sensitive to new physics effects. Using a sample of 234 million $B\overline{B}$ pairs, BABAR obtained a

much improved upper limit for the modes: $\mathcal{B}(B^+ \to D_s^+\phi) < 1.9\times10^{-6}$ and $\mathcal{B}(B^+ \to D_s^{*+}\phi) < 1.2\times10^{-5}$ [89].

Electroweak penguin decays:

More than a decade has passed since the CLEO experiment first observed an exclusive radiative $b \to s\gamma$ transition, $B \to K^*(892)\gamma$ [90], thus providing the first evidence for the one-loop FCNC electromagnetic penguin decay. Using much larger data samples, both Belle and BABAR have updated this analysis [91], and have added several new decay modes such as $B \to K_1\gamma$, $K_2^*(1430)\gamma$ *etc.* [92].

Compared to $b \to s\gamma$, the $b \to d\gamma$ transitions such as $B \to \rho\gamma$, are much suppressed because of the small CKM element V_{td}. Both BABAR and Belle have searched for these decays. Analyzing a sample of 3.86×10^8 $B\overline{B}$ pairs, Belle has obtained $\mathcal{B}(B \to (\rho,\omega)\gamma) = (1.32^{+0.34+0.10}_{-0.31-0.09})\times10^{-6}$ [93], where $B \to \rho\gamma$ and $\omega\gamma$ results are combined using isospin relations. On the other hand, using a sample of 2.11×10^8 $B\overline{B}$ pairs, BABAR obtained $\mathcal{B}(B \to (\rho,\omega)\gamma) < 1.2\times10^{-6}$ [94]. Using a theoretical calculation [95], a constraint on the magnitude of V_{td} is obtained from the Belle result: $|V_{td}/V_{ts}| = 0.199^{+0.026+0.018}_{-0.025-0.015}$ [93].

The observed branching fractions were used to constrain a large class of SM extensions [96]. However, due to the uncertainties in the hadronization, only the inclusive $b \to s\gamma$ rate can be reliably compared with theoretical calculations. This rate can be measured from the endpoint of the inclusive photon spectrum in B decay. By combining the measurements of $B \to X_s\gamma$ from CLEO, Belle, and BABAR experiments [97], HFAG obtains the new average: $\mathcal{B}(B \to X_s\gamma) = (3.55\pm0.26)\times10^{-4}$ [13]. Consistent results have been reported by ALEPH for inclusive b–hadrons produced at the Z. The measured branching fraction can be compared to recent theoretical calculations by Chetyrkin, Misiak, and Munz, and by Kagan and Neubert, which predict $\mathcal{B}(b \to s\gamma) = (3.29\pm0.33)\times10^{-4}$ [98–100].

According to the SM, the CP asymmetry in $b \to s\gamma$ is smaller than 1 %, but some non-SM models allow significantly larger CP asymmetry ($\sim$ 10 %) without altering the inclusive branching fraction [101–103]. CLEO first searched for CP violation in this mode, and set a range on $A_{CP}(b \to s\gamma)$. Now, with improved measurements from Belle and BABAR, the range on $A_{CP}(b \to s\gamma)$ has become much more stringent. The average charge asymmetry calculated by HFAG is: $A_{CP} = -0.010\pm0.028$ [13].

In addition, all three experiments have measured the inclusive photon energy spectrum for $b \to s\gamma$, and by analyzing the shape of the spectrum they obtained the first and second moments for photon energies. The results on photon energy moments can be used to extract non-perturbative HQET parameters that are needed for precise determination of the CKM matrix element V_{ub}.

Additional information on FCNC processes can be obtained from $B \to X_s\ell^+\ell^-$ decays, which are mediated by electroweak penguin and W-box diagrams. Exclusive $B \to K\ell^+\ell^-$ decay was first observed by Belle [109]. Recently, both BABAR [110] and Belle [111] updated the measurements and the branching fractions are: $\mathcal{B}(B \to K\ell^+\ell^-) = (0.34\pm0.08)\times10^{-6}$ (BABAR), and $(0.55\pm0.08)\times10^{-6}$ (Belle). Similarly, the branching fraction for $B \to K^*(892)\ell^+\ell^-$ is also measured by both experiments: $\mathcal{B}(B \to K^*(892)\ell^+\ell^-) = (0.78^{+0.22}_{-0.21})\times10^{-6}$ (BABAR), and $(1.65^{+0.25}_{-0.24})\times10^{-6}$ (Belle). There seem to be slight discrepancies between the two measurements; nevertheless, each one is consistent with the SM expectation.

Additional information on FCNC can be obtained from $B^0_{(s)} \to \mu^+\mu^-$ decays. These decays can only proceed at second order in weak interactions in the SM, but may have large contributions from Supersymmetric loops, proportional to $(\tan\beta)^6$. They have both been searched for, and CDF and D0 have both obtained results that start to exclude a portion of the region allowed by SUSY models. The current best limits are 1.5×10^{-7} and 0.39×10^{-7}, respectively, for B_s^0 and B_d^0 [20].

Summary and Outlook: The study of B mesons continues to be one of the most productive fields in particle physics. CP violation has been observed for the first time outside the kaon system. Evidences for direct CP violations have been observed. Many rare decays such as hadronic $b \to u$ transitions and $b \to s(d)$ gluonic penguin decays have been observed, and the emerging pattern is still full of surprises. The coming years look equally promising. With the two asymmetric B-factory experiments, Belle and BABAR, we now have a combined data sample of nearly 1 ab^{-1}, and the CKM picture of the CP violation is tested with better precision ever.

At Fermilab, CDF and D0 have accumulated approximately 1 fb^{-1}, which is the equivalent of 10^{11} B hadrons produced. Albeit with low reconstruction efficiency, this has allowed reconstruction of large samples of some modes, and has given a start to a program of studies on B_s and b-flavored baryons. Moreover, in about a year, the LHC will start operating and produce huge samples of B-hadrons.

These experiments promise a rich spectrum of rare and precise measurements that have the potential to fundamentally affect our understanding of the SM and CP-violating phenomena.

A NOTE ON HFAG ACTIVITIES

Updated April 2006 by S. Prell (Iowa State Univ., Ames) and S. Eidelman (Budker Institute, Novosibirsk).

The Heavy Flavor Averaging Group (HFAG) has been formed, continuing the activities of the LEP Heavy Flavor Steering group, to provide the averages for measurements dedicated to the b-flavor related quantities. The HFAG consists of representatives and contacts from the experimental groups: BaBar, Belle, CDF, CLEO, DØ , LEP, and SLD.

In the averaging the input parameters used in the various analyses are adjusted (rescaled) to common values, and all known correlations are taken into account. The HFAG has five subgroups providing averages for b-hadron lifetimes and B-oscillation parameters, CP-violation measurements, semileptonic parameters, rare branching fractions, and b-hadron decays to charm. The averages provided by the HFAG are listed as "OUR EVALUATION" with a corresponding note.

The most up-to-date and complete listing of averages and more detailed information on the averaging procedures are available at:

`http://www.slac.stanford.edu/xorg/hfag` and also at `http://belle.kek.jp/mirror/hfag` (KEK mirror site).

$B^{\pm}$

$I(J^P) = \frac{1}{2}(0^-)$

Quantum numbers not measured. Values shown are quark-model predictions.

See also the $B^{\pm}/B^0$ ADMIXTURE and $B^{\pm}/B^0/B_s^0$/b-baryon ADMIXTURE sections.

$B^{\pm}$ MASS

The fit uses m_{B^+}, $(m_{B^0} - m_{B^+})$, and m_{B^0} to determine m_{B^+}, m_{B^0}, and the mass difference.

VALUE (MeV)	EVTS	DOCUMENT ID		TECN	COMMENT
5279.0±0.5 OUR FIT					
5279.1±0.5 OUR AVERAGE					
5279.1±0.4 ±0.4	526	[1] CSORNA	00	CLE2	$e^+e^- \to \Upsilon(4S)$
5279.1±1.7 ±1.4	147	ABE	96B	CDF	$p\overline{p}$ at 1.8 TeV
• • • We do not use the following data for averages, fits, limits, etc. • • •					
5278.8±0.54±2.0	362	ALAM	94	CLE2	$e^+e^- \to \Upsilon(4S)$
5278.3±0.4 ±2.0		BORTOLETTO92		CLEO	$e^+e^- \to \Upsilon(4S)$
5280.5±1.0 ±2.0		[2] ALBRECHT	90J	ARG	$e^+e^- \to \Upsilon(4S)$
5275.8±1.3 ±3.0	32	ALBRECHT	87C	ARG	$e^+e^- \to \Upsilon(4S)$
5278.2±1.8 ±3.0	12	[3] ALBRECHT	87D	ARG	$e^+e^- \to \Upsilon(4S)$
5278.6±0.8 ±2.0		BEBEK	87	CLEO	$e^+e^- \to \Upsilon(4S)$

[1] CSORNA 00 uses fully reconstructed 526 $B^+ \to J/\psi^{(\prime)} K^+$ events and invariant masses without beam constraint.
[2] ALBRECHT 90J assumes 10580 for $\Upsilon(4S)$ mass. Supersedes ALBRECHT 87C and ALBRECHT 87D.
[3] Found using fully reconstructed decays with $J/\psi(1S)$. ALBRECHT 87D assume $m_{\Upsilon(4S)}$ = 10577 MeV.

$B^{\pm}$ MEAN LIFE

See $B^{\pm}/B^0/B_s^0$/b-baryon ADMIXTURE section for data on B-hadron mean life averaged over species of bottom particles.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account corrections between the measurements and asymmetric lifetime errors.

[4] Measurement performed using a combined fit of CP-violation, mixing and lifetimes.
[5] Measurement performed using an inclusive reconstruction and B flavor identification technique.
[6] Measured mean life using fully reconstructed decays.
[7] Events are selected in which one B meson is fully reconstructed while the second B meson is reconstructed inclusively.
[8] Data analyzed using $D/D^*\ell$X event vertices.
[9] Data analyzed using charge of secondary vertex.
[10] ABREU 95Q assumes B($B^0 \to D^{**-}\ell^+\nu_\ell$) = 3.2 ± 1.7%.
[11] Data analyzed using vertex-charge technique to tag B charge.
[12] Combined result of $D/D^*\ell$X analysis and fully reconstructed B analysis.
[13] Combined ABREU 95Q and ADAM 95 result.

B^+ DECAY MODES

B^- modes are charge conjugates of the modes below. Modes which do not identify the charge state of the B are listed in the $B^{\pm}/B^0$ ADMIXTURE section.

The branching fractions listed below assume 50% $B^0\overline{B}^0$ and 50% B^+B^- production at the $\Upsilon(4S)$. We have attempted to bring older measurements up to date by rescaling their assumed $\Upsilon(4S)$ production ratio to 50:50 and their assumed D, D_s, D^*, and ψ branching ratios to current values whenever this would affect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

For inclusive branching fractions, *e.g.*, $B \to D^{\pm}$anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

[a] An ℓ indicates an e or a μ mode, not a sum over these modes.

[b] An $CP(\pm 1)$ indicates the CP=+1 and CP=−1 eigenstates of the D^0-$\overline{D}^0$ system.

[c] D denotes D^0 or $\overline{D}^0$.

[d] D^{*0}_{CP+} decays into $D^0\pi^0$ with the D^0 reconstructed in CP-even eigenstates K^+K^- and $\pi^+\pi^-$.

[e] $X(3872)^+$ is a hypothetical charged partner of the $X(3872)$.

[f] $\Theta(1710)^{++}$ is a possible narrow pentaquark state and $G(2220)$ is a possible glueball resonance.

CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 11 measurements and one constraint to determine 3 parameters. The overall fit has a χ^2 = 7.2 for 9 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\rm total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$1.06\pm0.12\pm0.18$	227,231 AUBERT,B	04B	BABR	$e^+e^- \to \Upsilon(4S)$

226 Perform measurements of absolute branching fractions using a missing mass technique.

227 The ratio of $B(B^\pm \to K^\pm\eta_c)\ B(\eta_c \to K\overline{K}\pi) = (7.4 \pm 0.5 \pm 0.7)\times10^{-5}$ reported in AUBERT,B 04B and $B(B^\pm \to K^\pm\eta_c) = (8.7 \pm 1.5)\times10^{-3}$ reported in AUBERT 06E contribute to the determination of $B(\eta_c \to K\overline{K}\pi)$, which is used by others for normalization.

228 AUBERT,B 05L reports $[B(B^+ \to \eta_c K^+) \times B(\eta_c(1S) \to p\overline{p})] = (1.8\ ^{+0.3}_{-0.2} \pm 0.2)\times10^{-6}$. We divide by our best value $B(\eta_c(1S) \to p\overline{p}) = (1.3 \pm 0.4)\times10^{-3}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

229 Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

230 EDWARDS 01 assumes equal production of B^0 and B^+ at the $\Upsilon(4S)$. The correlated uncertainties (28.3)% from $B(J/\psi(1S) \to \gamma\eta_c)$ in those modes have been accounted for.

231 AUBERT,B 04B reports $[B(B^+ \to \eta_c K^+) \times B(\eta_c(1S) \to K\overline{K}\pi)] = (0.074 \pm 0.005 \pm 0.007)\times10^{-3}$. We divide by our best value $B(\eta_c(1S) \to K\overline{K}\pi) = (7.0 \pm 1.2)\times10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

<4.8	90	[291] EDWARDS	01	CLE2	$e^+e^- \to \Upsilon(4S)$

[285] AUBERT,B 05N reports $(0.66 \pm 0.22 \pm 0.08) \times 10^{-6}$ for $B(B^+ \to \chi_c^0 K^+) \times B(\chi_c^0 \to \pi^+\pi^-)$. We compute $B(B^+ \to \chi_c^0 K^+)$ using the PDG value $B(\chi_c^0 \to \pi^+\pi^-) = (7.1 \pm 0.6) \times 10^{-3}$ and 2/3 for the $\pi^+\pi^-$ fraction.
[286] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.
[287] Perform measurements of absolute branching fractions using a missing mass technique.
[288] The measurement performed using decay channels $\chi_c^0 \to \pi^+\pi^-$ and $\chi_c^0 \to K^+K^-$. The ratio of the branching ratios for these channels is found to be consistent with world average.
[289] AUBERT 04P reports $B(B^+ \to \chi_c^0 K^+) \times B(\chi_c^0 \to \pi^+\pi^-) = (1.5 \pm 0.4 \pm 0.1) \times 10^{-6}$ and used PDG value of $B(\chi_c^0 \to \pi\pi) = (7.4 \pm 0.8) \times 10^{-3}$ and Clebsh-Gordan coefficient to compute $B(B^\pm -> \chi_c^0 K^+)$.
[290] ABE 02B measures the ratio of $B(B^+ \to \chi_c^0 K^+)/B(B^+ \to J/\psi(1S)K^+) = 0.60 + 0.21 - 0.18 \pm 0.05 \pm 0.08$, where the third error is due to the uncertainty in the $B(\chi_c^0 \to \pi^+\pi^-)$, and uses $B(B^+ \to J/\psi(1S)K^+) = (10.0 \pm 1.0) \times 10^{-4}$ to obtain the result.
[291] EDWARDS 01 assumes equal production of B^0 and B^+ at the $\Upsilon(4S)$. The correlated uncertainties (28.3)% from $B(J/\psi(1S) \to \gamma\eta_c)$ in those modes have been accounted for.

19 ±13 ±6		[300] ALBRECHT	92E	ARG	$e^+e^- \to \Upsilon(4S)$

[296] Perform measurements of absolute branching fractions using a missing mass technique.
[297] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.
[298] ACOSTA 02F uses as reference of $B(B \to J/\psi(1S)K^+) = (10.1 \pm 0.6) \times 10^{-4}$. The second error includes the systematic error and the uncertainties of the branching ratio.
[299] AUBERT 02 reports $(7.5 \pm 0.9 \pm 0.8) \times 10^{-4}$ for $B(\chi_{c1}(1P) \to \gamma J/\psi(1S)) = 0.273 \pm 0.016$. We rescale to our best value $B(\chi_{c1}(1P) \to \gamma J/\psi(1S)) = (35.6 \pm 1.9) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.
[300] ALBRECHT 92E assumes no $\chi_{c2}(1P)$ production and $B(\Upsilon(4S) \to B^+B^-) = 50\%$.

POLARIZATION IN B^+ DECAY

In decays involving two vector mesons, one can distinguish among the states in which meson polarizations are both longitudinal (L) or both are transverse and parallel ($\|$) or perpendicular ($\perp$) to each other with the parameters Γ_L/Γ, $\Gamma_\perp/\Gamma$, and the relative phases $\phi_\|$ and $\phi_\perp$. See the definitions in the note on "Polarization in B Decays" review in the B^0 Particle Listings.

VALUE (°)	*DOCUMENT ID*		*TECN*	*COMMENT*
75±20 OUR AVERAGE				
$70 \pm 31^{+18}_{-15}$	[629] AUBERT,B	05Y	BABR	$e^+e^- \to \Upsilon(4S)$
$77^{+17}_{-19} \pm 17$	[630] POLUEKTOV	04	BELL	$e^+e^- \to \Upsilon(4S)$

[629] Uses a Dalitz plot analysis of neutral $D \to K^0_S \pi^+ \pi^-$ decays coming from $B^{\pm} \to D K^{\pm}$ and $B^{\pm} \to D^{*0} K^{\pm}$ followed by $D^{*0} \to D\pi^0$, $D\gamma$. The corresponding two standard deviations interval for gamma is $12^\circ < \gamma < 137^\circ$.

[630] Uses a Dalitz plot analysis of the 3-body $D \to K^0_S \pi^+ \pi^-$ decays coming from $B^{\pm} \to D K^{\pm}$ and $B^{\pm} \to D^* K^{\pm}$ followed by $D^* \to D\pi^0$; here we use D to denote that the neutral D meson produced in the decay is an admixture of D^0 and $\overline{D}^0$. The corresponding two standard deviations interval for γ is $26^\circ < \gamma < 126^\circ$. POLUEKTOV 04 also reports the amplitude ratios and the strong phases.

B^0

$I(J^P) = \frac{1}{2}(0^-)$

Quantum numbers not measured. Values shown are quark-model predictions.

See also the $B^{\pm}/B^0$ ADMIXTURE and $B^{\pm}/B^0/B^0_s$/b-baryon ADMIXTURE sections.

See the Note "Production and Decay of b-flavored Hadrons" at the beginning of the $B^{\pm}$ Particle Listings and the Note on "B^0-$\overline{B}^0$ Mixing" near the end of the B^0 Particle Listings.

B^0 MASS

The fit uses m_{B^+}, $(m_{B^0} - m_{B^+})$, and m_{B^0} to determine m_{B^+}, m_{B^0}, and the mass difference.

VALUE (MeV)	EVTS	DOCUMENT ID		TECN	COMMENT

[1] CSORNA 00 uses fully reconstructed 135 $B^0 \to J/\psi^{(\prime)} K^0_S$ events and invariant masses without beam constraint.
[2] ALBRECHT 90J assumes 10580 for $\Upsilon(4S)$ mass. Supersedes ALBRECHT 87C and ALBRECHT 87D.
[3] Found using fully reconstructed decays with J/ψ. ALBRECHT 87D assume $m_{\Upsilon(4S)}$ = 10577 MeV.

$m_{B^0} - m_{B^+}$

−0.4 ±0.6 ±0.5	BORTOLETTO	92	CLEO	$e^+e^- \to \Upsilon(4S)$
−0.9 ±1.2 ±0.5	ALBRECHT	90J	ARG	$e^+e^- \to \Upsilon(4S)$
2.0 ±1.1 ±0.3	[4] BEBEK	87	CLEO	$e^+e^- \to \Upsilon(4S)$

[4] BEBEK 87 actually measure the difference between half of $E_{\rm cm}$ and the $B^{\pm}$ or B^0 mass, so the $m_{B^0} - m_{B^{\pm}}$ is more accurate. Assume $m_{\Upsilon(4S)}$ = 10580 MeV.

$m_{B^0_H} - m_{B^0_L}$

See the B^0-$\overline{B}^0$ MIXING PARAMETERS section near the end of these B^0 Listings.

B^0 MEAN LIFE

See $B^{\pm}/B^0/B^0_s$/b-baryon ADMIXTURE section for data on B-hadron mean life averaged over species of bottom particles.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account corrections between the measurements and asymmetric lifetime errors.

[5] Measured using a simultaneous fit of the B^0 lifetime and $\overline{B}^0 B^0$ oscillation frequency Δm_d in the partially reconstructed $B^0 \to D^{*-}\ell\nu$ decays.
[6] Measured mean life using $B^0 \to J/\psi K_s$ decays.
[7] Measured mean life using $B^0 \to J/\psi K^{*0}$ decays.
[8] Measurement performed using a combined fit of CP-violation, mixing and lifetimes.
[9] Measured using the time-dependent angular analysis of $B^0_d \to J/\psi K^{*0}$ decays.
[10] Measurement performed using an inclusive reconstruction and B flavor identification technique.

[11] Measurement performed with decays $B^0 \to D^{*-}\pi^+$ and $B^0 \to D^{*-}\rho^+$ using a partial reconstruction technique.
[12] Measured mean life using fully reconstructed decays.
[13] Data analyzed using partially reconstructed $\overline{B}^0 \to D^{*+}\ell^-\overline{\nu}$ decays.
[14] Events are selected in which one B meson is fully reconstructed while the second B meson is reconstructed inclusively.
[15] Data analyzed using $D/D^*\ell$X event vertices.
[16] Data analyzed using charge of secondary vertex.
[17] Data analyzed using inclusive $D/D^*\ell X$.
[18] Measured mean life using partially reconstructed $D^{*-}\pi^+$X vertices.
[19] ABREU 95Q assumes B($B^0 \to D^{**-}\ell^+\nu_\ell$) = 3.2 ± 1.7%.
[20] Data analyzed using vertex-charge technique to tag B charge.
[21] AKERS 95T assumes B($B^0 \to D_s^{(*)}D^{0(*)}$) = 5.0 ± 0.9% to find B^+/B^0 yield.
[22] AUBERT 03C uses a sample of approximately 14,000 exclusively reconstructed $B^0 \to D^*(2010)^-\ell\nu$ and simultaneously measures the lifetime and oscillation frequency.
[23] Combined result of $D/D^*\ell$x analysis, fully reconstructed B analysis, and partially reconstructed $D^{*-}\pi^+$X analysis.
[24] Combined ABREU 95Q and ADAM 95 result.
[25] WAGNER 90 tagged B^0 mesons by their decays into $D^{*-}e^+\nu$ and $D^{*-}\mu^+\nu$ where the D^{*-} is tagged by its decay into $\pi^-\overline{D}^0$.
[26] AVERILL 89 is an estimate of the B^0 mean lifetime assuming that $B^0 \to D^{*+}$ + X always.

MEAN LIFE RATIO τ_{B^+}/τ_{B^0}

τ_{B^+}/τ_{B^0} (direct measurements)

[27] Data analyzed using $D/D^*\mu$X vertices.
[28] Measurement performed using a combined fit of CP-violation, mixing and lifetimes.
[29] Measurement performed using an inclusive reconstruction and B flavor identification technique.
[30] Measured using fully reconstructed decays.
[31] Events are selected in which one B meson is fully reconstructed while the second B meson is reconstructed inclusively.
[32] Data analyzed using charge of secondary vertex.
[33] ABREU 95Q assumes B($B^0 \to D^{**-}\ell^+\nu_\ell$) = 3.2 ± 1.7%.
[34] Data analyzed using vertex-charge technique to tag B charge.
[35] AKERS 95T assumes B($B^0 \to D_s^{(*)}D^{0(*)}$) = 5.0 ± 0.9% to find B^+/B^0 yield.
[36] Combined result of $D/D^*\ell$X analysis and fully reconstructed B analysis.

τ_{B^+}/τ_{B^0} (inferred from branching fractions)

These measurements are inferred from the branching fractions for semileptonic decay or other spectator-dominated decays by assuming that the rates for such decays are equal for B^0 and B^+. We do not use measurements which assume equal production of B^0 and B^+ because of the large uncertainty in the production ratio.

[37] ARTUSO 97 uses partial reconstruction of $B \to D^*\ell\nu_\ell$ and independent of B^0 and B^+ production fraction.
[38] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.
[39] ATHANAS 94 uses events tagged by fully reconstructed B^- decays and partially or fully reconstructed B^0 decays.
[40] Assumes equal production of B^0 and B^+.
[41] ALBRECHT 92G data analyzed using $B \to D_s\overline{D}$, $D_s\overline{D}^*$, $D_s^*\overline{D}$, $D_s^*\overline{D}^*$ events.
[42] BEAN 87B assume the fraction of $B^0\overline{B}^0$ events at the $\Upsilon(4S)$ is 0.41.

sgn(Re(λ_{CP})) $\Delta\Gamma_{B^0_d}$ / $\Gamma_{B^0_d}$

$\Gamma_{B^0_d}$ and $\Delta\Gamma_{B^0_d}$ are the decay rate average and difference between two B^0_d CP eigenstates (light − heavy). The λ_{CP} characterizes B^0 and $\overline{B}^0$ decays to states of charmonium plus K^0_L, see the review on "CP Violation" in the reviews section.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. [44] Using the measured τ_{B^0}=1.55 ± 0.03 ps.
[45] BEHRENS 00B uses high-momentum lepton tags and partially reconstructed $\overline{B}^0 \to D^{*+}\pi^-$, ρ^- decays to determine the flavor of the B meson.
[46] Assumes Δ_{md}=0.478 ± 0.018 ps^{-1} and τ_{B^0}=1.548 ± 0.032 ps.

B^0 DECAY MODES

$\overline{B}^0$ modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing. Modes which do not identify the charge state of the B are listed in the $B^\pm/B^0$ ADMIXTURE section.

The branching fractions listed below assume 50% $B^0\overline{B}^0$ and 50% B^+B^- production at the $\Upsilon(4S)$. We have attempted to bring older measurements up to date by rescaling their assumed $\Upsilon(4S)$ production ratio to 50:50 and their assumed D, D_s, D^*, and ψ branching ratios to current values whenever this would affect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

For inclusive branching fractions, *e.g.*, $B \to D^\pm$anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

[a] An ℓ indicates an e or a μ mode, not a sum over these modes.

[b] $X(3872)^+$ is a hypothetical charged partner of the $X(3872)$.

[c] Stands for the possible candidates of $K^*(1410)$, $K_0^*(1430)$ and $K_2^*(1430)$.

[d] B^0 and B_s^0 contributions not separated. Limit is on weighted average of the two decay rates.

[e] The value is for the sum of the charge states or particle/antiparticle states indicated.

[f] $\Theta(1540)^+$ denotes a possible narrow pentaquark state.

B^0 BRANCHING RATIOS

For branching ratios in which the charge of the decaying B is not determined, see the $B^{\pm}$ section.

$\Gamma(\ell^+\nu_\ell\text{anything})/\Gamma_{\text{total}}$ Γ_1/Γ

10.9 ±0.7 ±1.1	ATHANAS	94	CLE2	Sup. by ARTUSO 97

[47] The measurements are obtained for charged and neutral B mesons partial rates of semileptonic decay to electrons with momentum above 0.6 GeV/c in the B rest frame, and their ratio of B($B^+ \rightarrow e^+\nu_e X$)/B($B^0 \rightarrow e^+\nu_e X$) = 1.08 ± 0.05 ± 0.02.

[48] ARTUSO 97 uses partial reconstruction of $B \rightarrow D^*\ell\nu_\ell$ and inclusive semileptonic branching ratio from BARISH 96B (0.1049 ± 0.0017 ± 0.0043).

$\Gamma(D^-\ell^+\nu_\ell)/\Gamma_{\text{total}}$ Γ_2/Γ

ℓ denotes e or μ, not the sum.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account corrections between the measurements.

[49] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[50] BUSKULIC 97 assumes fraction (B^+) = fraction (B^0) = (37.8 ± 2.2)% and PDG 96 values for B lifetime and branching ratio of D^* and D decays.

[51] ATHANAS 97 uses missing energy and missing momentum to reconstruct neutrino.

[52] FULTON 91 assumes assuming equal production of B^0 and B^+ at the $\Upsilon(4S)$ and uses Mark III D and D^* branching ratios.

[53] ALBRECHT 89J reports 0.018 ± 0.006 ± 0.005. We rescale using the method described in STONE 94 but with the updated PDG 94 B($D^0 \rightarrow K^-\pi^+$).

$\Gamma(D^*(2010)^-\ell^+\nu_\ell)/\Gamma_{\text{total}}$ Γ_3/Γ

0.070 ±0.012 ±0.019	47	[73] ALBRECHT	87J	ARG	$e^+e^- \to \Upsilon(4S)$

[54] Measured using fully reconstructed D^* sample.

[55] Uses the combined fit of both $B^0 \to D^*(2010)^- \ell\nu$ and $B^+ \to \overline{D}(2007)^0 \ell\nu$ samples.

[56] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[57] ABREU 01H measured using about 5000 partial reconstructed D^* sample.

[58] ABBIENDI 00Q assumes the fraction $B(b \to B^0) = (39.7^{+1.8}_{-2.2})\%$. This result is an average of two methods using exclusive and partial D^* reconstruction.

[59] BUSKULIC 97 assumes fraction (B^+) = fraction (B^0) = (37.8 ± 2.2)% and PDG 96 values for B lifetime and D^* and D branching fractions.

[60] Combines with previous partial reconstructed D^* measurement.

[61] The results are based on the same analysis and data sample reported in ADAM 03.

[62] ACKERSTAFF 97G assumes fraction (B^+) = fraction (B^0) = (37.8±2.2)% and PDG 96 values for B lifetime and branching ratio of D^* and D decays.

[63] ABREU 96P result is the average of two methods using exclusive and partial D^* reconstruction.

[64] BARISH 95 use $B(D^0 \to K^-\pi^+)$ = (3.91 ± 0.08 ± 0.17)% and $B(D^{*+} \to D^0\pi^+)$ = (68.1 ± 1.0 ± 1.3)%.

[65] BUSKULIC 95N assumes fraction (B^+) = fraction (B^0) = 38.2 ± 1.3 ± 2.2% and τ_{B^0} = 1.58 ± 0.06 ps. $\Gamma(D^{*-}\ell^+\nu_\ell)$/total = [5.18 − 0.13(fraction(B^0)−38.2)−1.5(τ_{B^0} − 1.58)]%.

[66] ALBRECHT 94 assumes $B(D^{*+} \to D^0\pi^+)$ = 68.1 ± 1.0 ± 1.3%. Uses partial reconstruction of D^{*+} and is independent of D^0 branching ratios.

[67] ALBRECHT 93 reports 0.052 ± 0.005 ± 0.006. We rescale using the method described in STONE 94 but with the updated PDG 94 $B(D^0 \to K^-\pi^+)$. We have taken their average e and μ value. They also obtain $\alpha = 2*\Gamma^0/(\Gamma^- + \Gamma^+) - 1 = 1.1 \pm 0.4 \pm 0.2$, $A_{AF} = 3/4*(\Gamma^- - \Gamma^+)/\Gamma = 0.2 \pm 0.08 \pm 0.06$ and a value of $|V_{cb}| = 0.036$–0.045 depending on model assumptions.

[68] Combining $\overline{D}^{*0}\ell^+\nu_\ell$ and $\overline{D}^{*-}\ell^+\nu_\ell$ SANGHERA 93 test $V-A$ structure and fit the decay angular distributions to obtain $A_{FB} = 3/4*(\Gamma^- - \Gamma^+)/\Gamma = 0.14 \pm 0.06 \pm 0.03$. Assuming a value of V_{cb}, they measure V, A_1, and A_2, the three form factors for the $D^*\ell\nu_\ell$ decay, where results are slightly dependent on model assumptions.

[69] ANTREASYAN 90B is average over B and $\overline{D}^*(2010)$ charge states.

[70] The measurement of ALBRECHT 89C suggests a D^* polarization γ_L/γ_T of 0.85 ± 0.45. or $\alpha = 0.7 \pm 0.9$.

[71] ALBRECHT 89J is ALBRECHT 87J value rescaled using $B(D^*(2010)^- \to D^0\pi^-)$ = 0.57 ± 0.04 ± 0.04. Superseded by ALBRECHT 93.

[72] We have taken average of the the BORTOLETTO 89B values for electrons and muons, 0.046 ± 0.005 ± 0.007. We rescale using the method described in STONE 94 but with the updated PDG 94 $B(D^0 \to K^-\pi^+)$. The measurement suggests a D^* polarization parameter value $\alpha = 0.65 \pm 0.66 \pm 0.25$.

[73] ALBRECHT 87J assume μ-e universality, the $B(\Upsilon(4S) \to B^0\overline{B}^0) = 0.45$, the $B(D^0 \to K^-\pi^+)$ = (0.042 ± 0.004 ± 0.004), and the $B(D^*(2010)^- \to D^0\pi^-) = 0.49 \pm 0.08$. Superseded by ALBRECHT 89J.

$\Gamma(\overline{D}^0\pi^+\ell^+\nu_\ell)/\Gamma_{total}$ Γ_4/Γ

VALUE (units 10^{-3})	DOCUMENT ID		TECN	COMMENT
3.2±0.9±0.3	[74] LIVENTSEV	05	BELL	$e^+e^- \to \Upsilon(4S)$

[74] LIVENTSEV 05 reports [$B(B^0 \to \overline{D}^0\pi^+\ell^+\nu_\ell)$ / $B(B^+ \to \overline{D}^0\ell^+\nu_\ell)$] = 0.15 ± 0.03 ± 0.03. We multiply by our best value $B(B^+ \to \overline{D}^0\ell^+\nu_\ell) = (2.15 \pm 0.22) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

$\Gamma(\overline{D}^{*0}\pi^+\ell^+\nu_\ell)/\Gamma_{total}$ Γ_5/Γ

<4.1	90	[83] BEAN	93B	CLE2	$e^+e^- \to \Upsilon(4S)$

[77] B^+ and B^0 decays combined assuming isospin symmetry. Systematic errors include both experimental and form-factor uncertainties.

[78] ATHAR 03 reports systematic errors $^{+0.47}_{-0.5} \pm 0.41 \pm 0.01$, which are experimental systematic, systematic due to residual form-factor uncertainties in the signal, and systematic due to residual form-factor uncertainties in the cross-feed modes, respectively. We combine these in quadrature.

[79] Averaging with ALEXANDER 96T results including experimental and theoretical correlations considered, BEHRENS 00 reports systematic errors $^{+0.33}_{-0.46} \pm 0.41$, where the second error is theoretical model dependence. We combine these in quadrature.

[80] Uses isospin constraints and extrapolation to all electron energies according to five different form-factor calculations. The second error combines the systematic and theoretical uncertainties in quadrature.

[81] BEHRENS 00 reports $^{+0.35}_{-0.40} \pm 0.50$, where the second error is the theoretical model dependence. We combine these in quadrature. B^+ and B^0 decays combined using isospin symmetry: $\Gamma(B^0 \to \rho^-\ell^+\nu) = 2\Gamma(B^+ \to \rho^0\ell^+\nu) \approx 2\Gamma(B^+ \to \omega\ell^+\nu)$. No evidence for $\omega\ell\nu$ is reported.

[82] ALEXANDER 96T reports $^{+0.5}_{-0.7} \pm 0.5$ where the second error is the theoretical model dependence. We combine these in quadrature. B^+ and B^0 decays combined using isospin symmetry: $\Gamma(B^0 \to \rho^-\ell^+\nu) = 2\Gamma(B^+ \to \rho^0\ell^+\nu) \approx 2\Gamma(B^+ \to \omega\ell^+\nu)$. No evidence for $\omega\ell\nu$ is reported.

[83] BEAN 93B limit set using ISGW Model. Using isospin and the quark model to combine $\Gamma(\rho^0\ell^+\nu_\ell)$ and $\Gamma(\omega\ell^+\nu_\ell)$ with this result, they obtain a limit $<(1.6$–$2.7) \times 10^{-4}$ at 90% CL for $B^+ \to (\omega \text{ or } \rho^0)\ell^+\nu_\ell$. The range corresponds to the ISGW, WSB, and KS models. An upper limit on $|V_{ub}/V_{cb}| < 0.08$–0.13 at 90% CL is derived as well.

700 ±500		5	[119] BEHRENDS	83	CLEO	$e^+e^- \to \Upsilon(4S)$

[115] Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

[116] No assumption about the intermediate mechanism is made in the analysis.

[117] BORTOLETTO 92 assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D. The product branching fraction into $D_0^*(2340)\pi$ followed by $D_0^*(2340) \to D^0\pi$ is < 0.0001 at 90% CL and into $D_2^*(2460)$ followed by $D_2^*(2460) \to D^0\pi$ is < 0.0004 at 90% CL.

[118] BEBEK 87 assume the $\Upsilon(4S)$ decays 43% to $B^0\overline{B}^0$. We rescale to 50%. $B(D^0 \to K^-\pi^+) = (4.2 \pm 0.4 \pm 0.4)\%$ and $B(D^0 \to K^-\pi^+\pi^+\pi^-) = (9.1 \pm 0.8 \pm 0.8)\%$ were used.

[119] Corrected by us using assumptions: $B(D^0 \to K^-\pi^+) = (0.042 \pm 0.006)$ and $B(\Upsilon(4S) \to B^0\overline{B}^0) = 50\%$. The product branching ratio is $B(B^0 \to \overline{D}^0\pi^+\pi^-)B(\overline{D}^0 \to K^+\pi^-) = (0.39 \pm 0.26) \times 10^{-2}$.

[120] BRANDENBURG 98 assume equal production of B^+ and B^0 at $\Upsilon(4S)$ and use the D^* reconstruction technique. The first error is their experiment's error and the second error is the systematic error from the PDG 96 value of $B(D^* \to D\pi)$.

[121] ALAM 94 assume equal production of B^+ and B^0 at the $\Upsilon(4S)$ and use the CLEO II $B(D^*(2010)^+ \to D^0\pi^+)$ and absolute $B(D^0 \to K^-\pi^+)$ and the PDG 1992 $B(D^0 \to K^-\pi^+\pi^0)/B(D^0 \to K^-\pi^+)$ and $B(D^0 \to K^-\pi^+\pi^+\pi^-)/B(D^0 \to K^-\pi^+)$.

[122] BORTOLETTO 92 reports $0.0040 \pm 0.0010 \pm 0.0007$ for $B(D^*(2010)^+ \to D^0\pi^+) = 0.57 \pm 0.06$. We rescale to our best value $B(D^*(2010)^+ \to D^0\pi^+) = (67.7 \pm 0.5) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D.

[123] ALBRECHT 90J reports $0.0028 \pm 0.0009 \pm 0.0006$ for $B(D^*(2010)^+ \to D^0\pi^+) = 0.57 \pm 0.06$. We rescale to our best value $B(D^*(2010)^+ \to D^0\pi^+) = (67.7 \pm 0.5) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D.

[124] BEBEK 87 reports $0.0028^{+0.0015}_{-0.0012}{}^{+0.0010}_{-0.0006}$ for $B(D^*(2010)^+ \to D^0\pi^+) = 0.57 \pm 0.06$. We rescale to our best value $B(D^*(2010)^+ \to D^0\pi^+) = (67.7 \pm 0.5) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Updated in BERKELMAN 91 to use same assumptions as noted for BORTOLETTO 92 and ALBRECHT 90J.

[125] Assumes $B(Z \to b\overline{b}) = 0.217$ and 38% B_d production fraction.

[126] ALBRECHT 87C use PDG 86 branching ratios for D and $D^*(2010)$ and assume $B(\Upsilon(4S) \to B^+B^-) = 55\%$ and $B(\Upsilon(4S) \to B^0\overline{B}^0) = 45\%$. Superseded by ALBRECHT 90J.

[127] ALBRECHT 86F uses pseudomass that is independent of D^0 and D^+ branching ratios.

[128] Assumes $B(D^*(2010)^+ \to D^0\pi^+) = 0.60^{+0.08}_{-0.15}$. Assumes $B(\Upsilon(4S) \to B^0\overline{B}^0) = 0.40 \pm 0.02$ Does not depend on D branching ratios.

0.081 ±0.029 $^{+0.059}_{-0.024}$	19	[140] CHEN	85	CLEO	$e^+e^- \to \Upsilon(4S)$

[135] Assumes equal production of B^0 and B^+ at the $\Upsilon(4S)$ resonance. The second error combines the systematic and theoretical uncertainties in quadrature. CSORNA 03 includes data used in ALAM 94. A full angular fit to three complex helicity amplitudes is performed.

[136] BORTOLETTO 92 reports $0.019 \pm 0.008 \pm 0.011$ for $B(D^*(2010)^+ \to D^0\pi^+) = 0.57 \pm 0.06$. We rescale to our best value $B(D^*(2010)^+ \to D^0\pi^+) = (67.7 \pm 0.5) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D.

[137] ALBRECHT 90J reports $0.007 \pm 0.003 \pm 0.003$ for $B(D^*(2010)^+ \to D^0\pi^+) = 0.57 \pm 0.06$. We rescale to our best value $B(D^*(2010)^+ \to D^0\pi^+) = (67.7 \pm 0.5) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D.

[138] ALAM 94 assume equal production of B^+ and B^0 at the $\Upsilon(4S)$ and use the CLEO II $B(D^*(2010)^+ \to D^0\pi^+)$ and absolute $B(D^0 \to K^-\pi^+)$ and the PDG 1992 $B(D^0 \to K^-\pi^+\pi^0)/B(D^0 \to K^-\pi^+)$ and $B(D^0 \to K^-\pi^+\pi^+\pi^-)/B(D^0 \to K^-\pi^+)$.

[139] This decay is nearly completely longitudinally polarized, $\Gamma_L/\Gamma = (93 \pm 5 \pm 5)\%$, as expected from the factorization hypothesis (ROSNER 90). The nonresonant $\pi^+\pi^0$ contribution under the ρ^+ is less than 9% at 90% CL.

[140] Uses $B(D^* \to D^0\pi^+) = 0.6 \pm 0.15$ and $B(\Upsilon(4S) \to B^0\overline{B}^0) = 0.4$. Does not depend on D branching ratios.

[172] GIBAUT 96 reports $0.0087 \pm 0.0024 \pm 0.0020$ for $B(D_s^+ \to \phi\pi^+) = 0.035$. We rescale to our best value $B(D_s^+ \to \phi\pi^+) = (4.4 \pm 0.6) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

[173] ALBRECHT 92G reports $0.017 \pm 0.013 \pm 0.006$ for $B(D_s^+ \to \phi\pi^+) = 0.027$. We rescale to our best value $B(D_s^+ \to \phi\pi^+) = (4.4 \pm 0.6) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes PDG 1990 D^+ branching ratios, e.g., $B(D^+ \to K^-\pi^+\pi^+) = 7.7 \pm 1.0\%$.

[174] BORTOLETTO 92 reports $0.0080 \pm 0.0045 \pm 0.0030$ for $B(D_s^+ \to \phi\pi^+) = 0.030 \pm 0.011$. We rescale to our best value $B(D_s^+ \to \phi\pi^+) = (4.4 \pm 0.6) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$ and uses Mark III branching fractions for the D.

[175] BORTOLETTO 90 assume $B(D_s \to \phi\pi^+) = 2\%$. Superseded by BORTOLETTO 92.

		327 ALBRECHT	94G	ARG	$e^+e^- \to \Upsilon(4S)$
4.0 ±0.30		328 ALBAJAR	91E	UA1	$E_{cm}^{p\overline{p}} = 630$ GeV
3.3 ±0.18	5	329 ALBRECHT	87D	ARG	$e^+e^- \to \Upsilon(4S)$
4.1 ±0.18	5	330 ALAM	86	CLEO	Repl. by BEBEK 87

319 Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

320 ABE 98O reports $[B(B^0 \to J/\psi(1S)K^*(892)^0)]/[B(B^+ \to J/\psi(1S)K^+)] = 1.76 \pm 0.14 \pm 0.15$. We multiply by our best value $B(B^+ \to J/\psi(1S)K^+) = (9.9\pm1.0)\times10^{-4}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

321 Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

322 BORTOLETTO 92 reports $(1.1 \pm 0.5 \pm 0.3)\times10^{-3}$ for $B(J/\psi(1S) \to e^+e^-) = 0.069 \pm 0.009$. We rescale to our best value $B(J/\psi(1S) \to e^+e^-) = (5.94 \pm 0.06)\times10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

323 ALBRECHT 90J reports $(1.1\pm0.5\pm0.2)\times10^{-3}$ for $B(J/\psi(1S) \to e^+e^-) = 0.069 \pm 0.009$. We rescale to our best value $B(J/\psi(1S) \to e^+e^-) = (5.94 \pm 0.06)\times10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

324 BEBEK 87 reports $(3.5\pm1.6\pm0.3)\times10^{-3}$ for $B(J/\psi(1S) \to e^+e^-) = 0.069\pm0.009$. We rescale to our best value $B(J/\psi(1S) \to e^+e^-) = (5.94 \pm 0.06)\times10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Updated in BORTOLETTO 92 to use the same assumptions.

325 ABE 96H assumes that $B(B^+ \to J/\psi K^+) = (1.02 \pm 0.14)\times10^{-3}$.

326 The neutral and charged B events together are predominantly longitudinally polarized, $\Gamma_L/\Gamma = 0.080 \pm 0.08 \pm 0.05$. This can be compared with a prediction using HQET, 0.73 (KRAMER 92). This polarization indicates that the $B \to \psi K^*$ decay is dominated by the $CP = -1$ CP eigenstate. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

327 ALBRECHT 94G measures the polarization in the vector-vector decay to be predominantly longitudinal, $\Gamma_T/\Gamma = 0.03\pm0.16\pm0.15$ making the neutral decay a CP eigenstate when the K^{*0} decays through $K^0_S\pi^0$.

328 ALBAJAR 91E assumes B^0_d production fraction of 36%.

329 ALBRECHT 87D assume $B^+B^-/B^0\overline{B}^0$ ratio is 55/45. Superseded by ALBRECHT 90J.

330 ALAM 86 assumes $B^\pm/B^0$ ratio is 60/40. The observation of the decay $B^+ \to J/\psi K^*(892)^+$ (HAAS 85) has been retracted in this paper.

$\Gamma(J/\psi(1S)K^*(892)^0)/\Gamma(J/\psi(1S)K^0)$ $\Gamma_{138}/\Gamma_{136}$

0.51±0.15±0.03	[373] AUBERT	02	BABR	$e^+e^-\to\Upsilon(4S)$

[373] AUBERT 02 reports $0.66\pm0.11\pm0.17$ for $B(\chi_{c1}(1P)\to\gamma J/\psi(1S))=0.273\pm0.016$. We rescale to our best value $B(\chi_{c1}(1P)\to\gamma J/\psi(1S))=(35.6\pm1.9)\times10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Assumes equal production of B^+ and B^0 at the $\Upsilon(4S)$.

$\Gamma(\chi_{c1}(1P)K^*(892)^0)/\Gamma(\chi_{c1}(1P)K^0)$ $\Gamma_{167}/\Gamma_{166}$

POLARIZATION IN B DECAYS

Written March 2006 by A.V. Gritsan (Johns Hopkins University) and J.G. Smith (University of Colorado at Boulder)

We review the notation used in polarization measurements of B decays and discuss CP-violating observables in polarization measurements. We look at several examples of vector-vector B meson decays, while more details about the theory and experimental results in B decays can be found in a separate mini-review [1] in this *Review*.

The angular distribution of the B meson decay to two vector mesons with the sequential decay of each vector meson is of special interest because it reflects both weak- and strong-interaction dynamics. Using the helicity formalism [2], this distribution can be expressed as a function of three helicity angles which describe the flight direction of the vector meson daughters in the decay chain. An equivalent set of transversity angles can be used to reparameterize the angular distribution [3]. While the function of the angles depends on the quantum numbers of the vector mesons daughters, the differential decay width has three complex amplitudes A_λ corresponding to the vector meson helicity $\lambda = 0$ or ±1 [4], where the last two can be expressed in terms of parity-even and parity-odd amplitudes $A_{\parallel,\perp} = (A_{+1} \pm A_{-1})/\sqrt{2}$. The angular distribution involves the terms proportional to the absolute values squared of the three amplitudes, plus the interference terms $\mathcal{I}m(A_\perp A_\parallel^*)$, $\mathcal{R}e(A_\parallel A_0^*)$, and $\mathcal{I}m(A_\perp A_0^*)$. Therefore, spin alignment in the vector-vector decay can be expressed with the parameters $f_L = |A_0|^2/\Sigma|A_\lambda|^2$, $f_\perp = |A_\perp|^2/\Sigma|A_\lambda|^2$, and the relative phases $\phi_\parallel = \arg(A_\parallel/A_0)$, $\phi_\perp = \arg(A_\perp/A_0)$.

Moreover, CP-violation can be tested in the angular distribution of the decay as the difference between the B and $\bar{B}$. This includes the vector triple-product asymmetries, direct-CP asymmetries in the amplitudes, and mixing-induced CP asymmetries in the time evolution. Overall, six non-trivial CP-violating parameters can be constructed from the $\bar{A}_\lambda$ and A_λ amplitudes [4]. Three parameters are equivalent to the three direct CP violating quantities, and in Ref. 5 they are chosen as the asymmetries in the overall decay rate $\mathcal{A}_{CP}$, in the f_L fraction $\mathcal{A}_{CP}^0$, and in the $f_\perp$ fraction $\mathcal{A}_{CP}^\perp$. Two other CP violating parameters are the weak phase differences:

$$\Delta\phi_\parallel = \frac{1}{2}\arg(\bar{A}_\parallel A_0/A_\parallel\bar{A}_0) \quad (1)$$

$$\Delta\phi_\perp = \frac{1}{2}\arg(\bar{A}_\perp A_0/A_\perp\bar{A}_0) - \frac{\pi}{2} \quad (2)$$

The $\frac{\pi}{2}$ term in Eq. (2) reflects the fact that $A_\perp$ and $\bar{A}_\perp$ differ in phase by π if CP is conserved. The two parameters $\Delta\phi_\parallel$ and $\Delta\phi_\perp$ are equivalent to triple-product asymmetries constructed from the vectors describing the decay angular distribution [4]. Finally, one CP-violating asymmetry is equivalent to the mixing-induced asymmetries studied in other decays [1].

B meson decays to heavy vector particles with charm, such as $B \to J/\psi K^*$, $D^*\rho$, D^*K^*, D^*D^*, $D^*D_s^*$, show substantial fraction of the amplitudes corresponding to transverse polarization of the vector mesons ($A_{\pm1}$), in agreement with the factorization prediction. Most of these decays arise from tree-level $b \to c$ transitions and the amplitude hierarchy $|A_0| > |A_+| > |A_-|$ is expected from analyses based on quark-helicity conservation [6]. The larger the mass of the vector meson daughters, the weaker the inequality. The detailed amplitude analysis of the $B \to J/\psi K^*$ decays has been performed by the BABAR [7], Belle [8], CDF [9], and CLEO [10] collaborations. Most analyses are performed under the assumption of the absence of direct CP violation. The parameter values are given in the particle listing of this *Review*. The difference of the strong phases $\phi_\parallel$ and $\phi_\perp$ deviates significantly from zero. The most recent measurements [8] of CP-violating terms similar to those in $B \to \phi K^*$ [5] are consistent with zero.

In addition, the mixing-induced *CP*-violating asymmetry is measured in the *CP*-eigenstate mode $B^0 \to J/\psi K^{*0}$ [1,7,8]. This allows one to resolve the sign ambiguity of the $\cos 2\beta = \cos 2\phi_1$ term which appears in the time-dependent angular distribution due to interference of parity-even and parity-odd terms. This analysis relies on the knowledge of discrete ambiguities in the strong phases $\phi_\parallel$ and $\phi_\perp$ as discussed below. The BABAR experiment used a novel method based on the dependence on the $K\pi$ invariant mass of the interference between the *S*- and *P*-waves to resolve the discrete ambiguity in the determination of the strong phases $(\phi_\parallel, \phi_\perp)$ in $B \to J/\psi K^*$ decays [7]. The result is in agreement with the amplitude hierarchy expectation [6]. The CDF [9] and D0 [11] experiments have studied the $B_s^0 \to J/\psi\phi$ decay and provided new lifetime measurements in addition to polarization results.

The interest in the polarization and *CP* asymmetry measurements in $B \to \phi K^*$ decays is mainly motivated by their potential sensitivity to physics beyond the Standard Model. In the Standard Model these decays are expected to arise only from the virtual loop effects in $b \to s$ penguin transitions. The amplitude hierarchy $|A_0| \gg |A_+| \gg |A_-|$ was expected in the B decays to light vector particles in penguin transitions [12,13] similarly to the tree-level transition analysis [6]. The decay amplitudes for $B \to \phi K^*$ have been measured by the BABAR and Belle experiments [5,14–16]. The fractions of longitudinal polarization $f_L = 0.50 \pm 0.07$ for the $B^+ \to \phi K^{*+}$ decay and $f_L = 0.48 \pm 0.04$ for the $B^0 \to \phi K^{*0}$ decay indicate significant departure from the naive expectation of predominant longitudinal polarization and suggests other contributions to the decay amplitude, previously neglected, either within or beyond the Standard Model [13,17]. The complete set of ten amplitude parameters measured in the $B^0 \to \phi K^{*0}$ decay are given in Table 1. Several other parameters could be constructed from the above ten parameters, as suggested in Ref. 18.

Table 1: Polarization and *CP*-violation parameters [5,16], along with the branching fraction $\mathcal{B}$ [5,15,19] measured in the $B^0 \to \phi K^{*0}$ decay.

parameter	average
$\mathcal{B}$	$(9.5 \pm 0.9) \times 10^{-6}$
f_L	0.48 ± 0.04
$f_\perp$	0.26 ± 0.05
$\phi_\parallel$	$2.36^{+0.18}_{-0.16}$
$\phi_\perp$	2.49 ± 0.18
A_{CP}	0.01 ± 0.07
A^0_{CP}	0.01 ± 0.09
$A^\perp_{CP}$	-0.16 ± 0.15
$\Delta\phi_\parallel$	0.02 ± 0.28
$\Delta\phi_\perp$	0.03 ± 0.33

There is a discrete ambiguity in the phase $(\phi_\parallel, \phi_\perp, \Delta\phi_\parallel, \Delta\phi_\perp)$ measurements and simple transformation of phases, for example, $(-\phi_\parallel, \pi - \phi_\perp, -\Delta\phi_\parallel, -\Delta\phi_\perp)$, give rise to another set of values which produce the same angular distribution. The values closest to $(\pi, \pi, 0, 0)$ are given in Table 1, which is the preferred solution from *s*-quark helicity conservation [6,12,13]. However, this assumption is violated in the measurement of f_L and in the departure of $\phi_\parallel$ and $\phi_\perp$ from π, and needs experimental confirmation.

Like $B \to \phi K^*$, the decays $B \to \rho K^*$ and $B \to \omega K^*$ may be sensitive to New Physics. First measurements of the longitudinal polarization fraction in $B^+ \to \rho^0 K^{*+}$ [14] and $B^+ \to \rho^+ K^{*0}$ [20] have larger uncertainties due to lower yields and larger backgrounds. Only limits have been reported for the other $B \to \rho K^*$ and $B \to \omega K^*$ decays [21,22] and further improved measurements in all $B \to \rho K^*$ and $B \to \omega K^*$ decays are necessary to distinguish different interpretations [17].

The other class of vector-vector B meson decays is expected to arise from tree-level $b \to u$ transition. There is experimental confirmation of predominantly longitudinal polarization in the decays $B^0 \to \rho^+\rho^-$ [23], $B^+ \to \rho^0\rho^+$ [14,24], and $B^+ \to \omega\rho^+$ [21], which is consistent with the analysis of the quark helicity conservation [6]. Because the longitudinal amplitude dominates the decay, a detailed amplitude analysis is not possible with current B samples. Only limits have been set on the $B^0 \to \rho^0\rho^0$ [14,22,25] and $B^0 \to \omega\rho^0$ [21,26] decays, indicating that $b \to d$ penguin pollution is small in the charmless, strangeless vector-vector B decays.

In summary, there has been considerable recent interest in the polarization measurements of B meson decays because they reveal both weak- and strong-interaction dynamics [17,27]. New measurements will further elucidate the pattern of spin alignment measurements in rare B decays and further test the Standard Model and strong interaction dynamics, including the non-factorizable contributions to the B decay amplitudes.

POLARIZATION IN B^0 DECAY

In decays involving two vector mesons, one can distinguish among the states in which meson polarizations are both longitudinal (L) or both are transverse and parallel ($\|$) or perpendicular ($\perp$) to each other with the parameters Γ_L/Γ, $\Gamma_\perp/\Gamma$, and the relative phases $\phi_\|$ and $\phi_\perp$. See the definitions in the note on "Polarization in B Decays" review in the B^0 Particle Listings.

B^0–$\overline{B}^0$ MIXING

Updated April 2006 by O. Schneider (Ecole Polytechnique Fédérale de Lausanne).

There are two neutral B^0–$\overline{B}^0$ meson systems, B_d^0–$\overline{B}_d^0$ and B_s^0–$\overline{B}_s^0$ (generically denoted B_q^0–$\overline{B}_q^0$, $q = s, d$), which exhibit particle-antiparticle mixing [1]. This mixing phenomenon is described in Ref. 2. In the following, we adopt the notation introduced in Ref. 2, and assume CPT conservation throughout. In each system, the light (L) and heavy (H) mass eigenstates,

$$|B_{\rm L,H}\rangle = p|B_q^0\rangle \pm q|\overline{B}_q^0\rangle\,, \tag{1}$$

have a mass difference $\Delta m_q = m_{\rm H} - m_{\rm L} > 0$, and a total decay width difference $\Delta\Gamma_q = \Gamma_{\rm L} - \Gamma_{\rm H}$. In the absence of CP violation in the mixing, $|q/p| = 1$, these differences are given by $\Delta m_q = 2|M_{12}|$ and $|\Delta\Gamma_q| = 2|\Gamma_{12}|$, where M_{12} and Γ_{12} are the off-diagonal elements of the mass and decay matrices [2]. The evolution of a pure $|B_q^0\rangle$ or $|\overline{B}_q^0\rangle$ state at $t = 0$ is given by

$$|B_q^0(t)\rangle = g_+(t)\,|B_q^0\rangle + \frac{q}{p}\,g_-(t)\,|\overline{B}_q^0\rangle\,, \tag{2}$$

$$|\overline{B}_q^0(t)\rangle = g_+(t)\,|\overline{B}_q^0\rangle + \frac{p}{q}\,g_-(t)\,|B_q^0\rangle\,, \tag{3}$$

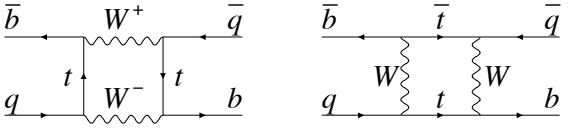

Figure 1: Dominant box diagrams for the $B_q^0 \to \overline{B}_q^0$ transitions ($q = d$ or s). Similar diagrams exist where one or both t quarks are replaced with c or u quarks.

which means that the flavor states remain unchanged (+) or oscillate into each other (−) with time-dependent probabilities proportional to

$$|g_\pm(t)|^2 = \frac{e^{-\Gamma_q t}}{2}\left[\cosh\left(\frac{\Delta\Gamma_q}{2}\,t\right) \pm \cos(\Delta m_q\, t)\right]\,, \tag{4}$$

where $\Gamma_q = (\Gamma_{\rm H} + \Gamma_{\rm L})/2$. In the absence of CP violation, the time-integrated mixing probability $\int |g_-(t)|^2\,dt/(\int |g_-(t)|^2\,dt + \int |g_+(t)|^2\,dt)$ is given by

$$\chi_q = \frac{x_q^2 + y_q^2}{2(x_q^2+1)}\,, \quad \text{where} \quad x_q = \frac{\Delta m_q}{\Gamma_q}\,, \quad y_q = \frac{\Delta\Gamma_q}{2\Gamma_q}\,. \tag{5}$$

Standard Model predictions and phenomenology

In the Standard Model, the transitions $B_q^0 \to \overline{B}_q^0$ and $\overline{B}_q^0 \to B_q^0$ are due to the weak interaction. They are described, at the lowest order, by box diagrams involving two W bosons and two up-type quarks (see Fig. 1), as is the case for K^0–$\overline{K}^0$ mixing. However, the long range interactions arising from intermediate virtual states are negligible for the neutral B meson systems, because the large B mass is off the region of hadronic resonances. The calculation of the dispersive and absorptive parts of the box diagrams yields the following predictions for the off-diagonal element of the mass and decay matrices [3],

$$M_{12} = -\frac{G_F^2 m_W^2 \eta_B m_{B_q} B_{B_q} f_{B_q}^2}{12\pi^2}\, S_0(m_t^2/m_W^2)\,(V_{tq}^* V_{tb})^2\,, \tag{6}$$

$$\Gamma_{12} = \frac{G_F^2 m_b^2 \eta_B' m_{B_q} B_{B_q} f_{B_q}^2}{8\pi} \times \left[(V_{tq}^* V_{tb})^2 + V_{tq}^* V_{tb} V_{cq}^* V_{cb}\; \mathcal{O}\left(\frac{m_c^2}{m_b^2}\right) + (V_{cq}^* V_{cb})^2\; \mathcal{O}\left(\frac{m_c^4}{m_b^4}\right)\right]\,, \tag{7}$$

where G_F is the Fermi constant, m_W the W boson mass, and m_i the mass of quark i; m_{B_q}, f_{B_q} and B_{B_q} are the B_q^0 mass, weak decay constant and bag parameter, respectively. The known function $S_0(x_t)$ can be approximated very well by $0.784\,x_t^{0.76}$ [4], and V_{ij} are the elements of the CKM matrix [5]. The QCD corrections η_B and η_B' are of order unity. The only non-negligible contributions to M_{12} are from box diagrams involving two top quarks. The phases of M_{12} and Γ_{12} satisfy

$$\phi_M - \phi_\Gamma = \pi + \mathcal{O}\left(\frac{m_c^2}{m_b^2}\right)\,, \tag{8}$$

implying that the mass eigenstates have mass and width differences of opposite signs. This means that, like in the K^0–$\overline{K}^0$ system, the heavy state is expected to have a smaller decay width

than that of the light state: $\Gamma_H < \Gamma_L$. Hence, $\Delta\Gamma = \Gamma_L - \Gamma_H$ is expected to be positive in the Standard Model.

Furthermore, the quantity

$$\left|\frac{\Gamma_{12}}{M_{12}}\right| \simeq \frac{3\pi}{2}\frac{m_b^2}{m_W^2}\frac{1}{S_0(m_t^2/m_W^2)} \sim \mathcal{O}\left(\frac{m_b^2}{m_t^2}\right) \qquad (9)$$

is small, and a power expansion of $|q/p|^2$ yields

$$\left|\frac{q}{p}\right|^2 = 1 + \left|\frac{\Gamma_{12}}{M_{12}}\right|\sin(\phi_M - \phi_\Gamma) + \mathcal{O}\left(\left|\frac{\Gamma_{12}}{M_{12}}\right|^2\right). \qquad (10)$$

Therefore, considering both Eqs. (8) and (9), the CP-violating parameter

$$1 - \left|\frac{q}{p}\right|^2 \simeq \mathrm{Im}\left(\frac{\Gamma_{12}}{M_{12}}\right) \qquad (11)$$

is expected to be very small: $\sim \mathcal{O}(10^{-3})$ for the B_d^0–$\overline{B}_d^0$ system and $\lesssim \mathcal{O}(10^{-4})$ for the B_s^0–$\overline{B}_s^0$ system [6].

In the approximation of negligible CP violation in mixing, the ratio $\Delta\Gamma_q/\Delta m_q$ is equal to the small quantity $|\Gamma_{12}/M_{12}|$ of Eq. (9); it is hence independent of CKM matrix elements, *i.e.*, the same for the B_d^0–$\overline{B}_d^0$ and B_s^0–$\overline{B}_s^0$ systems. It can be calculated with lattice QCD techniques; typical results are $\sim 5 \times 10^{-3}$ with quoted uncertainties of $\sim 30\%$. Given the current experimental knowledge on the mixing parameter x_q (obtained from published results only),

$$\begin{cases} x_d = 0.776 \pm 0.008 & (B_d^0\text{–}\overline{B}_d^0 \text{ system}) \\ x_s > 19.9 \text{ at } 95\% \text{ CL} & (B_s^0\text{–}\overline{B}_s^0 \text{ system}) \end{cases}, \qquad (12)$$

the Standard Model thus predicts that $\Delta\Gamma_d/\Gamma_d$ is very small (below 1%), but $\Delta\Gamma_s/\Gamma_s$ considerably larger ($\sim 10\%$). These width differences are caused by the existence of final states to which both the B_q^0 and $\overline{B}_q^0$ mesons can decay. Such decays involve $b \to c\bar{c}q$ quark-level transitions, which are Cabibbo-suppressed if $q = d$ and Cabibbo-allowed if $q = s$.

Experimental issues and methods for oscillation analyses

Time-integrated measurements of B^0–$\overline{B}^0$ mixing were published for the first time in 1987 by UA1 [7] and ARGUS [8], and since then by many other experiments. These measurements are typically based on counting same-sign and opposite-sign lepton pairs from the semileptonic decay of the produced $b\overline{b}$ pairs. Such analyses cannot easily separate the contributions from the different b-hadron species, therefore, the clean environment of $\Upsilon(4S)$ machines (where only B_d^0 and charged B_u mesons are produced) is in principle best suited to measure χ_d.

However, better sensitivity is obtained from time-dependent analyses aiming at the direct measurement of the oscillation frequencies Δm_d and Δm_s, from the proper time distributions of B_d^0 or B_s^0 candidates identified through their decay in (mostly) flavor-specific modes, and suitably tagged as mixed or unmixed. This is particularly true for the B_s^0–$\overline{B}_s^0$ system, where the large value of x_s implies maximal mixing, *i.e.*, $\chi_s \simeq 1/2$. In such analyses, the B_d^0 or B_s^0 mesons are either fully reconstructed, partially reconstructed from a charm meson, selected from a lepton with the characteristics of a $b \to \ell^-$ decay, or selected from a reconstructed displaced vertex. At high-energy colliders (LEP, SLC, Tevatron), the proper time $t = \frac{m_B}{p}L$ is measured from the distance L between the production vertex and the B decay vertex, and from an estimate of the B momentum p. At asymmetric B factories (KEKB, PEP-II), producing $e^+e^- \to \Upsilon(4S) \to B_d^0\overline{B}_d^0$ events with a boost $\beta\gamma$ (= 0.425, 0.55), the proper time difference between the two B candidates is estimated as $\Delta t \simeq \frac{\Delta z}{\beta\gamma c}$, where Δz is the spatial separation between the two B decay vertices along the boost direction. In all cases, the good resolution needed on the vertex positions is obtained with silicon detectors.

The average statistical significance $\mathcal{S}$ of a B_d^0 or B_s^0 oscillation signal can be approximated as [9]

$$\mathcal{S} \approx \sqrt{N/2}\, f_{\rm sig}\,(1-2\eta)\, e^{-(\Delta m\,\sigma_t)^2/2}, \qquad (13)$$

where N is the number of selected and tagged candidates, $f_{\rm sig}$ is the fraction of signal in that sample, η is the total mistag probability, and σ_t is the resolution on proper time (or proper time difference). The quantity $\mathcal{S}$ decreases very quickly as Δm increases; this dependence is controlled by σ_t, which is therefore a critical parameter for Δm_s analyses. At high-energy colliders, the proper time resolution $\sigma_t \sim \frac{m_B}{\langle p\rangle}\sigma_L \oplus t\frac{\sigma_p}{p}$ includes a constant contribution due to the decay length resolution σ_L (typically 0.05–0.3 ps), and a term due to the relative momentum resolution σ_p/p (typically 10–20% for partially reconstructed decays), which increases with proper time. At B factories, the boost of the B mesons is estimated from the known beam energies, and the term due to the spatial resolution dominates (typically 1–1.5 ps because of the much smaller B boost).

In order to tag a B candidate as mixed or unmixed, it is necessary to determine its flavor both in the initial state and in the final state. The initial and final state mistag probabilities, η_i and η_f, degrade $\mathcal{S}$ by a total factor $(1-2\eta) = (1-2\eta_i)(1-2\eta_f)$. In lepton-based analyses, the final state is tagged by the charge of the lepton from $b \to \ell^-$ decays; the largest contribution to η_f is then due to $\overline{b} \to \overline{c} \to \ell^-$ decays. Alternatively, the charge of a reconstructed charm meson (D^{*-} from B_d^0 or D_s^- from B_s^0), or that of a kaon hypothesized to come from a $b \to c \to s$ decay [10], can be used. For fully inclusive analyses based on topological vertexing, final state tagging techniques include jet charge [11] and charge dipole [12,13] methods.

At high-energy colliders, the methods to tag the initial state (*i.e.*, the state at production), can be divided into two groups: the ones that tag the initial charge of the $\overline{b}$ quark contained in the B candidate itself (same-side tag), and the ones that tag the initial charge of the other b quark produced in the event (opposite-side tag). On the same side, the charge of a track from the primary vertex is correlated with the production state of the B if that track is a decay product of a B^{**} state or the first particle in the fragmentation chain [14,15]. Jet- and vertex-charge techniques work on both sides and on the opposite side, respectively. Finally, the charge of a lepton from $b \to \ell^-$ or of a kaon from $b \to c \to s$ can be used as opposite side

tags, keeping in mind that their performance is degraded due to integrated mixing. At SLC, the beam polarization produced a sizeable forward-backward asymmetry in the $Z \to b\overline{b}$ decays, and provided another very interesting and effective initial state tag based on the polar angle of the B candidate [12]. Initial state tags have also been combined to reach $\eta_i \sim 26\%$ at LEP [15,16], or even 22% at SLD [12] with full efficiency. In the case $\eta_f = 0$, this corresponds to an effective tagging efficiency $Q = \epsilon D^2 = \epsilon(1-2\eta)^2$, where ϵ is the tagging efficiency, in the range $23-31\%$. The equivalent figure achieved by CDF during Tevatron Run I was $\sim 3.5\%$ [17] reflecting the fact that tagging is more difficult at hadron colliders. The current CDF and DØ analyses of Tevatron Run II data reach $\epsilon D^2 = (1.5 \pm 0.1)\%$ [18] and $(2.5 \pm 0.2)\%$ [19] for opposite-side tagging, while same-side kaon tagging (for B_s^0 oscillation analyses) is contributing an additional $(3.4 \pm 1.0)\%$ at CDF [18].

At B factories, the flavor of a B_d^0 meson at production cannot be determined, since the two neutral B mesons produced in a $\Upsilon(4S)$ decay evolve in a coherent P-wave state where they keep opposite flavors at any time. However, as soon as one of them decays, the other follows a time-evolution given by Eqs. (2) or (3), where t is replaced with Δt (which will take negative values half of the time). Hence, the "initial state" tag of a B can be taken as the final state tag of the other B. Effective tagging efficiencies Q of 30% are achieved by BABAR and Belle [20], using different techniques including $b \to \ell^-$ and $b \to c \to s$ tags. It is worth noting that, in this case, mixing of the other B (*i.e.*, the coherent mixing occurring before the first B decay) does not contribute to the mistag probability.

In the absence of experimental observation of a decay-width difference, oscillation analyses typically neglect $\Delta\Gamma$ in Eq. (4), and describe the data with the physics functions $\Gamma e^{-\Gamma t}(1 \pm \cos(\Delta m t))/2$ (high-energy colliders) or $\Gamma e^{-\Gamma|\Delta t|}(1 \pm \cos(\Delta m \Delta t))/4$ (asymmetric $\Upsilon(4S)$ machines). As can be seen from Eq. (4), a non-zero value of $\Delta\Gamma$ would effectively reduce the oscillation amplitude with a small time-dependent factor that would be very difficult to distinguish from time resolution effects. Measurements of Δm_d are usually extracted from the data using a maximum likelihood fit. To extract information useful for the interpretation of B_s^0 oscillation searches and for the combination of their results, a method [9] is followed in which a B_s^0 oscillation amplitude $\mathcal{A}$ is measured as a function of a fixed test value of Δm_s, using a maximum likelihood fit based on the functions $\Gamma_s e^{-\Gamma_s t}(1 \pm \mathcal{A}\cos(\Delta m_s t))/2$. To a good approximation, the statistical uncertainty on $\mathcal{A}$ is Gaussian and equal to $1/\mathcal{S}$ from Eq. (13). If Δm_s is equal to its true value, one expects $\mathcal{A} = 1$ within the total uncertainty $\sigma_{\mathcal{A}}$; in case a signal is seen, its observed (or expected) significance will be defined as $\mathcal{A}/\sigma_{\mathcal{A}}$ (or $1/\sigma_{\mathcal{A}}$). However, if Δm_s is (far) below its true value, a measurement consistent with $\mathcal{A} = 0$ is expected. A value of Δm_s can be excluded at 95% CL if $\mathcal{A} + 1.645\,\sigma_{\mathcal{A}} \leq 1$ (since the integral of a normal distribution from $-\infty$ to 1.645 is equal to 0.95). Because of the proper time resolution, the quantity $\sigma_{\mathcal{A}}(\Delta m_s)$ is a steadily increasing function of Δm_s. We define the sensitivity for 95% CL exclusion of Δm_s values (or for a $3\,\sigma$ or $5\,\sigma$ observation of B_s^0 oscillations) as the value of Δm_s for which $1/\sigma_{\mathcal{A}} = 1.645$ (or $1/\sigma_{\mathcal{A}} = 3$ or 5).

B_d^0 mixing studies

Many B_d^0–$\overline{B}_d^0$ oscillations analyses have been published [21] by the ALEPH [22], BABAR [23], Belle [24], CDF [14], DELPHI [13,25], L3 [26], and OPAL [27] collaborations. Although a variety of different techniques have been used, the individual Δm_d results obtained at high-energy colliders have remarkably similar precision. Their average is compatible with the recent and more precise measurements from asymmetric B factories. The systematic uncertainties are not negligible; they are often dominated by sample composition, mistag probability, or b-hadron lifetime contributions. Before being combined, the measurements are adjusted on the basis of a common set of input values, including the b-hadron lifetimes and fractions published in this *Review*. Some measurements are statistically correlated. Systematic correlations arise both from common physics sources (fragmentation fractions, lifetimes, branching ratios of b hadrons), and from purely experimental or algorithmic effects (efficiency, resolution, tagging, background description). Combining all published measurements [13,14,22–27] and accounting for all identified correlations yields $\Delta m_d = 0.507 \pm 0.003(\text{stat}) \pm 0.003(\text{syst})\ \text{ps}^{-1}$ [28], a result now dominated by the B factories.

On the other hand, ARGUS and CLEO have published time-integrated measurements [29–31], which average to $\chi_d = 0.182 \pm 0.015$. Following Ref. 31, the width difference $\Delta\Gamma_d$ could in principle be extracted from the measured value of Γ_d and the above averages for Δm_d and χ_d (see Eq. (5)), provided that $\Delta\Gamma_d$ has a negligible impact on the Δm_d measurements. However, direct time-dependent studies published by DELPHI [13] and BABAR [32] yield stronger constraints, which can be combined to yield $\text{sign}(\text{Re}\lambda_{\text{CP}})\Delta\Gamma_{\text{d}}/\Gamma_{\text{d}} = 0.009 \pm 0.037$ [28].

Assuming $\Delta\Gamma_d = 0$ and no CP violation in mixing, and using the measured B_d^0 lifetime of $1.530 \pm 0.009\ \text{ps}^{-1}$, the Δm_d and χ_d results are combined to yield the world average

$$\Delta m_d = 0.507 \pm 0.005\ \text{ps}^{-1} \tag{14}$$

or, equivalently,

$$\chi_d = 0.188 \pm 0.003\,. \tag{15}$$

Evidence for CP violation in B_d^0 mixing has been searched for, both with flavor-specific and inclusive B_d^0 decays, in samples where the initial flavor state is tagged. In the case of semileptonic (or other flavor-specific) decays, where the final state tag is also available, the following asymmetry [2]

$$\mathcal{A}_{\text{SL}} = \frac{N(\overline{B}_d^0(t) \to \ell^+\nu_\ell X) - N(B_d^0(t) \to \ell^-\overline{\nu}_\ell X)}{N(\overline{B}_d^0(t) \to \ell^+\nu_\ell X) + N(B_d^0(t) \to \ell^-\overline{\nu}_\ell X)} \simeq 1 - |q/p|_d^2 \tag{16}$$

has been measured, either in time-integrated analyses at CLEO [31,33], CDF [34] and DØ [35], or in time-dependent analyses at LEP [36–38], BABAR [32,39] and Belle [40]. In

the inclusive case, also investigated at LEP [37,38,41], no final state tag is used, and the asymmetry [42]

$$\frac{N(B^0_d(t) \to \text{all}) - N(\overline{B}^0_d(t) \to \text{all})}{N(B^0_d(t) \to \text{all}) + N(\overline{B}^0_d(t) \to \text{all})} \simeq \mathcal{A}_{\rm SL}\left[\frac{x_d}{2}\sin(\Delta m_d\, t) - \sin^2\left(\frac{\Delta m_d\, t}{2}\right)\right] \quad (17)$$

must be measured as a function of the proper time to extract information on CP violation. In all cases, asymmetries compatible with zero have been found, with a precision limited by the available statistics. A simple average of all published results for the B^0_d meson [31–33,36,38,39,41] yields $\mathcal{A}_{\rm SL} = -0.005 \pm 0.012$, or $|q/p|_d = 1.0026 \pm 0.0059$, a result which does not yet constrain the Standard Model.

The Δm_d result of Eq. (14) provides an estimate of $2|M_{12}|$, and can be used, together with Eq. (6), to extract the magnitude of the CKM matrix element V_{td} within the Standard Model [43]. The main experimental uncertainties on the resulting estimate of $|V_{td}|$ come from m_t and Δm_d; however, the extraction is at present completely dominated by the uncertainty on the hadronic matrix element $f_{B_d}\sqrt{B_{B_d}} = 244 \pm 26$ MeV obtained from lattice QCD calculations [44].

B^0_s mixing studies

B^0_s–$\overline{B}^0_s$ oscillations have been the subject of many studies from ALEPH [45], DELPHI [13,16,46], OPAL [47], SLD [12,48, 49], CDF [18,50] and DØ [19,51]. The most sensitive analyses at LEP appear to be the ones based on inclusive lepton samples. Because of their better proper time resolution, the small data samples analyzed inclusively at SLD, as well as the fully reconstructed B_s decays at LEP and at the Tevatron, are also very useful to explore the high Δm_s region.

All results are limited by the available statistics. They can easily be combined, since all experiments provide measurements of the B^0_s oscillation amplitude. All published results [12,13,16,45–48,50] are averaged [28] to yield the combined amplitudes $\mathcal{A}$ shown in Fig. 2 (top) as a function of Δm_s. The individual results have been adjusted to common physics inputs, and all known correlations have been accounted for; the sensitivities of the inclusive analyses, which depend directly through Eq. (13) on the assumed fraction f_s of B^0_s mesons in an unbiased sample of weakly-decaying b hadrons, have also been rescaled to a common average of $f_s = 0.102 \pm 0.009$. The combined sensitivity for 95% CL exclusion of Δm_s values is found to be 18.2 ps^{-1}. All values of Δm_s below 14.4 ps^{-1} are excluded at 95% CL, which we express as

$$\Delta m_s > 14.4 \text{ ps}^{-1} \quad \text{at 95\% CL}. \quad (18)$$

The values between 14.4 and 21.8 ps^{-1} cannot be excluded, because the data is compatible with a signal in this region. However, the largest deviation from $\mathcal{A} = 0$ in this range is a $1.9\,\sigma$ effect only, so no signal can be claimed.

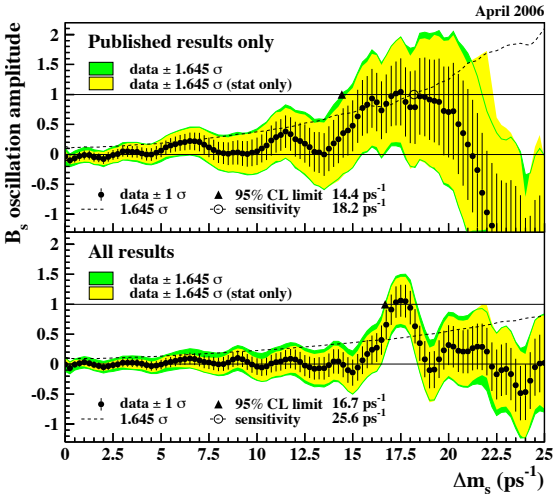

Figure 2: Combined measurements of the B^0_s oscillation amplitude as a function of Δm_s, based on published results only (top) or on all published and unpublished results (bottom) available at the end of April 2006. The measurements are dominated by statistical uncertainties. Neighboring points are statistically correlated. See full-color version on color pages at end of book.

The above average does not include the very recent results from Tevatron Run II, based on 1 fb^{-1} of data. In a paper submitted for publication [19], DØ reports the first direct two-sided bound established by a single experiment of $17 < \Delta m_s < 21$ ps^{-1} (90% CL) and a most probable value of 19 ps^{-1} with an observed (expected) significance of $2.5\,\sigma$ ($0.9\,\sigma$). A preliminary and subsequent analysis from CDF [18] is more sensitive and leads to the first direct evidence of B^0_s oscillations and the following measurement:

$$\Delta m_s = 17.33^{+0.42}_{-0.21}(\text{stat}) \pm 0.07(\text{syst}) \text{ ps}^{-1}. \quad (19)$$

Both the observed significance and the expected significance of this signal are equal to $3.1\,\sigma$. The CDF collaboration is quoting a 0.5% probability that their data would fluctuate to produce, at any value of Δm_s, a fake signal as significant as the observed one, corresponding to a $2.6\,\sigma$ effect. Both DØ and CDF quote their Δm_s results assuming that they see the oscillation signal.

Including all unpublished analyses [18,19,49] in the average leads to the combined amplitude spectrum of Fig. 2 (bottom), which is dominated by the new CDF result, and where a consolidated signal is seen with a significance of $4.0\,\sigma$. A preliminary world average is

$$\Delta m_s = 17.4^{+0.3}_{-0.2} \text{ ps}^{-1}. \quad (20)$$

The information on $|V_{ts}|$ obtained, in the framework of the Standard Model, from the combined amplitude spectrum, is hampered by the hadronic uncertainty, as in the B^0_d case. However, several uncertainties cancel in the frequency ratio

$$\frac{\Delta m_s}{\Delta m_d} = \frac{m_{B_s}}{m_{B_d}}\,\xi^2\left|\frac{V_{ts}}{V_{td}}\right|^2, \quad (21)$$

where $\xi = (f_{B_s}\sqrt{B_{B_s}})/(f_{B_d}\sqrt{B_{B_d}}) = 1.210\,^{+0.047}_{-0.035}$ is an SU(3) flavor-symmetry breaking factor obtained from lattice QCD calculations [44]. Using the averages of Eqs. (14) and (20), one can extract

$$\left|\frac{V_{td}}{V_{ts}}\right| = 0.208 \pm 0.002(\text{exp})\,^{+0.008}_{-0.006}(\text{lattice})\,, \qquad (22)$$

in good agreement with (but more precise than) the recent result obtained by the Belle collaboration based on the observation of the $b \to d\gamma$ transition [52]. The CKM matrix can be constrained using experimental results on observables such as Δm_d, Δm_s, $|V_{ub}/V_{cb}|$, ϵ_K, and $\sin(2\beta)$ together with theoretical inputs and unitarity conditions [43,53,54]. The constraint from our knowledge on the ratio $\Delta m_s/\Delta m_d$ is presently more effective in limiting the position of the apex of the CKM unitarity triangle than the one obtained from the Δm_d measurements alone, due to the reduced hadronic uncertainty in Eq. (21). We also note that the measured value of Δm_s is consistent with the Standard Model prediction obtained from CKM fits where no experimental information on Δm_s is used, *e.g.* 21.2 ± 3.2 ps^{-1} [53] or $16.5\,^{+10.5}_{-3.4}$ ps^{-1} [54].

Information on $\Delta\Gamma_s$ can be obtained by studying the proper time distribution of untagged B_s^0 samples [55]. In the case of an inclusive B_s^0 selection [56], or a semileptonic (or flavour-specific) B_s^0 decay selection [16,57,58], both the short- and long-lived components are present, and the proper time distribution is a superposition of two exponentials with decay constants $\Gamma_{\rm L,H} = \Gamma_s \pm \Delta\Gamma_s/2$. In principle, this provides sensitivity to both Γ_s and $(\Delta\Gamma_s/\Gamma_s)^2$. Ignoring $\Delta\Gamma_s$ and fitting for a single exponential leads to an estimate of Γ_s with a relative bias proportional to $(\Delta\Gamma_s/\Gamma_s)^2$. An alternative approach, which is directly sensitive to first order in $\Delta\Gamma_s/\Gamma_s$, is to determine the lifetime of B_s^0 candidates decaying to CP eigenstates; measurements exist for $B_s^0 \to J/\psi\phi$ [59,60] and $B_s^0 \to D_s^{(*)+}D_s^{(*)-}$ [61], which are mostly CP-even states [62]. However, in the case of $B_s^0 \to J/\psi\phi$ this technique has now been replaced by more sensitive time-dependent angular analyses that allow the simultaneous extraction of $\Delta\Gamma_s/\Gamma_s$ and the CP-even and CP-odd amplitudes [63]. An estimate of $\Delta\Gamma_s/\Gamma_s$ has also been obtained directly from a measurement of the $B_s^0 \to D_s^{(*)+}D_s^{(*)-}$ branching ratio [61], under the assumption that these decays account for all the CP-even final states (however, no systematic uncertainty due to this assumption is given, so the average quoted below will not include this estimate).

Applying the combination procedure of Ref. 28 (including the constraint from the flavour-specific lifetime measurements) on the published results [16,57,59,61,63] yields

$$\Delta\Gamma_s/\Gamma_s = +0.31\,^{+0.11}_{-0.13} \quad \text{and} \quad 1/\Gamma_s = 1.398\,^{+0.049}_{-0.050}\ \text{ps}\,, \quad (23)$$

or equivalently

$$1/\Gamma_{\rm L} = 1.21 \pm 0.09\ \text{ps} \quad \text{and} \quad 1/\Gamma_{\rm H} = 1.66\,^{+0.11}_{-0.12}\ \text{ps}\,. \quad (24)$$

This result can be compared with the theoretical prediction $\Delta\Gamma_s/\Gamma_s = +0.12 \pm 0.05$ [64] within the Standard Model.

Average b-hadron mixing probability and b-hadron production fractions in Z decays and at high energy

Mixing measurements can significantly improve our knowledge on the fractions f_u, f_d, f_s and $f_{\rm baryon}$, defined as the fractions of B_u, B_d^0, B_s^0 and b-baryon in an unbiased sample of weakly decaying b hadrons produced in high-energy collisions. Indeed, time-integrated mixing analyses performed with lepton pairs from $b\overline{b}$ events at high energy measure the quantity

$$\overline{\chi} = f'_d\,\chi_d + f'_s\,\chi_s\,, \qquad (25)$$

where f'_d and f'_s are the fractions of B_d^0 and B_s^0 hadrons in a sample of semileptonic b-hadron decays. Assuming that all b hadrons have the same semileptonic decay width implies $f'_q = f_q/(\Gamma_q\tau_b)$ $(q = s, d)$, where τ_b is the average b-hadron lifetime. Hence $\overline{\chi}$ measurements, together with the χ_d average of Eq. (15) and the very good approximation $\chi_s = 1/2$ (in fact $\chi_s > 0.4988$ at 95% CL from Eqs. (5), (18) and (23)), provide constraints on the fractions f_d and f_s.

The LEP experiments have measured $f_s \times \text{BR}(B_s^0 \to D_s^-\ell^+\nu_\ell X)$ [65], $\text{BR}(b \to \Lambda_b^0) \times \text{BR}(\Lambda_b^0 \to \Lambda_c^+\ell^-\overline{\nu}_\ell X)$ [66], and $\text{BR}(b \to \Xi_b^-) \times \text{BR}(\Xi_b^- \to \Xi^-\ell^-\overline{\nu}_\ell X)$ [67] from partially reconstructed final states, including a lepton, $f_{\rm baryon}$ from protons identified in b events [68], and the production rate of charged b hadrons [69]. The b-hadron fractions measured at CDF with electron-charm final states [70] are at slight discrepancy with the ones measured at LEP. Furthermore the values of $\overline{\chi}$ measured at LEP, 0.1259 ± 0.0042 [71], and at CDF, 0.152 ± 0.013 [72], show a $1.9\,\sigma$ deviation with respect to each other. This may be a hint that the fractions at the Tevatron might be different from the ones in Z decays. Combining [28] all the available information under the constraints $f_u = f_d$ and $f_u + f_d + f_s + f_{\rm baryon} = 1$ yields the two set of averages shown in Table 1. The second set, obtained using both LEP and Tevatron results, has larger errors than the first set, obtained using LEP results only, because we have applied scale factors as advocated by the PDG for the treatment of marginally consistent data.

Table 1: $\overline{\chi}$ and b-hadron fractions (see text).

	in Z decays	at high energy
$\overline{\chi}$	0.1259 ± 0.0042	0.1283 ± 0.0076
$f_u = f_d$	0.399 ± 0.010	0.398 ± 0.012
f_s	0.102 ± 0.009	0.103 ± 0.014
$f_{\rm baryon}$	0.100 ± 0.017	0.100 ± 0.020

Summary and prospects

B^0–$\overline{B}^0$ mixing has been and still is a field of intense study. The mass difference in the B_d^0–$\overline{B}_d^0$ system is now very precisely known (with an experimental error of 0.9%) but, despite an impressive theoretical effort, the hadronic uncertainty keeps limiting the precision of the extracted estimate of $|V_{td}|$ within the Standard Model (SM). On the other hand measurements of $\Delta\Gamma_d$ and of CP violation in B_d^0–$\overline{B}_d^0$ mixing are consistent

with zero, with an uncertainty still large compared to the SM predictions. Impressive new B_s^0 results are becoming available from Run II of the Tevatron: preliminary direct evidence for B_s^0–$\overline{B}_s^0$ oscillations has been reported, with a frequency in agreement with the SM. New time-dependent angular analyses of $B_s^0 \to J/\psi\phi$ decays at CDF and DØ have improved our knowledge of $\Delta\Gamma_s/\Gamma_s$ to an absolute uncertainty of $\sim 10\%$, of the same size as the central value of the SM prediction. The data clearly prefer $\Gamma_L > \Gamma_H$ as predicted in the SM.

Improved results on B_s^0–$\overline{B}_s^0$ mixing are still to come from the Tevatron, with very promising prospects in the next couple of years, both for Δm_s and $\Delta\Gamma_s$. With a few fb^{-1} of data, the CDF and DØ collaborations will have the potential to confirm their Δm_s signals and make $> 5\,\sigma$ observations of B_s^0 oscillations. Further studies with $B_s^0 \to J/\psi\phi$ decays will not only improve on $\Delta\Gamma_s$, but perhaps also allow a very first investigation of the CP-violating phase ϕ_s induced by B_s^0–$\overline{B}_s^0$ mixing, about which nothing is known experimentally at present. However, the SM value of ϕ_s is very small ($\phi_s = -2\beta_s$ where $\beta_s \equiv \arg(-V_{ts}V_{tb}^*/(V_{cs}V_{cb}^*))$ is about one degree), and a full search for new physics effects in this observable will require much larger statistics. These will become available at CERN's Large Hadron Collider scheduled to start operation in 2007, where the LHCb collaboration expects to be able to measure ϕ_s down to the SM value after several years of operations [73].

B mixing may not have delivered all its secrets yet, because it is one of the phenomena where new physics might still reveal itself (although a dominant contribution is becoming unlikely). Theoretical calculations in lattice QCD have become more reliable, and further progress in reducing hadronic uncertainties is expected. In the long term, a stringent check of the consistency, within the SM, of the B_d^0 and B_s^0 mixing amplitudes (magnitudes and phases) with all other measured flavour-physics observables (including CP asymmetries in B decays) will be possible, leading to further limits on new physics or, better, new physics discovery.

B^0-$\overline{B}^0$ MIXING PARAMETERS

For a discussion of B^0-$\overline{B}^0$ mixing see the note on "B^0-$\overline{B}^0$ Mixing" in the B^0 Particle Listings above.

χ_d is a measure of the time-integrated B^0-$\overline{B}^0$ mixing probability that a produced $B^0(\overline{B}^0)$ decays as a $\overline{B}^0(B^0)$. Mixing violates $\Delta B \neq 2$ rule.

$$\chi_d = \frac{x_d^2}{2(1+x_d^2)}$$

$$x_d = \frac{\Delta m_{B^0}}{\Gamma_{B^0}} = (m_{B^0_H} - m_{B^0_L})\,\tau_{B^0}\ ,$$

where H, L stand for heavy and light states of two B^0 CP eigenstates and $\tau_{B^0} = \frac{1}{0.5(\Gamma_{B^0_H}+\Gamma_{B^0_L})}$.

χ_d

This B^0-$\overline{B}^0$ mixing parameter is the probability (integrated over time) that a produced B^0 (or $\overline{B}^0$) decays as a $\overline{B}^0$ (or B^0), e.g. for inclusive lepton decays

$$\chi_d = \Gamma(B^0 \to \ell^- X \text{ (via } \overline{B}^0))/\Gamma(B^0 \to \ell^{\pm} X)$$
$$= \Gamma(\overline{B}^0 \to \ell^+ X \text{ (via } B^0))/\Gamma(\overline{B}^0 \to \ell^{\pm} X)$$

Where experiments have measured the parameter $r = \chi/(1-\chi)$, we have converted to χ. Mixing violates the $\Delta B \neq 2$ rule.

Note that the measurement of χ at energies higher than the $\Upsilon(4S)$ have not separated χ_d from χ_s where the subscripts indicate $B^0(\overline{b}d)$ or $B_s^0(\overline{b}s)$. They are listed in the $B^{\pm}/B^0/B_s^0/b$-baryon ADMIXTURE section.

The experiments at $\Upsilon(4S)$ make an assumption about the $B^0\overline{B}^0$ fraction and about the ratio of the $B^\pm$ and B^0 semileptonic branching ratios (usually that it equals one).

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account corrections between the measurements, includes χ_d calculated from Δm_{B^0} and τ_{B^0}.

<0.27	90	[649] AVERY	84	CLEO	$e^+e^- \to \Upsilon(4S)$

[640] BEHRENS 00B uses high-momentum lepton tags and partially reconstructed $\overline{B}^0 \to D^{*+}\pi^-$, ρ^- decays to determine the flavor of the B meson.

[641] ALBRECHT 94 reports r=0.194 ± 0.062 ± 0.054. We convert to χ for comparison. Uses tagged events (lepton + pion from D^*).

[642] BARTELT 93 analysis performed using tagged events (lepton+pion from D^*). Using dilepton events they obtain $0.157 \pm 0.016^{+0.033}_{-0.028}$.

[643] ALBRECHT 92L is a combined measurement employing several lepton-based techniques. It uses all previous ARGUS data in addition to new data and therefore supersedes ALBRECHT 87I. A value of $r = 20.6 \pm 7.0\%$ is directly measured. The value can be used to measure $x = \Delta M/\Gamma = 0.72 \pm 0.15$ for the B_d meson. Assumes $f_{+-}/f_0 = 1.0 \pm 0.05$ and uses $\tau_{B^\pm}/\tau_{B^0} = (0.95 \pm 0.14)$ (f_{+-}/f_0).

[644] Uses $D^{*+}K^\pm$ correlations.

[645] Uses $(D^{*+}\ell^-)\ K^\pm$ correlations.

[646] These experiments see a combination of B_s and B_d mesons.

[647] ALBRECHT 87I is inclusive measurement with like-sign dileptons, with tagged B decays plus leptons, and one fully reconstructed event. Measures r=0.21 ± 0.08. We convert to χ for comparison. Superseded by ALBRECHT 92L.

[648] BEAN 87B measured $r < 0.24$; we converted to χ.

[649] Same-sign dilepton events. Limit assumes semileptonic BR for B^+ and B^0 equal. If $B^0/B^\pm$ ratio <0.58, no limit exists. The limit was corrected in BEAN 87B from $r < 0.30$ to $r < 0.37$. We converted this limit to χ.

$\Delta m_{B^0} = m_{B^0_H} - m_{B^0_L}$

$\Delta m_{B^0_s}$ is a measure of 2π times the B^0-$\overline{B}^0$ oscillation frequency in time-dependent mixing experiments.

The second "OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account corrections between the measurements.

The first "OUR EVALUATION", also provided by the HFAG, includes Δm_d calculated from χ_d measured at $\Upsilon(4S)$.

[650] Measured using a simultaneous fit of the B^0 lifetime and $\overline{B}^0B^0$ oscillation frequency Δm_d in the partially reconstructed $B^0 \to D^{*-}\ell\nu$ decays.

[651] Measurement performed using a combined fit of CP-violation, mixing and lifetimes.

[652] Events with a high transverse momentum lepton were removed and an inclusively reconstructed vertex was required.

[653] HASTINGS 03 measurement based on the time evolution of dilepton events. It also reports $f_+/f_0 = 1.01 \pm 0.03 \pm 0.09$ and CPT violation parameters in B^0-$\overline{B}^0$ mixing.

[654] ZHENG 03 data analyzed using partially reconstructed $\overline{B}^0 \to D^{*-}\pi^+$ decay and a flavor tag based on the charge of the lepton from the accompanying B decay.

[655] Uses a tagged sample of fully-reconstructed neutral B decays at $\Upsilon(4S)$.

[656] Measured based on the time evolution of dilepton events in $\Upsilon(4S)$ decays.

[657] Data analyzed using partially reconstructed $\overline{B}^0 \to D^{*+}\ell^-\overline{\nu}$ decay and a combination of flavor tags from the rest of the event.

[658] Uses di-muon events.

[659] Uses jet-charge and lepton-flavor tagging.

[660] Uses $\ell^- D^{*+} -\ell$ events.

[661] Uses π-B in the same side.

[662] Uses ℓ-ℓ.

[663] Uses ℓ-$Q_{\rm hem}$.

[664] Uses ℓ-ℓ with impact parameters.

[665] Uses $D^{*\pm}$-$Q_{\rm hem}$.

[666] Uses $\pi_s^\pm\ell$-$Q_{\rm hem}$.

[667] Uses $D^{*\pm}$-$\ell/Q_{\rm hem}$.

[668] Uses $D^{*\pm}\ell$-$Q_{\rm hem}$.

[669] Uses $D^{*\pm}$-ℓ.

[670] AUBERT 03C uses a sample of approximately 14,000 exclusively reconstructed $B^0 \to D^*(2010)^-\ell\nu$ and simultaneously measures the lifetime and oscillation frequency.

[671] AUBERT 02N result based on the same analysis and data sample reported in AUBERT 02I.

[672] Uses a tagged sample of B^0 decays reconstructed in the mode $B^0 \to D^*\ell\nu$.

[673] Uses a tagged sample of fully-reconstructed hadronic B^0 decays at $\Upsilon(4S)$.

[674] ACCIARRI 98D combines results from ℓ-ℓ, ℓ-$Q_{\rm hem}$, and ℓ-ℓ with impact parameters.

[675] ABREU 97N combines results from $D^{*\pm}$-$Q_{\rm hem}$, ℓ-$Q_{\rm hem}$, $\pi_s^\pm\ell$-$Q_{\rm hem}$, and ℓ-ℓ.

[676] ACKERSTAFF 97V combines results from ℓ-ℓ, ℓ-$Q_{\rm hem}$, D^*-ℓ, and $D^{*\pm}$-$Q_{\rm hem}$.

[677] BUSKULIC 97D combines results from $D^{*\pm}$-$\ell/Q_{\rm hem}$, ℓ-$Q_{\rm hem}$, and ℓ-ℓ.

[678] ABREU 96Q analysis performed using lepton, kaon, and jet-charge tags.

[679] ALEXANDER 96V combines results from $D^{*\pm}$-ℓ and $D^{*\pm}\ell$-$Q_{\rm hem}$.

[680] AKERS 95J combines results from charge measurement, $D^{*\pm}\ell$-$Q_{\rm hem}$ and ℓ-ℓ.

$x_d = \Delta m_{B^0}/\Gamma_{B^0}$

The second "OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account corrections between the measurements.

The first "OUR EVALUATION", also provided by the HFAG, includes χ_d measured at $\Upsilon(4S)$.

VALUE	DOCUMENT ID
0.776±0.008 OUR EVALUATION	First
0.776±0.008 OUR EVALUATION	Second

Re(λ_{CP} / $|\lambda_{CP}|$) Re(z)

The λ_{CP} characterizes B^0 and $\overline{B}^0$ decays to states of charmonium plus K^0_L. Parameter z is used to describe CPT violation in mixing, see the review on "CP Violation" in the reviews section.

[684] Measured using inclusive dilepton events from B^0 decay.

CP VIOLATION PARAMETERS

Re(ϵ_{B^0})/(1+|ϵ_{B^0}|^2)

CP impurity in B^0_d system. It is obtained from either $a_{\ell\ell}$, the charge asymmetry in like-sign dilepton events or a_{cp}, the time-dependent asymmetry of inclusive B^0 and $\overline{B}^0$ decays.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account corrections between the measurements.

2 ± 7 ±3	[690] ACKERSTAFF	97U	OPAL	$e^+e^- \to Z$
• • • We do not use the following data for averages, fits, limits, etc. • • •				
4 ±18 ±3	[691] BEHRENS	00B	CLE2	Repl. by JAFFE 01
< 45	[692] BARTELT	93	CLE2	$e^+e^- \to \Upsilon(4S)$

[685] AUBERT 04C reports $|q/p| = 1.029 \pm 0.013 \pm 0.011$ and we converted it to $(1-|q/p|^2)/4$.
[686] AUBERT 02K uses the charge asymmetry in like-sign dilepton events.
[687] BARATE 01D measured by investigating time-dependent asymmetries in semileptonic and fully inclusive B^0_d decays.
[688] JAFFE 01 finds $a_{\ell\ell}$ = 0.013 ± 0.050 ± 0.005 and combines with the previous BEHRENS 00B independent measurement.
[689] Data analyzed using the time-dependent asymmetry of inclusive B^0 decay. The production flavor of B^0 mesons is determined using both the jet charge and the charge of secondary vertex in the opposite hemisphere.
[690] ACKERSTAFF 97U assumes CPT and is based on measuring the charge asymmetry in a sample of B^0 decays defined by lepton and $Q_{\rm hem}$ tags. If CPT is not invoked, Re(ϵ_B) = −0.006 ± 0.010 ± 0.006 is found. The indirect CPT violation parameter is determined to Im(δB) = −0.020 ± 0.016 ± 0.006.
[691] BEHRENS 00B uses high-momentum lepton tags and partially reconstructed $\overline{B}^0 \to D^{*+}\pi^-$, ρ^- decays to determine the flavor of the B meson.
[692] BARTELT 93 finds $a_{\ell\ell} = 0.031 \pm 0.096 \pm 0.032$ which corresponds to $|a_{\ell\ell}| < 0.18$, which yields the above $|{\rm Re}(\epsilon_{B^0})/(1+|\epsilon_{B^0}|^2|$.

$A_{T/CP}$

$A_{T/CP}$ is defined as

$$\frac{P(\overline{B}^0 \to B^0) - P(B^0 \to \overline{B}^0)}{P(\overline{B}^0 \to B^0) + P(B^0 \to \overline{B}^0)},$$

the CPT invariant asymmetry between the oscillation probabilities P($\overline{B}^0 \to B^0$) and P($B^0 \to \overline{B}^0$).

$|\lambda|$ $(B^0 \to c\overline{c}K^0)$

The same λ quantity, defined in the $C_{\pi\pi}$ datablock above.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account corrections between the measurements.

[769] Measurement based on 152×10^6 $B\overline{B}$ pairs.
[770] Measurement based on 227×10^6 $B\overline{B}$ pairs.
[771] Measurement in which the J/ψ decays to hadrons or to muons that do not satisfy the standard identification criteria.
[772] AFFOLDER 00C uses about 400 $B^0 \to J/\psi(1S)K^0_S$ events. The production flavor of B^0 was determined using three tagging algorithms: a same-side tag, a jet-charge tag, and a soft-lepton tag.
[773] BARATE 00Q uses 23 candidates for $B^0 \to J/\psi(1S)K^0_S$ decays. A combination of jet-charge, vertex-charge, and same-side tagging techniques were used to determine the B^0 production flavor.
[774] ACKERSTAFF 98Z uses 24 candidates for $B^0_d \to J/\psi(1S)K^0_S$ decay. A combination of jet-charge and vertex-charge techniques were used to tag the B^0_d production flavor.
[775] ABE 02U result is based on the same analysis and data sample reported in ABE 01G.
[776] ABE 02Z result is based on 85×10^6 $B\overline{B}$ pairs.
[777] AUBERT 02N result based on the same analysis and data sample reported in AUBERT 01B.
[778] AUBERT 02P result is based on 88×10^6 $B\overline{B}$ pairs.
[779] First observation of *CP* violation in B^0 meson system.
[780] ABE 98U uses 198 ± 17 $B^0_d \to J/\psi(1S)K^0$ events. The production flavor of B^0 was determined using the same side tagging technique.

$B^\pm/B^0$ ADMIXTURE

B DECAY MODES

The branching fraction measurements are for an admixture of B mesons at the $\Upsilon(4S)$. The values quoted assume that $B(\Upsilon(4S) \to B\overline{B}) = 100\%$.

For inclusive branching fractions, *e.g.*, $B \to D^\pm$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

$\overline{B}$ modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing.

	Mode		Fraction (Γ_i/Γ)	Scale factor/ Confidence level	
Semileptonic and leptonic modes					
Γ_1	$B \to e^+\nu_e$ anything	[a]	(10.78 ± 0.18) %		
Γ_2	$B \to \overline{p}e^+\nu_e$ anything		< 5.9	$\times 10^{-4}$	CL=90%
Γ_3	$B \to \mu^+\nu_\mu$ anything	[a]	(10.78 ± 0.18) %		
Γ_4	$B \to \ell^+\nu_\ell$ anything	[a,b]	(10.78 ± 0.18) %		
Γ_5	$B \to D^-\ell^+\nu_\ell$ anything	[b]	(2.8 ± 0.9) %		
Γ_6	$B \to \overline{D}^0\ell^+\nu_\ell$ anything	[b]	(7.2 ± 1.5) %		
Γ_7	$B \to D^{*-}\ell^+\nu_\ell$ anything	[c]	(6.7 ± 1.3)	$\times 10^{-3}$	
Γ_8	$B \to \overline{D}^{*0}\ell^+\nu_\ell$ anything				
Γ_9	$B \to \overline{D}^{**}\ell^+\nu_\ell$	[b,d]	(2.7 ± 0.7) %		
Γ_{10}	$B \to \overline{D}_1(2420)\ell^+\nu_\ell$ anything		(3.8 ± 1.3)	$\times 10^{-3}$	S=2.4
Γ_{11}	$B \to D\pi\ell^+\nu_\ell$ anything + $D^*\pi\ell^+\nu_\ell$ anything		(2.6 ± 0.5) %		S=1.5
Γ_{12}	$B \to D\pi\ell^+\nu_\ell$ anything		(1.5 ± 0.6) %		
Γ_{13}	$B \to D^*\pi\ell^+\nu_\ell$ anything		(1.9 ± 0.4) %		
Γ_{14}	$B \to \overline{D}_2^*(2460)\ell^+\nu_\ell$ anything		(4.4 ± 1.6)	$\times 10^{-3}$	
Γ_{15}	$B \to D^{*-}\pi^+\ell^+\nu_\ell$ anything		(1.00 ± 0.34) %		
Γ_{16}	$B \to D_s^-\ell^+\nu_\ell$ anything	[b]	< 7	$\times 10^{-3}$	CL=90%
Γ_{17}	$B \to D_s^-\ell^+\nu_\ell K^+$ anything	[b]	< 5	$\times 10^{-3}$	CL=90%
Γ_{18}	$B \to D_s^-\ell^+\nu_\ell K^0$ anything	[b]	< 7	$\times 10^{-3}$	CL=90%
Γ_{19}	$B \to \ell^+\nu_\ell$ charm		(10.61 ± 0.17) %		
Γ_{20}	$B \to X_u\ell^+\nu_\ell$		(2.33 ± 0.22)	$\times 10^{-3}$	
Γ_{21}	$B \to K^+\ell^+\nu_\ell$ anything	[b]	(6.2 ± 0.6) %		
Γ_{22}	$B \to K^-\ell^+\nu_\ell$ anything	[b]	(10 ± 4)	$\times 10^{-3}$	
Γ_{23}	$B \to K^0/\overline{K}^0\ell^+\nu_\ell$ anything	[b]	(4.6 ± 0.5) %		
D, D^*, or D_s modes					
Γ_{24}	$B \to D^\pm$ anything		(22.8 ± 1.4) %		
Γ_{25}	$B \to D^0/\overline{D}^0$ anything		(64.0 ± 3.0) %		S=1.2
Γ_{26}	$B \to D^*(2010)^\pm$ anything		(22.5 ± 1.5) %		
Γ_{27}	$B \to D^*(2007)^0$ anything		(26.0 ± 2.7) %		
Γ_{28}	$B \to D_s^\pm$ anything	[e]	(8.6 ± 1.2) %		
Γ_{29}	$B \to D_s^{*\pm}$ anything		(6.5 ± 1.2) %		
Γ_{30}	$B \to D_s^{*\pm}\overline{D}^{(*)}$		(3.4 ± 0.7) %

[a] These values are model dependent.

[b] An ℓ indicates an e or a μ mode, not a sum over these modes.

[c] Here "anything" means at least one particle observed.

[d] D^{**} stands for the sum of the $D(1\,^1P_1)$, $D(1\,^3P_0)$, $D(1\,^3P_1)$, $D(1\,^3P_2)$, $D(2\,^1S_0)$, and $D(2\,^1S_1)$ resonances.

[e] The value is for the sum of the charge states or particle/antiparticle states indicated.

[f] $D^{(*)}\overline{D}^{(*)}$ stands for the sum of $D^*\overline{D}^*$, $D^*\overline{D}$, $D\overline{D}^*$, and $D\overline{D}$.

[g] $Y(3940)$ denotes a near-threshold enhancement in the $\omega J/\psi$ mass spectrum.

[h] Inclusive branching fractions have a multiplicity definition and can be greater than 100%.

$B^{\pm}/B^0$ ADMIXTURE BRANCHING RATIOS

$\Gamma(\ell^+ \nu_\ell \text{anything})/\Gamma_{\text{total}}$ Γ_4/Γ

These branching fraction values are model dependent.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account corrections between the measurements.

VALUE	DOCUMENT ID	TECN	COMMENT
0.1078±0.0018 OUR EVALUATION

• • • We do not use the following data for averages, fits, limits, etc. • • •			
0.108 ±0.002 ±0.0056	[1] HENDERSON 92	CLEO	$e^+e^- \to \Upsilon(4S)$

[1] HENDERSON 92 measurement employs e and μ. The systematic error contains 0.004 in quadrature from model dependence. The authors average a variation of the Isgur, Scora, Grinstein, and Wise model with that of the Altarelli-Cabibbo-Corbò-Maiani-Martinelli model for semileptonic decays to correct the acceptance.

$\Gamma(e^+ \nu_e \text{anything})/\Gamma_{\text{total}}$ Γ_1/Γ

These branching fraction values are model dependent.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account corrections between the measurements.

0.132 ±0.008 ±0.014	[13] KLOPFEN... 83B	CUSB	Direct e at $\Upsilon(4S)$

[2] The measurements are obtained for charged and neutral B mesons partial rates of semileptonic decay to electrons with momentum above 0.6 GeV/c in the B rest frame, and their ratio of B($B^+ \to e^+\nu_e X$)/B($B^0 \to e^+\nu_e X$) = 1.08 ± 0.05 ± 0.02.

[3] The semileptonic branching ratio, $|V_{cb}|$ and other heavy-quark parameters are determined from a simultaneous fit to moments of the hadronic-mass and lepton-energy distribution.

[4] Uses charge and angular correlations in $\Upsilon(4S)$ events with a high-momentum lepton and an additional electron.

[5] ALBRECHT 93H analysis performed using tagged semileptonic decays of the B. This technique is almost model independent for the lepton branching ratio.

[6] Uses the high-momentum lepton tag method and requires the electron energy above 0.6 GeV.

[7] Uses the high-momentum lepton tag method. They also report $|V_{cb}| = 0.0423 \pm 0.0007(\text{exp}) \pm 0.0020(\text{theo.})$.

[8] Uses the high-momentum lepton tag method. ABE 02Y also reports $|V_{cb}| = 0.0408 \pm 0.0010(\text{exp}) \pm 0.0025(\text{theo.})$. The second error is due to uncertainties of theoretical inputs.

[9] BARISH 96B analysis performed using tagged semileptonic decays of the B. This technique is almost model independent for the lepton branching ratio.

[10] YANAGISAWA 91 also measures an average semileptonic branching ratio at the $\Upsilon(5S)$ of 9.6–10.5% depending on assumptions about the relative production of different B meson species.

[11] ALBRECHT 90H uses the model of ALTARELLI 82 to correct over all lepton momenta. 0.099 ± 0.006 is obtained using ISGUR 89B.

[12] Using data above $p(e) = 2.4$ GeV, WACHS 89 determine $\sigma(B \to e\nu\text{up})/\sigma(B \to e\nu\text{charm}) < 0.065$ at 90% CL.

[13] Ratio $\sigma(b \to e\nu\text{up})/\sigma(b \to e\nu\text{charm}) < 0.055$ at CL = 90%.

2.24±0.27±0.47	[39,40] AUBERT 04I	BABR	Repl. by AUBERT,B 05X

[35] Obtained from the partial rate $\Delta B = (0.572 \pm 0.041 \pm 0.065) \times 10^{-3}$ for the electron momentum interval of 2.0–2.6 GeV/c based on BLNP method.

[36] Determined from the partial rate $\Delta B = (3.54 \pm 0.33 \pm 0.34) \times 10^{-4}$ measured for electron energy > 2 GeV and hadronic mass squared < 3.5 GeV^2, and calculated acceptance 0.14 in that region. The V_{ub} is measured as $(3.95 \pm 0.26^{+0.63}_{-0.49}) \times 10^{-3}$.

[37] Uses electrons in the momentum interval 1.9–2.6 GeV/c in the center-of-mass frame. The V_{ub} is found to be $(5.08 \pm 0.47^{+0.49}_{-0.48}) \times 10^{-3}$.

[38] BORNHEIM 02 uses the observed yield of leptons from semileptonic B decays in the end-point momentum interval 2.2–2.6 GeV/c with recent CLEO-2 data on $B \to X_s\gamma$. The V_{ub} is found to be $(4.08 \pm 0.34 \pm 0.53) \times 10^{-3}$.

[39] Used BaBar measurement of Semileptonic branching fraction $B(B \to X\ell\nu_\ell) = (10.87 \pm 0.18 \pm 0.30)\%$ to convert the ratio of rates to branching fraction.

[40] The third error includes the systematics and theoretical errors summed in quadrature.

$\Gamma(X_u \ell^+ \nu_\ell)/\Gamma(\ell^+ \nu_\ell \text{anything})$ Γ_{20}/Γ_4

ℓ denotes e or μ, not the sum. These experiments measure this ratio in very limited momentum intervals.

<4.0	90		[47] BEHRENDS	87	CLEO	$e^+e^- \to \Upsilon(4S)$
<4.0	90		CHEN	84	CLEO	Direct e at $\Upsilon(4S)$
<5.5	90		KLOPFEN...	83B	CUSB	Direct e at $\Upsilon(4S)$

[41] The third error includes the systematics and theoretical errors summed in quadrature.

[42] ALBRECHT 94C find $\Gamma(b \to c)/\Gamma(b \to \text{all}) = 0.99 \pm 0.02 \pm 0.04$.

[43] BARTELT 93B (CLEO II) measures an excess of $107 \pm 15 \pm 11$ leptons in the lepton momentum interval 2.3–2.6 GeV/c which is attributed to $b \to u\ell\nu_\ell$. This corresponds to a model-dependent partial branching ratio ΔB_{ub} between $(1.15 \pm 0.16 \pm 0.15) \times 10^{-4}$, as evaluated using the KS model (KOERNER 88), and $(1.54 \pm 0.22 \pm 0.20) \times 10^{-4}$ using the ACCMM model (ARTUSO 93). The corresponding values of $|V_{ub}|/|V_{cb}|$ are 0.056 ± 0.006 and 0.076 ± 0.008, respectively.

[44] ALBRECHT 91C result supersedes ALBRECHT 90. Two events are fully reconstructed providing evidence for the $b \to u$ transition. Using the model of ALTARELLI 82, they obtain $|V_{ub}/V_{cb}| = 0.11 \pm 0.012$ from 77 leptons in the 2.3–2.6 GeV momentum range.

[45] ALBRECHT 90 observes 41 ± 10 excess e and μ (lepton) events in the momentum interval $p = 2.3$–2.6 GeV signaling the presence of the $b \to u$ transition. The events correspond to a model-dependent measurement of $|V_{ub}/V_{cb}| = 0.10 \pm 0.01$.

[46] FULTON 90 observe 76 ± 20 excess e and μ (lepton) events in the momentum interval $p = 2.4$–2.6 GeV signaling the presence of the $b \to u$ transition. The average branching ratio, $(1.8 \pm 0.4 \pm 0.3) \times 10^{-4}$, corresponds to a model-dependent measurement of approximately $|V_{ub}/V_{cb}| = 0.1$ using $B(b \to c\ell\nu) = 10.2 \pm 0.2 \pm 0.7\%$.

[47] The quoted possible limits range from 0.018 to 0.04 for the ratio, depending on which model or momentum range is chosen. We select the most conservative limit they have calculated. This corresponds to a limit on $|V_{ub}|/|V_{cb}| < 0.20$. While the endpoint technique employed is more robust than their previous results in CHEN 84, these results do not provide a numerical improvement in the limit.

0.98 ± 0.16 ± 0.12	[53] ALAM	87B	CLEO	$e^+e^- \to \Upsilon(4S)$

[52] GIBBONS 97B from charm counting using $B(D_s^+ \to \phi\pi) = 0.036 \pm 0.009$ and $B(\Lambda_c^+ \to pK^-\pi^+) = 0.044 \pm 0.006$.

[53] From the difference between K^- and K^+ widths. ALAM 87B measurement relies on lepton-kaon correlations. It does not consider the possibility of $B\overline{B}$ mixing. We have thus removed it from the average.

[63] GIBBONS 97B reports $B(B \to D^*(2010)^+\text{anything}) = 0.239 \pm 0.015 \pm 0.014 \pm 0.009$ using CLEO measured D and D^* branching fractions. We rescale to our PDG 96 values of D and D^* branching ratios. Our first error is their experiment's error and our second error is the systematic error from using our best value.

[64] ALBRECHT 96D reports $B(B \to D^*(2010)^+\text{anything})$ 0.196 ± 0.019 using CLEO measured $B(D^*(2010)^+ \to D^0\pi^+) = 0.681 \pm 0.01 \pm 0.013$, $B(D^0 \to K^-\pi^+) = 0.0401 \pm 0.0014$, $B(D^0 \to K^-\pi^+\pi^+\pi^-) = 0.081 \pm 0.005$., We rescale to our PDG 96 values of D and D^* branching ratios. Our first error is their experiment's error and our second error is the systematic error from using our best value.

[65] BORTOLETTO 92 reports $B(B \to D^*(2010)^+\text{anything}) = 0.25 \pm 0.03 \pm 0.04$ using MARK II $B(D^*(2010)^+ \to D^0\pi^+) = 0.57 \pm 0.06$ and $B(D^0 \to K^-\pi^+) = 0.042 \pm 0.008$. We rescale to our PDG 96 values of D and D^* branching ratios. Our first error is their experiment's error and our second error is the systematic error from using our best value.

[66] ALBRECHT 91H reports $0.348 \pm 0.060 \pm 0.035$ for $B(D^*(2010)^+ \to D^0\pi^+) = 0.55 \pm 0.04$. We rescale to our best value $B(D^*(2010)^+ \to D^0\pi^+) = (67.7 \pm 0.5) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Uses the PDG 90 $B(D^0 \to K^-\pi^+) = 0.0371 \pm 0.0025$.

[67] BORTOLETTO 87 uses old MARK III (BALTRUSAITIS 86E) branching ratios $B(D^0 \to K^-\pi^+) = 0.056 \pm 0.004 \pm 0.003$ and also assumes $B(D^*(2010)^+ \to D^0\pi^+) = 0.60^{+0.08}_{-0.15}$. The product branching ratio for $B(B \to D^*(2010)^+)\, B(D^*(2010)^+ \to D^0\pi^+)$ is $0.13 \pm 0.02 \pm 0.012$. Superseded by BORTOLETTO 92.

[68] $V-A$ momentum spectrum used to extrapolate below $p = 1$ GeV. We correct the value assuming $B(D^0 \to K^-\pi^+) = 0.042 \pm 0.006$ and $B(D^{*+} \to D^0\pi^+) = 0.6^{+0.08}_{-0.15}$. The product branching fraction is $B(B \to D^{*+}X)\cdot B(D^{*+} \to \pi^+ D^0)\cdot B(D^0 \to K^-\pi^+) = (68 \pm 15 \pm 9) \times 10^{-4}$.

1.1 ±0.21 ±0.23	46	[92] HAAS	85	CLEO	Repl. by ALAM 86

[86] AUBERT 03F also reports the momentum distribution and helicity of $J/\psi \to \ell^+\ell^-$ in the $\Upsilon(4S)$ center-of-mass frame.

[87] MASCHMANN 90 reports $(1.12 \pm 0.33 \pm 0.25) \times 10^{-2}$ for $B(J/\psi(1S) \to e^+e^-) = 0.069 \pm 0.009$. We rescale to our best value $B(J/\psi(1S) \to e^+e^-) = (5.94 \pm 0.06) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

[88] ALBRECHT 87D reports $(1.07 \pm 0.16 \pm 0.22) \times 10^{-2}$ for $B(J/\psi(1S) \to e^+e^-) = 0.069 \pm 0.009$. We rescale to our best value $B(J/\psi(1S) \to e^+e^-) = (5.94 \pm 0.06) \times$

10^{-2}. Our first error is their experiment's error and our second error is the systematic error from using our best value. ALBRECHT 87D find the branching ratio for J/ψ not from $\psi(2S)$ to be 0.0081 ± 0.0023.

[89] ALAM 86 reports $(1.09 \pm 0.16 \pm 0.21) \times 10^{-2}$ for $B(J/\psi(1S) \to \mu^+\mu^-) = 0.074 \pm 0.012$. We rescale to our best value $B(J/\psi(1S) \to \mu^+\mu^-) = (5.93 \pm 0.06) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

[90] BALEST 95B reports $(1.12 \pm 0.04 \pm 0.06) \times 10^{-2}$ for $B(J/\psi(1S) \to e^+e^-) = 0.0599 \pm 0.0025$. We rescale to our best value $B(J/\psi(1S) \to e^+e^-) = (5.94 \pm 0.06) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.. They measure $J/\psi(1S) \to e^+e^-$ and $\mu^+\mu^-$ and use PDG 1994 values for the branching fractions. The rescaling is the same for either mode so we use e^+e^-.

[91] Statistical and systematic errors were added in quadrature. ALBRECHT 85H also report a CL = 90% limit of 0.007 for $B \to J/\psi(1S) + X$ where m_X <1 GeV.

[92] Dimuon and dielectron events used.

$\Gamma(J/\psi(1S)\text{ (direct) anything})/\Gamma_{\text{total}}$ Γ_{44}/Γ

[93] AUBERT 03F also reports the helicity of $J/\psi \to \ell^+\ell^-$ produced directly in B decay.

[94] Also reports the measurement of $J/\psi \to \ell^+\ell^-$ polarization produced directly from B decay.

[95] BALEST 95B assume PDG 1994 values for sub mode branching ratios. $J/\psi(1S)$ mesons are reconstructed in $J/\psi(1S) \to e^+e^-$ and $J/\psi(1S) \to \mu^+\mu^-$. The $B \to J/\psi(1S)X$ branching ratio contains $J/\psi(1S)$ mesons directly from B decays and also from feeddown through $\psi(2S) \to J/\psi(1S)$, $\chi_{c1}(1P) \to J/\psi(1S)$, or $\chi_{c2}(1P) \to J/\psi(1S)$. Using the measured inclusive rates, BALEST 95B corrects for the feeddown and finds the $B \to J/\psi(1S)$ (direct) X branching ratio.

seen	[113] GIANNINI	82	CUSB	$e^+e^- \to \Upsilon(4S)$

[111] ALBRECHT 93I value is not independent of the sum of $B \to K^+$ anything and $B \to K^-$ anything ALBRECHT 94C values.

[112] Assuming $\Upsilon(4S) \to B\overline{B}$, a total of $3.38 \pm 0.34 \pm 0.68$ kaons per $\Upsilon(4S)$ decay is found (the second error is systematic). In the context of the standard B-decay model, this leads to a value for (b-quark $\to$ c-quark)/(b-quark $\to$ all) of $1.09 \pm 0.33 \pm 0.13$.

[113] GIANNINI 82 at CESR-CUSB observed 1.58 ± 0.35 K^0 per hadronic event much higher than 0.82 ± 0.10 below threshold. Consistent with predominant $b \to cX$ decay.

2.32±0.57±0.35	ALAM	95	CLE2	Repl. by CHEN 01C

[134] The measurement reported is $3.27 \pm 0.18^{+0.55}_{-0.42}$ for $E_\gamma > 1.9$ GeV.

[135] We correct it to $E_\gamma > 1.6$ GeV using the method of hep-ph/0507253 (average of three theoretical models).

[136] The measurement reported is $3.21 \pm 0.43^{+0.32}_{-0.29}$ for $E_\gamma > 2.0$ GeV.

[137] The measurement reported is $3.55 \pm 0.32 \pm 0.32$ for $E_\gamma > 1.8$ GeV.

[138] ABE 01F reports their systematic errors $\pm 0.42^{+0.50}_{-0.54}$, where the second error is due to the theoretical uncertainty. We combine them in quadrature.

• • • We do not use the following data for averages, fits, limits, etc. • • •						
<0.08		2	[140] ALBRECHT	95D	ARG	$e^+e^- \to \Upsilon(4S)$

[139] COAN 98 uses D-ℓ correlation.

[140] ALBRECHT 95D use full reconstruction of one B decay as tag. Two candidate events for charmless B decay can be interpreted as either $b \to s$gluon or $b \to u$ transition. If interpreted as $b \to s$gluon they find a branching ratio of ~ 0.026 or the upper limit quoted above. Result is highly model dependent.

• • • We do not use the following data for averages, fits, limits, etc. • • •				
$6.2 \pm 1.6^{+1.3}_{-2.0}$	[144] BROWDER	98	CLE2	$e^+e^- \to \Upsilon(4S)$

[142] The reported branching ratio is for high momentum η between 2.0 and 2.7 GeV in the $\Upsilon(4S)$ center-of-mass frame. Xs represents a recoil system consisting of a kaon and zero to four pions.

[143] BONVICINI 03 observed a signal of 61.2 ± 13.9 events in $B \to \eta' X_{nc}$ production for high momentum η' between 2.0 and 2.7 GeV/c in the $\Upsilon(4S)$ center-of-mass frame. The X_{nc} denotes "charmless" hadronic states recoiling against η'. The second error combines systematic and background subtraction uncertainties in quadrature.

[144] BROWDER 98 observed a signal of 39.0 ± 11.6 events in high momentum $B \to \eta' X_s$ production between 2.0 and 2.7 GeV/c. The branching fraction is based on the interpretation of $b \to sg$, where the last error includes additional uncertainties due to the color-suppressed $b \to$ backgrounds.

0.076 ± 0.014	[171]	ALBRECHT	89K	ARG	$e^+e^- \to \Upsilon(4S)$

[170] ALBRECHT 92O result is from simultaneous analysis of p and Λ yields, $p\overline{p}$ and $\Lambda\overline{p}$ correlations, and various lepton-baryon and lepton-baryon-antibaryon correlations. Supersedes ALBRECHT 89K.

[171] ALBRECHT 89K obtain this result by adding their their measurements $(5.5 \pm 1.6)\%$ for direct protons and $(4.2 \pm 0.5 \pm 0.6)\%$ for inclusive Λ production. They then assume $(5.5 \pm 1.6)\%$ for neutron production and add it in also. Since each B decay has two baryons, they divide by 2 to obtain $(7.6 \pm 1.4)\%$.

$B^{\pm}/B^0/B_s^0/b$-baryon ADMIXTURE

$B^{\pm}/B^0/B_s^0/b$-baryon ADMIXTURE MEAN LIFE

Each measurement of the B mean life is an average over an admixture of various bottom mesons and baryons which decay weakly. Different techniques emphasize different admixtures of produced particles, which could result in a different B mean life.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account corrections between the measurements and asymmetric lifetime errors, but ignores the small differences due to different techniques.

[1] Measurement performed using an inclusive reconstruction and B flavor identification technique.

[2] Measured using inclusive $J/\psi(1S) \to \mu^+\mu^-$ vertex.

[3] ACCIARRI 98 uses inclusively reconstructed secondary vertex and lepton impact parameter.

[4] ACKERSTAFF 97F uses inclusively reconstructed secondary vertices.

[5] BUSKULIC 96F analyzed using 3D impact parameter.

[6] ABE,K 95B uses an inclusive topological technique.

[7] ABREU 94L uses charged particle impact parameters. Their result from inclusively reconstructed secondary vertices is superseded by ABREU 96E.

[8] ACTON 93L and ADRIANI 93K analyzed using lepton (e and μ) impact parameter at Z.

[9] BUSKULIC 93O analyzed using dipole method.

[10] Combines ABREU 96E secondary vertex result with ABREU 94L impact parameter result.

[11] From proper time distribution of $b \to J/\psi(1S)$ anything.

[12] ABE 93J analyzed using $J/\psi(1S) \to \mu\mu$ vertices.

[13] ABREU 93D data analyzed using $D/D^*\ell$ anything event vertices.

[14] ABREU 93G data analyzed using charged and neutral vertices.

[15] ACTON 93C analysed using $D/D^*\ell$ anything event vertices.

[16] ABREU 92 is combined result of muon and hadron impact parameter analyses. Hadron tracks gave $(12.7 \pm 0.4 \pm 1.2) \times 10^{-13}$ s for an admixture of B species weighted by production fraction and mean charge multiplicity, while muon tracks gave $(13.0 \pm 1.0 \pm 0.8) \times 10^{-13}$ s for an admixture weighted by production fraction and semileptonic branching fraction.

[17] ACTON 92 is combined result of muon and electron impact parameter analyses.

[18] BUSKULIC 92F uses the lepton impact parameter distribution for data from the 1991 run.

[19] BUSKULIC 92G use $J/\psi(1S)$ tags to measure the average b lifetime. This is comparable to other methods only if the $J/\psi(1S)$ branching fractions of the different b-flavored hadrons are in the same ratio.

[20] Using $Z \to e^+X$ or μ^+X, ADEVA 91H determined the average lifetime for an admixture of B hadrons from the impact parameter distribution of the lepton.

[21] Using $Z \to J/\psi(1S)X$, $J/\psi(1S) \to \ell^+\ell^-$, ALEXANDER 91G determined the average lifetime for an admixture of B hadrons from the decay point of the $J/\psi(1S)$.

[22] Using $Z \to eX$ or μX, DECAMP 91C determines the average lifetime for an admixture of B hadrons from the signed impact parameter distribution of the lepton.

[23] HAGEMANN 90 uses electrons and muons in an impact parameter analysis.

[24] LYONS 90 combine the results of the B lifetime measurements of ONG 89, BRAUNSCHWEIG 89B, KLEM 88, and ASH 87, and JADE data by private communication. They use statistical techniques which include variation of the error with the mean life, and possible correlations between the systematic errors. This result is not independent of the measured results used in our average.

[25] We have combined an overall scale error of 15% in quadrature with the systematic error of ±0.7 to obtain ±2.1 systematic error.

[26] Statistical and systematic errors were combined by BROM 87.

−0.001±0.012±0.008	[30] ABBIENDI	99J	OPAL	$e^+e^- \to Z$

[30] Data analyzed using both the jet charge and the charge of secondary vertex in the opposite hemisphere.

$\overline{b}$ PRODUCTION FRACTIONS AND DECAY MODES

The branching fraction measurements are for an admixture of B mesons and baryons at energies above the $\Upsilon(4S)$. Only the highest energy results (LEP, Tevatron, S$p\overline{p}$S) are used in the branching fraction averages. In the following, we assume that the production fractions are the same at the LEP and at the Tevatron.

For inclusive branching fractions, *e.g.*, $B \to D^{\pm}$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

The modes below are listed for a $\overline{b}$ initial state. b modes are their charge conjugates. Reactions indicate the weak decay vertex and do not include mixing.

Mode	Fraction (Γ_i/Γ)	Scale factor/ Confidence level

PRODUCTION FRACTIONS

The production fractions for weakly decaying b-hadrons at high energy have been calculated from the best values of mean lives, mixing parameters, and branching fractions in this edition by the Heavy Flavor Averaging Group (HFAG) as described in the note "B^0-$\overline{B}^0$ Mixing" in the B^0 Particle Listings. Values assume

$$\mathrm{B}(\overline{b} \to B^+) = \mathrm{B}(\overline{b} \to B^0)$$
$$\mathrm{B}(\overline{b} \to B^+) + \mathrm{B}(\overline{b} \to B^0) + \mathrm{B}(\overline{b} \to B_s^0) + \mathrm{B}(b \to b\text{-baryon}) = 100\ \%.$$

The notation for production fractions varies in the literature (f_d, d_{B^0}, $f(b \to \overline{B}^0)$, $\mathrm{Br}(b \to \overline{B}^0)$). We use our own branching fraction notation here, $\mathrm{B}(\overline{b} \to B^0)$.

[a] An ℓ indicates an e or a μ mode, not a sum over these modes.

[b] D_j represents an unresolved mixture of pseudoscalar and tensor D^{**} (P-wave) states.

[c] The value is for the sum of the charge states or particle/antiparticle states indicated.

[d] Inclusive branching fractions have a multiplicity definition and can be greater than 100%.

$B^{\pm}/B^0/B_s^0/b$-baryon ADMIXTURE BRANCHING RATIOS

$\Gamma(B^+)/\Gamma_{total}$ Γ_1/Γ

"OUR EVALUATION" is an average using rescaled values of the data listed below and from the best values of mean lives, mixing parameters, and branching fractions in this edition by the Heavy Flavor Averaging Group (HFAG) as described at http://www.slac.stanford.edu/xorg/hfag/.

VALUE	DOCUMENT ID		TECN	COMMENT
0.398 ±0.012 OUR EVALUATION				
0.4099±0.0082±0.0111	[31] ABDALLAH	03K	DLPH	$e^+e^- \to Z$

[31] The analysis is based on a neural network, to estimate the charge of the weakly-decaying b hadron by distinguishing its decay products from particles produced at the primary vertex.

$\Gamma(B_s^0)/[\Gamma(B^+)+\Gamma(B^0)]$ $\Gamma_3/(\Gamma_1+\Gamma_2)$

[37] Uses the combination of lepton transverse momentum spectrum and the correlation between the charge of the lepton and opposite jet charge. The first error is statistic and the second error is the total systematic error including the modeling.

[38] The experimental systematic and model uncertainties are combined in quadrature.

[39] ABBIENDI 00E result is determined by comparing the distribution of several kinematic variables of leptonic events in a lifetime tagged $Z \to b\overline{b}$ sample using artificial neural network techniques. The first error is statistic; the second error is the total systematic error.

[40] ACCIARRI 00 result obtained from a combined fit of $R_b = \Gamma(Z \to b\overline{b})/\Gamma(Z \to \text{hadrons})$ and $B(b \to \ell\nu X)$, using double-tagging method.

[41] ACCIARRI 96C result obtained by a fit to the single lepton spectrum.

[42] Assumes Standard Model value for R_B.

[43] ABREU 95D give systematic errors ±0.0019 (model) and 0.0012 (R_c). We combine these in quadrature.

[44] BUSKULIC 94G uses e and μ events. This value is from a global fit to the lepton p and p_T (relative to jet) spectra which also determines the b and c production fractions, the fragmentation functions, and the forward-backward asymmetries. This branching ratio depends primarily on the ratio of dileptons to single leptons at high p_T, but the lower p_T portion of the lepton spectrum is included in the global fit to reduce the model dependence. The model dependence is ±0.0026 and is included in the systematic error.

[45] ABREU 93C event count includes ee events. Combining ee, $\mu\mu$, and $e\mu$ events, they obtain 0.100 ± 0.007 ± 0.007.

[46] AKERS 93B analysis performed using single and dilepton events.

$\Gamma(e^+\nu_e\text{anything})/\Gamma_{total}$ Γ_8/Γ

0.0033 ±0.0010 ±0.0017	[69] ACCIARRI	98K L3	$e^+e^-\to Z$

[66] Obtained from the best fit of the MC simulated events to the data based on the $b\to X_u\ell\nu$ neutral network output distributions.

[67] ABREU 00D result obtained from a fit to the numbers of decays in $b\to u$ enriched and depleted samples and their lepton spectra, and assuming $|V_{cb}| = 0.0384\pm 0.0033$ and $\tau_b = 1.564\pm 0.014$ ps.

[68] Uses lifetime tagged $b\overline{b}$ sample.

[69] ACCIARRI 98K assumes $R_b = 0.2174\pm 0.0009$ at Z decay.

0.077 ±0.004 ±0.007	[82] AKERS	93B OPAL	Repl. by ABBIENDI 00E

[77] Uses the combination of lepton transverse momentum spectrum and the correlation between the charge of the lepton and opposite jet charge. The first error is statistic and the second error is the total systematic error including the modeling.

[78] The experimental systematic and model uncertainties are combined in quadrature.

[79] ABBIENDI 00E result is determined by comparing the distribution of several kinematic variables of leptonic events in a lifetime tagged $Z\to b\overline{b}$ sample using artificial neural network techniques. The first error is statistic; the second error is the total systematic error.

[80] ABREU 95D give systematic errors ±0.0033 (model) and 0.0032 (R_c). We combine these in quadrature. This result is from the same global fit as their $\Gamma(\overline{b}\to\ell^+\nu_\ell X)$ data.

[81] BUSKULIC 94G uses e and μ events. This value is from the same global fit as their $\Gamma(\overline{b}\to\ell^+\nu_\ell\text{anything})/\Gamma_{\text{total}}$ data.

[82] AKERS 93B analysis performed using single and dilepton events.

$<3.9 \times 10^{-4}$	[126] GROSSMAN	96	RVUE	$e^+e^- \to Z$

[126] GROSSMAN 96 limit is derived from the ALEPH BUSKULIC 95 limit $B(B^+ \to \tau^+\nu_\tau) < 1.8 \times 10^{-3}$ at CL=90% using conservative simplifying assumptions.

χ_b AT HIGH ENERGY

For a discussion of B-$\overline{B}$ mixing, see the note on "B^0-$\overline{B}^0$ Mixing" in the B^0 Particle Listings.

χ_b is the average B-$\overline{B}$ mixing parameter at high-energy $\chi_b = f'_d\chi_d + f'_s\chi_s$ where f'_d and f'_s are the fractions of B^0 and B_s^0 hadrons in an unbiased sample of semileptonic b-hadron decays.

"OUR EVALUATION" is an average using rescaled values of the data listed below. The average and rescaling were performed by the Heavy Flavor Averaging Group (HFAG) and are described at http://www.slac.stanford.edu/xorg/hfag/. The averaging/rescaling procedure takes into account corrections between the measurements.

[127] Measurement performed using events containing a dimuon or an e/μ pair.
[128] The average B mixing parameter is determined simultaneously with b and c forward-backward asymmetries in the fit.
[129] The experimental systematic and model uncertainties are combined in quadrature.
[130] ACCIARRI 99D uses maximum-likelihood fits to extract χ_b as well as the A^b_{FB} in $Z \to b\overline{b}$ events containing prompt leptons.
[131] This ABREU 94J result is from 5182 $\ell\ell$ and 279 $\Lambda\ell$ events. The systematic error includes 0.004 for model dependence.
[132] BUSKULIC 94G data analyzed using ee, $e\mu$, and $\mu\mu$ events.
[133] BUSKULIC 92B uses a jet charge technique combined with electrons and muons.
[134] ABE 91G measurement of χ is done with $e\mu$ and ee events.
[135] ALBAJAR 91D measurement of χ is done with dimuons.
[136] Uses di-muon events.
[137] ALEXANDER 96 uses a maximum likelihood fit to simultaneously extract χ as well as the forward-backward asymmetries in $e^+e^- \to Z \to b\overline{b}$ and $c\overline{c}$.
[138] UENO 96 extracted χ from the energy dependence of the forward-backward asymmetry.
[139] ABREU 94F uses the average electric charge sum of the jets recoiling against a b-quark jet tagged by a high p_T muon. The result is for $\overline{\chi} = f_d\chi_d + 0.9 f_s\chi_s$.
[140] This ABREU 94J result combines $\ell\ell$, $\Lambda\ell$, and jet-charge ℓ (ABREU 94F) analyses. It is for $\overline{\chi} = f_d\chi_d + 0.96 f_s\chi_s$.
[141] ALBAJAR 94 uses dimuon events. Not independent of ALBAJAR 91D.
[142] ABREU 93C data analyzed using ee, $e\mu$, and $\mu\mu$ events.
[143] AKERS 93B analysis performed using dilepton events.
[144] ACTON 92C uses electrons and muons. Superseded by AKERS 93B.
[145] ADEVA 92C uses electrons and muons.
[146] DECAMP 91 done with opposite and like-sign dileptons. Superseded by BUSKULIC 92B.
[147] ADEVA 90P measurement uses ee, $\mu\mu$, and $e\mu$ events from 118k events at the Z. Superseded by ADEVA 92C.
[148] These experiments are not in the average because the combination of B_s and B_d mesons which they see could differ from those at higher energy.
[149] The WEIR 90 measurement supersedes the limit obtained in SCHAAD 85. The 90% CL are 0.06 and 0.38.
[150] ALBAJAR 87C measured $\chi = (\overline{B}^0 \to B^0 \to \mu^+ X)$ divided by the average production weighted semileptonic branching fraction for B hadrons at 546 and 630 GeV.
[151] Limit is average probability for hadron containing B quark to produce a positive lepton.

V_{cb} and V_{ub} CKM Matrix Elements

OMITTED FROM SUMMARY TABLE

DETERMINATION OF V_{cb} AND V_{ub}

Written October 2005 by R. Kowalewski (Univ. of Victoria, Canada) and T. Mannel (Univ. of Siegen, Germany)

INTRODUCTION

Precision determinations of $|V_{ub}|$ and $|V_{cb}|$ are central to testing the CKM sector of the Standard Model, and complement the measurements of CP asymmetries in B decays. The length of the side of the unitarity triangle opposite the well-measured angle β is proportional to the ratio $|V_{ub}|/|V_{cb}|$, making its determination a high priority of the heavy flavor physics program.

The quark transitions $b \to c\ell\overline{\nu}_\ell$ and $b \to u\ell\overline{\nu}_\ell$ provide two avenues for determining these CKM matrix elements, namely through inclusive and exclusive final states. The experimental and theoretical techniques underlying these two avenues are independent, providing a crucial cross-check on our understanding. Significant progress has been made in both approaches since the previous reviews of $|V_{cb}|$ [1] and $|V_{ub}|$ [2].

The theory underlying the determination of $|V_{qb}|$ is mature. The theoretical approaches all use the fact that the mass m_b of the b quark is large compared to the scale $\Lambda_{\rm QCD}$ that determines low-energy hadronic physics. The basis for precise calculations is a systematic expansion in powers of $\Lambda_{\rm QCD}/m_b$, where effective-field-theory methods are used to separate non-perturbative from perturbative contributions. The expansion in $\Lambda_{\rm QCD}/m_b$ and α_s works well enough to enable a precision determination of $|V_{cb}|$ and $|V_{ub}|$ in semileptonic decays.

The large data samples available at the B factories have opened up new possibilities experimentally. Analyses where one B meson from an $\Upsilon(4S)$ decay is fully reconstructed allow a recoiling semileptonic B decay to be studied with higher purity than was previously possible. Improved knowledge of $\overline{B} \to X_c \ell \overline{\nu}_\ell$ decays allows partial rates for $\overline{B} \to X_u \ell \overline{\nu}_\ell$ transitions to be measured in regions previously considered inaccessible, increasing the acceptance for $\overline{B} \to X_u \ell \overline{\nu}_\ell$ transitions and reducing theoretical uncertainties.

At present the inclusive determinations of both $|V_{cb}|$ and $|V_{ub}|$ are more precise than the corresponding exclusive determinations. Improvement of the exclusive determinations remains an important goal, and future progress, in particular in lattice QCD, may provide this.

Throughout this review the numerical results quoted are based on the methods of the Heavy Flavor Averaging Group [3].

DETERMINATION OF V_{cb}

Summary: The determination of $|V_{cb}|$ from exclusive decays is currently at a relative precision of about 4%. The main limitation is the knowledge of the form factor near the maximum momentum transfer to the leptons. Further progress from lattice calculations of the form factors is needed to improve the precision.

Determinations of $|V_{cb}|$ from inclusive decays are currently at a level of 2% relative uncertainty. The limitations arise mainly from our ignorance of higher order perturbative and non-perturbative corrections.

The values obtained from inclusive and exclusive determinations are consistent with each other:

$$|V_{cb}| = (41.7 \pm 0.7) \times 10^{-3} \text{ (inclusive)} \quad (1)$$
$$|V_{cb}| = (40.9 \pm 1.8) \times 10^{-3} \text{ (exclusive)}. \quad (2)$$

While this consistency may be viewed as a validation, in which case further reduction of the uncertainty is unwarranted, we nevertheless provide an average value,

$$|V_{cb}| = (41.6 \pm 0.6) \times 10^{-3} \, . \quad (3)$$

The statistical component of the error, needed for input to subsequent averages, is 0.1×10^{-3}.

$|V_{cb}|$ from exclusive decays

Exclusive determinations of $|V_{cb}|$ are based on a study of semileptonic B decays into the ground state charmed mesons D and D^*. The main uncertainties in this approach stem from our ignorance of the form factors describing the $B \to D$ and $B \to D^*$ transitions. However, in the limit of infinite bottom and charm quark masses only a single form factor appears, the Isgur-Wise function [4], which depends on the product of the four-velocities v and v' of the initial and final-state hadrons.

The method used for the extraction of $|V_{cb}|$ refers to the spectrum in the variable $w \equiv v \cdot v'$ corresponding to the energy of the final state $D^{(*)}$ meson in the rest frame of the decay. Heavy Quark Symmetry (HQS) [4,5] predicts the normalization of the rate at $w = 1$, the maximum momentum transfer to the leptons, and $|V_{cb}|$ is obtained from an extrapolation of the spectrum to $w = 1$.

A precise determination requires corrections to the HQS prediction for the normalization as well as some information on the slope of the form factors near the point $w = 1$, since the phase space vanishes there. The corrections to the HQS prediction due to finite quark masses is given in terms of the symmetry-breaking parameter

$$\frac{1}{\mu} = \frac{1}{m_c} - \frac{1}{m_b} \, ,$$

which is practically $1/m_c$ for realistic quark masses. HQS ensures that the matrix elements corresponding to the currents that generate the HQS are normalized at $w = 1$, which means that some of the form factors either vanish or are normalized at $w = 1$. Due to Luke's Theorem [6](which is an application of the Ademollo-Gatto theorem [7] to heavy quarks), the leading correction to those form factors normalized due to HQS is quadratic in $1/\mu$, while for the form factors that vanish in the infinite mass limit the corrections are in general linear in $1/m_c$ and $1/m_b$. Thus we have, using the definitions as in Eq. (2.84) of Ref. [8]

$$h_i(1) = 1 + \mathcal{O}(1/\mu^2) \qquad \text{for} i = +, V, A_1, A_3 \, ,$$
$$h_i(1) = \mathcal{O}(1/m_c,\, 1/m_b) \qquad \text{for} i = -, A_2 \, . \quad (4)$$

In addition to these corrections there are perturbatively calculable radiative corrections from QCD and QED, which will be discussed in the relevant sections. Both - radiative corrections as well as $1/m$ corrections - are considered in the framework of Heavy Quark Effective Theory (HQET) [9], which provides for a systematic expansion.

$\overline{B} \to D^* \ell \overline{\nu}_\ell$

The decay rate for $\overline{B} \to D^* \ell \overline{\nu}_\ell$ is given by

$$\frac{d\Gamma}{dw}(\overline{B} \to D^* \ell \overline{\nu}_\ell) = \frac{G_F^2}{48\pi^3} |V_{cb}|^2 m_{D^*}^3 (w^2-1)^{1/2} P(w) (\mathcal{F}(w))^2 \quad (5)$$

where $P(w)$ is a phase space factor with $P(1) = 12(m_B - m_{D^*})^2$ and $\mathcal{F}(w)$ is dominated by the axial vector form factor h_{A_1} as

$w \to 1$. In the infinite-mass limit, the HQS normalization gives $\mathcal{F}(1) = 1$.

The form factor $\mathcal{F}(w)$ is parametrized as

$$\mathcal{F}(w) = \eta_{\rm QED}\eta_{\rm A}\left[1 + \delta_{1/m^2} + \cdots\right] + (w-1)\rho^2 + \mathcal{O}((w-1)^2) \quad (6)$$

where the QED [10] and QCD [11] short distance radiative corrections are

$$\eta_{\rm QED} = 1.007\,, \quad \eta_{\rm A} = 0.960 \pm 0.007 \quad (7)$$

and δ_{1/m^2} comes from non-perturbative $1/m^2$ corrections. Analyticity and unitarity may be used to restrict the form factors [12,13] from which the bound $-0.17 < \rho^2 < 1.51$ is obtained.

Recently, lattice simulations with finite quark masses have become possible, and have been used to calculate the deviation of $\mathcal{F}(1)$ from unity. The value quoted from these calculations, which still use the "quenched" approximation, is [14]

$$\mathcal{F}(1) = 0.919^{+0.030}_{-0.035} \quad (8)$$

where the errors quoted in Ref. [14] have been added in quadrature and the QED correction has been taken into account. This value is compatible with estimates based on non-lattice methods.

Many experiments [15–21] have measured the differential rate as a function of w. Fig. 1 shows the measured values and corresponding average of the product $|V_{cb}|\,F(1)$ and the slope ρ^2. The confidence level of the average is $\sim 1\%$, suggesting the need for further experimental work. The leading sources of experimental uncertainty come from the uncertainties on the form factor ratios $R_1 \propto A_2/A_1$ and $R_2 \propto V/A_1$, and on the background due to $\overline{B} \to D^*\pi\ell\overline{\nu}_\ell$ decays, along with particle reconstruction efficiencies. These can be significantly reduced with B-factory data sets. Using the value given above for $\mathcal{F}(1)$ and the average $|V_{cb}|\mathcal{F}(1)$=(37.6±0.9) × 10^{-3} gives

$$|V_{cb}| = (40.9 \pm 1.0_{\rm exp}{}^{+1.6}_{-1.3{\rm theo}}) \times 10^{-3}. \quad (9)$$

$\overline{B} \to D\ell\overline{\nu}_\ell$

The differential rate for $\overline{B} \to D\ell\overline{\nu}_\ell$ is given by

$$\frac{d\Gamma}{dw}(\overline{B} \to D\ell\overline{\nu}_\ell) = \frac{G_F^2}{48\pi^3}|V_{cb}|^2(m_B + m_D)^2 m_D^3 (w^2-1)^{3/2}(\mathcal{G}(w))^2. \quad (10)$$

The form factor is

$$\mathcal{G}(w) = h_+(w) - \frac{m_B - m_D}{m_B + m_D}h_-(w), \quad (11)$$

where h_+ is normalized due to HQS and h_- vanishes in the heavy mass limit. Thus

$$\mathcal{G}(1) = 1 + \mathcal{O}\left(\frac{m_B - m_D}{m_B + m_D}\frac{1}{m_c}\right) \quad (12)$$

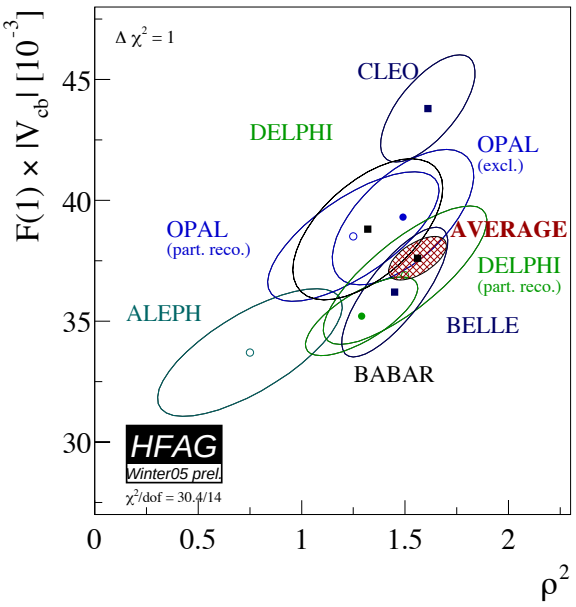

Figure 1: Measurements of $|V_{cb}|\mathcal{F}(1)$ and ρ^2 along with the average determined from a χ^2 fit. The hatched area corresponds to the $\Delta\chi^2 = 1$ contour. This plot is taken from [3]. See full-color version on color pages at end of book.

and the corrections to the HQET predictions are parametrically larger than was the case for $\overline{B} \to D^*\ell\overline{\nu}_\ell$.

However, it has been argued recently that the limit in which the kinetic energy μ_π^2 is equal to the chromomagnetic moment μ_G^2 (these quantities are discussed below in more detail) may be useful, and that deviations from this limit could be treated as small perturbations [22]. For the form factors this limit has quite far-reaching consequences, in particular it implies that for the $B \to D$ form factor the relations valid in the heavy mass limit hold in all orders in the $1/m_Q$ expansion. Based on these arguments

$$\mathcal{G}(1) = 1.04 \pm 0.01_{\rm power} \pm 0.01_{\rm pert} \quad (13)$$

is derived in Ref. [22]. If this notion gains acceptance, it could provide a rationale for reducing the uncertainties in $\mathcal{G}(1)$ from undetermined contributions of order $1/m_Q^4$.

Recently, lattice calculations that do not refer to the heavy mass limit have become available, and hence the fact that deviations from the HQET predictions are parametrically larger than in the case $\overline{B} \to D^*\ell\overline{\nu}_\ell$ is irrelevant. These calcuations quote a (preliminary) value [23]

$$\mathcal{G}(1) = 1.074 \pm 0.018 \pm 0.016 \quad (14)$$

which has an error comparable to the one quoted for $\mathcal{F}(1)$, although some uncertainties have not been taken into accounted.

The existing measurements of $|V_{cb}|\mathcal{G}(1)$ and ρ^2 are shown in Fig. 2, resulting in an average value $|V_{cb}|\mathcal{G}(1) = (42.2 \pm$

$3.7) \times 10^{-3}$. Using the value given above for $\mathcal{G}(1)$, accounting for the QED correction and conservatively adding the theory uncertainties linearly results in

$$|V_{cb}| = (39.0 \pm 3.4 \pm 3.0) \times 10^{-3} \quad (15)$$

where the first uncertainty is from experiment and the second from theory.

Measuring the differential rate at $w = 1$ is more difficult in $\overline{B} \to D\ell\overline{\nu}_\ell$ decays than in $\overline{B} \to D^*\ell\overline{\nu}_\ell$ decays, since the rate is smaller and the background from mis-reconstructed $\overline{B} \to D^*\ell\overline{\nu}_\ell$ decays is significant; this is reflected in the larger experimental uncertainty. The B factories may be able to address these limitations by studying decays recoiling against fully reconstructed B mesons or doing a global fit to $\overline{B} \to X_c\ell\overline{\nu}_\ell$ decays. Prospects for precise measurements of the total $\overline{B} \to D\ell\overline{\nu}_\ell$ rate are better, so theoretical input on the shape of the w spectrum in $\overline{B} \to D\ell\overline{\nu}_\ell$ is valuable.

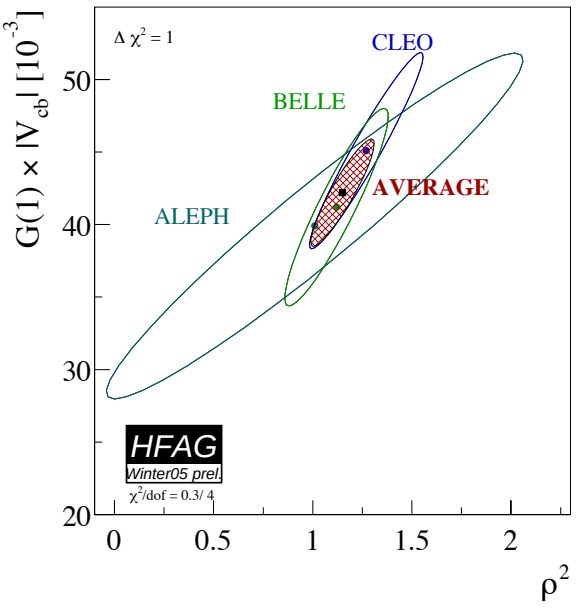

Figure 2: Measurements of $|V_{cb}|\mathcal{F}(1)$ and ρ^2 along with the average determined from a χ^2 fit. The hatched area corresponds to the $\Delta\chi^2 = 1$ contour. This plot is taken from [3]. See full-color version on color pages at end of book.

Prospects for Lattice determinations of the $B \to D^{(*)}$ form factors

The prospects for lattice determinations of the $B \to D^{(*)}$ form factors in the near term are rosy, because calculations with realistic sea quarks have begun to appear. The key [14,24] is a set of double-ratios, constructed so that all uncertainties scale with the deviation of the form factor from unity.

One of the important uncertainties in the existing lattice calculations is the chiral extrapolation, namely, the extrapolation from the light quark masses used in the numerical lattice computation to the up and down quark masses. This is under very good control for the $B \to D$ transition, but for $B \to D^*$ is complicated by the coincidence $m_\pi \approx m_{D^*} - m_D$. As a consequence, one must have exceptional analytic control over the extrapolation, including modifications of chiral perturbation theory for lattice QCD with non-zero lattice spacing.

With these developments, it will be possible to obtain full-QCD values for $\mathcal{F}(1)$ and $\mathcal{G}(1)$. The projected uncertainty will be 2-3%. This is not much smaller than before, but the foundation will be more reliable. This uncertainty needs to improve further to be comparable to the projected 1% uncertainty for the inclusive determination of $|V_{cb}|$.

To reach the target of 1% theoretical uncertainty more analytical work is needed. In lattice QCD, heavy-quark discretization effects are controlled by using HQET to match lattice gauge theory to continuum QCD, order-by-order in the heavy-quark expansion [25–28]. This matching must be carried out to higher order, and some of this is in progress [29,30]. But some aspects, such as the radiative corrections to the $1/m_Q$ corrections to the transition currents, and the $1/m_Q^2$ corrections to the currents, are not yet underway. The task involved is comparable to, perhaps a bit greater than, the effort needed for carrying out the heavy-quark expansion for the inclusive method to the same order.

$|V_{cb}|$ from inclusive decays

At present the most precise determinations of $|V_{cb}|$ come from inclusive decays. The method is based on a measurement of the total semileptonic decay rate, together with the leptonic energy and the hadronic invariant mass spectra of inclusive semileptonic decays. The total decay rate can be calculated quite reliably in terms of non-perturbative parameters that can be extracted from the information contained in the spectra.

Inclusive semileptonic rate

The theoretical foundation for the calculation of the total semileptonic rate is the Operator Product Expansion (OPE) which yields the Heavy Quark Expansion (HQE), a systematic expansion in inverse powers of the b-quark mass [31,32]. The validity of the OPE is proven in the deep euclidean region for the momenta (which is satisfied, *e.g.*, in deep inelastic scattering), but its application to heavy quark decays requires a continuation to time-like momenta $p_B^2 = M_B^2$, where possible contributions which are exponentially damped in the euclidean region could become oscillatory. The validity of the OPE for inclusive decays is equivalent to the assumption of parton-hadron duality, hereafter referred to simply as duality, and possible oscillatory contributions would be an indication of duality violation.

Duality-violating effects are in fact hard to quantify; in practice they would appear as unnaturally large coefficents of

higher order terms in the $1/m$ expansion [33]. Present fits include terms up to order $1/m_b^3$, the coefficients of which have sizes as expected a priori by theory. The consistency of the data with these OPE fits will be discussed later; no indication is found that terms of order $1/m_b^4$ or higher are large, and there is no evidence for duality violations in the data. Thus duality or, likewise, the validity of the OPE, is assumed in the analysis, and no further uncertainty is assigned to possible duality violations.

The OPE result for the total rate can be written schematically (the details of the expression can be found, *e.g.*, in [34]) as

$$\Gamma = |V_{cb}|^2 \hat{\Gamma}_0 m_b^5(\mu)(1+A_{ew})A^{\rm pert}(r,\mu)\times \left[z_0(r) + z_2(r)\left(\frac{\mu_\pi^2}{m_b^2},\frac{\mu_G^2}{m_b^2}\right) + z_3(r)\left(\frac{\rho_{\rm D}^3}{m_b^3},\frac{\rho_{\rm LS}^3}{m_b^3}\right) + ...\right] \quad (16)$$

where A_{ew} denotes the electroweak and $A^{\rm pert}(r,\mu)$ the QCD radiative corrections, r is the ratio m_c/m_b and the z_i are known phase-space functions. The expression is known up to $1/m_b^3$, where the HQE parameters are given in terms of forward matrix elements by

$$\begin{aligned}
\overline{\Lambda} &= M_B - m_b \\
\mu_\pi^2 &= -\langle B|\overline{b}(iD_\perp)^2 b|B\rangle \\
\mu_G^2 &= \langle B|\overline{b}(iD_\perp^\mu)(iD_\perp^\nu)\sigma_{\mu\nu} b|B\rangle \\
\rho_{\rm D}^3 &= \langle B|\overline{b}(iD_{\perp\mu})(ivD)(iD_\perp^\nu) b|B\rangle \\
\rho_{\rm LS}^3 &= \langle B|\overline{b}(iD_\perp^\mu)(ivD)(iD_\perp^\nu)\sigma_{\mu\nu} b|B\rangle
\end{aligned} \quad (17)$$

The non-perturbative matrix elements depend on the renormalization scale μ, on the chosen renormalization scheme and on the quark mass m_b. The rates and the spectra depend strongly on m_b (or equivalently on $\overline{\Lambda}$), which makes the discussion of renormalization issues mandatory.

Using the pole mass definition for the heavy quark masses, it is well known that the corresponding perturbative series of decay rates does not converge very well, making a precision determination of $|V_{cb}|$ in such a scheme impossible. The solution to this problem is either to chose an appropriate "short-distance" mass definition, as in the kinetic scheme [35,36], or to eliminate the heavy quark mass in favor of a physical observable, such as the $\Upsilon(1S)$ mass (a well-defined short-distance mass up to α_s^3), as in the 1S scheme [37]. Both of these schemes have been applied to semi-leptonic $b\to c$ transitions, yielding comparable results and uncertainties.

The 1S scheme eliminates the b quark pole mass by relating it to the mass of the 1S state of the Υ system. The ratio of these two masses can be computed perturbatively, assuming that possible non-perturbative contributions to the $\Upsilon(1S)$ mass are small. This is supported by an estimate performed in Ref. [38]. Eliminating the b quark pole mass in the semileptonic rate in favor of the $\Upsilon(1S)$ mass yields an expansion that converges rapidly.

Alternatively one may use a short-distance mass definition such as the $\overline{\rm MS}$ mass $m_b^{\overline{\rm MS}}(m_b)$. However, it has been argued that the scale m_b is unnaturally high for B decays, while for smaller scales $\mu\sim 1$ GeV $m_b^{\overline{\rm MS}}(\mu)$ is under poor control. For this reason the so-called "kinetic mass" $m_b^{\rm kin}(\mu)$, has been proposed. It is the mass entering the non-relativistic expression for the kinetic energy of a heavy quark, and is defined using heavy quark sum rules [36].

The HQE parameters also depend on the renormalization scale and scheme. The matrix elements displayed in Eq. (17) are defined with the full QCD fields and states, which is the definition employed in the kinetic scheme. In the 1S scheme, one usually uses the parameters λ_1 and λ_2 which are defined in the infinite mass limit. The relation between these parameters is

$$\begin{aligned}
\overline{\Lambda}_{\rm HQET} &= \lim_{m_b\to\infty}\overline{\Lambda}\,, \quad -\lambda_1 = \lim_{m_b\to\infty}\mu_\pi^2 \\
\lambda_2 &= \lim_{m_b\to\infty}\mu_G^2\,, \quad \rho_1 = \lim_{m_b\to\infty}\rho_D^3 \\
\rho_2 &= \lim_{m_b\to\infty}\rho_{LS}^3
\end{aligned}$$

Defining the kinetic energy and the chromomagnetic moment in the infinite-mass limit (as, *e.g.*, in the 1S scheme) requires that $1/m_b$ corrections to the matrix elements defined in Eq. (17) be taken into account once one goes beyond order $1/m_b^2$. As a result, additional quantities $\mathcal{T}_1\cdots\mathcal{T}_4$ appear at order $1/m_b^3$. However, these quantities are correlated such that the total number of non-perturbative parameters to order $1/m_b^3$ is the same as in the scheme where m_b is kept finite in the matrix elements which define the non-perturbative parameters. A detailed discussion of these issues can be found in [39].

In order to define the HQE parameters properly one must adopt a renormalization scheme, as was done for the heavy quark mass. Since all these parameters can again be determined by heavy quark sum rules, one may adopt a scheme similar to the kinetic scheme for the quark mass. The HQE parameters in the kinetic scheme depend on powers of the renormalization scale μ, and the above relations are valid in the limit $\mu\to 0$, leaving only logarithms of μ.

Some of these parameters also appear in the relation for the heavy hadron masses. The quantity $\overline{\Lambda}$ is determined once a definition is specified for the quark mass. The parameter μ_G^2 can be extracted from the mass splitting in the lowest spin-symmetry doublet of heavy mesons

$$\mu_G^2(\mu) = \frac{3}{4}C_G(\mu,m_b)(M_{B^*}^2 - M_B^2) \quad (18)$$

where $C_G(\mu,m_b)$ is a perturbatively-computable coefficient which depends on the scheme. In the kinetic scheme we have

$$\mu_G^2(1{\rm GeV}) = 0.35^{+0.03}_{-0.02}\,{\rm GeV}^2. \quad (19)$$

To relate these to the HQET parameters one needs to perform a change of schemes. As a rule of thumb one has, up to order α_s,

$$\overline{\Lambda}_{\rm HQET} = \overline{\Lambda}^{\rm kin}(1{\rm GeV}) - 0.255\,{\rm GeV}$$
$$-\lambda_1 = \mu_\pi^2(1{\rm GeV}) - 0.18\,({\rm GeV})^2\,.$$

Determination of HQE Parameters and $|V_{cb}|$

Several experiments have measured moments in $\overline{B} \to X_c\ell\overline{\nu}_\ell$ decays [40–48] as a function of the minimum electron momentum. The measurements of the moments of the electron energy spectrum ($0^{\rm th}$-$3^{\rm rd}$) and of the squared hadronic mass spectrum ($0^{\rm th}$-$2^{\rm nd}$) have statistical uncertainties that are roughly equal to their systematic uncertainties. They can be improved with more data and significant effort. Measurements of photon energy moments ($0^{\rm th}$-$2^{\rm nd}$) in $B \to X_s\gamma$ decays [49–52] as a function of the minimum accepted photon energy are still primarily statistics limited. Global fits to these moments [53–56] have been performed in the 1S and kinetic schemes. A global fit to a large set of hadron mass, electron energy and photon energy moments in the 1S scheme gives [55]

$$|V_{cb}| = (41.4 \pm 0.6 \pm 0.1) \times 10^{-3} \quad (20)$$
$$m_b^{\rm 1S} = 4.68 \pm 0.03\,{\rm GeV} \quad (21)$$
$$\lambda_1^{\rm 1S} = -0.27 \pm 0.04\,{\rm GeV} \quad (22)$$

where the first error includes experimental and theoretical uncertainties and the second error on $|V_{cb}|$ comes from the B lifetime. The same data along with some recent measurements of the $\overline{B} \to X_s\gamma$ energy moments have been fitted in the kinetic scheme, resulting in [56]

$$|V_{cb}| = (41.96 \pm 0.42 \pm 0.59) \times 10^{-3} \quad (23)$$
$$m_b^{\rm kin} = 4.591 \pm 0.040\,{\rm GeV} \quad (24)$$
$$\mu_\pi^2({\rm kin}) = 0.406 \pm 0.042\,{\rm GeV} \quad (25)$$

where the first error includes statistical and theoretical uncertainties and the second error on $|V_{cb}|$ is from the estimated accuracy of the HQE for the total semileptonic rate. The mass value may be compared with what is extracted from the threshold region of $e^+e^- \to b\overline{b}$ [57]:

$$m_b^{\rm kin} = 4.56 \pm 0.06\,{\rm GeV}. \quad (26)$$

In each case, theoretical uncertainties are estimated and included in performing the fits. Similar values for the parameters are obtained when only experimental uncertainties are used in the fits. The parameters determined from separate fits to electron energy moments and hadronic mass moments in semileptonic decays are compatible with each other and with those obtained from moments of the $\overline{B} \to X_s\gamma$ photon energy spectrum. The fit quality is good; the χ^2/dof is 17.6/41 (50.9/86) for the fit in the kinetic (1S) scheme, suggesting that the theoretical uncertainties may be overestimated, and showing no evidence for duality violations at a significant level. That said, a reliable method for quantifying the uncertainties from duality remains elusive.

The fits in the two schemes agree well on $|V_{cb}|$. We take the arithmetic averages of the values and of the errors to quote an inclusive $|V_{cb}|$ determination:

$$|V_{cb}| = (41.7 \pm 0.7) \times 10^{-3}\,. \quad (27)$$

The m_b values must be quoted in the same scheme to be directly compared. For this purpose both values are translated into the shape function mass scheme, either via a second-order calculation [58,59] or via a scheme-independent physical observable [56]:

$$m_b^{SF} = 4.59 \pm 0.03\,{\rm GeV}\ (1{\rm S\ fit}), \quad (28)$$
$$m_b^{SF} = 4.605 \pm 0.040\,{\rm GeV}\ ({\rm kinetic\ fit}). \quad (29)$$

The m_b^{SF} values from the two fits agree well, even though the uncertainty from the two-loop scheme translation has been omitted for the 1S results. The determination of $|V_{ub}|$ discussed below uses the value from Eq. (29).

The precision of these results can be further improved. The prospects for more precise moments measurements were discussed above. Improvements can be made in the theory by calculating higher order perturbative corrections [60] and, more importantly, by calculating perturbative corrections to the matrix elements defining the HQE parameters. The inclusion of still higher order moments may improve the sensitivity of the fits to higher order terms in the HQE.

Determination of $|V_{ub}|$

Summary: The determination of $|V_{ub}|$ has improved significantly in the last year, as new measurements have become available and theoretical calculations have been improved. The determination based on inclusive semileptonic decays has an uncertainty of 8%. The dominant uncertainty (5%) comes from a 40 MeV uncertainty on m_b based on HQE fits to moments in $\overline{B} \to X_c\ell\overline{\nu}_\ell$ and $\overline{B} \to X_s\gamma$ decays. Progress has also been made in measurements of $\overline{B} \to \pi\ell\overline{\nu}_\ell$ decays; the branching fraction is now known to 8% and the partial branching fraction at high q^2 ($> 16\,{\rm GeV}$), the region where lattice calculations are reliable, to 14%. Further improvements in form factor calculations are needed to take advantage of this precision.

The values obtained from inclusive and exclusive determinations are consistent:

$$|V_{ub}| = (4.40 \pm 0.20 \pm 0.27) \times 10^{-3}\ ({\rm inclusive}), \quad (30)$$
$$|V_{ub}| = (3.84\ ^{+0.67}_{-0.49}) \times 10^{-3} \qquad ({\rm exclusive}). \quad (31)$$

Again, the consistency may be viewed as validation, but we choose to average these values. Since in each case the dominant errors are on multiplicative factors (namely the calculated rate) we combine them weighting by relative errors to find

$$|V_{ub}| = (4.31 \pm 0.30) \times 10^{-3} \ . \quad (32)$$

The statistical component of the error, needed for input to subsequent averages, is 0.16×10^{-3}.

$|V_{ub}|$ from inclusive decays

The theoretical description of inclusive $\overline{B} \to X_u \ell \overline{\nu}_\ell$ decays is based on the Heavy Quark Expansion, as for $\overline{B} \to X_c \ell \overline{\nu}_\ell$ decays, and leads to a predicted total decay rate with uncertainties below 5% [61,62]. Unfortunately, the total decay rate is hard to measure due to the large background from CKM-favored $\overline{B} \to X_c \ell \overline{\nu}_\ell$ transitions. Calculating the partial decay rate in regions of phase space where $\overline{B} \to X_c \ell \overline{\nu}_\ell$ decays are suppressed is more challenging, as the HQE convergence in these regions is spoiled, requiring the introduction of a non-perturbative distribution function, the "shape function" (SF) [63,64], whose form is unknown. The shape function becomes important when the light-cone momentum component $P_+ \equiv E_X - |P_X|$ is not large compared to Λ_{QCD}. This additional difficulty can be addressed in two complementary ways. The shape function can be measured in the radiative decay $\overline{B} \to X_s \gamma$, and the results applied to the calculation of the $\overline{B} \to X_u \ell \overline{\nu}_\ell$ partial decay rate [59,65]; a great deal of theoretical activity has been focused in this area. Alternatively, measurements of $\overline{B} \to X_u \ell \overline{\nu}_\ell$ partial decay rates can be extended further into the $\overline{B} \to X_c \ell \overline{\nu}_\ell$-allowed region and consequently move closer to where the shape function becomes irrelevant and pure HQE calculations are accurate. Both of these approaches are being pursued and have begun to bear fruit.

The shape function is a universal property of B mesons at leading order. It has been recognized for over a decade [63,64] that the leading SF can be measured in $\overline{B} \to X_s \gamma$ decays. However, sub-leading shape functions [66–72] arise at each order in $1/m_b$, and differ in semileptonic and radiative B decays. The form of the shape functions cannot be calculated. Prescriptions that relate directly the partial rates for $\overline{B} \to X_s \gamma$ and $\overline{B} \to X_u \ell \overline{\nu}_\ell$ decays and thereby avoid any parameterization of the leading shape function are available [73–76]; uncertainties due to sub-leading SF remain in these approaches. Existing measurements, however, have tended to use parameterizations of the leading SF that respect constraints on the zeroth, first and second moments. At leading order the first and second moments are equal to $\overline{\Lambda} = M_B - m_b$ and μ_π^2, respectively. The relations between SF moments and the non-perturbative parameters of the HQE are known to second order in α_s [58]. As a result, measurements of HQE parameters from a variety of sources (electron energy and hadron mass moments in $\overline{B} \to X_c \ell \overline{\nu}_\ell$ decays, photon energy moments in $\overline{B} \to X_s \gamma$ decays) can now be used to constrain the SF moments, as well as provide accurate values of m_b and other parameters for use in the HQE calculation. The global fits of the HQE to $\overline{B} \to X_c \ell \overline{\nu}_\ell$ and $\overline{B} \to X_s \gamma$ moments discussed earlier have validated the application of the HQE to these distributions and provided significantly reduced parameter uncertainties. This is an important development. The possibility of measuring these HQE parameters directly from moments in $\overline{B} \to X_u \ell \overline{\nu}_\ell$ decays is also being explored [77], although the experimental precision achievable there is not yet competitive with other approaches.

A calculation [78] of the fully differential $\overline{B} \to X_u \ell \overline{\nu}_\ell$ rate formed the basis for determinations of $|V_{ub}|$ from inclusive semileptonic decays for several years. It was based on the HQE to order $1/m_b^2$ and included $O(\alpha_s)$ corrections, followed by a simple convolution with a shape function model, and was used to calculate an acceptance fraction f_u with which the total $\overline{B} \to X_u \ell \overline{\nu}_\ell$ branching fraction and $|V_{ub}|$ were determined. This approach has some limitations. The m_b value used in the HQE calculation is not independent of the $\overline{\Lambda}$ parameter of the shape function model, but the correlation is not well determined. Furthermore, it has been noted that the simple convolution of a shape function model with the HQE is not valid beyond leading order [79,80]. An updated approach from Bosch, Lange, Neubert and Paz [59] based on SCET, hereafter referred to as "BLNP", incorporates radiative corrections to the shape function, and has been used by the Heavy Flavor Averaging Group in determining the $|V_{ub}|$ values quoted in this review.

The BLNP calculations start from the triple diffential rate using the variables

$$P_l = M_B - 2E_l, \quad P_- = E_X + |\vec{P}_X|, \quad P_+ = E_X - |\vec{P}_X| \quad (33)$$

for which the differential rate becomes

$$\frac{d^3\Gamma}{dP_+ \, dP_- \, dP_l} = \frac{G_F^2 |V_{ub}|^2}{16\pi^2}(M_B - P_+) \quad (34)$$
$$\Big\{(P_- - P_l)(M_B - P_- + P_l - P_+)\mathcal{F}_1$$
$$+(M_B - P_-)(P_- - P_+)\mathcal{F}_2 + (P_- - P_l)(P_l - P_+)\mathcal{F}_3\Big\} .$$

The "structure functions" $\mathcal{F}_i$ can be calculated using factorization theorems that have been proven to subleading order in the $1/m_b$ expansion. These factorization theorems allow the $\mathcal{F}_i$ to be written in terms of perturbatively calculable hard coefficients H and jet functions J, which are convoluted with the (soft) light-cone distribution functions S, the shape functions of the B Meson.

The leading order term in the $1/m_b$ expansion of the $\mathcal{F}_i$ contains a single non-perturbative function and is calculated to subleading order in α_s, while at subleading order in the $1/m_b$ expansion there are several independent non-perturbative functions which have been calculated only at tree level in the α_s expansion.

To extract the non-perturbative input one can study the photon energy spectrum in $B \to X_s \gamma$ [65]. This spectrum is known at a similar accuracy as the P_+ spectrum in $B \to X_u \ell \overline{\nu}_\ell$. Going to subleading order in the $1/m_b$ expansion requires the modeling of subleading SFs, a large variety of which were studied in [59].

Going to subleading order in α_s requires the definition of a renormalization scheme for the HQE parameters and for the shape function. It has been noted that the relation between the moments of the shape function and the forward matrix elements of local operators is plagued by ultraviolet problems which require additional renormalization. A possible scheme for improving this behavior has been suggested in Refs. [59,65], which introduce a particular definition of the quark mass (the so-called shape function scheme) based on the first moment of the measured spectrum. Likewise, the HQE parameters can be defined from measured moments of spectra, corresponding to moments of the shape function.

While attempts to measure the shape function in $\overline{B} \to X_s\gamma$ decays are important, the impact of uncertainties in the shape function is significantly reduced in some recent measurements that cover a larger portion of the $\overline{B} \to X_u\ell\overline{\nu}_\ell$ phase space. Several measurements using a combination of cuts on the leptonic momentum transfer q^2 and the hadronic invariant mass M_X as suggested in Ref. [82] have been made. Measurements of the electron spectrum in $\overline{B} \to X_u\ell\overline{\nu}_\ell$ decays have been made down to 1.9 GeV, at which point shape function uncertainties are not dominant. Direct comparisons between the partial rates calculated in the "pure" HQE and those including a model shape function are instructive. The difference in these rates is, for many of the regions covered by existing measurements, already below 10%, suggesting that shape function uncertainties (including those from sub-leading SFs) are small. Furthermore, several of the measurements quoted below have used a variety of functional forms to parameterize the leading shape function; in no case does this lead to more than a 2% uncertainty on $|V_{ub}|$.

It has been pointed out [83,84] that Weak Annihilation (WA) can contribute significantly in the restricted region (at high q^2) accepted by measurements of $\overline{B} \to X_u\ell\overline{\nu}_\ell$ decays, and leptonic D_s decays have been used to estimate a $\sim 3\%$ uncertainty on the total $\overline{B} \to X_u\ell\overline{\nu}_\ell$ rate from the $\Upsilon(4S)$. The differential spectrum from WA decays is not well known, but they are expected to contribute predominantly in the high q^2 region, and can be a significant source of uncertainty for $|V_{ub}|$ measurements that accept only a small fraction of the total $\overline{B} \to X_u\ell\overline{\nu}_\ell$ rate. More direct experimental constraints on WA can be made by comparing the $\overline{B} \to X_u\ell\overline{\nu}_\ell$ decay rates of charged and neutral B mesons; results from such studies are not yet available. Another approach was recently explored in [85], where the CLEO data were fitted to a large range of models for WA decays, along with a spectator $\overline{B} \to X_u\ell\overline{\nu}_\ell$ component and background. An impact ratio $R = \Gamma(WA)/\Gamma(\overline{B} \to X_u\ell\overline{\nu}_\ell)$ was determined for different WA models and various analysis cuts. These estimates are used in the error analysis of BLNP.

Measurements

Progress has been made in measurements of $\overline{B} \to X_u\ell\overline{\nu}_\ell$. Large data samples and detailed studies of the charm background have allowed the momentum cut in lepton endpoint analyses to be placed well below the charm threshold; new measurements from BELLE and BABAR quote the partial rate for $\overline{B} \to X_u\ell\overline{\nu}_\ell$ decays for $E_e > 1.9$ and 2.0GeV, respectively. Other variables which allow the measurement of a large fraction of the $\overline{B} \to X_u\ell\overline{\nu}_\ell$ rate, *e.g.*, the hadron mass m_X, have been studied either with or without the reconstruction of the second B meson in the event. Given the improved precision and more rigorous theoretical interpretation of the recent measurements, earlier determinations [86–89] of $|V_{ub}|$ will not be further considered in this review.

In all cases, the experiments need to model $\overline{B} \to X_u\ell\overline{\nu}_\ell$ decays in order to calculate acceptances and efficiencies. While theoretical expressions exist based on the partonic decay $b \to u\ell\overline{\nu}_\ell$ and quark-hadron duality, they do not incorporate any resonant structure (*e.g.* $\overline{B} \to \pi\ell\overline{\nu}_\ell$); this must be added "by hand". The uncertainties arising from this procedure for typical measurements have been estimated by the experiments to be at the level of 1-2% on $|V_{ub}|$.

The approaches used fall into three basic categories:

1. Charged lepton momentum "endpoint" measurements. In these analyses, a single charged electron is used to determine a partial decay rate for $\overline{B} \to X_u\ell\overline{\nu}_\ell$, *i.e.*, no neutrino reconstruction is employed, resulting in a $\mathcal{O}(50\%)$ selection efficiency. The decay rate can be cleanly extracted for $E_e > 2.3$ GeV, but this is deep in the SF region, where theoretical uncertainties are large. Recent measurements push down to 2.0 or 1.9 GeV, but at the cost of a low ($< 1/10$) signal-to-background (S/B) ratio.
2. Untagged "neutrino reconstruction" measurements. In this case, both the charged electron and the missing momentum are measured, allowing the determination of q^2 and providing additional background rejection. This allows a much higher S/B~ 0.7 at the same E_e cut and a $\mathcal{O}(5\%)$ selection efficiency, but at the cost of a smaller accepted phase space for $\overline{B} \to X_u\ell\overline{\nu}_\ell$ decays and uncertainties associated with the determination of the missing momentum.
3. "Tagged" measurements in which one B meson is fully reconstructed. In this case the E_e cut is typically 1.0 GeV, and the full range of signal-side variables (q^2, M_x, P_+, etc.) is available for study. The S/B ratio can be quite high (~ 2) but the selection efficiency is $\mathcal{O}(10^{-3})$, and the impact of undetected particles from $\overline{B} \to X_c\ell\overline{\nu}_\ell$ decay (*e.g.*, K_L^0 and additional neutrinos) on the estimated background remains an important source of uncertainty.

The primary challenge in reducing the lepton momentum cut in the endpoint method is controling the $\overline{B} \to X_c\ell\overline{\nu}_\ell$ background at the required precision. In the analysis of CLEO [90], the inclusive electron momentum spectrum, after subtraction of the continuum background, was fit to a combination of a model $\overline{B} \to X_u\ell\overline{\nu}_\ell$ spectrum and components ($D\ell\overline{\nu}$+$D^*\ell\overline{\nu}$, $D^{**}\ell\overline{\nu}$ and non-resonant $D^{(*)}\pi\ell\overline{\nu}$) of the $\overline{B} \to X_c\ell\overline{\nu}_\ell$ spectrum. Only the normalizations of these spectra varied in the fit; uncertainties in the shapes were treated as systematic errors. BELLE [91] and BABAR [92] take similar approaches, choosing to fit for slightly

different combinations of $\overline{B} \to X_c \ell \overline{\nu}_\ell$ components. The resulting partial branching fractions for various E_e cuts are given in Table 1. As expected, the leading uncertainty at the lower lepton momentum cuts comes from the $\overline{B} \to X_c \ell \overline{\nu}_\ell$ background. It should be noted that the only $\overline{B} \to X_c \ell \overline{\nu}_\ell$ decays that contribute significantly for $E_e > 2.0\,\mathrm{GeV}$ are $D\ell\overline{\nu}$ and $D^*\ell\overline{\nu}$. Reducing the lepton momentum cut further will require better knowledge of the semileptonic decays to higher mass $X_c\ell\overline{\nu}$ states. The determination of $|V_{ub}|$ from these measurements is discussed below.

An analysis from BABAR is based on the combination of a high energy electron with a measurement of the missing momentum vector [93]. The selection makes requirements on the difference between the missing energy and the magnitude of the missing momentum, and uses q^2 and E_e in the combination [94] $s_{\rm h}^{\rm max} = m_B^2 + q^2 - 2m_B(E_e + q^2/4E_e)$ for $\pm 2E_e > \pm\sqrt{q^2}$ and $s_{\rm h}^{\rm max} = m_B^2 + q^2 - 2m_B\sqrt{q^2}$ otherwise (BABAR include additional terms, omitted here, to account for the motion of the B in the $\Upsilon(4S)$ frame). No $\overline{B} \to X_c \ell \overline{\nu}_\ell$ decay can have $s_{\rm h}^{\rm max}$ below m_D^2 before accounting for resolution. The requirements $E_e > 2.0\,\mathrm{GeV}$ and $s_{\rm h}^{\rm max} < 3.5\,\mathrm{GeV}$ are imposed, resulting in an accepted fraction $f_u = 0.19$ of $\overline{B} \to X_u \ell \overline{\nu}_\ell$ decays. The quality of the neutrino reconstruction, of the modeling of the selection efficiency and of the modeling of the $\overline{B} \to X_c \ell \overline{\nu}_\ell$ background are evaluated on a sample of $\Upsilon(4S) \to B\overline{B}$ decays where one B is reconstructed as $\overline{B} \to D^0(X)e\overline{\nu}$ with $D^0 \to K^-\pi^+$ and kinematic cuts limiting the (X) to no more than a soft transition π or γ. The partial branching fraction and $|V_{ub}|$ are given in Table 1.

The large samples accumulated at the B factories allow studies in which one B meson is fully reconstructed and the recoiling B decays semileptonically [95]. The experiments can correctly reconstruct a B candidate in about 0.5% (0.3%) of B^+B^- ($B^0\overline{B}^0$) events. An electron or muon with center-of-mass momentum above 1.0 GeV is required amongst the charged tracks not assigned to the tag B. Further requirements are imposed to reject $\overline{B} \to X_c \ell \overline{\nu}_\ell$ decays with additional missing particles. For example, the square of the missing mass is required to be consistent with zero (*e.g.,* $< 0.5\,\mathrm{GcV}$), and candidates with identified kaons or slow-pions from a $D^* \to D$ transition are rejected. The full set of kinematic properties (E_ℓ, M_X, q^2, *etc.*) are available for studying the semileptonically decaying B, making possible selections that accept up to 70% of the full $\overline{B} \to X_u \ell \overline{\nu}_\ell$ rate.

BELLE has measured partial rates with cuts on E_ℓ, M_X and q^2, and P_+ based on a sample of 275 million $B\overline{B}$ events [96]. The corresponding partial branching fractions are given in Table 1. As these are highly correlated measurements, only one (the most accurate, $M_X < 1.7$ GeV) is used in the average. A BABAR analysis measures the partial rate in the region $M_X < 1.7\,\mathrm{GeV}$ and $q^2 > 8\,\mathrm{GeV}$ based on a sample of 232 million $B\overline{B}$ events [97](see Table 1). In each case the experimental systematics have significant contributions from the modeling of $\overline{B} \to X_u \ell \overline{\nu}_\ell$ and $\overline{B} \to X_c \ell \overline{\nu}_\ell$ decays and from the detector response to charged particles, photons and neutral hadrons.

A previous BELLE analysis [98] used simulated annealing to associate particles to the semileptonic B decay and measured the partial rate with cuts on M_X and q^2, achieving higher efficiency but poorer S/B (1/6) than the tagged analyses.

Apart from the closely related measurements from Ref. [96] cited above, the statistical correlations amongst the measurements made by the same experiment are tiny (due to small overlaps among signal events and large differences in S/B ratios) and have been ignored in performing the average.

Determination of $|V_{ub}|$

The determination of $|V_{ub}|$ from the measured partial rates requires input from theory. The BLNP calculation described previously is used to determine $|V_{ub}|$ from all measured partial $\overline{B} \to X_u \ell \overline{\nu}_\ell$ rates; the values are given in Table 1. The uncertainties on the average are: statistical—2.2%; experimental—2.6%; $\overline{B} \to X_c \ell \overline{\nu}_\ell$ modeling—2.0%; $\overline{B} \to X_u \ell \overline{\nu}_\ell$ modeling—2.2%; HQE parameters (including m_b)—4.7%; subleading SFs—3.5%; Weak Annihilation—2.0%. The uncertainty on m_b dominates the uncertainty on $|V_{ub}|$ from HQE parameters; the uncertainty on $|V_{ub}|$ due to μ_π^2 is a factor of 5 or more smaller for most measurements.

Table 1: $|V_{ub}|$ from inclusive $\overline{B} \to X_u \ell \overline{\nu}_\ell$ measurements. The first uncertainty on $|V_{ub}|$ is experimental, while the second includes both theoretical ($\sim 5\%$) and HQE parameter uncertainties (the remainder). The HQE parameter input used was [56] $m_b^{SF} = 4.605 \pm 0.040$ GeV and $\mu_\pi^2(SF) = 0.20 \pm 0.04$ GeV^2.

	nominal f_u	$\lvert V_{ub}\rvert \times (10^{-3})$
*CLEO [90] $E_e > 2.1\,\mathrm{GeV}$	0.19	$4.05 \pm 0.47 \pm 0.36$
*BABAR [93] E_e, $s_{\rm h}^{\rm max}$	0.19	$4.08 \pm 0.27 \pm 0.37$
*BABAR [92] $E_e > 2.0\,\mathrm{GeV}$	0.26	$4.41 \pm 0.30 \pm 0.32$
*BELLE [91] $E_e > 1.9\,\mathrm{GeV}$	0.34	$4.85 \pm 0.45 \pm 0.31$
*BABAR [97] M_X/q^2	0.34	$4.79 \pm 0.35 \pm 0.33$
*BELLE [98] M_X/q^2	0.34	$4.41 \pm 0.46 \pm 0.30$
BELLE [96] M_X/q^2	0.34	$4.71 \pm 0.37 \pm 0.32$
BELLE [96] $P_+ < 0.66\,\mathrm{GeV}$	0.57	$4.16 \pm 0.35 \pm 0.29$
*BELLE [96] $M_X < 1.7\,\mathrm{GeV}$	0.66	$4.10 \pm 0.27 \pm 0.25$
Average of * $\chi^2 = 6.3/6$, CL=0.39		$4.40 \pm 0.20 \pm 0.27$

As was the case with $|V_{cb}|$, it is hard to assign an uncertainty to $|V_{ub}|$ for possible duality violations. Since the subleading terms in the case of $|V_{ub}|$ are much less explored, we also cannot rely on the consistency of the data and hence this remains an open issue here. On the other hand, unless duality violations are much larger in $\overline{B} \to X_u \ell \overline{\nu}_\ell$ decays than in $\overline{B} \to X_c \ell \overline{\nu}_\ell$ decays, the precision of the $|V_{ub}|$ determination is not yet at the level where duality violations are likely to be significant. If one proceeds along the lines suggested in Ref. [81], an ad-hoc estimate for the uncertainty from potential duality violations

can be obtained using the set of measurements in Table 1. Fitting those measurements to a function of f_u under the assumption that duality violations scale as $(1-f_u)/f_u$, the resulting bias is $-2.0 \pm 4.3\%$ relative to the assumption of no duality violations. This is consistent with the uncertainty from duality violation being small; we do not consider it appropriate to add this uncertainty to the average.

An independent calculation by Bauer, Ligeti and Luke [82] is available for the case of cuts on M_X and q^2. Using the same input for m_b, translated into the 1S scheme, yields a $|V_{ub}|$ value 3.5% larger than obtained with BLNP; this is within the quoted theory error.

HQE parameters and shape function input

The global fits to $\overline{B} \to X_c \ell \overline{\nu}_\ell$ moments discussed earlier provide input values for the heavy quark parameters needed in calculating $\overline{B} \to X_u \ell \overline{\nu}_\ell$ partial rates. These HQE parameters are also used to constrain the first and second moments of the shape function. Additional information on the leading shape function and HQE parameters is obtained from the photon energy spectrum in $\overline{B} \to X_s \gamma$ decays. There are two means of extracting information from the spectrum; fitting the full spectrum using a functional ansatz for the shape function, or determining the low-order moments above a threshold energy cut.

BELLE, BABAR and CLEO have measured the $\overline{B} \to X_s \gamma$ spectrum and its moments [49–52] down to $E_\gamma = 1.8\,\text{GeV}$, $1.9\,\text{GeV}$ and $2.0\,\text{GeV}$, respectively. The experimental data are most precise at the very highest photon energies where the background, especially from B decays, is smallest. In most analyses the photon energy is measured in the $\Upsilon(4S)$ rest frame, which produces a significant smearing of the spectrum. One of the BABAR analyses [50], based on the sum of $\overline{B} \to X_s \gamma$ exclusive states involving a kaon and up to 4 pions, avoids this smearing by using the measured invariant mass of the recoiling hadron as the observable, resulting in excellent E_γ resolution in the B rest frame. This analysis shows a clear K^* peak near the endpoint of the photon spectrum, and highlights the issue of how sensitive a fit to the full spectrum is to local quark-hadron duality (even when lumping the K^* region into a single bin). In addition, the form of the shape function is unknown; multiple functional ansatze must be employed to estimate the uncertainty arising from this model dependence.

Fits to the full $\overline{B} \to X_s \gamma$ spectrum have been performed using the calculation of Ref. [99], which includes the NLO relations between the spectra of $b \to s\gamma$ and $b \to u \ell \overline{\nu}_\ell$ in the shape function scheme and is an improvement on earlier work [100]. A recent fit from BABAR gives [50] $m_b^{SF} = 4.67 \pm 0.07\,\text{GeV}$; if instead they take the same data and fit the first and second moments of the E_γ spectrum for $E_\gamma > 1.897\text{GeV}$ they find $m_b^{SF} = 4.60^{+0.12}_{-0.14}\,\text{GeV}$. BELLE determines [103] $m_b^{SF} = 4.52 \pm 0.07\,\text{GeV}$ from a fit to their spectrum.

Another theoretical approach using "dressed gluon exponentiation" has recently become available for calculating decay spectra for $\overline{B} \to X_s \gamma$ and $\overline{B} \to X_u \ell \overline{\nu}_\ell$ [104].

Predictions of the photon energy moments in terms of HQE parameters are available in several mass renormalization schemes and several approaches [60, 101, 102]. The predicted moments at low photon energy cuts (*e.g.* $E_\gamma > 1.6$ GeV) are insensitive to shape function uncertainties. For cuts of ~ 1.8 GeV, corrections [105] need to be applied, and the associated theoretical uncertainty becomes sizable for cuts above ~ 2.0 GeV. The experimental accuracy on the truncated moments is best at high E_γ cuts and degrades significantly at lower cuts due to large backgrounds. In a compromise between these two sources of uncertainty, the global HQE fits discussed earlier use moments at E_γ cuts up to 2.0 or 2.1 GeV, and include an estimate of the theoretical uncertainty from SF effects.

Status and outlook

At present, as indicated by the average given above, the uncertainty on $|V_{ub}|$ is at the 8% level. The uncertainty on m_b taken here is 40 MeV, contributing an uncertainty of 4.5% on $|V_{ub}|$; reducing this further will be increasingly difficult due to theoretical uncertainties in the determination of m_b from the global fits to moments. However, further progress can be expected on some of the other leading sources of uncertainty. The uncertainties on $|V_{ub}|$ quoted in the BLNP calculation are at the 5% level. The Weak Annihilation component of this can be better addressed experimentally at the B factories. Reducing the remaining theory uncertainty will require improvements in the calculations. For the approaches making use of the shape function this amounts to improvements in relating the spectra from $\overline{B} \to X_u \ell \overline{\nu}_\ell$ and $\overline{B} \to X_s \gamma$ decays by calculating radiative corrections and the effects of subleading shape functions, while approaches less sensitive to shape functions require calculations of higher-order radiative corrections. Experimental uncertainties will be reduced through higher statistics and better understanding of $\overline{B} \to X_c \ell \overline{\nu}_\ell$ decays and of D decays. The two approaches discussed earlier, namely (1) determining the shape function from the $\overline{B} \to X_s \gamma$ photon spectrum and applying it to $\overline{B} \to X_u \ell \overline{\nu}_\ell$ decays and (2) pushing the measurements into regions where shape function and duality uncertainties become negligeable, are fairly complementary and should both be pursued.

$|V_{ub}|$ from exclusive decays

Exclusive charmless semileptonic decays offer a complementary means of determining $|V_{ub}|$. For the experiments, the specification of the final state provides better background rejection, but the lower branching fraction reflects itself in lower yields compared with inclusive decays. For theory, the calculation of the form factors for $\overline{B} \to X_u \ell \overline{\nu}_\ell$ decays is challenging, but brings in a different set of uncertainties from those encountered in inclusive decays. In this review we focus on $\overline{B} \to \pi \ell \overline{\nu}_\ell$, as it is the most promising mode for both experiment and

theory, and recent improvements have been made in both areas. Measurements of other exclusive states can be found in Refs. [107–111].

$\overline{B} \to \pi\ell\overline{\nu}_\ell$ form factor calculations The relevant form factors for the decay $\overline{B} \to \pi\ell\overline{\nu}_\ell$ are usually defined as

$$\langle\pi(p_\pi)|V^\mu|B(p_B)\rangle = \tag{35}$$
$$f_+(q^2)\left[p_B^\mu + p_\pi^\mu - \frac{m_B^2 - m_\pi^2}{q^2}q^\mu\right] + f_0(q^2)\frac{m_B^2 - m_\pi^2}{q^2}q^\mu$$

in terms of which the rate becomes (in the limit $m_\ell \to 0$)

$$\frac{d\Gamma}{dq^2} = \frac{G_F^2|V_{ub}|^2}{24\pi^3}|p_\pi|^3|f_+(q^2)|^2 \tag{36}$$

where p_π is the momentum of pion in the B meson rest frame.

Currently available non-perturbative methods for the calculation of the form factors include lattice QCD and light-cone sum rules. The two methods are complementary in phase space, since the lattice calculation is restricted to the kinematical range of high momentum transfer q^2 to the leptons, due to large discretization errors, while light-cone sum rules provide information near $q^2 = 0$. Interpolations between these two regions may be constrained by unitarity and analyticity.

Unquenched simulations, for which quark loop effects in the QCD vacuum are fully incorporated, have become quite common, and the first results based on these simulations for the $\overline{B} \to \pi\ell\overline{\nu}_\ell$ form factors have been obtained recently by the Fermilab/MILC collaboration [112] and the HPQCD collaboration [113].

The two calculations differ in the way the b quark is simulated, with HPQCD using nonrelativistic QCD and Fermilab/MILC the so-called Fermilab heavy quark method. Results by the two groups for $f_0(q^2)$ and $f_+(q^2)$ are shown in Fig. 3. The two calculations agree within the quoted errors.

In order to obtain the partially-integrated differential rate, the BK parameterization [114]

$$f_+(q^2) = \frac{c_B(1-\alpha_B)}{(1-\tilde{q}^2)(1-\alpha_B\tilde{q}^2)}, \tag{37}$$
$$f_0(q^2) = \frac{c_B(1-\alpha_B)}{(1-\tilde{q}^2/\beta_B)}, \tag{38}$$

with $\tilde{q}^2 \equiv q^2/m_{B^*}^2$ is used to extrapolate to small values of q^2. It includes the leading pole contribution from B^*, and higher poles are modeled by a single pole. The heavy quark scaling is satisfied if the parameters c_B, α_B and β_B scale appropriately. However, the BK parameterization should be used with some caution, since it is not consistent with SCET [115]. Alternatively, one may use analyticity and unitarity bounds to constrain the form factors. The use of lattice data in combination with a data point at small q^2 from SCET or sum rules provides a stringent constraint on the shape of the form factor [116].

The results for the integrated rate with $q^2 > q^2_{\rm cut} = 16{\rm GeV}^2$ are

$$\Gamma = |V_{ub}|^2 \times (1.31 \pm 0.33)\,{\rm ps}^{-1}, \quad \text{HPQCD;}$$
$$= |V_{ub}|^2 \times (1.80 \pm 0.48)\,{\rm ps}^{-1}, \quad \text{Fermilab/MILC.}$$

Here the statistical and systematic errors are added in quadrature.

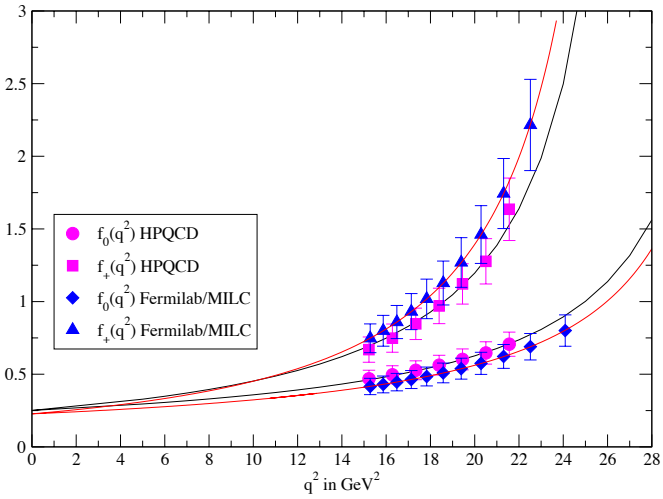

Figure 3: The form factors $f_0(q^2)$ and $f_+(q^2)$ versus q^2 by the Fermilab/MILC [112] and HPQCD [113] collaborations. The full curves are the BK parameterization [114] fits to the simulation results at large q^2, with $f_0(0)$ and $f_+(0)$ constrained to be equal. Errors are statisical plus systematic added in quadrature. See full-color version on color pages at end of book.

Much work remains to be done, since the current combined statistical plus systematic errors in the lattice results are still at the 10-14% level on $|V_{ub}|$ and need to be reduced. Reduction of errors to the $5 \sim 6\%$ level for $|V_{ub}|$ may be feasible within the next few years, although that could involve carrying out a two-loop (or fully non-perturbative) matching between lattice and continuum QCD heavy-to-light current operators, and/or going to smaller lattice spacing.

Another established non-perturbative approach to obtain the form factors is through Light-Cone QCD Sum Rules (LCSR), although some skepticism has been expressed from the point of view of SCET [117]. The sum-rule approach provides an approximation for the product $f_B f_+(q^2)$, valid in the region $0 < q^2 < \sim 14\,{\rm GeV}^2$. The determination of $f_+(q^2)$ itself requires knowledge of the decay constant f_B, which usually is obtained by replacing f_B by its two-point QCD (SVZ) sum rule [118] in terms of perturbative and condensate contributions. The advantage of this procedure is the approximate cancellation of various theoretical uncertainties in the ratio $(f_B f_+)/(f_B)$.

The LCSR for $f_B f_+$ is based on the light-cone OPE of the relevant vacuum-to-pion correlation function, calculated in full QCD at finite b-quark mass. The resulting expressions actually comprise a triple expansion: in the twist t of the operators near the light-cone, in α_s, and in the deviation of the pion distribution amplitudes from their asymptotic form, which is fixed from conformal symmetry.

After identifying all sources of uncertainties in LCSR, the updated analysis of [119](see also [120]) gives the following value

$$f_+(0) = 0.27\Big[1 \pm (5\%)_{tw>4} \pm (3\%)_{m_b,\mu} \pm (3\%)_{\langle\overline{q}q\rangle} \pm (3\%)_{s_0^B,M} \pm (8\%)_{a_{2,4}^\pi}\Big], \quad (39)$$

where the uncertainties are displayed individually. Here s_0^B, M labels the uncertainty estimated from the use of the sum rule (threshold and Borel parameters) and $a_{2,4}^\pi$ labels the uncertainty due to non-asymptotic contributions of the pion distribution amplitude.

Combining the uncertainties one obtains

$$f_+(0) = 0.27 \pm 0.04\,, \quad (40)$$

where the first four uncertainties are combined in quadrature and the last uncertainty is added linearily. This value is consistent with the value quoted in [121]

$$f_+(0) = 0.258 \pm 0.031 \quad (41)$$

It is interesting to note that the results from the LQCD and LCSR are consistent with each other when the BK parameterization is used to relate them. This increases confidence in the theoretical predictions for the rate of $\overline{B} \to \pi\ell\overline{\nu}_\ell$.

An alternative determination of $|V_{ub}|$ has been proposed by several authors [122–126]. It is based on a model-independent relation between rare decays such as $\overline{B} \to K^*\ell^+\ell^-$ and $\overline{B} \to \rho\ell\overline{\nu}_\ell$, which can be obtained at large momentum transfer q to the leptons. This method is based on the HQET relations between the matrix elements of the $B \to K^*$ and the $B \to \rho$ transitions and a systematic, OPE-based expansion in powers of m_c^2/q^2 and $\Lambda_{\rm QCD}/q$. The theoretical uncertainty is claimed to be of the order of 5% for $|V_{ub}|$; however, it requires a precise measurement of the exclusive rare decay $\overline{B} \to K^*\ell^+\ell^-$, which is a task for future ultra-high-rate experiments.

$\overline{B} \to \pi\ell\overline{\nu}_\ell$ measurements

The $\overline{B} \to \pi\ell\overline{\nu}_\ell$ measurements fall into two broad classes: untagged, in which case the reconstruction of the missing momentum of the event serves as an estimator for the unseen neutrino, and tagged, in which the second B meson in the event is fully reconstructed in either a hadronic or semileptonic decay mode. The tagged measurements have high and uniform acceptance, S/B$\sim$ 3, but low statistics. The untagged measurements have somewhat higher background levels (S/B$\sim$ 1) and make slightly more restrictive kinematic cuts, but offer large-enough statistics to be sensitive to the q^2 dependence of the form factor. The averages of the full and partial branching fractions from the tagged measurements are currently of comparable precision to the corresponding averages of the untagged measurements.

Table 2: Total and partial branching fractions for $\overline{B}^0 \to \pi^+\ell^-\overline{\nu}_\ell$. The uncertainties are from statistics and systematics. The measurements of $\mathcal{B}(B^- \to \pi^0\ell^-\overline{\nu}_\ell)$ have been multiplied by a scale factor $2\tau_{B^0}/\tau_{B^+}$ to obtain the value quoted below. The confidence level of the total branching fraction average is 0.33.

	$\mathcal{B}\times10^4$	$\mathcal{B}(q^2>16)\times10^4$
CLEO π^+,π^0 [110]	$1.32 \pm 0.18 \pm 0.13$	$0.25 \pm 0.09 \pm 0.05$
BABAR π^+,π^0 [111]	$1.38 \pm 0.10 \pm 0.18$	$0.49 \pm 0.05 \pm 0.06$
Average of untagged	$1.35 \pm 0.10 \pm 0.14$	$0.41 \pm 0.04 \pm 0.05$
BELLE SL π^+ [128]	$1.48 \pm 0.20 \pm 0.16$	$0.40 \pm 0.12 \pm 0.05$
BELLE SL π^0 [128]	$1.40 \pm 0.24 \pm 0.16$	$0.41 \pm 0.15 \pm 0.04$
BABAR SL π^+ [130]	$1.02 \pm 0.25 \pm 0.13$	$0.21 \pm 0.14 \pm 0.05$
BABAR SL π^0 [131]	$3.31 \pm 0.68 \pm 0.42$	NA
BABAR had π^+ [132]	$1.24 \pm 0.29 \pm 0.16$	$0.70 \pm 0.22 \pm 0.11$
BABAR had π^0 [132]	$1.45 \pm 0.37 \pm 0.12$	$0.46 \pm 0.20 \pm 0.04$
Average of tagged	$1.36 \pm 0.11 \pm 0.08$	$0.39 \pm 0.07 \pm 0.03$
Average	$1.35 \pm 0.08 \pm 0.08$	$0.40 \pm 0.04 \pm 0.04$

CLEO has analyzed $\overline{B} \to \pi\ell\overline{\nu}_\ell$ and $\overline{B} \to \rho\ell\overline{\nu}_\ell$ using an untagged analysis [110]. A similar analysis has been done by BABAR [111]. The measured q^2 dependence favors QCD-inspired form factor calculations (lattice or LCSR) over the widely used ISGW2 [127] model. The leading systematic uncertainties in the untagged $\overline{B} \to \pi\ell\overline{\nu}_\ell$ analyses are associated with modeling the missing momentum reconstruction and with varying the form factor for the $\overline{B} \to \rho\ell\overline{\nu}_\ell$ decay, which is a major source of background. The values obtained for the full and partial branching fractions are listed in Table 2.

BELLE has performed an analysis based on reconstructing a B^0 in the $D^{(*)-}\ell^+\nu_\ell$ decay mode and looking for a $\overline{B}^0 \to \pi^+\ell^-\overline{\nu}_\ell$ or $\overline{B}^0 \to \rho^+\ell\overline{\nu}_\ell$ decay amongst the remaining particles in the event; the most recent Belle results are given in Ref. [128]. The fact that the B and $\overline{B}$ are back-to-back in the $\Upsilon(4S)$ frame is used to construct a discriminating variable and obtain a signal-to-noise ratio above unity for all q^2 bins. A related technique was discussed in Ref. [129]. BABAR has done similar analyses [130,131] in the $\overline{B}^0 \to \pi^+\ell^-\overline{\nu}_\ell$ and $B^- \to \pi^0\ell^-\overline{\nu}_\ell$ channels, where in the latter case the tagging decays are $B^+ \to \overline{D}^0\ell^+\nu(X)$ and kinematic requirements accept decays to $\overline{D}^{*0}\ell^+\nu$ where the π^0 or γ from the $\overline{D}^{*0} \to \overline{D}^0$ transition is unreconstructed. In addition, the sample of fully-reconstructed B mesons in BABAR has been used to measure exclusive charmless semileptonic decays [132], giving very clean but low-yield samples. The resulting full and partial branching fractions are given in Table 2.

The outlook for improvements in these measurements with increasing B-factory data samples is good. The tagged measurements in particular will improve; the current estimates of systematic uncertainties in these measurements have a significant statistical component, so the total experimental uncertainty should fall as $1/\sqrt{N}$ for some time.

Table 3: Determinations of $|V_{ub}|$ based on $\overline{B} \to \pi\ell\overline{\nu}_\ell$ decays.

Method	$\lvert V_{ub}\rvert \times (10^{-3})$
LCSR, [121] full q^2	$3.37 \pm 0.14^{+0.66}_{-0.41}$
LCSR, [121] $q^2 < 16$	$3.27 \pm 0.16^{+0.54}_{-0.36}$
HPQCD, [113] full q^2	$3.93 \pm 0.17^{+0.77}_{-0.48}$
HPQCD, [113] $q^2 > 16$	$4.47 \pm 0.30^{+0.67}_{-0.46}$
FNAL, [112] full q^2	$3.76 \pm 0.16^{+0.87}_{-0.51}$
FNAL, [112] $q^2 > 16$	$3.78 \pm 0.25^{+0.65}_{-0.43}$

Table 3 shows the $|V_{ub}|$ values obtained based on form factor calculations from QCD sum rules and lattice QCD. We quote an average based on three inputs: the measured partial branching fractions in the region $q^2 > 16$ GeV^2 with theory input from the two unquenched lattice calculations, and the partial branching fractions in the region $q^2 < 16$ GeV^2 with theory input from LCSR. The uncertainty on the theory input is large compared to the uncertainty from the measurements. We form the arithmetic averages of the values and of the errors to find

$$|V_{ub}| = (3.84\ ^{+0.67}_{-0.49}) \times 10^{-3}\ . \qquad (42)$$

The uncertainty is dominated by the form factor normalization, the calculations of which were discussed previously.

Conclusion

The study of semileptonic B meson decays continues to be an active area for both theory and experiment. Substantial progress has been made in the application of HQE calculations to inclusive decays, with fits to moments of $\overline{B} \to X_c\ell\overline{\nu}_\ell$ and $B \to X_s\gamma$ decays providing precise values for $|V_{cb}|$ and m_b. In particular, the precision on $|V_{cb}|$ now approaches that of the Cabibbo angle, underlining the fantastic progress made in this area. Furthermore, the consistency of the values extracted from exclusive and inclusive measurements gives us confidence, since the theoretical and experimental approaches are completely uncorrelated.

Improved measurements of $\overline{B} \to X_u\ell\overline{\nu}_\ell$ decays, along with a more comprehensive theoretical treatment and improved knowledge of m_b, have led to a significantly more precise determination of $|V_{ub}|$. Further progress in these areas is possible, but will require higher order radiative corrections from the theory and, in the case of $|V_{ub}|$, improved experimental knowledge of the $\overline{B} \to X_c\ell\overline{\nu}_\ell$ background. While there has been impressive progress in the past few years, new challenges will need to be overcome to achieve a precision below 5% on $|V_{ub}|$ from inclusive decays.

Progress in both $b \to u$ and $b \to c$ exclusive channels depends crucially on progress in lattice calculations. Here the prospects are rosy (see, *e.g.*, Ref. [133]) , since unquenched lattice simulations are now possible, although the ultimate attainable precision is hard to estimate.

The measurements of $\overline{B} \to \pi\ell\overline{\nu}_\ell$ have improved significantly, and high-purity tagged measurements now provide a precision comparable to the one from untagged measurements. The experimental input will continue to improve as B-factory data sets increase. Reducing the theoretical uncertainties to a comparable level will require significant effort, but is clearly vital in order to compare the extracted $|V_{ub}|$ with the one obtained from inclusive decays.

Both $|V_{cb}|$ and $|V_{ub}|$ are indispensable inputs into unitarity triangle fits. In particular, knowing $|V_{ub}|$ with a precision of better than 10% allows a test CKM unitarity in the most direct way, by comparing the length of the $|V_{ub}|$ side of the unitarity triangle, with the measurement of $\sin(2\beta)$. This is a comparison of a "tree" process ($b \to u$) with a "loop-induced" process ($B^0 - \overline{B}^0$ mixing), and provides sensitivity to possible contributions from new physics. While the effort required to further improve our knowledge of these CKM matrix elements is large, it is well motivated.
